- A minimum of 6 trial-run teaching situations (see Chapter 7) in each of the two subject qualifications of a teacher (e.g. economics and trade, home economics and English) must be completed during the 2-year-programme. This makes a total of 12 experiments in which trainees invite senior teachers and teacher trainers to sit in and advise on the lesson itself as well as on written lesson plans for those case studies. These lesson plans had been prepared by the trainees beforehand and document the methods chosen, the didactical path as well as the objectives for this very lesson.

- Furthermore, a "Planning and Development Talk" (Planungs- *und Enwtwicklungsgespraech*) is required halfway through the training program. A colloquium with teacher trainers from the VETTIs as well as mentors from the schools is held, not as an exam, but to look back as well as forward and to serve as a counseling mechanism for the junior teachers.

Finally, at the end of the two-year-program the junior teachers must undergo the Second State Board Exam:

"The State Board Exam verifies if and to what extent the teachers have participated in the two-year vocational teacher program and gives an accreditation to the candidates in form of a grade." (§ 52 OVP, Accreditation System for Teacher Training).

Senior teacher trainers from teacher training institutes and mentors from the vocational schools grade the Second State Board Exam. The Exam is composed of three parts: A written thesis, two case study teaching situations and a colloquium.

First, a written thesis must be submitted. The thesis must be written in one of the two subject qualifications of the junior teacher and must be related to their own teaching experience in their vocational school. For example, a teacher with a university degree in economics might choose to write a thesis on **"Planning, Carrying out and Evaluating a Teaching Sequence With Apprentices in Industrial Management on How to Set up a Marketing Project for the new Ford Fiesta in NRW"**. Theses are written towards the end of the two-year – program, simultaneously with junior teachers' regular teaching, seminar work and so on. The thesis typically documents a sequence of 3-8 hours that the trainee has actually taught, with the planning, teaching, grading and evaluation aspects each documented. Theses usually range from 30-50 pages in length and are graded by teacher trainers from the Cologne institute as well as teacher trainers from other institutes.

Secondly, two case study teaching situations in the two different subjects of each trainee must be presented as an exam, in which senior teachers as well as trainers from the teacher training institute sit in and assess the accomplishments. For example, in an economics class for bank clerks *(Bankkaufleute),* **"The importance of economic growth for an active income distribution policy in Germany"** might be a trial-run teaching situation while in a business administration class of a Commercial College for full-time students going for the final degree in secondary education (*Handelsschüler*), a teaching situation on **"We develop employment criteria and plan a job interview for an apprenticeship post in a supermarket"** might be presented.

Finally, the exam includes a colloquium with the teacher trainers and coordinators from the respective schools on teaching and training aspects. A typical colloquium in Cologne presents students with a hypothetical but concrete teaching exercise targeted at a specific learning group.

Hypothetical Questions in a Second State Board Exam Colloquium

"A new three-year vocational school career track (*Bildungsgang*) in wholesaling has just been established at your new school. How would you plan, carry out and evaluate an excursion with first-year students to the regional market leader in paper products, using reflection learning methods with your students?"

or

"How will you plan your new subject, general business administration (*Allgemeine Wirtschaftslehre*), for apprenticeship classes of IT –clerks, keeping in mind that you want to include as many projects as possible with other colleagues and other subjects such as mathematics, computer programming and systems operation!"[4]

The State Board Exam is graded by teacher trainers from the VETTIs, teacher training mentors from the vocational schools and representatives from the Ministry of Education. The results of the different parts of the state board exam are weighed differently and compiled into a grade point average that indicates the quality of the junior teacher, who is now a qualified teacher. He or she can then apply for a job with the Ministry of Education in NRW in a vocational college of his or her own or the Ministry's choice. In the last few years some changes have been made inasmuch the vocational schools also have the right to employ trained teachers in vocational education directly. This is an additional incentive for schools to do their best during the two-year training, since they can then retain good people that have got to know the school very well[5].

3.2. The Didactical Principles of the Teacher Training Program in Cologne

The didactical principles of the teacher training program in Cologne are based on assumptions about learning processes in adults and have a profound influence on the institute setting for teacher training.

---

[4] This kind of planning is called Annual Didactical Planning in vocational education in Germany.

[5] The framework for all the teacher training institutes in NRW is provided by the *SRK*. Compared to the *OVP*, the *SRK* is a more specific legal instruction for teacher trainers and it lays out teaching standards for future trainers, describes functions of a good teacher in vocational education, stresses the importance of reflection learning, describes possible methods in vocational schools and emphasizes the importance of a training program, where the different actors in teacher training (vocational education teacher training institutes, schools, mentors and industry) work together as much as possible.

Assumptions About the Learning Process of Young Teachers in Vocational Education

The Cologne vocational education teacher training institute "philosophy" is based on a number of assumptions about learning of junior teachers. These are

- Adult trainees come to the institute because they have an interest in learning; they want to improve and are highly motivated (naturally they also come to the institute to obtain the degree!);
- The institute confronts trainees with reflection patterns that might be new to them. Their prior experiences and their biographies may have "biased" them in their way of looking at learning processes;
- We assume that learning to become a teacher is a unique experience for everyone and requires permanent exercise and reflection (principle of utmost individualization of learning);
- Very often young trainees ask for models and ready-made solutions. However, the teacher trainers in the Cologne institute also propose learning in uncertainty and advocate trying ways that fit each individual best;
- Teacher training is not like pressing skills through a funnel, assuming that ready-made teachers come out! On the contrary, it is an ongoing process that can be initiated, challenged, supported, provoked, accompanied - in other words, supported, all along;
- Principle of reflection learning: learning should be related to real-life and problem situations;
- Principle of reversibility in learning and teaching: teachers are learners but learners can be teachers at times; both can mutually benefit from one other;
- Principle of self-organization and individual responsibility in teacher training: Trainees take responsibility for their own development of

    - ✓ Curricular-didactical competencies,
    - ✓ Methodological-communicative competencies and
    - ✓ Pedagogical-social competencies;

- Learning how to become a teacher works through networks and team work plays a very important role in this;
- Principle of vocational and life background: Learning in vocational schools should always be related to the work and life experience of our students and should always keep that in mind;
- Principal of life-long learning: The in-service teacher training institute is only the first phase in teacher training, to be immediately followed with further teacher training (which in NRW is given on the job and is organized by a separate training body)!

4. Organizing In-service Vocational Education Teacher Training in an Institute - A Collaborative Effort Among School Staff, VETTIs and Junior Teachers

The organization of the two-year training program is a major logistical challenge, requiring a lot of coordination and understanding throughout the two years among the various partners:

- Junior teachers;
- Vocational school staff; and
- Vocational education teacher training institutes

It is the VETTI that organizes the work and sets the organizational framework.

The phrase “Dual System” describes the system of Germany apprenticeship training which takes place both in vocational schools as well as in companies. In a way this expression does not only refer to the German apprenticeship system, but also to its teacher training.

This is because training teachers in vocational schools **and** vocational education teacher training institutes is influenced by the aspect that institutes and schools both look at themselves as training grounds for junior teachers and are prepared to open up learning arrangements for the junior teachers.

This chapter describes where the different parts of training (*Ausbildung im Studienseminar = Hauptseminar und Fachseminar, Praxis in der Schule, Begleitprogramm, kooperative Ausbildung in Seminar und/oder Schule und Peergroup*) take place in Cologne, and how many hours are allotted to each part of the training. Later, Chapter 7 goes into more detail using the example of training in economics and business administration (*Fachseminar Wirtschaftswissenschaften*) to illustrate the various aspects of organization.

Training takes place in vocational schools as well as in the teacher training institute. The training is divided into:

- Teaching in schools as well as other activities there (such as conferences, open houses, excursions, teacher-parent-days, etc.)
- Accompanying Program;
- Cooperative training sessions between institute and schools;
- Peer group work; and
- Training in the teacher training institute.

The following table shows the various training and venues, hours spent and frequency over the 24-month program, and where they are covered in this paper.

Table 1: Organization of Teacher Training

Training Type and Venues	**Total Hours**	**Frequency**	**Where in this paper**
Teaching and other Practical Elements in Vocational Schools	825 teaching lessons	12 hours per week (6 in each subject)	Chapter 7 - Case Study Teaching
Accompanying Program	70 hours	2 hours bi-weekly	Chapter 6 - Advisory Groups
Cooperative Program between Institute and Schools	100 hours	Once or twice during the two year program, intensively over a period of 6-8 weeks, once a week a whole day in the schools	For examples, see Boxes 3 and 4
Peer group work	20 hours	For example 5 times 4 hours	Chapter 6 - Working in Groups
Training in the institute (In Cologne there is one fixed seminar day and on this day the trainees get all the three seminars listed in the right column)	440 training hours	Field-related group 1, e.g. Economics: 120 hours (2 hours/week) Field-related group 2, e.g. English: 120 hours (2 hours/week) General Vocational Pedagogy and Didactics: 200 hours (3-4 hours/week)	Chapter 5 - Essentials Chapter 7 – Trial-run Teaching See also Boxes 1 and 2

The whole training period covers 1455 hours in the entire two years or roughly 25 – 30 hours a week, depending on the schedule of the various group activities. This does not include, however, preparation time, self-study periods, participation in extra-curricular activities and homework assignments.

A typical weekly schedule for a trainee in school and institute might look like this:

Table 2: Typical Weekly Schedule of Junior Teachers

Monday	Tuesday	Wednesday	Thursday	Friday
8-12 General Pedagogy and Didactics In Vocational Education Teacher Training Institute (Essential 1: Biographical Work)	8-10 Teaching English in a Full-time Commercial College Class (Case-study teaching situation, supervised teaching) 10-12 Observing teachers in their classes in labor economics	8-10 Teaching in Business Administration in Wholesalers Classes: Aspects of Contract of Sale (unsupervised teaching) 10-12 Observing Teachers in Teaching Business Correspondence	8-10 Observing Teaching Grammar in English Apprenticeship Classes of future Bank Clerks 10-12 Teaching Income Distribution Policies in Apprenticeship Classes of future Industrial Managers (*Industriekaufleute*), unsupervised teaching	8-3 Cooperation between Institute and School: Participation in Future Lab Experiment (see Box 3) in a Vocational School with Junior Teachers, Teacher Trainers, Senior Teachers and Classes
1-2.30 Field-related Group1: Business Administration (Planning a Management Game)			1-3 Peer Group Work	
3-4.30 Field-related Group2: English (Teaching English Literature)		3-4.30 (Bi-weekly) Accompanying Program in Vocational School		

In addition, there are so-called pedagogical weeks, once or twice during the training programs. These are held outside the institute venue and are prepared, carried out and evaluated by the trainees. The topics in these pedagogical weeks are related to subjects of general interest for vocational schools. Past pedagogical weeks for example have dealt with how to use gestalt therapy in vocational education or how to prepare a week of project work in a vocational school.

Furthermore, teacher trainers in the institute offer special voluntary courses, related to the "essentials" described in the previous chapter.

One of these extra courses offered in the institute in Cologne is POLIS.

Box 1: POLIS (*Politik und Internationale Sicherheit*) - A Strategy Game for Teaching International Economic Policy and International Security

POLIS is a multi-functional game that reflects the world situation politically, economically and militarily. The structure of the game is marked by the world being divided into 11 regions (Africa, Asia, Western Europe, Eastern Europe, North America, South America, China, Russia, the Arabic Countries, Japan, Oceania). Each region has a certain starting position, which is based on its present resources and its economic and military situation. Economically four goods are being produced or are found in this region: industrial products; agrarian products; energy and natural resources such as gas, oil and coal; and the potential for renewable energies.

The aim of the game is to develop global and regional strategies that *either* allow one's own region to prosper without any other region suffering overly; *or* - even better - to lead the entire world into a more peaceful situation. Each region is played by a minimum of 2 players, and up to 4 players can easily play per region to fill all the roles (a politician, an economist, a military player and an opposition player trying to topple his own government). The tasks for each player are handed out before the game; present international contracts are made available to the players; a huge world map illustrates the regional economic and military situation.

Roles can change during the play when players start identifying too much with their own role, though. In addition, there are players to play the World Bank, the international press and the international moderators. Two moderators are sufficient for playing the game.

The game is a true simulation of the world situation and it is based on an econometric estimate of the world situation. For such a complex game enough time should be allowed to play through a scenario: A minimum of 2 days is required, 3 days are better. The game is divided into phases of 2-3 hours in which specific political, economic and military decisions can be made. The consequences are discussed at the end of each round in an international round where each politician has to give a speech in front of the United Nations Security Council and defend his/her specific approach. International Committees and Conferences can be called in to discuss crises in world politics and world economics. Military conflicts can be set up and then have to be dealt with in the game.

The game gives junior teachers a good overview of how to bring a big crowd of learners together and practice self-oriented teamwork. Various subjects are covered such as economics, international policy, German (giving speeches and negotiating) and English and French (e.g. World Bank can be played in English, Africa for example partly in French) in a truly interdisciplinary way.

Junior teachers in Cologne liked this game so much that they started using it themselves in their respective vocational schools.

5. Teaching the "Essentials" in the Main Seminar in Cologne – what Junior Teachers Should Expect

"Essentials" in Cologne are considered the key areas to be covered in teacher training and this is why they are covered in the general courses on pedagogy and didactics (*Hauptseminare*). In blocks of approximately 20 hours they are offered to the trainees in different periods of the two-year program. The trainees document these "essentials" in their Teacher Training Reference Book (see Annex 1).

Of course, all the essentials are being fed with the latest literature as well as with texts and sheets from the relevant ministries for vocational teacher training in Cologne in the State of NRW in Germany.

These major in-service training elements within the teacher training center are mostly completed in the institute itself. They deal in different phases of the two-year training program with the following (trainees') questions and statements:

5.1. Why Do I Want to Become a Teacher in Vocational Education?

In this essential it is most important that the trainees realize that their own history had an impact on their becoming a teacher now. Trainees must come to terms with the fact that their personal experience has shaped their "teacher profile" and they must - with regard to their future development – be open to improve their teacher personality in the two-year training program.

A course "biographical self-reflection" pursues the understanding of his or her own biography and tries to make it transparent to each trainee. [6] Methods used in this course are based on psychological counseling and cover for example things like painting, acting, and doing fantasy journeys, just to name a few of the approaches.

[6] By the way, some trainees have also used this course to reflect about other settings in their lives outside the teaching occupation.

A first important part of this essential is done in the first week, before the trainees even see their vocational schools for the first time. After this one-week basic training course at the very beginning of the program, a two-day further training workshop at the end of the two-year program is carried out together with the schools. This further training has the objective of contrasting the intentions of the junior teacher in the first week, with his/her achievements and developments within the whole program.

5.2. How Do I Define My Own Didactic Concept?

Of late, vocational schools in Germany have been asked to take over more responsibility, act more independently and work in a more self-conscious and team approach. These principles also apply when it comes to developing one’s own guidelines for didactic work. The VETTI in Cologne teaches that teachers must develop their own didactical strategies. Naturally they have to relate to professional profiles, curricula and board exam requirements. However, the objective is for teachers to experiment with different didactical approaches and in the end to find their own way. This "way" is then in turn more than a mere strategy for planning lessons.

Training work in didactics puts trainees into the situation of students and encourages them to develop lessons that are age and school career appropriate. For example, the "Economic Principle" as a subject must be presented differently in an apprenticeship class for future bankers than in a class for full-time commercial college students (*Handels- oder Höhere Handelsschüler*).

Moreover, in the institute it is believed that curricular content must be translated into lesson topics that will strongly interest and stimulate these particular students: For example, which lesson topic is more likely to motivate learning: “The Equilibrium Price in Quantitative Theory”? Or “The Price Does it – We are Setting a Sale Price for our own Students’ Newspaper” - after the students have been through planning, designing, advertising for and preparing the lay-out of their own newspaper in previous lessons in economics and business administration!

Questions that junior teachers have, such as:

- How do students learn and what needs to be done to support this?
- What is the teacher’s (hidden) agenda in defining content, for example in economic policies such as the ecological tax reform in Germany?
- What is the general vocational and educational mandate of my school?
- Where may the students have been exposed to specific contents before this lesson (e.g. teaching marketing implies thinking before the lesson where the students have been exposed to it already)?
- What is the relevance of this specific topic for my students in their future? For example, when I teach the contract of sale, how does this relate to my students in apprenticeship classes or full-time students who have never had work experience?

- How can I make content very concrete and tangible? What should the examples look like and how do I structure the lesson so that my students are motivated?

  are all dealt with in a variety of didactic sessions.

The development of the didactical concept of each junior teacher is an essential that has a very high importance and it is greatly emphasized and that is why it takes part in the first quarter (i.e. the first six months) of the teacher training program. In a way, all the other later essentials have a supporting function for this one.

5.3. Selecting Methods That Fit Me!

The objective of this essential is to build up methodological competencies in junior teachers by presenting different kinds of methods that can be used in teaching. In Cologne this is done by teacher trainers using methods in their own groups for vocational pedagogy and in field-related courses, or by demonstrating methods in teaching in schools, and also in conferences, workshops and exam situations.

What is very important in the VETTI philosophy is that the trainer – unlike in some cultures where the role of the trainer is seen with an authoritarian touch - is seen as a moderator in learning processes for self-organized team work and his job as a coach is to make sure that permanent communication takes place among the participants. To this end it is so important that junior teachers learn how to get these competencies.

The junior teachers will perceive the content of this field of learning “methods” as an experienced work form, in other words they will see methods in their training program as carried out by their teacher trainers, their mentors in the schools and others. This is considered particularly important, because methods are believed to be used better after having seen them in operation first before attempting to use them in one’s own setting.

In the first step, trainees learn what is considered the basic repertoire in teaching in vocational education for example

- Phasing a lesson;
- Using group and partner work in a class comfortably;
- Motivating different groups of learners;
- Preparing different kinds of learning arrangements;
- Steering class activity;
- Offering patterns of learning; and
- Reflecting and debating together with vocational students.

As time goes on, junior teachers are confronted with increasingly sophisticated methods such as complex case studies, projects, moderation cycles, future labs and scenario techniques. To demonstrate the more advanced methods, close cooperation with the schools is sought by the institute.

5.4. Professional Communication – How Do I Implement This in Class?

Studies show that it is still the case in vocational schools in Germany that 60-80% of all the words said come from the teachers rather than from the students. It is no wonder then that some students graduate with communication deficiencies. [7]

Therefore it is regarded as very important that junior teachers reassess their communication competencies and come to a professionalization of their communication skills in the light of the above. Reflection and diagnosis competencies of teachers are supported in this essential.

The content in this area is therefore to

- Learn to be able to take a role in discussions;
- Structure the tasks;
- Listen actively and carefully;
- Provide and receive feedback; and
- Summarize results in groups.

When referring to professional communication, it is always better done than talked about. This is why in the institute, communication exercises are offered in a variety of situations. A very handy and vivid tool in improving professional communication is certainly the video recorder to provide feedback after videotaped sessions. This tool is used a lot in VETTIs.

5.5. Working and Learning in and with Groups

Junior teachers teach in ever changing groups, they work in different conference and project groups and they have to adapt to new groups all the time. The objective in this essential is for trainees to become more and more aware of group processes and increasingly capable of actively steering, promoting and evaluating group processes.

Five different group settings are offered in the VETTI in Cologne:

- Field-related groups for each of the two academic fields of the junior teachers;
- Groups for general pedagogy and didactics for dealing with the essentials of teacher training in vocational education;
- Advisory groups for work with the vocational school staff;
- Peer groups of junior teachers for exchange of information and experience; and
- Project groups for specific cooperation among junior teachers, school staff and VETTI.

---

[7] Of course, communication skills are also dependent on class and educational level of parents.

The group work focus as it will be shown below in Chapter 6 is one of the key elements in the Cologne teacher training approach. Junior teachers are supposed to feel comfortable in their own learning groups as well. A lot of work is done with group dynamic approaches.

In a basic training phase, those trainees who have not had experience in youth or social groups are put together so that they can become better acquainted with the typical phases of group processes. In a further training phase, trainees can select from the following:

- Group lessons: initiating, accompanying, wrapping up and evaluating group work phases of students
- Group intervention methods
- Observing, steering and reflecting social processes and
- Improving social behavior and team competencies of students

5.6. Media – More Than Just Learning Devices

In the VETTI in Cologne it is the goal to use media when they are justified for learning with the junior teachers and their usage in schools should be derived from their usefulness and necessity for learning with vocational students. We consider media useful and necessary, when the following criteria are met:

- Media are tools in a process of getting students to learn better;
- Media are no means in itself;
- Media can be used to shape the problem analysis in a lesson;
- Media can be used to better visualize solutions and show transfer of competencies gained in the lessons; but also
- Good media usage alone never makes good teachers!

In principle, media should be selected or prepared by the trainees themselves (if possible). The content of this essential is *how* and *when?* to use media such as blackboards, overhead projectors, information sheets, school books, flip charts and others. Using media is considered to be part of the job and every trainee should be comfortable using these.

In a further step in this essential, some field-related groups usually produce their own media, such as videos and CDs. However, media production is seen as a side product of this essential and it is only done, if enough time for this can be provided within the VETTI.

Junior teachers should be able to handle media comfortably and this is also why the institute puts emphasis on dealing with more sophisticated media in vocational schools. This is the reason why the “European Internet Driver’s License” is expected from students at the end of their training, as is the ability and the willingness to experiment with other media. Video can be used in school, it can also be used to tape case study teaching situations and discuss them afterwards vis-à-vis the following video usage criteria for trial-run teaching situations, such as:

- Organizing recognizable phases in teaching;
- Setting up learning arrangements for the students;
- Communicating with students;
- Using different strategies to make students participate;
- Promoting competencies in teaching situation;
- Dealing with disruptions in class;
- Relating with the students (such as appreciation and understanding).

Last but not least, Cologne has the reputation of being the City of Media in Germany because so many media, television and radio companies are based there. In teacher training and also in every day vocational education, this often provides opportunities to work with the apprenticeship program of "Media Clerks" in Cologne on a very high technical level.

5.7. Making Assessments and Judgments as a Teacher

Every one of us has had the experience in school of how painful it can be when we felt that our teacher did not grade us correctly! Now the junior teachers change sides and for the first time they have to grade, too.

In this essential the junior teachers learn how to put together written tests and check achievements in

- Learning;
- Methodical; and
- Social competencies.

In this essential structured help is given to the junior students as to how to

- Set up tests covering the same topics for different age groups;
- Cover all the competencies laid out in the previous lessons;
- Deal with the aspect of turning competency achievements into "gradable" tasks;
- Return tests with a maximum of "learning" to all the students in the class.

However, it is not only the grading that they learn: at least as important seems to be learning how to support and promote those students who have not done so well. Special emphasis is given ways to deal with underperformers in vocational classes and how to get them back into the "main stream" of learning.

In other words, trainees learn how to put together written tests, grade them and return them to their class following certain guidelines. They learn – with the help of teacher trainers and senior teachers in schools - how to develop alternative grading procedures, for example when it comes to making assessments about group or project work[8]. And they develop criteria on how to assess and judge reflection learning of their students, using qualitative criteria in measuring different competencies.

They learn about typical misjudgments of vocational teachers, and they learn how to prepare written reports about students and how to defend them in grading conferences in their schools.

5.8. From Advice to Counseling – An Important Difference!

We all have given advice in our lives here and there and some of us are even paid for that as consultants! However, counseling as understood here goes beyond advice. Counseling starts a process that is not only learning to give advice, but also convincing people to accept it. At the end of this process, the trainee should be capable of giving advice to others in such a way that those on the receiving end are capable of integrating it into their repertoire.

The objective of this essential is to build up counseling competencies in the junior teachers that enable them to carry out their counseling tasks in school professionally. One thing is helping students find their way through the jungle of possible school careers in vocational education, and this is among other counseling opportunities in daily school life one that is appreciated very much by the junior teachers.

In this essential, junior teachers learn the basics of systemic counseling, cooperative reflection counseling (*kollegiale Praxisberatung*, see Box 2) gestalt therapy, and elements from the neuro-linguistic programming, NLP, counseling approaches.

In Cologne, once again, the thrust is learning counseling through actually doing counseling, and so many life-counseling situations are offered in the institute. Furthermore, the school as the learning venue for counseling is used a lot e.g. counseling parents, other teachers, firms and of course students.

5.9. Completing the Teacher Functions with Administrating and Organizing

Daily administration and organizing duties shape the routine work of our vocational teachers. The objective of this essential is to prepare them for basic administrational and organizational tasks, such as running a class journal, informing students about vocational school laws, understanding legal aspects of being a teacher and the legal results of misjudgment and misbehavior, telling students about cooperation opportunities with training companies, encouraging junior teachers to participate in school profile development, and the like.

---

[8] For those interested in measuring group or project work, you will find an example of how group work can be graded creatively with the help of the "fish bowl method" in Chapter 8!

In addition, junior teachers are trained in forms of self-organization in school. They receive guidance in organizing class trips and how to work with parents and other partners in vocational school life.

6. Working in Teams – An Important Self-Organized Planning Tool

Group and teamwork is one of the key instruments of the VETTI in Cologne. The reason why this is advocated so much in Cologne is that the teacher trainers there believe that groups provide an excellent framework for junior teachers to:

- Benefit from synergic group effects and the number of opinions expressed in each group;
- Communicate with others about their own theories and models in didactics and methods;
- Search for clarification within familiar groups and support others in this quest;
- Activate energy to turn their group into their “Pedagogic Home” and develop gradually their professionalisation; and
- Find comfort and support in their own peer group and help to provide a special learning climate within the group.

These objectives are tackled in the Cologne teacher institute through a number of organized groups as well as with spontaneously- organized groups, including:

1. **Field-related groups (*Fachseminare*)**
2. **Groups for general vocational pedagogy and didactics (*Hauptseminare*)**
3. **Advisory groups (*Beratungsgruppen*)**
4. **Peer groups**
5. **Project groups**

1. With the beginning of teacher training for vocational schools, trainees start two **field-related groups (*Fachseminare*)**, which are related to those two subjects where they got their university degree in, for example a so-called First State Board Exam in Economics and English. In Cologne a number of vocational subjects are offered alongside with so-called general ones for field-related group work.

Some vocational subjects offered in the VETTI in Cologne are:
Economics and Business Administration (*Wirtschaftswissenschaften*), Banking (*Bankwesen*), Insurances (*Versicherungswesen*), Trade (*Handel*), Taxes (*Steuerlehre*), Home Economics (*Hauswirtschaftslehre*), Food Technology (*Lebensmitteltechnologie*), Automation Technology (*Steuerungstechnik),* Automotive Technology *(Kraftfahrzeugtechnik)*, Production Technology

(Fertigungstechnik), Electronic Engineering *(Elektrotechnik)* and IT-Technology (*Wirtschaftsinformatik*).
In the so-called general subjects German, English, French, Political Science, Sports, Physics and Spanish, among others, are found.

Each of the two subjects is offered once a week for two hours. For heavily frequented subjects (for example economics and business administration in the 1998 training program had almost 70 trainees), several groups are in place. For each group, one teacher trainer is in charge throughout the whole two-year training program. In any case, the size of each of the field-related seminars should not exceed more than 15 participants because of group dynamics and learning economies of scale.

2. When the new teachers join the vocational education teacher training institute at the beginning of their two-year training program, a number of **groups for general pedagogy and didactics (***Hauptseminare***)** are built by the teacher trainers and course work following the “essentials” (see Chapter 5) is developed by them. These courses are usually offered once a week for 3-4 hours and last 6-8 weeks and the trainees can pick those they like with the individual trainers that handle them. These courses cover all the "essentials" considered necessary in the Cologne institute and the trainees get to know different teacher trainers in their respective teaching styles. Furthermore with the learning groups changing every 6-8 weeks, the trainees also get to know many different fellow junior teachers at the beginning of their training.

After about 1/3 (=8 months) of their training period, trainees choose their teacher trainer in charge of general pedagogy and didactics for the rest of the training. This teacher trainer (*Hauptseminarleiter*) then is in charge of accompanying the trainees through the rest of their training and preparing his/her own group for the exam situation. These teacher trainers work very closely with the ones in the field-related groups (*Fachseminare*) and are also invited to visit case-study teaching situations (see Chapter 7) of their trainees. Moreover, these teacher trainers write the final reports (which summarize the trainee’s development in the two-year program and finish with a grade) and are present in the final state board exams. Evidence has shown that the junior teachers are very happy with this reliability and certainty in the last two thirds of their program.

3. **Advisory Groups** (*Beratungsgruppen*) are put in place together with the vocational schools. The objectives of these advisory groups are to give advice to each other in a specific school setting as well as discuss teaching situations in various parts of a vocational school. The VETTI in Cologne has drafted a contract with each vocational school in and around Cologne that participates in vocational teacher training to specify the cooperation between them as to what each vocational school is willing and capable of doing.

Usually the schools agree to setting up advisory groups (or so-called newcomers groups). Junior teachers (depending on the school, varying from as little as 2 to 7 or even in some cases more than that) from one vocational school are put together in these groups. A specially nominated teacher training mentor (*Ausbildungskoordinator*) from each school invites and chairs meetings that can be held bi-weekly or once a month, with 1 hour a week of this kind of group work counting as credit for the teacher training program. All of these activities at the schools are called the Accompanying Program and this program is monitored and evaluated by each school.

A special method is proposed for these advisory groups by the VETTI in Cologne, which is called "Cooperative Reflection Counseling" (*kollegiale Praxisberatung*).

Box 2: "Cooperative Reflection Counseling" (Kollegiale Praxisberatung) – Problem Solving in Teacher Training Using Group Synergies

This counseling approach has been developed in the Cologne institute and is used frequently there. It is practiced with junior teachers and senior vocational teachers as well as with teacher trainers. Cooperative Reflection Counseling is structured in six phases plus an agreement both at the beginning and at the end.

The agreement at the beginning sets the tone for the counseling and identifies seating arrangements, regulates meeting frequency, promises total discretion and agrees on the moderators.

In phase 1, the group identifies a problem within the highest priority. To that end it is important that every participant is clear about what kind of counseling they need for themselves and that the moderator lets the group decide which person's request it wants to deal with.

In the second phase, the person whose problem is taken up explains his/her specific situation and why the problem is so urgent. Certain questions can help identifying the problem in this phase, such as:

- What happened?
- What are my thoughts?
- What is my problem in this?
- Whom does this intimidate other than me?

In phase 3 the person seeking counseling gets feedback from the rest of the group. The participants usually give two kinds of feedback; one is the so-called "outer perception" relating to verbal expressions, language used, pitch of voice, interaction (*Appell, Selbstoffenbarung, Beziehung*), and also relating to non-verbal expressions such as gestures, mimics, body language etc. The other perception level is called "inner perception" and relates to the participants of the group and their reactions, feelings, images, fantasies after listening to the person that is seeking counseling. The protagonist gets the chance to respond to the feedback.

Phase 4 raises other perspectives and multiple meanings that result from the problem layout. The participants come in with sentences like
In your position I would …
I make the hypothesis that …
I have a wild thought …
It is important in this phase that everything goes and nothing is forbidden!

In phase 5 the whole team develops alternatives. Helpful are sentences like "I as the teacher, … student, … teacher trainer, … director, … mother, … chamber of commerce representative would do …". The group is supposed to come up with a lot of alternatives and new patterns. The protagonist should then pick out what suits best and also give a feedback to the group.

In phase 6 the protagonist decides what is good for her/him in that situation and which alternative will be taken over in his/her repertoire. A role-play trying out these new habits at the end of this phase is good for exercising new patterns before going out into school routine again.

The final agreement is always helpful for the protagonist, because a certain degree of commitment is made. A sentence like "I am going to try it out and I will let you know next time!" is good when it is wrapped into questions like:

- Who does this with whom?
- What exactly do I want to do?
- How do I want to do it?
- When and where will I do it?

I have personal memories of the following counseling situations in which cooperative teaching counseling was practiced and interesting new patterns were developed:

- A teacher trainer seeking counseling, because he had a junior teacher in his group who was absolutely resistant to counseling in case study teaching situations;
- A trainee who had the impression that her teacher trainer in economics would never appreciate her work in creative methods, but would rather criticize her for lacking didactic considerations;
- A training coordinator at a vocational school who had difficulties with trainees in her school who would not open up their thoughts before going into case studies and thus were repeating the same mistakes all over again.

4. Experience in Cologne has shown that junior teachers in vocational education benefit a lot when they are grouped together with **peers**, i.e. junior teachers from different vocational schools and not necessarily always with the same technical backgrounds. These people meet regularly in groups of 4-6 and discuss best practices they have seen or done themselves and find patterns of why things work in some settings but not in others.

These groups can pick issues that are relevant for a specific vocational school such as for example how to handle learning resistances of full-time students in Commercial Colleges (*Handelsschulen*). The students in these schools are usually between 16 and 18 years of age and have not completed a secondary school; they also very often do not have the best chances in entering the labor market after graduation.

The peer groups can also select issues that are of a more general nature such as preparing for a teacher's conference or for a parent-teacher day at a school or something for an open house of the vocational school.

The participants can choose the number of meetings. Some formal things, however, such as the obligation to write minutes of each meeting as well as a minimum peer group duration of 20 hours throughout the two-year program are required. Evidence shows that trainees are very comfortable with this group and even tend to spend much more time working like this.

5. **Project groups** round up the group learning approach in Cologne. These project groups are put into place, when specific cooperation is called for, such as supporting and promoting the idea of reflection learning, or using teaching methods in vocational training that require special arrangements.

These project groups are in place for a minimum of 6 weeks and work very closely with the vocational schools. Ideally, cooperation among a group of junior teachers and one or two teacher trainers from the institute, a vocational school class and one or more of their teachers will be developed.

Frequently trainees in the teacher training programs realize that the "honeymoon" in teaching is finished after a few weeks in school and the bonus of being a very new teacher is over very quickly. Disruptions and troublemakers are also part of our daily routines in vocational schools and everyone has to deal with these, including junior teachers. As an example of a project group, a group of junior teachers in the Cologne institute asked some teacher trainers for advice on this and an interesting project group was started, which is documented in Annex 4.

7. Trial-run Teaching Situations – Teaching and Feed-Back

Trial-run Teaching Situation (TRTS) is the English translation for the German *Unterrichtsbesuch*. There are many kinds of case-study teaching and TRTSs can be used to meet different objectives throughout the two-year program and even after that.

Trial-run Teaching Situations (TRTS) of junior teachers can be done:

i. In front of senior teachers from the teacher training center, or
ii. In front of members from the peer group or
iii. In front of colleagues at a vocational school or
iv. In front of members from the advisory groups or within project groups.

The important thing is that they are always “teaching experiments”, where the new teachers have the right to show where they are at in their development and they have the right to make mistakes.

A minimum of 6 TRTSs are required in each of the two teaching subjects of the vocational teachers. This brings it to a total of at least 12 teaching situations in which the trainees invite senior teachers and teacher trainers to first sit in the lesson and later discuss the experiments together with the junior teachers.

TRTS follow certain rules. The junior teacher, prior to the teaching situation, hands out a written preparation for the case study to all the participants. In Cologne, different ways of written preparations for TRTS exist. One that was developed by the Director of the Cologne VETTI, Mr. J. Martin Thees himself, is shown in Annex 2: Trial-run Teaching Observations. It has criteria for the main categories in:

- Planning competencies;
- Implementation competencies (with respect to content, methods and communication); as well as
- Teaching competencies in the class itself.

The worksheet shown in Annex 2 was developed for the participants in those situations in order to have a list of criteria and questions what exactly to look at. The guidelines are given to all the people observing the lesson and the focus is preparing the participants to talk about the teaching experiment later. It also helps teacher trainers to look at their own notes when they have to prepare for the "planning and development talk" with each trainee halfway through the training, as well as in preparing for the final report to be written about each individual trainee.

When correctly practiced, trial-run teaching gives invaluable quality feedback to trainees that will enhance their learning and give orientation to their improvements as vocational teachers.

In Cologne, TRTS are practiced very frequently - as mentioned above, in various group settings and with members of peer groups and project groups. Experience has shown that TRTS lose some of their "exam character" due to this frequency and varied settings, and hence trainees become more relaxed about them and look at them more as learning opportunities.

This is positive, because the real learning takes place in the counseling situations after the case-study teaching situations! Up to this point the trainees have planned and carried out a lesson and now they are open to feedback. Feedback can be given in the form of Cooperative Reflection Counseling, as described in Box 2 of this paper. It can also be done in different settings. It is of utmost importance that the trainee her/himself gets into the position that she/he comes to realize alone what to do differently next time.

Once again, it was discovered in the institute in Cologne that if giving advice here is practiced (instead of counseling!), then junior teachers will only accept this advice for the duration of the TRTS and will not change habits.

If, on the other hand, the trainees feel comfortable in these peer situations, then they may themselves come up with their own observations, like: "The students were so passive in participating. Do you think that could relate to my planning things too much, instead of involving them in the planning process more?"

If this is the conclusion of a talk at the end of TRTS, the trainees have learned indeed much more than by having received tons of advice by more experienced teachers of what to do better in this or that situation!

Furthermore, teacher trainers in Cologne believe that these TRTS should not be one-sided, with the same people always teaching and the same people always sitting and listening. Good teacher trainers themselves teach in various settings of vocational schools as well and let the trainees observe, listen and assess the good, but also the bad in senior teachers' lessons. One real situation, which some teacher trainers in Cologne put themselves into, is described in Annex 5.

8. The Field-related Group (*Fachseminar)* in Economics and Business Administration in 1998-2000

When junior teachers come to the teacher training institute, the key question for each seminar group in the beginning is certainly how to organize content and topics and how to relate objectives and essentials in a meaningful way. Annex 3:

Teacher Training in Economics and Business Administration (*Fachseminar*), illustrates the work done during the two years in my own group.

It should be mentioned here that this is just one example of one teacher trainer in one field. There are many more fields and many more teacher trainers, who might very well make other choices.

As can be seen there from my list of topics covered, the economics and business administration group placed a high importance on slowly adding tasks of higher sophistication.

What helped me as a teacher trainer in the economics and business administration group in my preparations was using the following didactical questions:

- **Q.: What should be covered in the first quarter of the training sessions? (Blocks I and II in Annex 3)**

A.: I found it particularly important to first expose the junior teachers to the different school careers in our branched out vocational education system in Germany (Block I,1-2). Criteria for good teaching were then examined and to this end we first worked on questioning techniques and how to get students to participate in lessons through skilled paraphrasing and affirmative commands in teaching (Block I, 3-5).

In a second block (Block II, 6-12) we learned how to turn content into topics in our lessons. For example, we would look at sales contracts in business administration, and I together with the junior teachers would jointly develop – for example – lessons on sales contracts aimed at making the topic interesting for different kinds of students. For example for a full-time commercial college class (*Handelsschule*) in office management we would design a lesson like "We want to enlarge our product range: how do we get information about pens and pencils?" This would lead to writing inquiries and eventually to a contract of sale cycle. After coming up with modules, we would select examples for the lesson and design lesson openings and conclusions for different groups.

- **Q.: Why do I put so much emphasis on working in learning fields and learning situations? (Block III: Learning Fields and Learning Situations)**

A.: In the third block of the field-related work (Block III, 13-18) the reader might notice the expressions "learning fields" and "learning situations". These characterize real-life or employment-related situations that are used to structure the learning in vocational education. Let's take an example in business administration: In the curriculum in business administration for practically all school careers you can find a sentence like "Students should be able to plan a marketing concept for a specific product".

Until 10 years ago this would have been covered by the teacher in business administration alone and he/she would have taught what a marketing concept is and then the students would have learned it by heart and produce their knowledge in multiple-choice test (and most likely forget it soon after!).

In planning a learning situation now, teachers from one school career (*Bildungsgang*), for example in a full-time commercial class would sit together and see how this situation could be covered not only by the teacher in business administration but also

- by the teacher in mathematics (since there is a lot of calculation involved when it comes to pricing the product);
- by the teacher in English (since the product might be sold in South Africa or India);
- by the teacher in German (since oral presentations of the marketing concept to the management of the company will be trained in this learning situation); and
- by the teacher in accounting (since the costs for designing and the revenues that will flow from a good marketing concept will have to be calculated).

I think it becomes obvious from this example that learning situations change our thinking as teachers in vocational education dramatically and require new thinking. This is trained in every field-related group and requires putting so much emphasis on this block.

- **Q.: How can this topic best be learnt? (Block IV: POLIS)**

A.: Learning fields and learning situations can be developed by teachers and junior teachers, but they can also be generated from methods and games that can be used in business administration and economics (like in Block III, 19-21).

My experience in preparing the strategy game POLIS (see Box 2) has shown that studying as well as teaching international economic policy can rather be learnt best by using this game that not only motivates but also kind of playfully teaches more international economics than a teacher can possibly get across in the same amount of time in conventional teaching.

Moreover, and that is the nice thing about this game, POLIS can be used at the beginning of the school year and together with the students (yes, with the students, too!) learning situations can be earmarked that are worth working on in the continuation of class teaching in economics.

In my own experience after having played POLIS, students in my vocational college wanted to focus much more on price mechanisms in international economics (since they did not quite understand, why there are so many agrarian products in the world, but apparently not everybody would benefit from that in the game and if so, they did benefit only at extremely high prices for food!). This apparent problem situation was used to structure my learning situations and thus referred to students' interests in economics (which, let us be honest, does not show off so obviously very often!)

- **Q.: How can I grade written and oral contributions of my vocational students? (Block V)**

  A.: A different way of teaching requires a different way of assessing students' accomplishments. The following techniques were used in my seminar in Block V. Reflection learning calls for independent student planning, implementing, monitoring and evaluating. If this notion is accepted, then assessing those learning processes has to go through the same cycle.

  This is why in this part of the field-related work, heavy emphasis is put on showing junior teachers how to organize written tests. Coming back to the marketing example, a written test would consist of an open task that would be turned into a marketing strategy. The students would have to show their abilities in planning, implementing and evaluating and thus prove a number of different competencies. Of course in such a test there is no master copy of the test in the hand of the teacher. Individual solutions will have to be assessed individually. This will be learned in Block V.

  Assessing oral participation is covered at length in this part of the training. For example, it is often said that group work is hard to measure and even harder to turn into quantitative grades. In reflection learning processes it has been found that it is useful to have more than 50% of the final grade come from oral participation. To this end qualitative indicators are introduced here, such as criteria for oral achievements.

One approach to assessing group results practiced with my students was the “fish bowl method”. At the end of a group activity or working group, the moderator calls one representative from each group to come into an inner circle, while the rest sits in an outside circle. The inside circle then discusses the achievements of each individual group vis-a –vis criteria previously agreed. The outside circle can speak up any time when someone thinks that the discussion is not accurate. The fish bowl continues until for each group a grade or validated accomplishment has been found.

- **Q.: Where will cooperation be successful and which learning methods are considered helpful in specific situations (such as projects, learning in peer groups, future labs, scenario techniques etc.)? (Additional Block)**

  A.: As can be seen from Annex 3 (Additional Block), there was a heavy emphasis in my seminar on special projects - teaching sessions going beyond the 45-minute rhythms. Future labs, scenario techniques and POLIS have been explained in some length in this paper already.

  For example, I used the first module in accounting in commercial apprenticeship as a way to learn to use reflection learning techniques in accounting (Additional Block, 2). My junior teachers developed lessons involving their apprenticeship students in their vocational schools in a situation where a school library would be set up (together with the German teacher). The task of the junior teachers now was to transform this project “school library” into a reasonable accounting system which documented books bought, sold or given away, balance sheets by the end of the year, profit or loss statements etc. I have never seen teachers develop so much interest in teaching accounting!

  The other block we dealt with is called the *Lernbüro*. Physically a *Lernbüro* is an office, not a classroom. The students carry out office work for small “artificial companies”. Each *Lernbüro* is run by a teacher or a team of two teachers who behave not like teachers, but more like the owner-operators of a small enterprise.

  The work in *Lernbüros* in NRW was started some 17 years ago and now *Lernbüro* work is a school subject in itself with 3 hours a week in most classes. Junior teachers learn how to teach in

Lernbüros when they are in the VETTIs, and *Lernbüros* are a part of every group in economics and administration as well as of the focus of the trial-run teaching situations.

- **Q.: And what will be the focus immediately before the exam? (Block VI)**

  A.: The focus immediately before the exam is of course on getting the whole field-related work rounded up. That means that colloquium exam situations will be role-played. Expectations for trial-run teaching situations (TRTSs) will be elevated to exam level and each junior teacher's reference book (see Annex 1) will be checked to ensure that all the necessary work has been completed (see Table 1).

Purposely, in order to "teach by example", teacher training in my field-related group of economics resembled trial-run teaching situations of my own junior teachers in school, with the teacher trainer in this group obliging himself to lay out his planning activities, list his objectives for the training session, carry out the seminar and at the end get feedback from his junior teachers on his performance in that particular training session. Written preparations of the teacher trainer were also open to the feedback phase at the end of each training session.

In this field-related group of economics and business administration my junior teachers first examined who were their students and what would interest them, and only then started developing lesson plans. They looked at learning processes in economics and began to develop more complex teaching learning situations. And finally they became comfortable with other vocational teacher functions in economics such as assessing performance, counseling students and parents and learning how to be comfortable with reflection learning processes in economics, through learning arrangements going beyond the 45-minute rhythms of our daily routines in vocational schools.

9. Monitoring and Evaluating Mechanisms by Teacher Trainers in Cologne – Continuous Improvement Assured

In this chapter, some monitoring and evaluation mechanisms will be described that are routinely being used in Cologne during and after each two-year training and certification period. The results of these evaluations are then fed either directly into the ongoing seminars or into the following cycles of teacher training.

Briefly, five different activities for quality control will be described in this chapter.

1. “Jour fixe”

The “jour fixe” is a regular meeting of all the teacher trainers. As a way of giving feedback among the teacher trainers and providing a forum for ongoing work among the various field-related groups (*Fachseminare*) and groups for general vocational pedagogy and didactics (*Hauptseminare*), bi-weekly to monthly meetings are held, which are called “jour fixe” in the Cologne vocational education teacher training institute terminology. The "jour fixe" brings together the entire teacher trainers in the institute.

These half-day to full day meetings have the function of critically monitoring the ongoing training cycle and providing a forum for discussion. For each jour fixe, 4-6 teacher trainers sign on as responsible moderators; they are in charge of clarifying the agenda with their colleagues, moderating and documenting outcomes. Lately meetings have focused on

- Implementing new legal framework for teacher training into daily work in the institute;
- Identifying training needs for teacher trainers; and
- Developing identical criteria for good lesson planning and implementation.

2. Further Training Programs for the Teacher Trainers

Training programs are also offered for teacher trainers in the institute and lately have focused on

- “Systemic Counseling”;
- Mastering “Topic-centered Interaction” (*TZI=Themenzentrierte Interaktion*), a communication approach;
- Working with new media (Internet, Multi-media) in field-related groups (*Fachseminare*);
- Developing special learning promotion programs for weaker students;
- Using scenario techniques and future labs comfortably with junior teachers and students;
- Identifying “creative ways” to release organizational duties in schools

These training programs for teacher trainers usually take place outside of the institute itself, and outside experts help. They take place a minimum of once or twice a year and last a weekend or a couple of workdays.

3. Training of New Teacher Trainers by the Institute’s Director

This part of the program is used whenever new teacher trainers are appointed to the institute. When new teacher trainers come to the institute, they usually need training in order to be equipped to carry out all the tasks of a teacher trainer competently. Of course, these senior teachers have already completed teacher trainings before, such as in the Teacher Training Center for Further Teacher Training in Soest, NRW (*Landesinstitut für Schule und Weiterbildung*), and very often have a lot of experience.

A typical preparatory training for new teacher trainers consists of 4-6 hour sessions each, for example in:

- Developing criteria for a "good" teacher trainer;
- Discussing and implementing counseling situations after trial-run teaching situations;
- Dealing with feedback from the field-related groups (*Fachseminare*);
- Accompanying written theses by junior teachers;
- Writing final reports for our trainees; and
- Assessing in a State Board Exam Situation

4. Evaluations in the Institute by Teacher Trainers

After each two-year cycle, evaluations of the program are done. Evaluation sheets are developed and distributed among the teacher trainers and the trainees. As a result of the evaluation, changes are made; in the last cycle for example, it was decided to put more emphasis on observing trial-run teaching situations in groups of junior teachers (*Gruppenhospitationen*), and the functions of the mentor programs in schools were strengthened.

The state board exam phase is also regularly up for evaluation. The last evaluation, for example, brought to light that the trainees seemed a bit weak in the didactical and planning parts of their exams, but on the other hand grades in the final reports of the teacher trainers correlated significantly with the final grades in the exams. It also came out that using the so-called "circular question method" more might help trainees in colloquium situations overcome situations in which they were blocked.

5. Evaluations in the Institute by Trainees

This evaluation is done on a voluntary basis by junior teachers who have been through the program. As a way of getting feedback from the trainees, the VETTI frequently asks the trainees to write down their impression of the program. The trainees describe their points of view, their experiences and their suggestions for future changes of the program. A flashback by a former trainee is given who has been through the two-year program and who has been in my field-related group of economics and business administration. Annex 6 gives her statement.

Annex 1: The Teacher Training Reference Book

Each junior teacher keeps a little booklet in which he/she writes down the different kinds of training they receive. In the teacher training reference book the six different teaching functions are listed, which are

- Teaching;
- Educating;
- Counseling;
- Assessing;
- Administrating/Organizing and
- Innovating.

For each essential training seminar – as listed in Chapter 5 – a cross-reference is made and it is summarized with its title, the number of hours and the name and the signature of the teacher trainer in this teacher training reference book. An extract from this book might look like this:

Vocational Education Teacher Training Institute, Cologne

XYZ

Institute Reference Book

Junior Teacher's Name: ____________________________

Function: Teaching Essential: Didactical Concept		
Topic	Hours	Teacher Trainer

Function: Assessments Grading Achievements – Promoting Students		
Topic	Hours	Teacher Trainer

….

Annex 2: A Form for Recording Trial-run Teaching Observations

Trial-run Teaching Situation Observations with Ms./Mr. …………… On Lesson In Topic Class

1 Planning the Lesson

Class Situation

Didactic Decisions

Selection of Content
- Reduction
- Setting priorities

Objectives
- Interdisciplinary
- Competency-based
- Oriented towards real life and employment
- Educational

Process Planning

Intended Students' Independence

Articulation

Work Forms

Media and materials

Learning Success Control

Innovative Potential

Conclusion for Planning Competency: **Didactic Competency**

2. Implementing the Lesson (Content)

Recognizable Phases

Independent planning of students

Shaping out objectives

Independent carrying out by students

- Appropriate level for students
- Content correctness
- Setting priorities
- Oriented towards real life and employment

Independent assessment by students

Learning Success Control

Conclusion for Implementation Competency (Content):

2. **Implementing the Lesson (Methods and Communication)**

Learning Arrangement
(Training, Lecture, Project)

Social Class Activity
(Group, Individual, or
Partner Work)

Didactic Function (Exercise,
Transfer, Application, Control etc.)

Patterns of Learning

Communication Competency

- Communication structure
- Clarity and Style
- Modulation

- Division of communication between students and teacher

Media and material usage

Student Participation and means to make students participate

Conclusion for Implementation Competency (Methods And Communication):

3. **Teacher Activity**

General Behavior/Activities (Security, Calmness etc)

Promotion of

- Self-orientation
- Methodical competency
- Learning competency
- Social competency
- Morale
- Communication competency

Activities in disruptions

Educational competency

Relation with the students
- Appreciation
- Understanding
- Emotions

Conclusion for Teacher's Activities: **Pedagogical and social competencies**

Annex 3: My Economics and Business Administration Group (*Fachseminar in Wirtschaftswissenschaften*)

(Each topic refers to 180-minute sessions)

Block I: Students in Different School Careers

1. We identify expectations within the *Fachseminar* of economics
2. First experiences with a vast number of school careers in our schools
3. We develop criteria for "good" teaching when we observe senior teachers
4. Educational backgrounds of our students in different school careers
5. We analyze the consequences of students' backgrounds for our lessons in economics

Block II: The Topics in our Lessons in Economics

6. The "good" teacher in economics
7. My path to find a topic
8. My lesson should have a topic – bringing in a perspective
9. Developing a didactical planning aspect
10. We develop a didactical analysis
11. Didactical work in analysis and learning situations
12. Alternative didactics in economics

Block III: Planning of Teaching and Learning Processes

13. Reflection learning, learning fields and learning situations in economics – definitions and dissociation
14. Learning objectives and competencies – where are the differences?
15. Contd.
16. Learning how to "learn" in economics
17. Sharpening our didactical profiles in economics
18. Analysis and structure of written case-study teaching experiments

Block IV: Enhancing Teaching Competencies - Preparation of a Strategy Game

19. We develop didactical principles for strategy games
20. We plan the strategy game POLIS
21. We submit roles, identify strategies and discuss teacher intervention mechanisms for POLIS

Block V: Annual Didactical Planning; and Safeguard, Assess and Grade Learning in Economics

22. After POLIS: what do students want to do with their new skills: we build learning situations in economics – also according to the students' interests!
23. Assessing student learning in reflection learning contexts
24. Independent student assessment in economics – does that work at all?
25. We work with the introduced school book in economics
26. We develop class tests, grade them and return them to our students in a meaningful way
27. We develop strategies how to measure oral participation in classes in economics and integrate it into our grading repertoire
28. Assessing group work creatively: the fish-bowl method

Block VI: Counseling, School Career Didactics and Specific Exam Preparations

29. Systemic counseling – what for in vocational schools?
30. Beginners classes in full-time classes of vocational colleges (*Höhere Handelsschulen*) – we prepare the first week of teaching these students together with our colleagues in our vocational schools
31. Counseling these students regarding their entrance into the labor market
32. Using videos in economics and business administration
33. Personal computers and Internet – how can it be integrated in economics?
34. Simulation of a school career conference and carrying out annual didactical planning in one school career (*Didaktische Jahresplanung*)
35. Simulation of a colloquium situation in the final exam

Additional Block: Further Training in Economics – Going beyond the 45-minute Rhythms

1. Cooperation Project among schools “Problems in our School” (see Annex 4) – 3 one day training sessions
2. Cooperation Phase within the institute “Reflection Learning in Accounting”– five 4-hour sessions in the institute
3. Planning, carrying-out and evaluating playing a management game with students – POLIS (see Box 1) – a two-day training course
4. Trial-run teaching situations by teacher trainers – Using a scenario technique in business administration (see Annex 5) – a weekend training course in a vocational college
5. Simulated Enterprise Offices in Vocational Schools (*Lernbüros*) – a one-day training course on how to work in *Lernbüros* shown in one selected vocational school

Annex 4: "Problems in our Lessons" – A Vocational School Class (*Höhere Handelsschule*) Finds Its Own Amazing Solutions Using Robert Jung's Method of the "Future Lab" (*Zukunftswerkstatt*)

Teacher trainers from the institute were asked by teachers from a specific vocational school to work with them and their students on the situation "Problems in our Lessons". The time span available was three whole teaching days (8a.m. – 3p.m.) in that school, bringing together a full-time vocational class of 28 students, 4 of their teachers, 15 junior teachers (most of whom knew this specific class as well) and 2 teacher trainers from the teacher training institute.

It was decided to use one method of Robert Jung for this teaching experiment. Robert Jung had done research in the 60s and 70s in Italy about bringing out creative potential in people and developed a method, which is widely known as *Zukunftswerkstatt* in German, the English translation would probably be "Future Lab".

In the first phase of a future lab, participants criticize the present situation; everything is allowed to be said without evaluation. Criticism is written on cards, structured, clustered and headlines for joint points are found.

The second phase throws the participants into a phantasy and utopian situation in which coming up with "wild" solutions is called for. The participants are asked to fantasize about utopian solutions and to present their solutions in words, texts, role-plays, or whatever comes to their minds.

The third phase brings the participants down to earth again, asking them to think about how they can realize their ideas in real life and which steps are necessary to do that. Finally, each group has to present its solutions, and milestones will be set up to monitor and evaluate the success of each plan.

In this particular school situation, the future lab was played on three consecutive school Mondays. It was decided that the two teacher trainers from the teacher training institute, who had had previous experience with future labs, would serve as the moderators of the teaching experiment. The whole class showed up on all three sessions and nobody left even a minute early. Breaks were made when necessary, but certainly not when the school bell rang.

In the first phase, the students came up with heaps of discomfort. Various interactive and group-dynamic methods were used to work with the whole group. After all the criticism was expressed it was piled, structured and clustered. At that point it was hard to believe that anything could be done about it. This phase lasted the first day.

However, the second phase came up with very creative ideas by the students and the junior teachers and the groups had enough time to research and present their ideas. The work forms and the intensity of the work transcended everything the students and the trainees had experienced before in school and in the VETTI, and a lot of laughter, but also sincerity and willpower was found on the second day of this experiment. The presentation of the utopias in the plenary by students and junior teachers was both funny and very creative.

Before the last day, the groups were mixed again such as before the second day and the students, trainees and teachers worked again on preparing strategies to implement their plans. To this end, some of them went out to research food prices, others went to talk to the director of the vocational school to convince him of their plan, and others went on the Internet to research information. In the end – late in the afternoon of the third day, long after school bells had rung for the students to go home! - the moderators invited the director of the school to attend the presentation phase and see which of the projects could eventually be turned into real-life projects in that school.

The director of that school was not easy to convince about the usefulness of these projects, but in the end he let the students and the junior teachers do the following things in the months thereafter:

- Plan, set up and run a student café in the entrance hall of the college;
- Develop action lines for a to-be-established "Mediation Board" at that college; and
- Have students participate in class conferences together with their teachers.

In fact, methodologies similar to that used in future labs in Germany are used widely in many organizations and meetings when open-ended thinking is intended. Such brainstorming approaches are as useful with students of vocational schools in Germany complaining about school problems as with politicians from the Ministry of Education in Ethiopia in identifying bottlenecks in current teacher qualifications for commercial colleges or with teacher trainers in South India trying to overcome old structures in teacher training and using this method in order to plan their new teacher training institute structure.

Wherever it is used, in the end it is always a fascinating method that brings out both intuitive-emotional capabilities as well as rational-analytical ones in all the participants and it is always a fun-way of learning!

Annex 5:" Paving the Future" – Using Scenario Techniques to Teach Future Planning to IT-Students and Junior Teachers

Scenario techniques are methods that can deliver pictures of future situations. Scenarios are not prognoses, neither are they utopias and fantasies like future labs, but they provide quantitative data and information with the help of which detailed descriptions and possible future situations can be developed.

In each go, three different scenarios are developed:

- A positive scenario which describes the most advantageous future (best-case scenario);
- A negative scenario which shapes out the negative aspects (worst-case scenario); and
- A scenario that extrapolates current trends into the future (trend-extrapolation.

Some of the teacher trainers in the Cologne institute work with scenario techniques and one teacher trainer in Cologne carried out an interdisciplinary experiment working with scenario techniques, with an adult class in an Executive MBA Program specialized in computer science (*Fachschule für Wirtschaftsinformatik – Staatlicher geprüfter Betriebswirt),* together with an Information Technology (IT)- apprenticeship class of systems analysts (*Systemanalytiker*).

Participants were these two groups of students, about 10 junior teachers, and two experienced junior teachers on three consecutive whole days working an approximate 24 work hours. The work was done in the 5 classical phases of a scenario technique.

The starting point in the first phase is a problem where solutions are being desperately looked for. In the school situation with the classes mentioned, both groups had strong interests as well as a strong background in IT (one group was more focused on the commercial aspects, the other more on the technical ones).

The starting question was:”When you think of IT technology in Germany in the next 20 years, which opportunities and which risks do you see?” The answers were structured and clustered, for example in our case into economy, environment, society, and technical development.

In the second phase (which is called "impact analysis and descriptor definition") the clustered answers are used to find certain influential factors. Quantitative factors, for example the development of PC usage in Germany as well as qualitative ones, the attitude towards new technologies in Germany, were assessed. Of course, it is essential to have prepared a good documentation of information beforehand and to let the students also use other sources of information (such as the Internet) in this phase. In scenario techniques, this is the phase of gaining information and identifying factors that will influence the previously identified areas.

In the third phase, each factor, with its descriptors, gets projected into the future and its impact measured (e.g. positive technological developments might be counterweighed by measurements from the German data protection Board). Different descriptors might influence the trends differently, but their influence is always measured quantitatively if possible.

Phase 4 is the most interesting one, in which holistic scenarios of the future are drafted based on the quantitative and qualitative data. In our experience it was interesting to have more than 3 groups develop the different scenarios (best-, worst and trend). Having six groups instead of only three has proven to be ideal in order to be able to compare different views in each area. This phase ends with a presentation of the group results.

Finally, in the last phase, activities and reflection patterns are developed in order to find out what can be done to reinforce - or if it is undesired, to avoid - a certain trend. To this end a catalogue of activities is made that raises questions like:

- What can we do?
- How do we have to implement it?
- What might be the obstacles?
- How can we deal with them?
- Etc.

Scenario techniques were used in the German car industry at the beginning of the 90s a lot when the car crises was at its height and companies like VW, Daimler and Porsche were facing serious restructuring problems. Apparently, some of the German carmakers found creative solutions to come out of this crisis, while others did not!

It is not that long ago that these methods found their way into vocational schools in Germany. As can be seen from this example, the amount of reflection that is done when this method is used is quite amazing. It should be said, however, that running this method requires a lot of experience as well as discipline on the side of the moderators.

Annex 6: Flash Back – A Former Trainee in the VETTI in Cologne Looks Back After Completing the Program

"I did my teacher training from 1998-2000 in Cologne. Among others, Michael Axmann was one of my teacher trainers (*Fachseminarleiter*).

Teacher training in Cologne was certainly interesting if not always the way you expected it to be. This is one of the things typical for the Cologne institute – unconventional methods. Before I came there I expected to be trained in different teaching methods, provided with a lot of "tricks" and good advice. What I found was questions with no one providing answers but myself. This might sound unpedagogical, but what at the beginning seemed arbitrary, turned out to have a method behind it indeed. You had to find your own way. No one ever told you that what you did was good or bad – they just provided help in analyzing yourself.

The very first week, for example, felt more like a course in psychology than in didactics. We were asked to make ourselves the subject of discussion by analyzing our "biography". What the hell does that have to do with teaching, I thought. Well, I can tell you. Knowing yourself, knowing your reactions towards people, knowing how you yourself behaved as a pupil, knowing your innermost strengths and weaknesses – all that makes you acknowledge the kind of teacher you are and enables you to define your role as a teacher.

The courses were divided into "*Hauptseminare*" (main seminars concentrating on basic didactic work without referring to any special school subjects) and so-called "*Fachseminare*" (subject-related seminars providing information about certain didactic approaches for the specific subject, e.g. business studies).
The good thing about the **main seminars** was, that we were free to choose from a variety of topics. In that way, everyone had the possibility to choose something meeting his/her specific needs, e.g. if you felt you needed to learn something about how to handle classroom conflicts, then you would choose the corresponding course. As you met different teacher-trainees and teacher trainers every other month or so, the main seminars not only offered a wide range of topics but also a wide range of people to discuss with and to learn from.

The **subject-related seminars** were quite another matter, but nonetheless very instructive. They kind of got down to the core of it. If the things discussed in the main seminar often sounded vague and you didn't really know how to put them into practice at school, the subject-related seminars offered help in doing so.

Of course, none of the seminars would have been of any use without the daily work at **school**. With the help of experienced teachers who we were allowed to observe during class and who watched us doing our first steps in classroom, I became continually more experienced and self-confident. But again here, as in the seminars, it was mostly a question of your own initiative whether you learnt something or not. You had to find teachers to tutor you, you had to make them watch and discuss your lessons – all extra work not included in the teacher's salary. I was lucky to have found at least three teachers of that kind who accompanied me throughout my teacher training and whose feedback was invaluable to my learning process.

Communication between the junior teachers was regarded as highly important by the Cologne institute; so we were asked to form **peer groups** of three to six in order to discuss classroom matters. Those peer groups were not tutored or supervised by anyone; it was purely a matter of self-steered learning by exchanging experiences and discussing problems arising in school. Although it had a compulsory touch behind it, I quite liked the idea of being together with peers. It was comforting and reassuring to find out that they had similar problems. The peer groups provided room for discussing such matters and finding solutions to them.

The last thing I would like to mention are a couple of **special projects** that were offered during the two years of teacher training. Some were compulsory, others on a voluntary basis. There was a "pedagogical week" toward the end of the second year with all kinds of workshops, a ski-holiday focusing on group dynamics, a so-called "future workshop/scenario?" together with pupils and teachers of a vocational school and many other activities. I preferred the special projects to the regular seminars because they offered facilities the Cologne institute could not offer. The future workshop/scenario for example, was much more instructive than the theoretical seminars because it was a "real" situation with pupils and teachers, not a constructed situation. Also, during most projects, the atmosphere between junior teachers and tutors was quite a different one. It was a good chance to get to know each other and also find out some personal details both from fellow trainees and tutors.

Summing up I can say that those two years of teacher training provided me with invaluable information for my further career. It was not what I expected it to be in the beginning and I know that many fellow teachers were not quite content with the methodological approach of the seminars. For many (and at times also for me) there was a certain lack of input. Most courses consisted mainly of discussions and analyses of certain classroom situations while there were only little tips on how to manage them. Being a junior teacher in the Cologne institute required the ability to work independently as well as a potential for self-analysis and "self-steering". But only in that way was I able to find my "professional self"."

TABLES

Preface

This book is the culmination of a journey that started several years ago when experts from multilateral and bilateral aid agencies met to discuss the need to develop a uniform methodology for evaluating industrial training. As a result of this and subsequent meetings, the Agency for Technical Cooperation of the Federal Republic of Germany, the Overseas Development Administration of the United Kingdom, the Swedish International Development Agency, and the World Bank decided to underwrite the cost of producing a comprehensive evaluation guide.

The project required the cooperation of economists, educators, and vocational and technical specialists. We were fortunate to have the advice and help of Peter Sloane, Solomon Cohen, and Gunther Kolheyer during the writing of this manual, and we thank them wholeheartedly. Special recognition should go to Douglas Shaw of the Operational Development Section of the International Labour Organisation, who participated in our mission to Indonesia, where the manual was tested in the field, and who contributed many valuable suggestions to the final version.

We are also grateful to the representatives of multilateral and bilateral agencies who, at a meeting in London in July 1984, discussed a preliminary version of this guide and offered constructive criticism and helpful suggestions.

Introduction

This guide is intended to fill a gap in the resources available for evaluating training programs. The aim is not to write another textbook—with extended definitions of concepts, discussions of their theoretical underpinnings, and references to the literature—or another lengthy cookbook to guide the completely uninitiated reader step by laborious step through every problem and its variations. Rather, it is meant to be a systematic checklist for evaluators of vocational training institutions and for directors of schools or skill centers who want to identify the areas of their own institutions that need improvement.

As with any guide, the type of questions and the data requirements have to be adapted to the specific task at hand and to local conditions. For evaluation of a central training system, more specific questions may be needed; for assessments of in-plant training, many of the suggested questions may be superfluous, and for such problems as comparing the cost-effectiveness of different modes of training, the section on evaluating the efficiency of operations may be omitted or used as background. Although the guide is most useful as a tool for identifying critical points for improving the efficiency of training institutions or systems, it can easily be adapted, in part or as a whole, to all types of evaluations, and its usefulness is not confined to industrial training.

As chapter 1 emphasizes, the approach to the evaluation of a project depends on the purpose of the analysis. For this book we assume that we are engaged in evaluating, from the point of view of society, a training institution that offers pre-career, entirely off-the-job courses.

Diagnosing the efficiency of operations and, in particular, identifying inefficiencies and their causes require both qualitative and quantitative analysis. Chapter 2 explains the use of three checklists and supplementary worksheets (placed at the end of the text as appendixes) for these purposes. Appendix A (the checklist for the qualitative evaluation) provides a format for systematically recording subjective judgments on the key factors in the institution's internal operations. Appendix B (the checklist for the quantitative evaluation) calls for information on resources, costs, and student performance. (Questionnaires and forms for collecting supporting observations and data for these checklists are in appendixes D and E.) Although our main concern is with individual institutions, we have also included, in appendix C, a checklist and forms for describing the policies and procedures of the responsible central agency that affect the institution.

The checklists can be used not only for formal evaluations but also for periodic in-house assessments by school management. The user is free to adapt the checklists and worksheets to the particular occasion and institution. For example, if a school is using the checklists for its own evaluations, not all the supporting material in appendixes D and E will have to be collected anew each time. And whether or not a school undertakes regular self-evaluations, administrators may find that many of the worksheets are useful for keeping running records of operations.

Chapter 3 describes methods for assessing costs and outcomes in order to evaluate external efficiency—the effectiveness with which an institution fulfills its purpose. The literature on the subject emphasizes quantitative assessment—increased earnings of graduate trainees, employment rates of graduates, and so on. This chapter discusses extensively various cost-outcome measures but also makes the point that many outcomes are not easily quantified and that observations and interviews are important aids in interpreting the quantitative data. Examples of questionnaires that might be used to interview employers and former students concerning the value of the training are provided in appendix F. Because the indicators described in this chapter would be collected by outside evaluators rather than by schools, we have gone into less detail in this chapter than in that on efficiency of operations. Nevertheless, the purposely concise discussion of measures of effectiveness should be of interest to school administrators, and the examples of questionnaires may be useful in the school's own program of following up the employment experience of graduates.

Chapter 4 presents a compact format for summarizing results of the evaluation, using a numeric scale that can be used to compare several institutions as well as to identify the strengths and weaknesses of particular institutions. In addition, it suggests concrete procedures for conducting an evaluation, provides a sample timetable, and discusses issues that have to be considered in drawing up and administering questionnaires.

Throughout this guide we stress that an evaluation is much more than a series of cardinal measurements that somehow can be manipulated to yield a single figure on an efficiency scale. An evaluation also must include the impressions and qualitative assessments of experts whose experience provides a solid basis for judgment. It is hoped that the gestalt approach suggested here, which permits the blending of quantitative indicators with informed judgments, will be a further step toward the development of a comprehensive evaluation methodology.

1

Defining the Purpose of the Evaluation

Project evaluation involves the ex-post analysis of the functioning, outcomes, and costs of a project. If the evaluation is done as part of midterm monitoring, it will focus on ways of improving the project (for example, by redesigning its mode, curricula, or management) or perhaps on decisions about its continuation, expansion, or replication. If it comes at the end of a project, it will be mainly concerned with the project's success or failure and with drawing lessons applicable to subsequent projects.

The nature of the project is important to evaluation. Are we looking at a training system as a whole, a training institution, or a course? If at a course, is it intended for precareer training or for upgrading? Is it short or long? Off-the-job or on-the-job? The objectives of the project also affect our approach. Are the objectives defined in terms of efficiency, in one sense or another, or of equity? Finally, we need to know from whose viewpoint the analysis is being conducted.

The Nature of the Project

Evaluating a single precareer course that is entirely off-the-job is a straightforward type of project analysis. Here it is relatively easy to isolate costs and benefits. In the case of a course intended to upgrade skills, workers' performance before and after training may be measured. Evaluating on-the-job training is more difficult because of questions of costing that require special treatment.

Analysis of an entire training institution (unless it offers only one course) is inevitably more complex than evaluating single courses. Many institutions offer courses in a bewildering variety of subject matter, length, skill level (initial or upgrading), format (on- or off-the-job, full-time or part-time), and purpose (vocational or nonvocational). In such cases analysis of the demand-supply situation has to cover a wide range of occupations, and outcome-cost analysis, whether concerned with external or with internal efficiency, has to be disaggregated to the level of the individual course. The same is true of analysis of a whole system, unless it consists of only one mode. Thus, evaluation of, say, an on-the-job apprenticeship system can be conducted at an aggregate level, but evaluation of a system that includes several routes has to be disaggregated.

The Objectives of the Project

The criteria used by a project analyst obviously depend on the objectives of the project, but identifying these can be difficult. Projects often have multiple, sometimes conflicting, objectives. Most projects aim at being efficient, in the sense of achieving the highest possible outcome-cost ratio, but efficiency has several dimensions.

Efficiency can be defined in terms of academic performance—which may not be fully measurable by test or examination scores, including as it does increases in skills, changes in attitudes, cognitive development, and acquisition of knowledge. We need to know who is supposed to learn what, under what conditions, and by what date.

Efficiency also can be defined in terms of skill on the job after graduation. Measurement of a project's impact in this respect will not be easy in any case, but it will be impossible unless we know what the project was trying to achieve.

Another dimension of efficiency is productivity and income in employment, which may or may not vary directly with the degree of skill acquired by the trainee.

In projects that are not oriented toward the labor market efficiency may be particularly difficult to define. Gains in academic achievement or acquisition of skill may be among the results, but the project may also have important, not easily measured, effects on the morale or well-being of the participants. (Adult literacy classes are an example.)

Finally, a project's efficiency may be defined partly in terms of its indirect or spillover effects, such as a change in the role of women or the wider impact on the labor market of changes in the supply of skills.

For some projects success is measured in terms of their impact on equity. Their objective is to improve the relative position of a given underprivileged group with respect to any or all of the effects discussed above.

Whatever the objectives of a project, the analyst needs to have them clearly set out before he can select his criteria for evaluation. Where there are multiple objectives, and particularly if they conflict, it may be necessary for him to assign weights to them to arrive at an overall assessment.

The Point of View

The criteria used in the analysis also depend on the viewpoint that is adopted. Are we looking at the project from the point of view of the nation, or of society as a whole (the most usual practice)? From the narrower budgetary point of view of the government or the treasury? Or from the perspective of the aid agency involved in financing the project, the local community, or the firm that sponsors a trainee or an individual student? Taking any of these viewpoints can be useful for different purposes, and each implies a variation in method.

The Initial Checklist

In order to be clear about the purpose of a project analysis, it is useful to fill out an initial checklist (table 1.1). In the following chapters we will assume, for purposes of exposition, that we have checked the following items: A.2, B.1.b, B.2.a, B.3.a, B.4.a, C.1.a–c, D.1. In other words, we assume that we are conducting an evaluation of a training institution that offers long-term precareer, entirely-off-the-job courses; that the project's objectives include efficiency in all except the non-labor-market and spillover senses; and that we are appraising it from the point of view of society as a whole.

2

Evaluating the Efficiency of Operations

This chapter deals with the efficiency of operations (the internal efficiency) of a technical school or vocational training center. It examines the main aspects of internal operations, including the content and relevance of the courses, the teaching methods, the quality of the staff, the adequacy and utilization of space, the appropriateness and use of equipment, the effectiveness of management, and the interrelations with industry.

Evaluation of the efficiency of operations (accompanied by an understanding of the underlying factors) is a powerful management tool, both for the director or principal of the school and for the ministry or agency responsible for supervising the institution. It is particularly important when a system or institution is being expanded or when measurements of external efficiency indicate deficiencies in the system that call for improvements in operations. Evaluation also provides a basis for comparing the performance of different institutions.

Assessing efficiency, and in particular identifying inefficiencies and their causes, require subjective judgment as well as quantitative analysis. The diagnosis must be carried out by an experienced technical educator, and it requires the full involvement and cooperation of the senior staff of the institution concerned.

The process of evaluation starts with identification of the key factors that are commonly recognized as being of primary importance in determining the efficiency of a system. In this chapter we identify those key factors and describe how they are assessed through the use of checklists, questionnaires, and other means.

A training program can be judged only after observing the teaching process, including practical laboratory and workshop activities, to assess the method and quality of instruction. Examination results provide data for the quantitative study of internal efficiency, but the quality of the examinations administered and the relevance of examination methods to the training must also be assessed. The source and quality of students and trainees and the processes by which they are selected and counseled at entry and assisted to find appropriate employment after training ends should also be evaluated.

An important factor in determining efficiency is the quantity and quality of teaching staff. The evaluation team will need to look at the procedures for selection, appointment, assignment, and promotion of staff, as well as their salaries and other conditions of service. The quality of staff is assessed and deficiencies and training needs are identified by studying personnel records that show qualifications and experience and by observing teachers' performance, the quality of the teaching programs and materials, and the students' work. The utilization and performance of support personnel, particularly laboratory and workshop employees and professional staff such as librarians, must also be evaluated.

The quality and effectiveness of training can be affected significantly by the adequacy and utilization of physical resources (buildings, equipment, and materials). Overprovision and underutilization are as inefficient as underprovision, with its consequent overcrowding and inadequate facilities. Here, as for the other key factors, the evaluation team must weigh carefully the quantitative and qualitative assessments. Facilities can be measured in unit areas of teaching space or unit costs of equipment; the actual utilization of space or equipment can be compared with the maximum theoretical use to yield utilization factors. For each quantitative measure there are broad values or norms that are accepted internationally as good practice. However, it must be kept in mind that an apparently adequate quantitative figure may conceal inefficient or ineffective procedures. For example, a reasonable average level of utilization (say, 75 percent for workshops) may represent extreme overcrowding for part of the time and zero use for the remainder. Workshops and equipment may be in use most of the time, but the training exercises and activities may be of poor quality. The expenditure on equipment may be reasonable, but the equipment may be inappropriate for the objectives of the training program.

The effectiveness of the school's management is evaluated by examining the organizational structure and the management style and effectiveness of the senior staff. The latter can be judged only qualitatively, but that judgment will be illuminated by the evaluation of other key factors; that is, good or poor ratings in such areas as utilization of facilities are part of the supporting data for judging management effectiveness.

The interrelationship of the training institution with industry is probably the most important single indicator of its efficiency and effectiveness. This interrelationship can be measured in terms of employment of trainees, formal links between the institution and industry, the staff's industrial experience and connections, and the extent to which the institution engages in production or other practical activities and creates an environment similar to that of industry. (These measures overlap with some used in determining external efficiency.)

Normally, a training center or school is part of a vocational training or technical education system and is responsible to a government organization such as the ministry of labor, manpower, or education. The system may impose constraints or conditions that have a major influence on the operations of the institution. For example, in an extremely centralized system in which curricula, courses, and training materials are developed centrally, teachers are recruited and appointed centrally, and all materials are procured and distributed from a central office, there may be little scope for the school or center to control its own efficiency. It is therefore necessary in any evaluation to look at relevant aspects of the national system.

We have mentioned costs only incidentally, since they are normally included under external efficiency. However, patterns and levels of expenditure on training activities—not just raw numbers—should be taken into account in evaluating operations. For example, a comparison of cost-effectiveness of two similar training institutions could give misleading indications of effectiveness if one center achieved lower costs over the short term by, for example, failing to replace equipment or restock consumable materials, or neglecting maintenance. The checklists and worksheets include questions designed to identify satisfactory or unsatisfactory budgetary practices.

The Qualitative Evaluation

Experience has shown that certain key factors, summarized in the outline below, have a primary influence on the overall efficiency of an institution. The checklist in appendix A (supported by appendixes D and E) uses these factors as a systematic basis for guiding the evaluation team in making value judgments on the quality of the institution's operations. Those judgments must be made by experienced technical educators and must take into account the environment and objectives of the project, as described in chapter 1. The goal is to build up a profile that shows the state of health of the institution with respect to each key factor so that deficiencies can be identified and the scope and nature of remedial action can be determined.

Level, Content, Quality, and Relevance of the Training Program

- The format and content of the curricula and syllabuses
- The implementation of the courses: the teaching process, methods, materials used, and training activities
- The examination scheme; content and conduct of examinations

Students

- Selection methods, entry qualifications, and sponsorship
- Counseling, guidance, placement, and follow-up
- Student-staff relationships

Staffing and Staff Development

- Staffing policy, salaries, and other conditions of service
- Selection and qualifications of staff
- Size and quality of staff; turnover
- Size, quality, and salaries of support staff
- Staff development plans; training (pre-service and in-service)

Physical Resources

- Range, areas, and layout of accommodations
- Facilities, services, and maintenance
- Range, relevance, and adequacy of equipment
- Equipment use, maintenance, and repair
- Replacement and updating of equipment
- Use, replacement, and storage of consumable materials

Organization and Management

- Institutional development plan and objectives
- Organizational structure and responsibilities
- Management information system: availability and use
- Management style and effectiveness

Interrelations with Industry

- Training and employment
- Formal links and services
- Industrial links of staff
- Industry-like environment

The Quantitative Evaluation

Quantitative indicators of efficiency of operations include student flow rates and performance, staff load, provision and utilization of facilities and resources, and breakdowns of training costs. The evaluation team uses the checklist in appendix B, backed up by appendixes D and E, to record this information.

Student Flow Rates

The most useful measures of student flow are

- *Admission rate* (the proportion of applicants admitted to the course)
- *Dropout rate* (the number of students who leave during the course without taking final tests or examinations, as a proportion of students enrolled at the beginning of the course)
- *Repetition rate* (the number of students who repeat a stage of training as a proportion of the students enrolled in that stage in the previous year)
- *Pass rate* (the number of students completing the course successfully as a proportion of the students enrolled in the final year or stage of the course).

Student Performance (Efficiency Indexes)

An overall indicator of internal efficiency in terms of student performance is found by dividing the number of graduates by the number of students entering at the beginning of the course to yield a percentage. If the amount of repetition is significant, however, it is more useful to employ a measure that indicates how much additional time over the planned time is required to produce graduates. Examples are

- Average time required to produce a graduate (total student-years spent on training (including time spent by dropouts) divided by number of graduates produced; this can then be compared with planned time
- Output-input ratio (the number of graduates, multiplied by planned course length in years, as a proportion of the total number of student-years spent in training).

Staffing

Indicators include

- Student-teacher ratio (by course or for the institution)
- Average class size (preferably separately for classroom work and laboratory or workshop activities)

- Average teacher workload (normally expressed as teaching hours or contact hours per week).

Facility Schedules and Utilization of Space

Indicators include

- Average area of workspace (area of classrooms, or laboratories, or workshops, divided by the normal working capacity)
- Average areas of support spaces (area of library, communal spaces, living accommodations, and the like divided by number of students using each kind of area)
- Space utilization (the actual student occupancy of total teaching space as a proportion of the total capacity of the teaching space).

Costs

The most important cost measure is the cost per student per year or cost per graduate. Other analyses of cost also provide valuable comparative data:

- Staff salaries as proportion of total cost
- Cost per student per year for consumable materials
- Maintenance cost as proportion of capital costs.

The Central Training System

The section deals with methods for evaluating the main aspects of the central government training system to gain an understanding of the context within which the training institution operates. Such an evaluation can also provide the basis for a study of the technical and vocational education system as a whole. Appendix C provides a format for recording observations and data.

The key factors in evaluating the central system are

- Policies, planning, and development
- Central and regional control
    - Training programs and courses
    - Staffing
    - Physical resources
    - Finances
    - Management organization

3

Evaluating External Efficiency

Conceivably, an institution could be extremely efficient internally—making good use of staff and physical resources and achieving a high ratio of graduates to entrants—and yet turn out graduates who fared no better in the workplace than untrained workers. External efficiency—how well the institution fulfills its stated purposes—is the subject of this chapter. Much of the information needed for assessing external efficiency—costs, outcomes, and their relation—can be expressed quantitatively. As in the analysis of efficiency of operations, however, informed judgment is essential in determining what kind of information is pertinent and what weight should be given to the various indicators.

Cost

How cost is defined depends on the point of view from which the project is being appraised. Since in this case we are taking the point of view of society as a whole, we are interested in the *social opportunity cost* of the project: what will society have to give up to build and operate this training institution? If we were looking at it from a narrower point of view—that of an individual, a local community, or even the treasury—we would still be interested in opportunity cost, but from that particular viewpoint.

The first step in calculating the cost of a project is to analyze from project documents and audited accounts the costs incurred during the gestation of the project—costs of planning, preparation, land value, construction, and equipment. These are *capital items* that depreciate over the lifetime of the project. Since tying up capital also means forgoing an annual return that could have been obtained by using that capital in another way, it is usual to multiply the cost of capital investment by an annualization factor that reflects both depreciation over the lifetime of the item and the return to the capital in an alternative use (that is, the social rate of discount, which is not necessarily the same as the official interest rate). The annualization factor (a) for any given expected service life (n) and social rate of discount (r) is given by the formula

$$a_{r,n} = \frac{r(1+r)^n}{(1+r)^n - 1}.$$

Values of the annualization factor for each expected service life and social rate of discount are found in table 3.1. If, for example, the price of a piece of workshop

Table 3.1. ***Values of the Annualization Factor***

	r (percent)				
n	*0*	*5*	*7.5*	*10*	*15*
1	1.000	1.000	1.000	1.000	1.000
2	0.500	0.538	0.557	0.576	0.615

25	0.040	0.071	0.090	0.110	0.155
50	0.020	0.055	0.077	0.101	0.150

Note: n, service life in years; *r*, social rate of discount.

equipment is $10,000 and its expected service life is 13 years, at a social rate of discount of 10 percent the annualization factor is 0.141 and the annual cost is $1,410.

The second step is to calculate the *recurrent costs* involved in the operation of the project: costs of teaching, training, administrative, and service staff; costs of materials, tools, books, maintenance, and replacement; costs of utilities; and costs for travel, consultants' services, medical services, insurance, and so on. In a situation in which prices change because of inflation, a price adjustment must be made so that costs will be in constant values. Where there is a physical input that involves no payment, such as the services of volunteer workers and teachers and even the time of the trainees themselves (if society is losing their output as a result of their participation in the project), we should assign to these services an opportunity cost in terms of forgone earnings. (These may admittedly be zero if no alternative opportunity for the use of that time exists.)

In some cases we also have to adjust for differences between market price and *social opportunity cost*, or shadow price. For example, from the point of view of society, as opposed to that of an individual, a tax on a piece of equipment should not be counted as a cost; similarly, a subsidy to a particular input reduces its price but not its social cost. So, taxes of all kinds should be deducted from the price of inputs, and subsidies should be added to that price. Also, if there is widespread unemployment or underemployment, so that labor can be withdrawn from an alternative use without much affecting output, the social cost of the labor is likely to be lower than its wage. If there is no active land market, the rent paid may understate the social cost of using a piece of land for the project; some estimate then has to be made of the returns that could be obtained from using the land in the best alternative way. Finally, if foreign exchange is undervalued (as indicated by a chronic balance of payments deficit and lack of foreign exchange reserves), imported inputs have to be valued at a price higher than the market price.

In this way it is possible to put together a year-by-year stream of costs adjusted for inflation and, if necessary, for differences between market price and social cost. Time series of costs by type of expenditure can be compared with costs of other similar institutions. An analysis of the trends of the level and structure of costs can also indicate future tendencies.

Outcome

Outcomes of a training project are assessed at different times and using different measures. *Educational* outcome can be measured at the end of the training period; application of *skills* and impact on *development* can be evaluated only after the trainee has returned to the workplace. Information on these latter types of outcome can be difficult to obtain. Follow-up studies of graduates provide data for only the first years of work life. Government statistical agencies may conduct regular, general surveys of employment and earnings, but they are likely to be highly aggregated and confined to the modern sector. Surveys of private sector salaries (sometimes carried out by private consulting firms) and of civil service salary scales may be of some use. Ways of supplementing these sources through direct observation and interviews are discussed below.

In measuring educational outcome we are interested first in knowing or estimating the success rate (the ratio of a given cohort of graduates from the final year of the course to the number who entered in the first year). The success rate reflects not only the pass rate in the final examination but also dropouts and repetition of course work and examinations by students; information on all these phenomena is useful. In addition, more sensitive measures of educational outcome are desirable. Ideally, the analyst will want to observe the learning process, hold discussions with students and teachers, and perhaps administer his own tests to measure the educational gains made by the trainees in comparison either with their own pretraining scores or with the scores of a control group similar to them in every respect except exposure to this form of training. These test results could be compared with results of external examinations. For example, examination results in institutions that take the program's graduates can be surveyed for evidence of the program's impact on the graduates' performance, compared with performance of trainees from other backgrounds. Examination and test results are often collected and analyzed by the responsible ministries. There may, indeed, be a government department or agency that is primarily concerned with the internal efficiency of training institutions and carries out regular surveys of examination systems, teaching methods, performance, and attitudes. In some countries results of government trade tests of craft skills can be a useful guide to the educational outcome of craft training. Directors of institutions that feed into the program being evaluated or of those that take the program's graduates can also provide useful information and comments.

For skill and development outcomes, the most promising source of information is probably the workplace. ("Workplace" should be interpreted broadly to include informal as well as formal places of work and such places of "nonwork" and job-seeking as marketplaces, factory gates, and official and unofficial employment exchanges. Managers of exchanges, as well as job-seekers, are useful sources of information.) What difference does the specific type of training make in the skill with which trainees do their jobs as compared with either their pretraining level of skill or with a control group? Again, personal observation by the analyst is the ideal method, but since this is usually not possible, it is necessary to fall back on indicators of physical productivity (for example, gross value of yield per acre in agriculture, the time taken to do a particular job compared with the norm estimated by management, the number of errors, or the scrap rate) or on the opinions of work supervisors.

Employers' opinions about the effectiveness of the program should be sought through questionnaires and interviews and, if possible, in the form of ratings of individual on-the-job performance. Employers can also provide factual information on the jobs and on wages and salaries of persons from different training backgrounds. Managers and supervisors can provide similar information and may be particularly useful in rating performance. The workers themselves can tell us about their age, trade, education and training, nature of current job, social background, and job and wage history since joining the labor force. (Examples of questionnaires for employers and employees are given in appendix F.)

For obtaining information on posttraining history, the most scientific method is undoubtedly the tracer project, which attempts to follow, often at regular intervals, a cohort from a particular training institution. Preferably, a number of parallel studies are carried out; this permits a comparison of the posttraining history of cohorts from different educational or training backgrounds. The problem with this method is that it is extremely expensive, particularly in a large country, and relies heavily on enumerators who have to demonstrate extraordinary qualities of ingenuity, honesty, and persistence if the studies are to be successful. Once members of the cohort are traced, a questionnaire can be administered to them. Alternatively, as a shortcut, an extended questionnaire can be administered to a sizable sample of the labor force, both employed and unemployed. The sample may be random or selective; in the latter case, care is taken to include certain categories—firms representing different sizes, locations, and sectors, firms on the books of the employment exchange, and so on. The purpose of the survey is to determine whether there is any measurable difference in labor market experience between persons from different educational and training backgrounds. The same sample of firms could be used to survey employers, managers, and supervisors, using the questionnaire as a basis but carrying out the survey by interview.

Since the ultimate aim of any project is to contribute to development, this is the most important dimension of outcome. Unfortunately, it is also the most difficult to measure. The usual practice is to use as a measure of benefit earnings—or, more precisely, the difference that the training makes to the lifetime earnings stream of those who undergo it. The difference is measured in relation either to what they could have expected without this training or to the expected lifetime earnings stream of a control group. This raises formidable problems of data. We need to know existing earnings patterns for workers of different ages, with and without such training, and the probability of their having jobs, and to guess how these patterns and probabilities will evolve over a period of thirty years or more. How far, for instance, will the increase in the number of trained people itself reduce differentials between the more and the less trained?

There are also conceptual problems. The use of earnings as a measure of benefit is derived from the marginal productivity theory of wages whereby a profit-maximizing employer will not expand his work force if an extra worker would add more to his costs than to his revenue. In a perfectly competitive labor market, the wage is equal to productivity at the margin; hence the use of wages or earnings to measure productivity or benefit. However, the profit-maximizing calculus does not apply to all employers. The public sector, for instance, has quite different objectives, and some adjustment of public sector wages may be necessary for our purposes. And if, as is often the case, labor markets are not perfectly competitive, the wage will be lower than marginal productivity even in the profit-maximizing sector.

Even if earnings broadly reflect productivity, there are important indirect effects that are not captured by this measure and that have to be taken into account.

First, on completion of their courses trainees may be placed in jobs that were held by others up to that point or may fill vacancies that would have been filled by others in the absence of the training scheme (the displacement effect). In the extreme case in which a trained worker merely bumps a less trained worker out of a job, taking over but not increasing the lifetime earnings stream associated with that job, the net social benefit from the training is zero.

Second, there may also be a replacement effect if the slot in the labor market vacated by the worker who joins a training scheme and subsequently moves into a higher occupational category is filled by another worker who would otherwise have remained unemployed. This should be counted as an extra benefit.

Third is the demonstration effect, whereby the skills acquired by trainees are diffused to others who have not undergone the training. This indirect effect can be quantitatively important, particularly in rural areas or among the urban self-employed.

Fourth, training may have important social effects that later yield economic benefits. For instance, training women may be important in reducing the fertility level.

Fifth, by breaking bottlenecks, training may have important dynamic effects not captured by the increase in earnings of the individual trainee. The resulting increase in output may open up employment opportunities for complementary workers who would otherwise be unemployed. And the creation of a pool of skilled labor may be an important factor in attracting more advanced technology to an economy, leading to a higher rate of growth in the future.

Enough has been said to suggest that earnings differentials are at best a partial and at worst a misleading measure of the impact on development of a training program. The list below summarizes the steps in the analysis of the impact on development of a training program. At each stage quantification should be taken as far as possible. But giving a qualitative answer to a question (indicating the direction in which quantities should be modified) is always better than pretending that the question does not exist.

1. Estimate year by year the lifetime earnings stream of an average trainee after completion of the training being evaluated, taking into account the probability of employment.
2. Estimate the expected lifetime earnings stream of an average trainee if he or she had not undergone this training, or of an average member of a control group similar in every other respect except exposure to this training.
3. Deduct (2) from (1) to derive the average differential in lifetime streams of earnings attributable to this program.
4. Adjust (3) downward if trainees are destined for an apparently overmanned part of the public sector, upward if for a part that is undermanned or overworked; upward if for an imperfect private sector labor market.
5. Adjust (3) upward if the replacement effect appears to be important.

6. Adjust (3) upward if the demonstration effect appears to be important.
7. Adjust (3) upward or downward to reflect net social effects.
8. Adjust (3) upward if the effect in breaking bottlenecks appears to be important.

Comparing Cost and Outcome

The simplest cost-outcome calculations are those that combine cost with not necessarily comparable outcomes in unit cost measures. For example, expenditure on plant and equipment for a proposed institution divided by the maximum number of students that can be enrolled in that institution at full capacity yields capital cost per student place. This allows comparisons among different projects (say, a polytechnical institution and a university) or different methods of building and equipping a given project. If capital costs are annualized as described above, capital and current costs can be combined as total cost per student or per graduate, which again allows comparisons among different projects or different ways of building and running a given project (for example, with more or fewer teachers per student). Cost per student raises no problems, being merely total cost over any time period divided by the number of students undergoing training in that period. Cost per graduate is slightly more complicated because estimates of the rates of dropout, repetition, and examination failure are needed.

Cost per graduate can be calculated using the equation

$$Cg = \frac{u \sum_{t}^{t-1} C + v \sum_{t}^{t-2} C + \cdots n \sum_{t}^{t-n} C + s \sum_{t}^{t-1} C + w \sum_{t}^{t-2} C + \cdots n \sum_{t}^{t-n} C}{g}$$

where Cg is cost per graduate in year t; C is average cost per student per year; g is number of graduates in year t; $u, v, \ldots, n$ are groups of graduates in year t classified according to number of years spent in training; and $s, w, \ldots, n$ are groups of dropouts and examination failures in year t classified according to number of years spent in training. As can be seen, use of the cost-per-graduate measure implies assigning a zero valuation to dropouts and examination failures, which may not be justified.

Where it is difficult to assign a money value to the outcome of a project, a cost-effectiveness measure is often used. If there is a scale of possible outcomes (as, say, in the case of examination scores), we can calculate the cost per unit of the appropriate measure. For instance, if there is a choice between three types of training institutions, each offering a similar one-year course but differing in the quality of intake and in final examination marks, the cost-effectiveness comparison can be made as in the example below.

	Total cost per student per year (dollars)	*Average score on entry (percent)*	*Final examination score (percent)*	*Effectiveness measure (change in score, in percentage points)*	*Cost – effectiveness measure*
Project A	600	40	60	20	30
Project B	375	50	65	15	25
Project C	350	60	70	10	35

Project B is the most cost effective in terms of least dollars spent per percentage point gained per student, even though project A is more effective and project C is less costly. The problem with comparisons of this kind is that they are based on the assumptions that percentage gains in scores (say, 40 to 60) are equally valuable all along the scale, and that other things are equal. From this point of view it would have been safer to compare projects with similar average scores on entry; but the decisionmaker still has to decide the marginal utility of a percentage gain in scores.

Where it is possible to attach money values to the outcome, some kind of cost-benefit calculation can be attempted. The most widely used approaches are to calculate the benefit-cost ratio or the net present value of the internal rate of return. Whichever approach is chosen, we start with the stream of costs (listed in the years that they occur) over the project's lifetime and the stream of benefits emanating from the project over the lifetimes of those who emerge from it (see "Cost" and "Outcome," above) and calculate the discounted present value of both streams. This must be done because resources have alternative uses. If, instead of being used for the project under consideration, $1 were invested elsewhere in the economy, it would yield an annual return at the social rate of discount and so in several years would have grown to much more than $1. By the same reasoning we would be willing to offer less than $1 now for the promise of $1 (at constant prices) some time in the future—how much less again depends on the social rate of discount. This present value of a future payment is known as the discounted present value and is given by the equation $PV = FV/(1 + r)^t$, where PV is present value in year 1 of the project, FV is future value, r is the social rate of discount, and t is the number of years hence. Table 3.2 shows the present value of a $1 payment made or received a given number of years in the future at a given social rate of discount. For instance, $1 to be paid thirteen years hence would be worth $0.29 today if the social rate of discount were 10 percent.

Once we have calculated, with the aid of such a present value table, the discounted present value of the stream of costs (C) and the discounted present value of the stream of benefits (B), the rest is easy. The benefit-cost ratio is simply B/C, and the net present value of the project is $B - C$. Thus, where for a particular project at a social discount rate of 10 percent B = $250,000 and C = $200,000, the benefit-cost ratio is 1.25 and the net present value is $50,000. On either count, since the benefit-cost ratio exceeds one and the net present value exceeds zero, it is worthwhile to proceed with the project.

Because such results are sensitive to the social rate of discount chosen, some analysts prefer to calculate an internal rate of return. This is defined as the discount rate at which the present value of the stream of benefits is exactly equal to the present value of the stream of costs. In equation form this is given by

$$\sum_{t=0}^{n} \frac{C_t}{(1+r)^t} = \sum_{t=0}^{n} \frac{B_t}{(1+r)^t}.$$

The most practical way of calculating the internal rate or return is by trial and error, calculating present values for successive assumptions about discount rate, which brings the two sides of the equation closer together.

Whenever possible, the results of cost-benefit calculations should be subjected to sensitivity analysis to test their sensitivity to changes in assumptions, for example, about the impact of the project on earnings differentials or, in the case of the benefit-cost ratio and net present value approaches, about the social rate of discount. Also, when the information available about cost and benefits is inadequate, a range of cost-benefit calculations can be made on plausible assumptions about likely maxi-

Note t, number of years from present, r, social rate of return

mums or minimums in each case. Even where potential errors are not quantifiable, it is advisable to think about the direction of their possible influence on the results.

The data demands of the cost-benefit approach are so heavy, particularly on the outcome side, that it is often necessary to look for a shortcut such as the following formula.

$$\frac{B}{C} = \frac{Y_k - Y_{k-\Delta t}}{C}$$

where Y_k is the present value of the mean or median annual earnings of a sample of graduates from the training program at the time of the interview; $Y_{k-\Delta t}$ is the present value of the mean or median of their estimates of what they would have been earning if they had not undergone the particular training program; and C

is the present value of the stream of total costs of the program divided by the total number of graduates. Though expressed here as a benefit-cost ratio, this information could be used to calculate net present value or internal rate of return in the usual way.

Labor Market Indicators

Formal cost-outcome analyses are also supplemented by analyzing indicators of the state of the part of the labor market that is relevant to the training program. Ideally, changes in such indicators over the lifetime of the project should be inspected for evidence of impact, but if this is not possible, some inferences about the immediate impact and long-term effects of the project can be drawn from an analysis of current information alone.

Some information can be derived from questionnaires or interviews administ... to training institutions and graduates. For instance, what is the employment ... of graduates, say, one year after graduation? Or what proportion of those employed are working in fields similar to those for which they were trained?

More general labor market information—available from such sources as the personnel department of the civil service or of the public sector as a whole, official employment exchanges, private recruitment agencies, and newspaper advertisements—may also be useful for this purpose. An example of relevant data is the number of unfilled vacancies currently being advertised by employers for the occupational category of interest. However, data on vacancies must be treated with care. Vacancies are often filled internally rather than being advertised or reported to employment exchanges. Particularly within the public sector, the number of "vacancies" reported in interviews or questionnaires often represents posts it would be desirable to fill if funds were available, rather than posts for which active recruitment (backed by the power to pay) is in process.

It is a common practice to combine information about vacancies with information about unemployment of people in the same occupational category. Thus if the ratio of unemployed to vacancies is equal to one, this part of the labor market is judged to be in balance; if the ratio is below one (that is, the number of vacancies exceeds the number of unemployed), the employment climate is said to be favorable. However, even in industrialized countries with highly developed social security and employment exchange systems, the ratio of unemployed to vacancies has not been found to be a reliable indicator. In countries where few people register with the official employment exchanges and where many of those who do are not unemployed but are looking for something better, this ratio is likely to be even less helpful.

The number of expatriates employed in the relevant job category may a... be a useful indicator of present excess demand. Such information is usually held by the immigration department.

An indicator of the demand for the type of training offered is the number of applications in relation to places; the higher the ratio of applicants to places, the higher the probable payoff to graduates of this type of training.

Finally, the evaluators may look at the impact on earnings over time of the type of training in question. If relative earnings of this occupation vis à vis similar occupations are rising, this may signal an emerging shortage.

The Equity Objective

So far we have implicitly confined ourselves to the efficiency objective of the project. But we have also assumed a concern with equity. How do we incorporate this into our analysis?

Our first task is to establish the private profitability of the training. For this purpose we use the same internal rate of return equation as before, but with costs and benefits defined in private rather than social terms. Thus C is defined as the private cost (the cost to the individual) of the training in question and E as the private benefit (the excess of posttax annual earnings of a person trained at this level over one trained at the level immediately below, net of income forgone during training). If this return is judged to be adequate, we compare the proportion of students from underprivileged groups with a target quota, perhaps based on the proportion of the total population represented by such groups. This is expressed in indicator form as U_t / U_p, where U_t is the proportion of the trainees in this program from the underprivileged group and U_p is the proportion of the total population represented by the underprivileged group. The aim is to achieve as high a value as possible for U_t / U_p, and certainly a value of greater than one. What is possible may be partly determined by cost. For example, abolition of fees or the provision of free meals for underprivileged students may be ways of increasing equity in access (they would also increase private profitability by reducing the private cost to the individual trainee), but the cost to government of such measures may be unacceptably high.

Finally, when a government is seriously engaged in restructuring its strategy toward satisfaction of basic needs and alleviation of poverty, an equity-oriented training policy takes on an extra task: that of imparting the skills required to produce goods and services for the underprivileged. There is no simple indicator of the extent to which a particular training program is oriented toward the needs of the underprivileged rather than the purchasing power of the privileged. The evaluators can begin by determining whether the syllabus of the program (and the job definition from which it derives) is need oriented or market oriented. A basic needs profile of the whole economy, combining data on income distribution and on deficiencies in satisfaction of basic needs, can be useful for this purpose. From such a profile it should be possible to identify types of training that are most relevant to the needs of the poorest. This may not always be easy. For instance, the skills needed to build a public transport vehicle may not be easily distinguishable from those required for sports car manufacture. And the foreign exchange earned by luxury exports may be used to import goods needed for development and for mass consumption. In other cases, however, the distinction will be clear: for instance, training for rural preventive health care as against urban hospital-based curative medicine, or for low-cost housing design as against luxury high-rise buildings.

However, a further check is needed on the effectiveness of need-oriented training. What proportion of graduates from the program actually find jobs doing need-oriented work? Will their need-oriented skills be demanded in the labor market? Broader government strategy and socioeconomic progress are important here if the training program is to have the desired effect.

4

Summary Assessment and Procedures

The main purpose of this manual is to provide management with a diagnostic tool for identifying areas that require improvement. However, it can also be used to provide a profile of an institution so that different institutions within a training system can be compared with each other or with a "standard" institution.

The summary assessment (table 4.1) is meant to facilitate both uses by telescoping the data gathered through questionnaires and observations into a convenient numeric profile. The summary is organized according to indicators of internal and external efficiency. A six-point scale is used, with values ranging from 1 for satisfactory to 6 for unsatisfactory. (For a fuller explanation of the scale, see appendix A.) Since no ranking or weighting of the key factors exists, the summary cannot be made much more compact—it is not possible to arrive at a single measure of the efficiency and effectiveness of a training institution. Instead, the summary provides a multidimensional picture of an institution and permits comparisons between schools.

It should be noted that the overall assessment is not an arithmetic average of all the items under the key factor. The evaluators should weigh the individual responses and make an intuitive judgment of the overall assessment.

The guidelines in this section will be particularly useful for ministries or agencies which have not yet conducted regular evaluations of their technical schools or vocational training centers. We have tried to achieve an appropriate balance of detail and coverage so that the evaluations can be carried out with reasonable expenditures of time and manpower and still provide a systematic and comprehensive evaluation of the performance of any institution. The guidelines are not rules. We expect that in practice they will be modified to suit local circumstances and purposes. The scope of the evaluation and the depth of detail will be decided with an eye to the cost, the staff available, and the use to be made of the results. In the same way, the procedures for conducting the evaluation will vary according to circumstances.

The technical and vocational education system may include tens or hundreds of institutions. If the number is large, we recommend that as a first stage a sample of about ten, representative in terms of type, size, location, and so on, be chosen for initial evaluation. These initial evaluations serve several purposes. They quickly lead to the identification of any common problems or issues. They also allow the guidelines to be adapted and questionnaires and instruments to be modified to suit the agency's needs. If the agency is attempting evaluation on a significantly more detailed basis than in the past, these initial evaluations also provide a training

Cost per student per year[1]	________
Cost per graduate	________
Cost per student ÷ cost per student in general high school	________
EXTERNAL EFFICIENCY (OUTCOMES AND COSTS)[2]	
Employers' opinions on employability of graduates	
Preferred to other applicants	☐
Same as other applicants	☐
Less qualified than other applicants	☐
No opinion	☐
Teachers' opinions of graduates	
Well prepared for a good job	☐
Only adequately prepared for a job	☐
Not well prepared for a job	☐
Graduates' opinions on their ability to secure employment in their field of training	
With my training it is easy to get a job	☐
With my training it is not easy to get a job	☐
With my training it is very difficult to get a job	☐
Employment rate of graduates one year after graduation	________
Proportion of those employed working in the same or similar fields for which they were trained	________
Rate of return of the program (as calculated in chapter 3)	________

1. For short courses use cost per student per hour
2. Based on interviews with employers, teachers, and graduates, and on quantitative indicators (where data are available) on employment and earnings of graduates.

experience for the staff. The early evaluations should also be designed to help the evaluators arrive at a reasonable consensus of standards through exchange of information and by varying the membership of teams.

If the ministry or agency is establishing regular evaluation as part of its management review process, it is advisable to set up a small unit responsible for the administration of evaluation. However, it is normally better not to create a team of full-time evaluators, but instead to create a panel or pool of senior ministry staff that also includes active principals or directors and, if possible, representatives from industry or technical ministries.

Internal Efficiency

Each institution to be evaluated is given a set of questionnaires to be completed in advance (appendix D), together with a general note prepared by the agency explaining the purpose of the evaluation. If possible, preliminary briefing meetings are held with the directors of the institutions and their senior staff so that the questionnaires can be distributed and the purpose of the evaluation explained. The briefings should stress the importance of evaluation in planning and its value in identifying needs for resources. The full cooperation of staff should be obtained; subsequently, throughout the conduct of the evaluation, the team members must be on their guard to avoid acting as inspectors or inquisitors. Opportunities should be taken to exchange experiences and provide advice as well as to gather information.

The evaluation of the school or center takes place one to four weeks after the questionnaires are distributed. The evaluation team should include at least two persons: a technical and vocational educator whose experience and knowledge cover both developing and developed countries, and a person with a background in economics, particularly manpower and labor market economics. The evaluation of specialized training programs may require the addition of relevant specialists. The team will establish its own work pattern. We suggest the procedure outlined below, using the checklists in appendixes A and B as the main framework and the questionnaires and forms in appendixes D and E to provide the detailed structure for interviews and data collection.

DAY 1. An initial meeting with the principal or director and key senior staff is held. The data, reports, and completed questionnaires that were requested in advance (appendix D) are presented to the team, and problems or missing data are identified (about two hours).

The team then makes a brief tour of the institution to gain familiarity with the main facilities and layout (about one hour).

Next, the team reviews the completed questionnaires and clarifies any apparent anomalies or errors in the answers. It then proceeds, in discussion with the director or principal and the senior staff, to complete appendix questionnaires E.1 through E.7 (about three hours). These questionnaires are to be used as a basis for structured interviews and need not be rigidly followed. To preserve confidentiality, the team may wish to interview the director alone to complete questionnaire E.1, but senior staff should be brought in for the subsequent discussions, both to take advantage of their knowledge and to give them experience in the process of conducting evaluations.

DAY 2. The evaluation team proceeds to the detailed observation of teaching and training activities and use of equipment and facilities. Questionnaires E.8 through E.15 are filled out at this stage. If there is a relatively large number of laboratories or workshops, it is advisable to choose only a sample for detailed study. During this period in the classrooms, laboratories, and workshops the evaluation team should review critically the content and treatment of the courses or subjects (about four hours).

The evaluation team may conduct its interviews of teaching staff and trainees while carrying out the observations in the classrooms and workshops. If, however, only a relatively small sample of the activities is covered, it would be better to arrange for more broadly based interviews with a group of six to eight staff members and a like group of trainees, using questionnaires E.14 and E.15 as the framework (about two hours).

At this stage the evaluation team should be able to complete its assessments of the key factors in checklists A and B, covering the qualitative and quantitative aspects of internal efficiency (about three hours).

A third day may be required if a very large institution (2,000 or more training places and a wide range of training programs) is being evaluated.

The evaluation team concludes its visit to the institution with a brief presentation to the senior staff of the main findings.

It will be clear from the above that the evaluation exercise is significantly more searching and revealing than the normal institutional visit, and only with practice will the team acquire the skills necessary to carry out the interviews and assemble the data. Since the team is required to make value judgments about quality of training, it is vital that the members' experience and background give them adequate status. Even so, they may find it difficult to make judgments about the quality of teaching in subjects that are outside their own specializations. In that case it would be advisable to form slightly larger teams covering a representative range of the technical specializations offered in the institution.

External Efficiency

The evaluation of external efficiency involves the collection of data from employers and graduates of the training programs, as set out in chapter 3. Arrangements for the interviews should be made beforehand, either by the local representatives of the responsible agency or by the director of the institution. It is useful for a staff member of the institution being evaluated (preferably the guidance counselor or the person in charge of liaison with industry) to be present.

THE SAMPLE. Only a sample of firms should be singled out for interviews, that is, six to eight in the city where centers or schools are being evaluated. The firms should be selected on the basis of two criteria: high probability of employing graduates from the institutions being evaluated, and size (large, medium, and small firms should be represented). The information is collected in interviews, initially with the personnel officer, then with foremen and with graduates of the school or recent trainees. These interviews, based on the questionnaires in appendix F, will usually require not more than one to two hours in each firm. The limited purpose of the evaluation should be made clear from the outset, and firms will usually give full cooperation.

THE QUESTIONNAIRE. As discussed in chapter 3, interviews and questionnaires, although costly and time-consuming, are extremely helpful in assessing the effectiveness of the training from the points of view of the trainee and the employer.

In planning a questionnaire survey, the first issue to be resolved is what groups to interview. At a minimum, graduates, dropouts, and supervisors of the graduates should be interviewed. However, if time and resources allow, teachers, directors of programs, and other employers could also be included.

The second issue is what areas to cover. In general, the questionnaires should include the characteristics of the respondent, the effects of training on employment and earnings, assessment of the training program, and assessment of the graduates.

For inquiry through questionnaires to succeed, efficient management and the cooperation of everyone concerned are required. In addition, attention must be given to the following considerations.

Drafting the questions requires great care. It demands a good knowledge of the language and culture of the interviewees, as well as some technical knowledge of the skill or occupation of interest. Whenever possible, questions should not be open-ended, since this invites a wide range of subjective replies and comments that are not comparable. Specific alternative replies to each question should therefore be offered to respondents. This also permits easy coding and tabulation of replies (see sample questionnaires in appendix F).

Better-educated respondents may be able to complete a well-made questionnaire by themselves, and budget limits may necessitate this shortcut. But in general, personal interviewing, although costly, yields the most complete and useful responses, since the interviewer is able to clear up misunderstandings and ask follow-up questions. At the very least, personal delivery and collection of the questionnaires, despite the expense, is preferable to expecting people to reply to an impersonal survey by mail.

Under ideal circumstances a significant statistical sample of former trainees should be drawn. When availability of funds determines the size and structure of the sample and the questionnaire or interview procedure, the only option may be to restrict the interviews to graduates at their place of work. This precludes interviewing unemployed trainees.

Training and instructions for interviewers must be careful and detailed to ensure uniform interpretation of the questions and the smooth evolution of the interview.

Finally the answers have to be coded, tabulated, and cross-tabulated so that the evaluator can draw the pertinent conclusions. Sufficient resources, time, and people must be allocated to do this routine but essential chore properly.

Similar answers to the same question, but from different viewpoints, reinforce conclusions. Conversely, answers that differ from one group to another may cast doubt on the validity of a single conclusion, and further evidence may be required. When graduates of the school are being appraised, a supervisor may be asked to rate graduates compared with nongraduates and a graduate may be asked to rate fellow graduates compared with other workers in his group. Similarly the graduate's assessment of the quality of teachers should be supplemented by the opinions of administrators. Because of the variety of institutional setups and the different characteristics of particular national and cultural environments, it is impossible to spell out beforehand the exact questions to be asked and the manner in which they are posed. But some basic issues are common to all evaluations and must be covered in questionnaires and interviews.

APPENDIXES

A

Checklist. Efficiency of Operations: Qualitative Evaluation

Note: Refer to completed appendixes D and E.

This checklist covers the key factors to be assessed by the evaluation team. For each key factor there is a set of questions that can be answered easily by checking the appropriate box; space for supplementary comments or explanations; and a block for overall assessment of performance for the key factor. The aim is not to arrive at an overall score based on adding up points for the individual factors. It is to compile a profile of the satisfactory and unsatisfactory aspects of performance for each factor.

The key factors cannot be evaluated without collecting and understanding a considerable amount of data and information and observing the school's operations. Forms and questionnaires for collecting the information and for recording observations are given in appendixes D and E.

Ratings used for the six-point scale are as follows:

Satisfactory ↑	1	Completely satisfactory
	2	Generally satisfactory; room for some improvement
	3	Acceptable; needs improvement in limited aspects, but not major or urgent
	4	Less than acceptable; needs improvement on fairly wide scale, but not major or urgent
	5	Generally unsatisfactory; needs attention
↓ Unsatisfactory	6	Completely unsatisfactory; needs urgent attention and improvement

In general, ratings of 4, 5, and 6 indicate a need for attention and improvement—in the case of 6, an urgent and critical need.

The evaluator should weigh the individual responses and use intuitive judgment to arrive at the overall assessment.

In all checklists, Y stands for yes and N for no.

Content and Quality of Courses

Format and Content of Curricula and Syllabuses

a. How satisfactorily are the course objectives expressed and related to training needs? [1] [2] [3] [4] [5] [6]

b. Is there a clear and detailed description of:
   - Time allocation for subjects? [Y] [N]
   - Time allocation for activities? [Y] [N]
   - Subject content? [Y] [N]
   - Learning objectives? [Y] [N]
   - Performance measures? [Y] [N]

c. How well does the content of curricula and syllabuses satisfy course objectives? [1] [2] [3] [4] [5] [6]

d. If the answer to (c) is 4, 5, or 6, indicate the main deficiencies:
   - Too much theory ☐
   - Does not provide appropriate level of practical training ☐
   - Too little theory ☐
   - Curricula content not relevant to industries' needs ☐
   - Time allocation not adequate for content ☐
   - Other (list) ☐

e. Does the course include project work? [Y] [N]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Quality of Curricula and Syllabuses

a. In relation to the course objectives,
   How well are major practical skills covered? [1] [2] [3] [4] [5] [6]
   How well are relevant theoretical areas covered? [1] [2] [3] [4] [5] [6]
   How satisfactorily are theoretical and practical areas coordinated? [1] [2] [3] [4] [5] [6]

b. How satisfactorily are different subjects in the courses coordinated? [1] [2] [3] [4] [5] [6]

c. How satisfactorily does the overall treatment correspond to current and foreseeable industrial needs? [1] [2] [3] [4] [5] [6]

d. If the responses above include 4, 5, or 6, indicate the main deficiencies.

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Review and Revision of Curricula and Syllabuses

a. Are curricula and syllabuses reviewed and revised regularly? [Y] [N]

b. Is industry involved in such reviews? [Y] [N]

c. How many years has it been since the last review? [<1] [1] [2] [3] [>3]

d. Is there an arrangement for feedback from graduates on course content? [Y] [N]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Teaching Methods

a. On the basis of observation, rate—
The use of teaching and training aids 1 2 3 4 5 6
The supply of notes or materials to students 1 2 3 4 5 6
The quality of teaching materials 1 2 3 4 5 6
The quality of students' work 1 2 3 4 5 6

b. Taking practical work alone,
How satisfactory is the quality of students' work? 1 2 3 4 5 6
Do the range and quantity of work appear satisfactory? 1 2 3 4 5 6

c. When observed,
What was the actual size of the practical work group? ________
Were the trainees being satisfactorily supervised? 1 2 3 4 5 6
Approximately what percentage of students in the laboratory or workshop actually were performing practical work? ________

d. Does there appear to be satisfactory coordination between
Theory and practice? Y N
Subjects? Y N

Comments:

Overall assessment: 1 2 3 4 5 6

Examinations and Assessment

a. Is there a clear description of the examination scheme? Y N

b. How well does the examination scheme relate to course objectives? 1 2 3 4 5 6

c. How satisfactory are the arrangements for determining passing or failure? 1 2 3 4 5 6

d. How satisfactory are the arrangements for continuous assessment? 1 2 3 4 5 6

Comments:

Overall assessment: 1 2 3 4 5 6

Students and Trainees

Entry and Selection

a. Are entry qualifications satisfactory in relation to course objectives? [Y] [N]

b. Is the selection process appropriate in relation to objectives? [Y] [N]

c. How satisfactory does the quality of students seem in relation to course objectives? [1] [2] [3] [4] [5] [6]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Counseling and Career Guidance

a. Is there a satisfactory scheme for advising potential students and trainees about courses and careers? [Y] [N]

b. Are there satisfactory arrangements for counseling students on the progress of their training? [Y] [N]

c. Is there a satisfactory scheme for assisting students to find employment? [Y] [N]

d. Is there a formal scheme for follow-up of students after graduation? [Y] [N]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Staff-Student Relationships

a. Do staff-student relationships appear satisfactory? [Y] [N]
b. Do students and trainees participate in meetings with staff on training? [Y] [N]

Comments: (refer also to interviews with staff and students):

Overall assessment: [1] [2] [3] [4] [5] [6]

Staffing and Staff Development

Staffing Policies

a. What is the weekly teaching duty, in hours? ________________
b. Are teaching duty hours satisfactory, bearing in mind such factors as the time required for preparation? [Y] [N]
c. Are salaries for teachers equivalent to salaries in industry for comparable qualifications? [Y] [N]
d. Are other conditions equivalent to those in industry? [Y] [N]
e. Is there a satisfactory scheme for grading staff in relation to experience, qualifications, and responsibilities? [Y] [N]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Selection and Qualifications

a. In relation to course objectives, are the qualifications and experience required for staff appointment—
   Satisfactory? [Y] [N]
   Relevant? [Y] [N]
b. How experienced and qualified are the staff with respect to—
   Theoretical training? [1] [2] [3] [4] [5] [6]
   Practical skills training? [1] [2] [3] [4] [5] [6]
   Training in teaching? [1] [2] [3] [4] [5] [6]
   Industrial experience? [1] [2] [3] [4] [5] [6]
c. Are the conditions for promotion satisfactory? [Y] [N]
d. Is there a satisfactory number of staff in post? [Y] [N]
e. Is the turnover reasonable? [Y] [N]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Staff Development and Training

a. Is there a satisfactory staff development plan for the institution? [Y] [N]

b. Are there satisfactory arrangements for pre-service training in—

Technical competence? [Y] [N]

Teaching methods? [Y] [N]

Management? [Y] [N]

c. Are there satisfactory arrangements for in-service training? [Y] [N]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Support Staff

a. Are the following staff levels satisfactory?

Technical support staff for laboratories and workshops [Y] [N]

Administrative staff [Y] [N]

Specialist staff, for example, librarians [Y] [N]

Storekeepers [Y] [N]

b. Are there satisfactory numbers of staff actually in the following posts?

Technical support staff for laboratories and workshops [Y] [N]

Administrative staff [Y] [N]

Specialist staff, for example, librarians [Y] [N]

Storekeepers [Y] [N]

c. Are salary levels for support personnel adequate to attract staff? [Y] [N]

d. How qualified and experienced are the support staff? [1] [2] [3] [4] [5] [6]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Physical Resources

Teaching Facilities

a. Are the amounts and range of the following satisfactory?

Classrooms	Y N
Specialist laboratories	Y N
Specialist workshops	Y N
Preparation rooms and stores	Y N

b. Is the physical layout and interrelationship satisfactory? Y N

c. Are services adequate? Y N

d. Are buildings and services maintained in a satisfactory state? Y N

e. Are safety features satisfactory? Y N

f. Are lighting and ventilation satisfactory? Y N

Comments:

Overall assessment: 1 2 3 4 5 6

Support Facilities

a. Are the areas and facilities for the following satisfactory?

Library	Y N
Administration	Y N
Central services	Y N
Communal areas	Y N

b. Is student housing adequate? Y N

c. Is staff housing adequate? Y N

Comments:

Overall assessment. 1 2 3 4 5 6

Utilization of Space (see appendix B, "Facilities: Schedule and Utilization")

a. How satisfactory is the utilization of the following?

Classrooms	1 2 3 4 5 6
Laboratories	1 2 3 4 5 6
Workshops	1 2 3 4 5 6
Libraries	1 2 3 4 5 6
Other	1 2 3 4 5 6

Comments:

Overall assessment: 1 2 3 4 5 6

Provision of Equipment

a. How comprehensive is the range of laboratory and workshop equipment?	1 2 3 4 5 6
b. How relevant is the equipment to course needs?	1 2 3 4 5 6
c. How satisfactory is the provision of equipment for individual practical work?	1 2 3 4 5 6
d. How satisfactory is the equipment in terms of being up to date?	1 2 3 4 5 6
e. How adequate is the provision and availability of the following support equipment?	
Overhead projectors	1 2 3 4 5 6
Screens	1 2 3 4 5 6
Reprographic equipment	1 2 3 4 5 6
Other audiovisual aids	1 2 3 4 5 6
f. How satisfactory is the program for replacement of equipment?	1 2 3 4 5 6

Comments:

Overall assessment: 1 2 3 4 5 6

Equipment Utilization

a. How satisfactory is the utilization of equipment? [1] [2] [3] [4] [5] [6]
b. What are the main reasons for equipment not being in regular use?
   - Lack of materials [Y] [N]
   - Not relevant to course needs [Y] [N]
   - Obsolete [Y] [N]
   - No instruction manuals [Y] [N]
   - Broken down; lack of spares [Y] [N]
c. How satisfactory is the maintenance program? [1] [2] [3] [4] [5] [6]
d. How satisfactory is the stock of spare parts? [1] [2] [3] [4] [5] [6]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Consumable Materials

a. How satisfactory are stocks of consumable materials? [1] [2] [3] [4] [5] [6]
b. How satisfactory is the stores and distribution system? [1] [2] [3] [4] [5] [6]
c. Are there satisfactory provisions in annual budgets for replacing materials? [Y] [N]
d. How satisfactory are the availability of materials and their use in the training? [1] [2] [3] [4] [5] [6]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Organization and Management

Objectives and Plans

a. How clearly are institutional objectives defined?	1 2 3 4 5 6
b. To what extent is there an institutional development plan covering	
Course development?	1 2 3 4 5 6
Enrollments?	1 2 3 4 5 6
Staffing?	1 2 3 4 5 6
Physical resources?	1 2 3 4 5 6
Capital and recurrent costs?	1 2 3 4 5 6
c. Are plans reviewed regularly and implementation monitored?	Y N
d. How effective is the system for monitoring implementation of development plans?	1 2 3 4 5 6

Comments:

Overall assessment: 1 2 3 4 5 6

Organizational Structure

a. How clear and well defined is the organizational structure?	1 2 3 4 5 6
b. Does the structure match the training functions?	1 2 3 4 5 6
c. Is there a local governing body?	Y N
d. If yes, is industry represented?	Y N

Comments:

Overall assessment: 1 2 3 4 5 6

Information System

a. How adequate and readily available is information on
   Enrollments? 1 2 3 4 5 6
   Student and trainee performance? 1 2 3 4 5 6
   Utilization of resources? 1 2 3 4 5 6
   Expenditure and income? 1 2 3 4 5 6

c. Does industry have employees who have had in-plant training take skills tests conducted by the institution? [Y] [N]

d. How effective is the organization or service provided by the institution to help trainees obtain employment after they finish training? [1] [2] [3] [4] [5] [6]

   Is there a full-time placement officer? [Y] [N]

   Is there a part-time placement officer? [Y] [N]

   Does industry regularly visit the institution to recruit workers? [Y] [N]

e. How effective is the institution's follow-up of trainees to obtain feedback information on training and employment? [1] [2] [3] [4] [5] [6]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Formal Links and Services

a. How effective is the participation of industry representatives in the following activities?

Governing body of the institution	1 2 3 4 5 6
Advisory committee	1 2 3 4 5 6
Training programs and curricula	1 2 3 4 5 6
Examinations or tests	1 2 3 4 5 6

b. Does industry participate in joint publicity or similar supporting activities, for example, the award of prizes to trainees? Y N

c. How effectively does the institution provide the following services to industry?

Technical advice	1 2 3 4 5 6
Technical services (measurements, testing)	1 2 3 4 5 6
Production assistance	1 2 3 4 5 6

Comments:

Overall assessment: 1 2 3 4 5 6

Industrial Links of Staff

a. How satisfactory is the extent and relevance of the teaching staff's experience in industry? 1 2 3 4 5 6

b. Is there a regular arrangement for staff to be attached to industry for experience? Y N

c. Does the institution make effective use of part-time staff from industry? Y N

d. Are there staff members who are responsible for liaison with industry? Y N

e. Do staff obtain any significant income from industry? Y N

Comments:

Overall assessment: 1 2 3 4 5 6

Industrial Environment

a. How effective is the institution in creating an environment similar to that in industry with respect to

General work environment?	1 2 3 4 5 6
Discipline?	1 2 3 4 5 6
Timekeeping?	1 2 3 4 5 6
Safety procedures?	1 2 3 4 5 6

b. Does the institution engage in production, construction, or repair activities? Y N

c. If yes,

Are students effectively involved?	Y N
Are staff effectively involved?	Y N
How effectively does the activity contribute to the content and standard of training?	1 2 3 4 5 6
How effectively does the activity contribute to income generation for the center?	1 2 3 4 5 6

Comments:

Overall assessment: 1 2 3 4 5 6

B

Checklist. Efficiency of Operations: Quantitative Evaluation

Note: Refer to completed appendixes D and E.

Student Flow Rates

a. Admission rate ____________
b. Dropout rate ____________
c. Repetition rate ____________
d. Pass/fail rate ____________

Efficiency Indexes

a. Average time required to produce a graduate ____________
b. Output-input ratio ____________

Staff Load

a. Student-staff ratio ____________
b. Average class size ____________
c. Average teacher workload (hours a week) ____________

Facilities: Schedules and Utilization

a. Average workspace per student (in square meters)
   Classrooms ____________
   Laboratories ____________
   Workshops ____________
b. Support space (capacity in square meters per student)
   Library ____________
   Communal space ____________
   Living accommodations ____________
c. Space utilization (list for selected categories of space and for specialized workshops and laboratories, for example, machine shop, welding workshop)

Costs

a. Total and unit costs

Total cost	________
Number of students	________
Number of graduates	________
Cost per student per year	________
Cost per graduate	________

b. Cost analysis (show each category as percentage of total costs)

Staff salaries	________
Consumable materials	________
Maintenance	________
Other (break down if exceeds 10 percent)	________

C

Checklist. The Central Training System

Policies, Planning, and Development

a. Is there a central policy for vocational training and education? [Y] [N]

b. Is there satisfactory coordination between the various training subsystems? [Y] [N]

c. Is there a current national development plan for training? [Y] [N]

d. If yes does the plan adequately cover:

- Enrollments? [Y] [N]
- Training programs? [Y] [N]
- Staffing? [Y] [N]
- Physical resources? [Y] [N]
- Capital costs? [Y] [N]
- Recurrent costs? [Y] [N]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Central and Regional Control

Control of Training Programs and Courses

a. Is the distribution of courses and enrollments centrally controlled? [Y] [N]
b. Is there a national training system? [Y] [N]
c. If yes, what percentage of trainees takes national standardized tests? [Y] [N]
d. Is there central control of
   Curricula and syllabuses? [Y] [N]
   Content of training materials? [Y] [N]
   Supply of training materials? [Y] [N]
   Examinations? [Y] [N]
e. Is there a system of national inspectors or advisers? [Y] [N]
f. Is quality of training monitored by central staff? [Y] [N]

Comments

Overall assessment: [1] [2] [3] [4] [5] [6]

Control of Staffing

a. Are staff salaries fixed nationally? [Y] [N]
b. Are staff levels fixed nationally? [Y] [N]
c. Are salaries comparable with those for other government work? [Y] [N]
d. Are salaries comparable with those in the private sector? [Y] [N]
e. Is there a national staff development and training plan? [Y] [N]
f. Is there adequate provision for the following types of in-service training? [Y] [N]
   Technical training [Y] [N]
   Teacher training [Y] [N]
   Management training [Y] [N]
g. Is staff performance monitored? [Y] [N]

Comments:

Overall assessment: [1] [2] [3] [4] [5] [6]

Physical Resources

a. Is there a national building development plan that is related to academic and training plans? Y N
b. Are building plans based on standard unit areas per trainee place? Y N
c. If yes, are the standards comparable to international standards? Y N
d. Is utilization of buildings monitored? Y N
e. Have standards been established for provision of
   Equipment? Y N
   Materials? Y N
f. Is equipment utilization monitored? Y N

Comments:

Overall assessment: 1 2 3 4 5 6

Finances

a. What are the sources of funds?
   Government (if so, check appropriate boxes below) ☐
      Direct budget allocation ☐
      Earmarked taxes ☐
      Combination of these two ☐
   Industry ☐
   Fees ☐
b. Are medium or long-term forecasts of availability of funds made? Y N
c. Are costs analyzed? Y N
d. Are costs and financial data used for management purposes? Y N

Comments:

Background Information and Questionnaires

Copies of the reports, documents, and statements listed below should be obtained before the evaluation.

- Organization charts of the central ministry and regional office showing relevant key posts and main responsibilities
- Copies or extracts of relevant government policy statements, decrees, development programs, and annual reports
- Regulations covering apprenticeship, training incentives, and so forth.

The following questionnaires should be completed.

- C.1. Annual Enrollments and Output, Technical and Vocational Education and Training Systems
- C.2. Central Agency Expenditures, by Program
- C.3. Sources and Uses of Funds for Training
- C.4. Training Services of the Central Agency

C.1. *Annual Enrollments and Output, Vocational Training System*

Instructions: Complete for past three years.

System	*19__/__*			*19__/__*			*19__/__*		
	Number of schools or centers	*Enroll-ment*	*Output*	*Number of schools or centers*	*Enroll-ment*	*Output*	*Number of schools or centers*	*Enroll-ment*	*Output*
Secondary vocational and technical schools									
Public (government)									
Industrial and technical									
Other vocational									
Private									
Industrial and technical									
Other vocational									
Vocational training									
Public (government)									
Industrial vocational training centers									
Other vocational training centers									
Privately financed or industry-sponsored									
Industrial vocational training									
Other vocational training									

C.2. *Central Agency Expenditures, by Program*

Instructions: Record expenditures, in local currency, for each category for the past two years. Separate tables are to be completed for each central agency (ministry of education, ministry of labor or manpower, central training authority).

	19_/_	19_/_
General administration		
Manpower planning		
Training services		
Curriculum development		
Production of teaching materials		
Skills testing		
Inspection		
Advisory services		
Staff development		
Research		
Employment services		
Placement		
Follow-up		
Total		

C.3. *Sources and Uses of Funds for Training*

A. Expenditures on vocational and technical training
Instructions: Give expenditures, in local currency, for past two years.

	19_/_	19_/_
Ministry of education		
a. Total expenditure on vocational and technical education[1]		
b. Expenditure on industrial vocational education[2]		
Ministry of labor or manpower, or central training agency		
a. Total expenditure on vocational training[1]		
b. Expenditure on industrial vocational training[2]		

B. Sources of funds
Instructions: Give data in local currency.

	Regular budget	*Earmarked taxes or levy*	*Income from fees*	*Development funds*	*Other*
Ministry of education					
Ministry of labor or manpower, or central training agency					

1 Includes industrial, agricultural, and home economics

2 Included in (a)

C.4. Training Services of the Central Agency

Evaluation team: Write in year (most recent full fiscal year).
Instructions: Please provide figures or check appropriate box.

1. Is there a national training advisory service that assists employers to identify training needs and to arrange training? __________
2. If yes,
   a. How many training officers are there? __________
   b. How many firms were assisted in 198_? __________
   c. How many workers were upgraded in 198_? __________
      Of these, how many were
         Apprentices (craft, technical, and engineering)? __________
         Adult workers? __________
         Supervisors and foremen? __________
   d. How much money, in local currency, was budgeted by the government for the service in 198_? __________
   e. How much money, in local currency, did employers contribute to the service in 198_? __________
3. Is training arranged for training officers and managers of firms? [Y] [N]
4. If yes,
   a. How many training officers and managers were trained in 198_? __________
   b. Were the courses for training officers and managers given by staff of the central training office? [Y] [N]
   c. If no, were the courses subcontracted to a management training unit of an institution for higher education? [Y] [N]
   d. How much money, in local currency, was budgeted for this service in 198_? __________
5. Is there an inspection service to supervise training centers and staff? [Y] [N]

6. If yes,
   a. How many supervisors are employed? ____________
   b. How many training centers were inspected in 198_? ____________
   c. How long does an inspection normally take? ____________
   b. Does the inspection include
      A review of the course program and lesson plans? [Y] [N]
      An assessment of the training methods employed? [Y] [N]
      An inspection of the training equipment, materials, and aids in use? [Y] [N]
      A review of text schemes and the quality of trainees' work? [Y] [N]
      An assessment of the upkeep of workshops and offices? [Y] [N]
      An evaluation of the quality of instruction and of training center management? [Y] [N]
      A meeting with the advisory body or other group of employers regarding the relevance to local needs of the training center and its programs? [Y] [N]
      A review of the budget and accounting system? [Y] [N]
   e. Are inspection reports available? [Y] [N]
      If yes, please provide evaluation team with examples.
   f. How much money is budgeted for inspection? ____________
7. Are there arrangements for evaluating the external efficiency of training programs? [Y] [N]
8. If yes,
   a. Is there a tracer and follow-up system for former trainees? [Y] [N]
   b. If yes,
      For how many years after graduation are trainees followed up? ____________
      What is the frequency of follow-up? ____________
      What is the annual budget for follow-up? ____________
   c. Are employers interviewed to ascertain their opinion of former trainees' performance? [Y] [N]
   d. If yes, are employers questioned on
      Skill levels of former trainees? [Y] [N]
      Relevance of the training? [Y] [N]
      Attitudes of former trainees? [Y] [N]

D

Efficiency of Operations: Background Information

The information requested in this appendix is to be collected in advance by the director and senior staff of the institution to be evaluated. If the evaluation team is multinational and translations will be needed, ask the responsible person to provide translations or translated summaries of the information, and specify the languages.

The responsible person should place a check mark in each box in the list below to show that the requested information has been gathered or the questionnaires completed. The questionnaires are intended as guides and may be modified by the team to fit the particular circumstances.

1. Basic information (D.1) ☐
2. Course curricula, syllabuses, and examinations
   a. Curricula of main courses showing time allocations by subject for each year or semester ☐
   b. Specimen syllabuses (provide examples for typical courses to show the format) ☐
   c. Examination regulations ☐
3. Students
   a. Entrance qualifications ☐
   b. Enrollment and output, by course (D.2) ☐
   c. Recent report on follow-up of graduates, if available ☐
4. Staff
   a. Curriculum vitae of director ☐
   b. Instructors' qualifications and experience (D.3) ☐
   c. Support staff (D.4) ☐
5. Physical resources
   a. Schedule for facilities (D.5) ☐
   b. Utilization of space (D.6) ☐

6. Management
   a. The institution's organization chart, showing main departments and units, key posts such as heads of departments, and advisory committees. Include brief details of constitution and terms of reference for staff. ☐
   b. The latest annual report of the institution ☐
   c. The development plan, if any, for the institution ☐
7. Costs
   a. Annual operating costs (D.7) ☐
   b. Capital expenditure (D 8) ☐

D.1. Basic Information

Name of center or school ______________________________

Address ______________________________

Name of director or head teacher ______________________________

Date institution began operations ______________________________

Main courses or specializations (include brief statement of main training activities):

Total number of students enrolled ____________

Total number of teaching or training staff ____________

Total number of other staff ____________

Does the center or school operate on a single or a double shift? ____________

Approximately what percentage of total training hours is alloted to

- Regular technical school courses ____________
- Courses for unemployed youth no longer in school ____________
- Courses for apprentices ____________
- Courses to upgrade employed workers ____________
- Supervisory training ____________
- Management training ____________
- Instructor training ____________
- Other ____________

Name and position of person completing questionnaire ______________________________

____

Date ______________________________

Name of school or center ____________

D.2. *Enrollment and Output, by Course or Specialization, 19__/__*

Instructions: Complete a separate table for each of the past three years. This form is suitable for courses lasting one to four years. If courses are shorter than one year, use only the first column. See specific notes below.

		Enrollment by course or specialization					
Course or specialization[1]	*Nature or length of course*[2]	*First year*	*Second year*	*Third year*	*Fourth year*	*Total*	*Output (number of graduates)*[3]
All courses							

1. List specializations or courses in which training is offered and students are enrolled (for example, mechanical engineering, auto mechanics, welding, electrical installation).
2. Enter separately for each major program or course. Indicate length in weeks or total hours per course or year; show whether course is full time or part time.
3. Number who completed course successfully.

Name of school or center ______________________________

D.3. *Instructors' Qualifications and Experience*

	Number of instructors				Average value for each specialization or trade[1]							
	Part-time											
Specialization[2]	Number	FTE[3]	Full-time	Total FTE	Years of general education	Years of technical education or vocational training	Years of technical teacher training	Years of teaching experience	Length of training overseas	Upgrading in-service training	Years of industrial experience	Relative salary[4]

1. Show the average value for each full-time equivalent (FTE) instructor for each specialization.
2. List specializations according to the main departmental or unit groupings, for example, mechanical, automotive, electrical, building construction, general science, and mathematics.
3. The number of full-time-equivalent teachers is obtained by dividing the total weekly hours (periods) taught by part-time teachers by the normal weekly teaching load of a full-time teacher.
4. Average salary divided by salary of industrial worker with equivalent qualifications.

Name of school or center ____________________

D.4. *Support Staff*

Instructions: Complete for each of the past three years.

	Number of support staff		
	19__/__	*19__/__*	*19__/__*
Laboratory technicians			
Workshop support staff			
Storekeepers			
Administrative staff			
Specialized support staff (librarians, accountants, and others)			
Total			

Name of school or center ______________________________

D.5. *Schedule for Facilities, 19__/__*

Instructions: Use information for past year.

Purpose	Unit area (approx., in square meters) (1)	Number of units (2)	Capacity (trainee places) Per unit (3)	Total (4)
Teaching				
Classroom[1]				
Laboratories[2]				
Workshops[2]				
Support				
Library				
Audio-visual				
Storage				
Administrative				
Other				
Catering (dining and kitchen)				
Student services				
Residential				
Staff residences (approximate size category and number in that category)				
Total number				
Student dormitories or hostels (total number of places)				
Male				
Female				

1. Group classrooms by approximate size.
2. List and group by specialization (include associated preparation rooms).

Name of school or center ______________________________

D.6. *Space Utilization*

Instructions: Provide information for each column (see also example that follows this form).

Col. 1. List spaces by type of use or specialization; for example, classrooms (could be treated as group), drawing offices, laboratories (by specialization, as electrical engineering, mechanical engineering, physics), workshops (by specialization, as mechanical, bench, machine, electrical).

Col. 2. Enter number of workplaces for each group of specialized spaces (from D.5, col. 4).

Col. 3. For the theoretical, or maximum, capacity, multiply the number of workplaces by the hours (or periods) per week that the center or school is open and multiply the product by the number of weeks per year (or semester) that the center or school is open.

Col. 4. For each group of specialized spaces list by year the courses that actually use that facility.

Col 5. Enter the actual number of students enrolled in the course for the year (or semester).

Col. 6. Enter the hours (or periods) per week when students are actually scheduled to be using the facility (from the course curriculum).

Col. 7. Enter the number of weeks per year (or per semester) when the course actually uses the facility.

Col. 8. Multiply (5) by (6) by (7).

Col. 9. Divide (8) by (3).

Teaching space(s) (1)	*Number of workplaces* (2)	*Capacity in place-hours (or periods) per year (or semester)* (3)	*Course(s) using the facility* (4)	*Number of students enrolled in each course* (5)	*Hours (periods) per week spent in the facility* (6)	*Number of weeks per year (or semester) for which course uses facility* (7)	*Actual use in student-hours (or periods) per year (or semester)* (8)	*Utilization factor* (9)

This example illustrates the method for calculating utilization of a mechanical workshop and a physics laboratory where these facilities are used by two courses, a mechanical course and an electrical course.

Teaching space (1)	*Courses using facility* (4)	*Number of students enrolled* (5)	*Hours or periods per week spent in facility*[1] (6)	*Number of weeks per year facility used* (7)	*Actual use in student-hours per year* [(7)·(6)·(5)] (8)
Mechanical workshop	Mechanical				
	First year	50	6	36	10,800
	Second year	40	8	36	11,520
	Third year	38	12	36	16,416
	Electrical				
	First year	25	2	36	1,800
	Second year	23	2	36	1,656
Total					42,192
Physics laboratory	Mechanical				
	First year	50	4	36	7,200
	Second year	40	4	36	5,760
	Third year	38	4	36	5,472
	Electrical				
	First year	25	4	36	3,600
	Second year	23	4	36	3,312
	Third year	26	4	36	3,744
Total					29,088

Notes Column numbers correspond to numbers in D.6. For this example we assume a course length of 36 weeks per year.

1 This information is derived from the school curricula, as shown below (numbers in italics correspond to column 6 in the example).

	Mechanical course (hours per week)			*Electrical course (hours per week)*		
Curriculum	*First year*	*Second year*	*Third year*	*First year*	*Second year*	*Third year*
Mathematics	6	6	6	6	6	6
Social studies	4	3	2	4	3	2
Physics						
Lab	*4*	*4*	*4*	*4*	*4*	*4*
Theory	2	2	2	2	2	2
Chemistry						
Lab	4	3	2	4	3	2
Theory	2	2	1	2	2	1

	Mechanical course (hours per week)			*Electrical course (hours per week)*		
Curriculum	*First year*	*Second year*	*Third year*	*First year*	*Second year*	*Third year*
Mechanical						
Workshop	*6*	*8*	*12*	*2*	*2*	*0*
Theory	4	4	6	1	1	0
Electrical						
Workshop	2	2	0	6	8	12
Theory	1	1	0	4	4	6
Total	35	36	35	36	35	35

Name of school or center ______________________________

D.7. *Annual Operating Costs*

Instructions: Complete for each of the past three years. Give expenditures in local currency. Operating costs are actual outlays of funds, regardless of their source. For example, if the government pays some part of salaries and a donor agency others, the combined cost to the government and the agency is recorded.

	Actual expenditure		
Item	*19__/__*	*19__/__*	*19__/__*
Salaries and allowances			
Teachers and instructors			
Salaries			
Other allowances			
Support staff, salaries and allowances			
Consumable materials[1]			
Maintenance of buildings and equipment			
Interest			
Utilities			
Travel			
Boarding costs			
Other[2]			
Total			

1. Consumable materials include such items as metal, wood, building materials, welding rods, oil, paper, small tools, and electronic components. It does not include equipment expected to have a working life of more than two years (for example, lathes, typewriters, and signal generators); these are capital items (see D.8).
2. If more than 10 percent of total expenditure, itemize. This category includes the cost of any student stipends.

D.8. *Capital Expenditure*

Instructions: Complete for each of the past three years. Give expenditures in local currency.

Item or category	*19__/__*	*19__/__*	*19__/__*

E

Efficiency of Operations: Forms for Interviews and Observation

The questionnaires and forms in this appendix are to be completed by the evaluation team. The forms provided here are intended as a guide for systematic collection of information; supplementary questions may be needed to clarify the arrangements in the particular center.

The first step is an initial interview with the director or head teacher, at which questionnaire E.1 is completed.

Next, at a meeting with the director or head teacher and the senior staff, the evaluation team completes a set of questionnaires:

E.2 (Selection and Admission of Students and Trainees)
E.3 (Job Placement and Follow-up)
E.4 (Staff Selection and Promotion)
E.5 (Staff Development Plans)
E.6 (External and Industrial Activities)
E.7 (Management)

The team then observes in detail the institution's teaching and training activities and the use of equipment and facilities. On the basis of these observations and discussions with trainees and staff, the team completes the following forms:

E.8 (Teaching Activities Observed)
E.9 (Quality of Teaching Materials and of Training Programs)
E.10 (Upkeep of Laboratories and Workshops)
E.11 (Utilization of Equipment)
E.12 (Availability and Use of Small Tools and Measuring Equipment)
E.13 Availability and Use of Consumable Materials

The team also completes, in small group (six to eight persons) discussions, E.14 (for instructors) and E.15 (for students).

Name of school or center ______________________________

E.1. Questionnaire for Director or Head Teacher

Instructions: Circle the appropriate answer.

Recruitment and Employment of Teachers and Instructors

1. In your opinion, is it possible to recruit an adequate number of qualified and experienced vocational instructors?
   a. Yes
   b. No
2. If no, why?
   a. Pay is too low to attract experienced people.
   b. This locality is not attractive.
   c. Other (explain)
3. What is the annual turnover of instructors, as a percentage of total teaching staff?
   a. More than 20 percent
   b. 11–19 percent
   c. 5–10 percent
   d. Less than 5 percent
4. If the turnover is greater than 10 percent a year, what is the principal reason?
   a. Death, retirement, or illness
   b. Transfer to private industry
   c. Transfer to other jobs in government service
   d. Transfer to another training center or school
   e. Other (explain)
5. If your staff members are moving to industry or other jobs, what is the reason?
   a. Better pay
   b. Better conditions and benefits
   c. Other (explain)
6. In your judgment, how satisfactory is the performance of your instructors?
   a. Staff as a whole is in need of major training and upgrading.
   b. Most staff need some additional training, skills, and experience.
   c. Generally satisfactory, but some staff members need more training in specific areas.
   d. Satisfactory
7. If staff need more training or experience, in what areas?
   a. Professional or technical knowledge
   b. Practical or technical skills
   c. Ability to teach
   d. Experience in industry
   e. Management training
   f. Other (explain)

Quality of Output and Graduates

8. Are graduates from your program prepared satisfactorily for employment in industry in fields relevant to their training?
   a. Yes
   b. No
9. If no, why?
   a. Training programs are too short.
   b. Teachers are not sufficiently well trained or experienced.
   c. Students are not sufficiently motivated.
   d. Content or balance of training course is not relevant to employment needs.
   e. Facilities and equipment are below standard.
   f. Other (explain)
10. How do your graduates get jobs?
   a. Industry approaches the center or school.
   b. The center or school contacts industries.
   c. Personal initiative is taken by graduates.
   d. Other (explain)
   e. Don't know
11. What percentage of your graduates get jobs in the fields they were trained for?
   a. 76–100 percent
   b. 50–75 percent
   c. Less than 50 percent

General

12. In your opinion, which *two* of the following measures would most improve the training offered in your institution?
   a. Improve buildings
   b. Improve equipment
   c. Change the course of study
   d. Improve training materials
   e. Increase number of instructors
   f. Upgrade instructors
   g. Increase supply of such materials as metals, paper, and spare parts
   h. Improve supervision of the institution by central ministry
   i. Improve guidance and counseling of students
   j. Improve the selection process for incoming students
   k. Establish closer relations with employers and industry
   l. Other (explain)

Name of school or center ______________________

E.2. Selection and Admission of Students and Trainees

Instructions: For the most recent year, check if applicable or provide information.

1. Tr:al number of applicants ______
2. Total number of admissions ______
3. What are the criteria for admission to a course as a trainee?
   a. Age (specify) ______
   b. Years of general education completed (specify) ______
   c. Nomination by government department ☐
   d. Sponsorship by industry ☐
   e. Ability to pay fee ☐
   f. Not employed ☐
   g. Other (specify) ______
4. What is the method of selection?
   a. Written information ☐
   b. Interviews ☐
   c. Practical test ☐
   d. Theory test ☐
   e. Health examination ☐
   f. Other (specify) ______
5. Is there a special budget for expenditures on selection? Y N
6. Is there special provision for admission of handicapped trainees? Y N
7. If yes, give details. ______
8. What percentage of students selected is sponsored by
   a. Government departments? ______
   b. Private industry? ______
9. What percentage of students admitted is recruited from
   a. The town or city in which the center is located? ______
   b. The province or region (but not the city or town) in which the center is located? ______
   c. Outside the province or region? ______

E.3. Job Placement and Follow-up

1. Are graduates helped to find employment? [Y] [N]
2. If yes,
   a. Does the school or training center operate a placement service? [Y] [N]
   b. Does the ministry of labor arrange placement? [Y] [N]
   c. What other help is given? (Specify.) ____________________
3. If yes to (2a), what services are provided? (Describe briefly.) ____________________
4. a. What percentage of graduates or trainees is in jobs within six months? 75 ☐ 50 ☐ 25 ☐ 10 ☐
   b. Within one year? 75 ☐ 50 ☐ 25 ☐ 10 ☐
5. In which trades is it easiest to place graduates? (1 indicates easiest.)
   1. ____________________
   2. ____________________
   3. ____________________
6. In which trades is it most difficult for graduates to obtain employment? (1 indicates most difficult.)
   1. ____________________
   2. ____________________
   3. ____________________
7. Is there a follow-up service? [Y] [N]
8. If yes,
   a. For how many years after graduation? ____________________
   b. What is the frequency of follow-up? ____________________
9. Is there a special budget for placement and follow-up services? [Y] [N]

E.4. Staff Selection and Promotion

1. What are the minimum criteria for appointment as assistant instructor?
   a. General education (how many years?) ☐ ______
   b. Technical education or vocational training (how many years?) ☐ ______
   c. Technical teacher training course (state length) ☐ ______
   d. Trade experience (how many years?) ☐ ______
   e. Practical test before appointment ☐
   f. Satisfactory personal interview ☐
   g. Medical ☐
   h. Age (specify) ☐ ______

E.5. Staff Development Plans

1. What is the basis for determining the number and type of instructors?
   a. Hours or periods of teaching required in each subject or specialization ☐
   b. Student-staff ratio, by course or training program ☐
   c. Student-staff ratio, for center as a whole ☐
   d. Combination of (a), (b), and (c) ☐
2. What is the nominal weekly teaching duty in periods (give length) or in hours? ________
3. What is the present average weekly teaching duty for all staff, in hours? ________
4. If (3) differs from (2), explain. ________
5. Is there a staff development plan? Y N
6. If yes, does the plan include arrangements for
   a. Technical upgrading? Y N
   b. Teacher training? Y N
      Pre-service Y N
      In-service Y N
   c. Management training for senior staff? Y N
7. If yes to (5), is the plan adequate? Y N
8. If yes to (5), is there a regular review of implementation of the plan? Y N
9. Is there a budget for staff development? Y N

E.6. External and Industrial Activities

1. Does the center provide any training programs designed jointly with a firm for that firm's employees? [Y] [N]
2. If yes, give details of the nature, length, and frequency of that program and the number trained.
3. Does the center provide any support—technical, financial, or the use of its facilities—for graduates who are self-employed entrepreneurs? [Y] [N]
4. If yes, describe. ______
5. Does the center provide any technical or other support to local industry? [Y] [N]
6. If yes, describe the nature and amount of such support. ______
7. Does the center or school undertake production activities or provide services other than training for which it receives income? [Y] [N]
8. If yes, list the products or services, the amount of production or activity, and the value or income.

Product or service	*Output (physical units, or hours of service)*	*Value or income*

9. If yes to (7), describe staff and trainee involvement in the activity. ______

E.7. Management

Responsibilities

Instructions: For each of the following, check Y if the school is directly responsible for that activity. If N is checked, indicate the body (for example, a central ministry or a regional office of a ministry) that is responsible.

a. Recruitment and appointment of teaching staff	Y	N	________
b. Recruitment and appointment of support staff	Y	N	________
c. Recruitment or selection of students	Y	N	________
d. Design of curricula and syllabuses	Y	N	________
e. Adaptation of curricula and syllabuses to local conditions	Y	N	________
f. Revision of curricula and syllabuses	Y	N	________
g. Preparation of teaching and training materials	Y	N	________
h. Design of examinations	Y	N	________
i. Marking of examinations or tests	Y	N	________
j. Purchase of equipment	Y	N	________
k. Purchase of consumable materials	Y	N	________

Coordination with Local Industry

a. Is there an advisory body? Y N
b. How often does it meet? ________________
c. In what areas is it active? ________________

Instructor Staff

a. Do instructors work as a team? Y N
b. Are there senior instructors or heads of department with responsibility for all courses in their trade? Y N
c. Are duties and terms of reference of staff given in writing? Y N
d. How often are staff meetings held? ________________

Organization

a. Does the center operate on single, double, or triple shifts (specify)? ____________
b. Is there a center timetable for the year? Y N
c. Is there a workshop loading chart? Y N
d. Are there individual staff teaching timetables? Y N
e. During what hours (or periods) is the center open each week? ________________
f. How many weeks each year does the center operate? ________________

Records

a. Does the center have records of trainee selection and admission? [Y] [N]
b. Are attendance registers maintained? [Y] [N]
c. Is there a chart or other method of monitoring trainee progress? [Y] [N]
d. Are records kept of trainee performance in trade tests or other examinations? [Y] [N]
e. Are records kept of trainees' careers after graduation? [Y] [N]
f. Are records kept of instructors' qualifications and experience? [Y] [N]
g. Are records kept on instructors' and trainees' absences? [Y] [N]
h. Are records kept on training taken by instructors? [Y] [N]
i. Are the following teaching records available for examination?
   Curricula [Y] [N]
   Course programs [Y] [N]
   Lesson plans [Y] [N]
   Instruction or job sheets [Y] [N]
j. Are the following financial records available for examination?
   Teaching staff salaries [Y] [N]
   Support staff salaries [Y] [N]
   Expenditure on consumable materials [Y] [N]
   Maintenance costs of buildings and equipment [Y] [N]
   Consumption and cost of electricity, gas, and other services [Y] [N]
   Taxes paid [Y] [N]

Equipment, Spare Tools, and Consumable Materials

a. Is an inventory of equipment and materials maintained? [Y] [N]
b. What is the system for controlling use of materials from stores? ________________
c. What is the procedure for purchasing imported items—equipment, spare parts, and materials? ________________
d. What is the procedure for purchasing locally made items or local materials? ________________

Accounting

a. Are accounts comprehensive and up to date? [Y] [N]
b. Are costs analyzed to give costs per trainee or per graduate? [Y] [N]
c. Are comparative costs used as a management tool? [Y] [N]

Name of school or center ____________________

Name of school or center ____________

E.11. *Utilization of Equipment*

Instructions: Complete for each laboratory or workshop inspected.

Laboratory or workshop (1)	What percentage of equipment is		If answer to (3) is less than 70 percent, this is because of						Is there a regular scheme for recording utilization of equipment?		Is there a regular maintenance program?		Give details of any major problems with utilization of equipment
	In good working order (2)	Used regularly (25 hours or more a week)	Shortage of materials	Lack of spare parts	Lack of instruments	Inappropriate equipment	Obsolete equipment	Other	Yes	No	Yes	No	

Name of school or center ______________________

E.12. Availability and Use of Small Tools and Measuring Equipment

a. Is there an adequate stock of small tools and measuring equipment? Y N
b. Are the small tools and measuring equipment in regular use? Y N
c. Are they well maintained and serviceable? Y N
d. Are the tool cupboards or tool stores well organized? Y N
e. Is there a system for controlling inflow and outflow of tools and equipment to trainees? Y N
f. Is there a storekeeper? Y N
g. If no, is the instructor responsible? Y N
h. If no to (7), is a trainee designated as storekeeper? Y N
i. Are worn-out and broken tools and equipment replaced without delay? Y N

Name of school or center ______________________________

E.13. Availability and Use of Consumable Materials

Note: Consumable materials are materials, such as metals, wood, building materials, welding rods, electric components, and paper, that are used in training. Small tools and instruments that have a working life of less than two years may also be included.

a. What is the approximate annual expenditure on consumable materials for each area or specialization for the past two years?

Skill area or specialization (list)	*Expenditure for consumable materials (local currency)*	
	198_/_	*198_/_*
Total expenditure		

b. Who determines annual expenditures? ______________________________
c. Who selects the materials to be purchased? ______________________________
d. How long does it normally take to procure materials? ______________________________
e. Is the store well organized? ______________________________
f. Is the storekeeper trained? ______________________________
g. What records are kept on use of materials? ______________________________

Name of school or center ______________________________

E.14. Questionnaire for Instructors

Instructions: This questionnaire is designed as a basis for an interview with a small group of instructors (about six to eight). The answers should record the consensus (if there is one) or indicate the diversity of views.

1. What course(s) do you teach?
2. In your opinion, are there enough instructors for the vocational program?
   a. Enough
   b. Too few
   c. No opinion
3. If there are too few instructors, what is the main reason?
   a. Pay is too low
   b. There is no interest in the speciality
   c. Other
4. What is your main reason for entering the teaching profession?
   a. Money
   b. Status or social position
   c. Good working conditions
   d. Employment stability
5. If you have colleagues who have left the teaching profession, what were the main reasons?
   a. Too few chances for promotion
   b. Mental fatigue or stress
   c. Pay too low
   d. Working conditions bad
   e. Duties too heavy
6. What is the range of class size in your courses? ______________
   Do you think this number is
   a. Adequate?
   b. Too large?
   c. Too small?
   d. No opinion
7. In your opinion, what is the level of the students' ability in relation to the planned level of the course?
   a. Superior
   b. Inferior
   c. The same
8. In your opinion, what is the main reason for students' dropping out?
   a. Inadequate level of knowledge
   b. Difficulty of travel to center or school
   c. Lack of discipline
   d. Health
   e. Financial reasons
   f. Availability of employment before graduation
   g. Family problems
   h. Other

9. Do you have enough teaching materials for your courses?
   a. Yes
   b. No
   c. Satisfactory in some ways, but not in others (give details)
10. Is the equipment adequate for your courses?
   a. Yes
   b. Insufficient in quantity
   c. Inadequate in quality or range
   d. Technologically obsolete
11. Is the equipment similar to that used in industry?
   a. Similar
   b. Superior
   c. Inferior
12. What do you think of the maintenance and cleanliness of workshops?
   a. Good
   b. Insufficient
13. In your opinion, is it easy for graduates to obtain employment?
   a. Easy
   b. Difficult
   c. Don't know
14. If it is difficult, what is the main reason?
   a. There is little demand for the specialty.
   b. The training is inadequate.
   c. Other (give details)
15. In your opinion, what two measures would contribute most to the improvement of the school or center?
   a. Improve buildings
   b. Provide more equipment
   c. Review and update curricula
   d. Improve materials
   e. Upgrade instructors
   f. Improve student selection
   g. Improve counseling and placement of graduates
   h. Coordinate courses more closely with the requirements of the market

Name of school or center ____________________

E.15. Questionnaire for Students or Trainees

Instructions: This questionnaire is designed as a basis for an interview with a small group of students or trainees (about six to eight). The answers should record the consensus (if there is one) or indicate the diversity of views.

1. What courses are you taking? (Record all courses mentioned.)

2. What were your main reasons for enrolling in the course?
   a. My employer is sponsoring me.
   b. I am unemployed or am a school leaver and want to improve my job prospects.
   c. I want to start my own business.
   d. I was not accepted in a course I preferred (give details).
   e. I want to learn a skill.
   f. Other
3. What do you think will be your chance of employment at the end of the course?
   a. Good
   b. Fair
   c. Poor
   d. Other
4. What is your opinion of the course, compared with your expectations?
   a. It meets my needs and expectations.
   b. I am disappointed by the course.
   c. If (b), give reasons.
5. In your opinion, which of the following aspects of the course are satisfactory or unsatisfactory? (S, satisfactory, U, unsatisfactory, ?, no opinion).

a. Level of training	S	U	?
b. Content of training	S	U	?
c. Number of instructors	S	U	?
d. Quality of instructors	S	U	?
e. Laboratory or workshop equipment	S	U	?
f. Exercises in laboratories or workshops	S	U	?
g. Discipline	S	U	?
h. Other aspects (specify)	S	U	?

6. What is the average class size in your courses?
   a. Theory class ____________
   b. Laboratory or workshop ____________

   For theory class, is this number
   a. Adequate?
   b. Too large?
   c. Too small?

   For laboratory or workshop, is this number
   a. Adequate?
   b. Too large?
   c. Too small?
7. In your opinion what is the level of training in the course in relation to the ability of the students? For theory course,
   a. Course too difficult
   b. Course too easy
   c. Level about right

   For laboratory or workshop,
   a. Course too difficult
   b. Course too easy
   c. Level about right
8. In your opinion, what is the main reason for students' dropping out?
   a. Course too difficult
   b. Difficulty of travel to center or school
   c. Lack of discipline
   d. Health
   e. Financial reasons
   f. Employment available before graduation
   g. Family problems
   h. Other
9. Do you consider that you have received adequate guidance
   a. About the course or training? Y N
   b. About job availability? Y N
   c. About other possible careers? Y N
10. In your opinion, what two actions would most improve the course(s)?
    a. Improve buildings
    b. Improve equipment
    c. Raise standard of training staff
    d. Raise standard of course
    e. Increase length of course
    f. Provide better guidance to trainees before course
    g. Tighten discipline

11. Do you consider your views to be representative of all students? [Y] [N]
    If no, give details.

F

External Efficiency: Sample Questionnaires

F.1. Questionnaire for Employers

Instructions: Check appropriate box or supply information requested.

Name of company ______________________________

Industry ______________________________

Number of workers 50–200 ☐ 200–500 ☐ more than 500 ☐

This questionnaire refers only to skilled workers and higher-skilled workers or craftsmen.

1. Approximately how many workers in these occupations did you hire last year?

	Skilled workers	*Higher-skilled workers*
a. Less than 10	☐	☐
b. 10–20	☐	☐
c. 20–30	☐	☐
d. 30–40	☐	☐
e. 50–100	☐	☐
f. 100–200	☐	☐
g. 200–300	☐	☐
h. More than 300	☐	☐

2. Can you easily get workers in these occupations?
   a. Skilled [Y] [N]
   b. Higher-skilled [Y] [N]
3. If yes, do they have the type of training you would like to see in your workers?
   a. Skilled [Y] [N]
   b. Higher-skilled [Y] [N]
4. If you answered no to (2) or (3), what do you do?
   a. Offer higher wages to attract better workers from other firms ☐
   b. Offer higher wages to attract new graduates ☐
   c. Offer more fringe benefits ☐
   d. Accept less qualified candidates ☐
   e. Other ☐

5. If you answered (a), (b), or (c), how much higher? or what extra fringe benefits?
   a. 10 percent ☐
   b. 20 percent ☐
   c. 30 percent ☐
   d. Type of fringe benefits ______________
6. How do you recruit new workers?
   a. Advertise in newspapers ☐
   b. Use word-of-mouth of employed workers ☐
   c. Contact vocational schools ☐
   d. Contact training institutes and skill-training centers ☐
   e. Provide own training ☐
   f. Other ☐
7. How many applicants do you get for each job opening?
   a. Skilled workers ______________
   b. Higher-skilled workers ______________
8. Which of the following criteria do you use when hiring new workers? (Choose the two most important ones.)
   a. References from former employers ☐
   b. References from other workers ☐
   c. References from vocational schools ☐
   d. References from institutes and training centers ☐
   e. Evaluation of vocational school grades ☐
   f. Examination and practical tests at the plant ☐
   g. Other ☐
9. Which candidate of those described below is most likely to be hired?

	Skilled workers	*Higher-skilled workers*
a. Middle school with skill-center training	☐	☐
b. Middle school with one year's experience	☐	☐
c. Technical vocational high school with no experience	☐	☐
d. Academic high school with one year's experience	☐	☐

10. Why do you prefer your choices? (Choose the two more important reasons for each.)

	Skilled workers	Higher-skilled workers
a. They have more theoretical knowledge.	☐	☐
b. They have more practical knowledge.	☐	☐
c. They have more theoretical and practical knowledge.	☐	☐
d. They have more initiative.	☐	☐
e. They are more productive immediately.	☐	☐
f. They can advance faster into higher skills.	☐	☐
g. They are more reliable.	☐	☐
h. They follow instructions better.	☐	☐
i. Their starting salary is lower.	☐	☐

11. Even though candidates seem to have the background you prefer, you probably reject some before hiring one. How many of the same background do you usually reject before hiring one worker?
    a. Skilled workers __________
    b. Higher-skilled workers __________

12. In general, why are candidates rejected?

	Skilled workers	Higher-skilled workers
a. They lack theoretical knowledge.	☐	☐
b. They lack practical knowledge.	☐	☐
c. They lack the proper attitude.	☐	☐
d. They ask too much money.	☐	☐
e. They lack theoretical and practical knowledge.	☐	☐

13. When you hire workers without experience, how do you train them?
    a. Foremen and other skilled persons show them how to work. ☐
    b. We provide special in-plant training. ☐
    c. We sponsor training in skill centers or vocational training institutes. ☐

14. Have you hired graduates from vocational high schools (skill centers), in the past few years? [Y] [N]

15. If yes, how do you rate the graduates of technical high schools (skill centers) compared with workers in the same occupation but with different educational backgrounds?

	Skilled workers	Higher-skilled workers
a. They are the same as other workers.	☐	☐
b. They are better.	☐	☐
c. They are not as good.	☐	☐
d. No opinion	☐	☐

16. If you answered that they are not as good, why?

	Skilled workers	Higher-skilled workers
a. They lack theoretical knowledge.	☐	☐
b. They lack practical knowledge.	☐	☐
c. They are not acquainted with the machinery in the plant.	☐	☐
d. They lack discipline.	☐	☐
e. Other ______	☐	☐

17. If you answered that they are as good or better, do the graduates usually demand higher wages than other applicants? [Y] [N]
    By how much (percent)? 10 ☐ 20 ☐ 30 ☐ more ☐
18. Are you familiar with the vocational school (skill center)? [Y] [N]
19. If so, what is your opinion of it?
    a. Good ☐
    b. Average ☐
    c. Poor ☐
    d. No opinion ☐

F.2. Questionnaire for Employees

Instructions: This questionnaire is designed as a basis for an interview with a small group of employees (about six to eight). The interview should record the consensus, if there is one, or indicate the diversity of views.

If it is not possible to administer a questionnaire to employees, find out whether employers can provide individual records on relevant employees. These might include occupation, sex, age, education, training, and earnings.

Name of company ______________________________

Industry ______________________________

Number of workers 50–200 ☐ 200–500 ☐ more than 500 ☐

Name of employee ______________________________

1. Occupation
2. Age
   a. 16–18
   b. 19–21
   c. 22–25
   d. 26 and older
3. Level of formal schooling before entering training program
   a. Primary school
   b. Middle school
   c. Academic high school
4. Type of training program
   a. Technical high school
   b. Training in skill center
   c. On-the-job training in industry
   d. Apprenticeship
   e. Other ______________________________
5. Type of program
   a. Mechanical
   b. Chemical
   c. Electrical
   d. Electronics
   e. Other
6. Length of training program
   a. 1–6 months
   b. 7–12 months
   c. 13–18 months
   d. 19–24 months
   e. 25–36 months
7. Year when graduated from formal school ____________
8. Year when graduated from (or finished) training ____________
9. Is this your first job? [Y] [N]
10. If no, what occupation did you have before this one? ____________

11. How long did it take you to find a job after training?
    a. I found a job immediately.
    b. 3 months
    c. 6 months
    d. 9 months
    e. 1 year
    f. More than a year
12. How much do you earn now? __________
13. How much did you earn last year? __________
    How much did you earn the year b[illegible]? __________
14. When you graduated, did you expect t[illegible]
    a. More than now?
    b. Less than now?
    c. About the same?
    d. Don't know
15. Is your present occupation related to your training? [Y] [N]
16. If no, why?
    a. I did not find work in the occupation for which I trained.
    b. I did not wish to work in the occupation for which I trained.
17. What type of knowledge do you think is primarily needed for performing efficiently in your job?
    a. Theoretical
    b. Practical
    c. Experience
    d. Theoretical and practical
    e. Theoretical and experience
    f. Practical and experience
18. Are you applying in your work what you learned during your training?
    a. No
    b. A little
    c. A lot
19. If you answered (b) or (c), of all the things you learned in your training, what is the one thing that is most useful for your work?
    a. Use of machinery
    b. Theoretical instruction
    c. Advice of teachers
20. In your work, are you using equipment similar to that used during your training? [Y] [N]
21. Was what you learned during your training enough to enable you to perform successfully on your job? [Y] [N]

22. If no, why?
    a. Training did not provide experience.
    b. Training did not provide practical knowledge.
    c. Training did not provide theoretical knowledge.
    d. Training did not provide practical or theoretical knowledge.
    e. Training was too short.
    f. Training was too long.
    g. Other
23. Did some of your co-workers go through the same type of training as you did? [Y] [N]
24. If yes, what is your opinion of their capacities compared with co-workers who did not go through the same type of training?
    a. They are better workers.
    b. They are not as good.
    c. They are equally good.
    d. Don't know.

25a. If the answer was (a), why are they better?
    a. They have more knowledge.
    b. They have more experience.
    c. They are more responsible.
    d. They behave better.

25b. If you consider your training mates less capable than other workers, why is that so?
    a. Other workers have more knowledge.
    b. Other workers have more experience.
    c. Other workers are more responsible.
    d. Other workers behave better.

26. Do you think having gone through your particular type of training has paid off? [Y] [N] Don't know [ ]
27. If you think it has paid off, why?
    a. I got a good job.
    b. I am earning more money than without the training.
    c. I have more prestige than somebody without my training.
    d. It opened up possibilities for employment and advancement.
28. If you don't think it has paid off, why?
    a. I didn't get a good job.
    b. I am not earning more than I would have earned otherwise.
    c. I have little status at work.
    d. It did not open up possibilities for advancement.

29. How did you get your job?
    a. Through school placement
    b. Through friends
    c. Through newspaper ads
    d. Through an employment agency
    e. Other
29. Would you recommend to your friends or relatives the same type of training you took? [Y] [N]

tively the institution uses the available resources—and at external efficiency—how well the institution fulfills the purposes for which it was established. To that end they take the reader step by step through the evaluation procedure, from the first contacts with school administrators, through observation of classes and workshops, to interviews with teachers, trainees, graduates, and employers.

The evaluation materials have many applications: as a basis for regular surveys and for comparison of a school's performance over the years, as a managerial tool for keeping running records of school operations, and as a convenient format for self-assessment and follow-up by the institution.

Gordon Hunting is a technical educator in the East Asia and Pacific Regional Office of the World Bank. Manuel Zymelman is special adviser for the economics of education in Africa for the World Bank. Martin Godfrey is a fellow at the Institute of Development Studies, University of Sussex, United Kingdom.

Diversified Secondary Education and Development: Evidence from Colombia and Tanzania

George Psacharopoulos and William Loxley

In the 1960s prevailing wisdom held that, to prepare young people for the labor market in developing countries, the secondary school curriculum should be diversified to include prevocational subjects. This book—the first in-depth analysis of diversified education—warns that the economic rationale for such programs should not be accepted uncritically. Case studies in Colombia and Tanzania indicate that graduates of diversified schools do not perform better in the labor market than do graduates of purely academic institutions, and that the cost of diversified programs is higher. The authors' findings will be of particular interest to teachers and administrators, policymakers, and educational researchers.

Education Finance Simulation Model

Manuel Zymelman and Fredrik K. Yhu

The computer model presented here simulates educational and financial policies of school systems in developing countries and allows decisionmakers to choose among a wide variety of policies that are feasible in the local context. The book contains a user's manual that describes the model's systems, design, input, output, and operational procedures. An optional program diskette is available that can be used with an IBM-PC computer; its use requires a minimal understanding of the "Multiplan" software package.

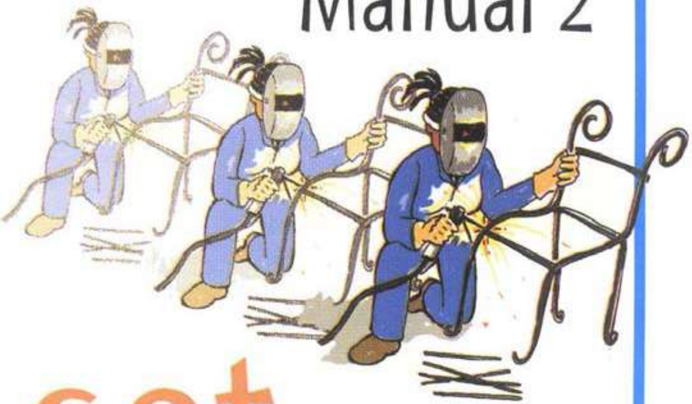
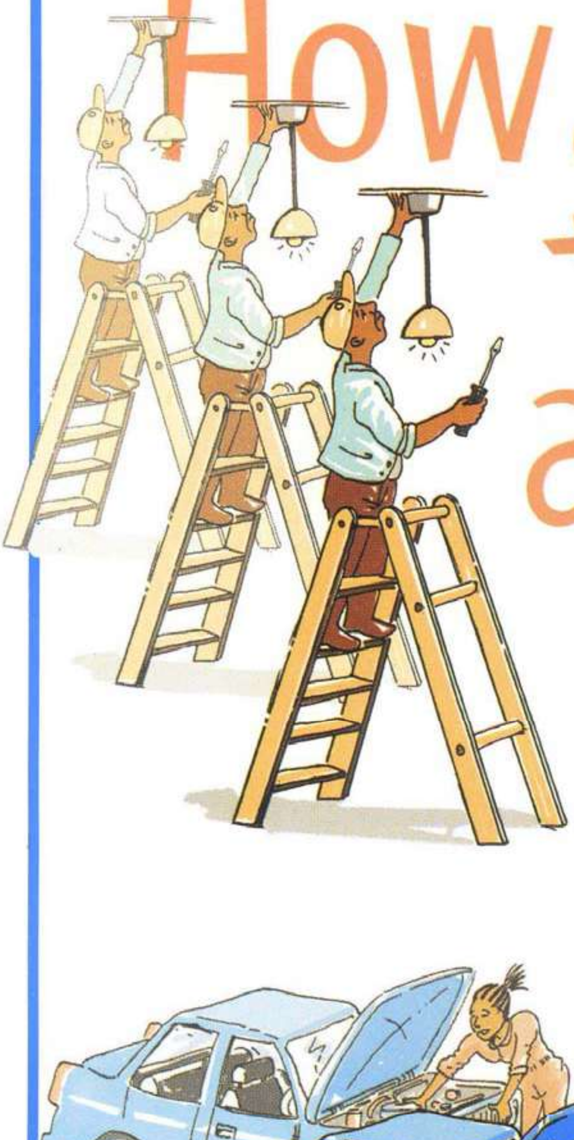
ADDING VALUE:

Manual 2



How to set up and run a TAP



Traditional Apprenticeship Programme

gtz - istarn

This manual is intended to provide guidelines and support to those interested in setting up their own Traditional Apprenticeship Programme (TAP). It takes the form of a workbook to guide implementers in making choices and decisions about their particular TAP.

This manual should help interested institutions and organisations develop a TAP Programme using the experiences of GTZ-ISTARN as a foundation. However, this manual is not a blueprint, which should be followed slavishly, it has been produced to provide guidelines based on what is thought to be best practice.

This manual has a complimentary first volume entitled 'Is a Traditional Apprenticeship Programme an Option for You?' which describes what a TAP is. Both manuals are seen as an aid to replication and to the implementation of technical training programmes for the informal sector in different circumstances and locations.

Layout and art work by **ACTION ,** Harare.

INTRODUCTION: What is ISTARN?

The Informal Sector Training and Resources Network (ISTARN) is a Zimbabwe-based programme. It is a joint venture between the Zimbabwean and German governments, and receives financial and technical support from the German government through the Deutsche Gesellschaft für Zusammenarbeit (GTZ). The project was initiated in 1995 in Masvingo, Zimbabwe, where a number of interventions were piloted, all of them aimed at assisting in the creation of jobs in the informal sector, in order to address the problem of unemployment which is endemic in Zimbabwe.

ISTARN has tried to develop an integrated approach to strengthening the informal sector, and its interventions have included a Small Business Advisory Programme, a Marketing Support Programme, and a programme to develop and strengthen Informal Sector Associations. The selection of interventions is intended to create an integrated package for the informal sector which will result in more, stronger and bigger businesses, creating sustainable jobs.

Among the initiatives piloted was a Traditional Apprenticeship Programme (TAP). This used a traditional practice of skills transfer to increase the potential for people learning skills through apprenticeships in the informal sector to set up and succeed in their own informal businesses. The intention of the TAP was to add value to the traditional practice, without excessive interference.

Initially piloted in 1996, the programme has shown very encouraging results, and has generated much interest. ISTARN is now in its replication phase, with Manicaland, Zimbabwe as the site of replication. The TAP is being piloted here in different forms, with different host agencies.

As part of the replication process, ISTARN has produced a set of two manuals, under the title Adding Value. The first describes what a TAP is and what is needed in order to set one up. This, the second manual, provides guidelines for implementation. By reading the first manual, we hope that decision-makers in organisations and institutions that are potential hosts for a TAP - training colleges, vocational training centres, business associations, non-governmental organisations (NGOs) and private training institutions - will get enough background and information to enable them to decide whether a TAP is the right option for them. Once they have decided to go ahead, then this second manual should provide a useful guide on what to do, when to do it and how to do it. Manual 2 is addressed to the team charged with implementing a TAP.

The manuals are not blueprints. They are intended, rather, as guides so that, as development workers, we are able to build on one another's experience and learnings. Manual 2 has been written as a workbook, and space is provided for you to think through your own situation so that you can make appropriate decisions for your particular context. We look forward to hearing from you about your TAP experiences.

The ISTARN Team

PART 1: STARTING OUT

SECTION 1: Starting a TAP in your organisation

In Manual 1 of this set, Is a Traditional Apprenticeship Programme an Option for You?, we describe a Traditional Apprenticeship Programme (TAP) as follows:

> A development intervention aimed at providing vocational skills training. It is cost-effective, relevant and accessible to relatively large numbers of people and is particularly effective where there is high unemployment and an established informal sector.
>
> A TAP is based on a traditional practice which has existed world-wide for many centuries and which has been shown to be widespread in southern Africa.
>
> A TAP adds value to the traditional practice by interventions that make it more likely that the graduates of the programme will be successful in creating jobs for themselves and, possibly, for others.
>
> In a typical TAP, based on the ISTARN model, participants come from the ranks of the unemployed, selection is based on entrepreneurial aptitude, the major site and vehicle of skills transfer is the workplace, appropriate skills involve manufacturing or service, value is added through short-term technical training, utilising existing facilities and training capacity, and by providing short-term business training and support.

A: Why have you decided to go ahead and set up a TAP?

In the first manual in this set, we discussed in detail the reasons why an institution or organisation might decide to set up a TAP. In summary, the reasons are likely to include the following:

- The trend towards increased unemployment in the formal sector is accelerating.
- The informal sector is increasingly becoming a more significant site of employment than the formal sector in sub-Saharan African countries.
- The TAP offers an innovative approach to skills development training that is relevant to the informal sector and cost effective in terms of the input required to create an employment opportunity.
- The TAP does not require entrants with relatively high level educational qualifications and so meets the challenge of equity.
- The TAP adds value to the existing traditional practice by injecting innovative practices, through the technical training component, into a sector that is notoriously conservative. Both quality and productivity can, thus, be improved.

B: Are your context and institution/organisation appropriate for a TAP?

If you have got as far as Manual 2, then you have decided that your context and institution/organisation are appropriate for a TAP.

A suitable external environment for a TAP is likely to include all or most of the following conditions:

• There is ongoing high unemployment and a low capacity in the formal sector to absorb or even retain workseekers.

• There is an existing informal sector, playing a significant role in the local economy.

• There are concentrations of business activity in certain nodal points, providing markets for informal sector outputs.

• There is already a traditional practice of informal apprenticeships.

• The approach of government to the informal sector, at the local, regional and national levels, is at least constructive, even if restrictive regulations are in place.

ISTARN invested time and money in doing detailed surveys of the traditional practice and of the informal sector in the pilot TAP area. At the very least, you need to know:

• That there is a traditional practice where people running small businesses based on a trade or skill take on “helpers” who learn the trade or skill, while providing cheap or free labour.

• What kinds of services and goods are offered in the informal sector in your area.

A suitable institutional or organisational environment for a TAP is likely to be characterised by at least some of the following:

• Clarity about the problem or issue the organisation is addressing - knowing what the programme is supposed to achieve.

• A carefully researched and thought through project concept which anticipates, to the degree possible, potential problems - although there is general agreement that there will always be problems no-one has anticipated!

• Sufficient staff with experience and skills appropriate to vocational training for the informal sector.

• An established administrative and co-ordinating infrastructure (but not necessarily a physical infrastructure, as training facilities belonging to other organisations and institutions can be used).

• A business and market-related orientation.

• Flexibility and creativity in both decision-making and implementation.

• Participation in a network of programmes involved in support to the informal sector.

• Flexible funding, linked to careful costing - in other words, costs should be kept low, but some funding needs to be available to be used flexibly as the needs of the programme become clearer.

• Good monitoring and evaluation systems.

C: Who should be involved in setting up and running a TAP?

In Manual 1, we describe the ideal TAP Team as being made up of:

• Someone with the power to make key decisions, particularly in relation to the use of the budget.

• The TAP Co-ordinator or Manager with overall responsibility for planning, implementation and monitoring and evaluation.

• Training providers, whether internal or external partners.

• One or more fieldworkers to support the Co-ordinator/Manager.

Some questions for you to answer?

1. Are you operating in an environment where there is high unemployment and a tow capacity for the formal sector to absorb workseekers?

____

2. Is there a traditional apprenticeship practice already operating in your area?

____

3. Are there opportunities for small scale entrepreneurs to set up their own trade/skill-based enterprises in your area?

____

4. What additional information do you need to be able to answer the above questions fully?

____
____
____

5. What needs to happen in your institution/organisation to make it a more suitable environment for the implementation of a successful TAP?

____
____
____

6. Do you think you have the right team to make a success of the TAP?

____

7. What roles and responsibilities will the different people in the team take on?

____
____
____
____
____

8. How are you going to ensure that the necessary steps are taken to give you the information you need and to increase the likelihood of your TAP succeeding?

____
____
____

SECTION 2: Thinking about the market

Although a TAP is a form of vocational skills training, what makes it different from the usual kind of training you might get at a technical training college, for example, is that it is directly related to market forces. This is because the emphasis in a TAP is on vocational skills training for self-employment.

- The choice of skills/trades offered should be determined by market factors - there need to be existing businesses based on these skills/trades in the market, so that apprenticeship placements can be found, but the market should not be saturated with such businesses, making it difficult for anyone in the skill/trade to earn a living income because of the competition.

- You need to know what the traditional practices for apprenticeship are in your area so that you do not undermine them through your intervention.

- You need to know about the trades that are significant in your area - if you are working in a predominantly rural area, you need to know about on-farm activities as well as rural small scale businesses and growth points.

Because of the surveying we had done, the ISTARN pilot programme knew:

- **About the manufacturing enterprises and service and repair enterprises in the informal sector in the area.**

- **The number of employees per enterprise.**

- **Which businesses were most likely to have larger numbers of staff.**

- **Which businesses had, at some stage, employed apprentices and/or were most likely to employ apprentices.**

- **The types of agreement that apprentices usually had with EOs about payment in cash or in food or shelter, and whether some apprentices were required to make a contribution to their training, or pay for their materials.**

- **The average length of training periods for apprentices in various trades.**

- **Whether or not EOs provided business training in the course of the apprenticeship.**

The ISTARN surveys excluded on-farm activities, as well as most home-based and many very rural, small scale businesses.

If you are concerned about including women in your programme, you wit! need specific information about trades/skills which are or could be "women-friendly".

Some questions for you to answer?

1. What are the most common manufacturing and service businesses in the informal sector in your area?

____
____
____

2. What do business or enterprise owners (EOs) offering these products or services earn in a month?

____
____

3. Are they one-person businesses, or do they employ others?

____
____

4. What businesses are less common, but do exist?

____
____

5. What do the owners of these businesses earn in a month, and do they employ or need staff to help them?

____
____
____

6. If you cannot answer any of these questions, what could you do to get the information you need?

____
____
____

SECTION 3: Different Starting Points

In Manual 1, we listed some of the different kinds of institutions/organisations which could decide to set up a TAP. They were:

- NGOs
- Technical Colleges
- Vocational Training Centres
- Private training Colleges.

You need to go back to the table in that manual to remind yourself about some of the issues and advantages and disadvantages that may apply to your particular kind of organisation or institution.

Some questions for you to answer?

1. What kind of an institution are you?

____

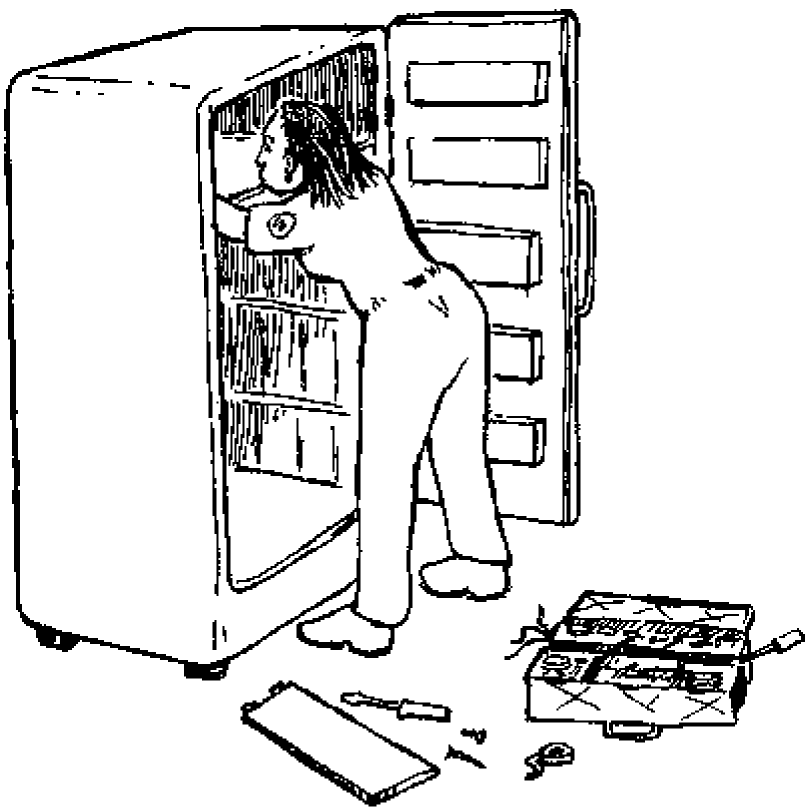
2. What are the potential strengths which you can build on in your TAP?

____
____
____

3. What are the potential weaknesses you will need to address if your TAP is to be a success?

____
____
____

When you get to this point in the manual, you will have done the preliminary work and/or thinking that will enable you to plan effectively for your TAP.



PART 2: THE PLANNING PHASE

Before you begin your detailed planning of the implementation of a TAP, there are certain things about which you need to be clear. Clarity will make the planning process easier, and will help to make implementation smoother.

SECTION 1: What are you trying to achieve?

This is the first question about which there needs to be clarity. A TAP is not just an alternative form of vocational skills training. It is an approach to vocational skills training which aims to ensure that graduates end up employed, preferably self-employed, probably in the informal sector.

A clear understanding of this purpose impacts at every level on the process of implementation. It impacts on:

- the kinds of formal skills training you offer;
- the kinds of participants you recruit and select, and how you go about selecting them;
- the sort of support package you offer;
- the kinds of information you collect for monitoring and evaluation.

The overall goal of the pilot ISTARN project was to increase employment opportunities in Masvingo Province, and the specific project purpose was defined as being to develop viable enterprises through a sustainable support system. The ISTARN TAP was meant to help the project to achieve this goal and purpose. It aimed to do this by leading to the creation of new employment opportunities through new, viable enterprises.

Because of this:

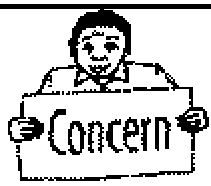
• The ISTARN TAP chose to offer skills which could be learned in a relatively short time, which were likely to be marketable, and for which there would not be a very big capital outlay in order for a graduate to start his/her own business.

• We tried to select "winners" - those most likely to succeed as entrepreneurs - and, after the first few intakes, made it a requirement of selection that the would-be apprentices must find placements before they could be considered for selection. Successfully doing this was seen as an indicator of independence and potential entrepreneurial aptitude. Although ISTARN takes wage employment as a successful outcome of the TAP, we assume (and results show this to be so) that most graduates will set up in business for themselves.

• The ISTARN TAP offers support services in the form of business training for alt apprentices, the option to access a tool hire-to-buy loan scheme, and access to business advisory services for those who go into their own businesses. All these services emphasise the aim of increasing employment opportunities through the creation of new, viable enterprises, Initially the pilot offered support in the form of access to subsistence grants and help in finding placements.

• The original apprenticeship agreements were between the enterprise owner (EO) and ISTARN. But these forms of support were dropped because they created in the apprentices a feeling of dependence on ISTARN, something the project wanted to avoid.

• ISTARN's monitoring records focus on how appropriate the formal training is to the actual workplace, and on what happens to graduates once their apprenticeship is complete. Monitoring and evaluation are related to what the project wants to achieve.



Our experience, and the evidence in international studies, is that ft is no use choosing people who expect, and want, to get jobs, when there are unlikely to be jobs for them when they graduate. A TAP has to assume that most graduates, if they want to use their skills to earn an income, will have to set up in business for themselves. This means that, if you want your TAP to be successful, you should select those who view self-employment favourably, and who have the potential to make a go of self-employment.

Your indicators (signposts) of success will be determined by what you are trying to achieve. If you are planning to create entrepreneurs, then your success will be measured by the number of graduates who go on to become successfully self-employed. Your evaluation of success will be done through tracer studies which track graduates and find out what they are doing. Because many small businesses collapse in the first few months after they are set up, you will need to track graduates over time.

ISTARN intends to track graduates for a three year period. This period has almost come to an end for the first graduates of the pilot programme, and results continue to be very encouraging.

Your interim indicators (the indicators that tell you you are making progress, even before you achieve full success) will also be determined by what you are trying to achieve. So, for example, because the TAP is a market-oriented process, the monitoring of apprentice placements and progress will be concerned with issues such as:

- Is the formal technical training appropriate to the workplace?

- Is the apprentice getting enough opportunity to practice the skill and to learn about how a business operates?

One of ISTARN's interim indicators of success was that the formal technical training should be appropriate to the workplace. In our monitoring process, we found that, while 90% of the dressmaking EOs in the first intake for the Manicaland replication TAP were very happy with the skills that the apprentices had learned in the initial technical training two weeks, those few who specialised in garments such as wedding dresses were very dissatisfied, because no "fancy" skills had been included in the training. This was picked up in the monitoring process and steps are being taken to remedy the problem.

If you are concerned about gender equity, and this is, and should be, a major concern for development projects, then you need to keep your monitoring and evaluation data in a way that differentiates between men and women apprentices. Your intake information needs to have a category to register gender, and so does your tracer information.

Some questions for you to answer?

1. What is the overall goal of your organisation or institution?

____
____
____

2. What do you hope that your TAP will achieve?

____
____
____
____

3. What will your indicators (signposts) of success be when you evaluate your TAP?

____
____
____
____

4. How will you collect the information you need to measure these indicators?

____
____
____
____

5. What interim indicators of success will you need to monitor in order to keep your TAP on track for long-term success?

____
____
____
____

6. How will you monitor these interim indicators?

____
____
____
____

SECTION 2: Are you clear on the basic principles that underpin a successful TAP?

The basic principles that underpin a successful TAP are:

The 10/90 Principle

This is the principle that, in an intervention such as a TAP, where success is so dependent on the mind-set of the participant, the implementing agency offers an opportunity which is 10% of the input required for success, but the other 90% of input required has to come from the participant. This means that the need for participant independence and entrepreneurial spirit must guide the planning and implementation process from the beginning.

ISTARN learned through experience that best practice in its TAP, in terms of the 10/90 Principle, excluded subsistence grants and any interference between the apprentice and the EO, but included the apprentices finding their own EOs, and being able to access loans to set themselves up in business.

Initially, ISTARN offered apprentices subsistence allowances, the apprentices paid nothing for training, and placements were negotiated for by ISTARN.

The Relevance Principle

This principle comes from the experience of training institutions which offer courses and programmes which are irrelevant to the needs of the market place. The result is that people go through lengthy and costly education and training processes, and then do not find jobs, and are not equipped for self-employment.

In Manual 1, we give the worrying statistics on unemployment for graduates of Zimbabwean technical colleges. We believe that an adaptation of the TAP might help to prepare these graduates for self-employment more appropriately.

Basic to a successful TAP is the need for relevance. This means that the training offered must be appropriate to the opportunities available in the market place. This should be reflected in:

- the selection of skills offered;
- the length and content of the formal technical training;
- the length and content of the apprenticeship placement;
- the support offered.

Skills offered should be marketable; the formal technical training should be as long and as complex as is necessary to provide sufficient skills to optimise the apprenticeship opportunity, but no longer; the apprenticeship placement should be as long as is needed to gain the necessary practical experience, the EO should be able to provide a busy and varied apprenticeship period, including exposure to business practice; the support offered should be aimed at enabling the graduate apprentice to run a viable business.

ISTARN, both in the pilot phase and in the replication phase, has departed from some of the accepted wisdoms of traditional apprenticeship programmes internationally, with regard to the relevance principle. So, for example:

- **we have selected some trades which require more than a six month apprenticeship (motor mechanics requires an 18 month apprenticeship);**

- **we have accepted that there is a possibility, even the probability, of a separate "journeyman" like interim employment period in some trades, before the graduate apprentice becomes self-employed.**

Both these departures have proved viable in the ISTARN experience. Nevertheless, the

principle of relevance remains a key principle for ISTARN, and requires ongoing monitoring and evaluation of the market, and adjustments to the programme where necessary.

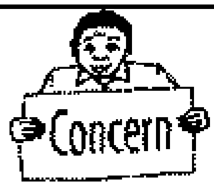
The Sustainability Principle

This is the principle that holds that a TAP should be sustainable, which means that it must be cost effective and low cost, that there should be some form of cost retrieval from participants, and that it must have the desired or advertised impact (self-employment or employment), so that it continues to attract participants.

The issue of protective clothing and equipment was one in which ISTARN learned something about keeping costs low and processes appropriate or relevant. In the initial intake of welders, there were complaints from apprentices that the EOs did not provide protective clothing, especially masks to protect their eyes. We tried to organise a special deal for the EOs in protective clothing, but they weren't interested. In the end, the apprentices learned the low cost way to protect themselves from sparks from the welding - they turned their heads aside when they saw sparks coming! One of the reasons why informal sector businesses can keep going when their formal sector counterparts may fail is exactly because they are not constrained by laws and regulations which govern such matters as safety, minimum wages and formal qualifications which have been negotiated by organised labour.

The Equity Principle

This is the principle which holds that a programme of this nature ought to be open to as many people as possible, and that it should not exclude people on the grounds of unnecessarily high academic qualifications, on the grounds of their location (for example, in rural areas), or because they do not have enough money. There should be little or no bar to entry.



It is important to note that some of these principles may, at times, appear to be contradictory.

- **The 10/90 principle and the Sustainability Principle may be at odds with the equity principle. For example, the decision not to provide subsistence grants may exclude rural people who are unable to find free or cheap accommodation near a business nodal point where there are apprenticeship placements available. The decision to insist on full cost recovery from the participants for the formal training may exclude poorer people, particularly in more costly trades such as motor mechanics.**

- **The Relevance Principle may be at odds with the Equity Principle a person from a rural area with no electricity chooses to be apprenticed to an electrical appliance fixer.**

- **Circumstances may also lead to problems with the principles. So, for example, the fact that the unemployed are so educated in Zimbabwe, means that EOs can choose to take on better educated apprentices, even if nothing more than basic literacy is required, in contradiction to both the Equity and Relevance Principles.**

- **EOs who have experienced the ISTARN TAP, usually, prefer ISTARN-linked apprentices to those who might just come locking for apprenticeships trough the traditional practice. One of the reasons for this is that the initial technical training makes them more immediately productive and less likely to waste raw materials.**

These contradictions cannot be avoided. Each TAP will have to make its own decisions about which principles it compromises, depending on its priorities. If, for example, the inclusion of rural people is seen as a priority, then it may be necessary to provide a small subsistence grant or loan. If you feel poorer people should be able to access trades such as motor mechanics, you may need to investigate part-scholarships.

Some questions for you to answer?

1. Do you agree that the basic principles described here should underpin a TAP?

____

2. What will you do in your programme to stress the 10/90 principle?

____
____
____
____

3. How will you ensure that your programme meets the requirements of the principle of relevance?

____
____

SECTION 3: Do you have the infrastructure you need in place?

By infrastructure we do not mean physical infrastructure such as buildings. We mean the basic requirements that are needed to make a TAP work. This is a very important point because too often the focus is on buildings which may then stand empty because of the lack of a viable programme. In fact, a TAP can make use of the physical infrastructure (lecture rooms) of another organisation or institution.

The kind of infrastructure that has to be in place includes:

- a co-ordinating and administrative infrastructure (e.g. a telephone, people capable of providing a secretariat function);
- financial resources to finance start-up;
- transport;
- a network that links you into training and business support services;
- access to training facilities and appropriate trainers.

In its pilot phase, and in the replication phase, ISTARN was fortunate to have a secretariat, a physical base (at the Masvingo Technical College and then the Mutare Technical College), sufficient financial resources and access to training facilities and trainers (at the Colleges, but also through NGOs). It also had its own integrated set of business support services (including a tool hire-to-buy scheme and a small business advisory service), and good links into other business networks.

However, for some time, particularly the monitoring and evaluation work was hampered because there was only one dedicated staff member on the TAP, and he only had access to a vehicle 20% of the time.

Some questions for you to answer?

1. What coordinating and administrative facilities and personnel do you have?

____
____
____
____

SECTION 4: What are the key decisions you need to make?

By this stage, you should have done some surveying of the market, you should know something about the informal sector and the traditional apprenticeship practice in your area. You should also be clear about what you are trying to achieve, and how you will know if and when you have achieved it, and about the basic principles on which the success of your TAP will depend. You should have in place, or be confident you can put in place, the infrastructure necessary to a successful TAP.

Before you can develop a written plan for your TAP, there are certain key decisions that you need to make, and which you should now be ready to make.

In which skills are you going to offer training?

Your decision should be made based on the following:

- there is a market demand for the kind of services and/or goods the skills result in;
- there are sufficient willing and competent EOs in the trade in the geographical area in which you operate;
- training and training materials are available;
- the length of the technical training required is relatively short;
- the length of apprenticeship time required to make entrepreneurship possible is relatively short;
- capitalisation costs involved in setting up a business in the trade are low.

This is one of the decisions that requires that you give some thought to gender. One way to ensure that women are included in the programme is to select at least some

skills/trades that are traditionally "women friendly". This might mean including knitting and dressmaking, but the market for these skiffs may already be saturated. If that is the case, then you need to look at areas that are not traditionally seen as "women's trades or skills", and think about how to encourage women to participate in them. There are also whole areas opening up which have not necessarily been gender stereotyped. Radio and TV repairs is an example of this.

ISTARN had a women carpentry apprentice in the first intake of the pilot project in Masvingo. She is now self-employed and has done very well. In an Interview she said:

**"Some laughed at me and thought I wouldn't succeed.
They are now admiring."**

To date, ISTARN has offered skills training, in the context of its TAP, in the following areas:

- **carpentry**
- **metalwork (welding)**
- **motor mechanics**
- **dressmaking**
- **radio and TV repair**
- **refrigeration**
- **solar electric installation.**

We are intending to produce training manuals for the technical training in some of these areas.

Of the above, Refrigeration (at Z$ 16 196.18 as the cost from training through to actual self-employment, including the tools necessary to set up in business) and Motor Mechanics (Z$ 15 608.36) are the most costly. Carpentry (Z$ 8221.28) is the least costly. The cost (including the training costs and the tools to set up in business) for the others is:

- **Dressmaking Z$ 11 958.21**
- **Welding Z$ 11 706.94**
- **Radio and TV Repairs Z$ 13 019.80**
- **Solar Electric Installation Z$ 12 688.38.**

The fact that training and setting up costs for one trade may be more than those for another does not, in itself, tell us anything about cost effectiveness. This depends on other factors such as the success rate of apprentices in their own businesses after graduation. If, however, the cost of setting up in business is too great, this may prevent graduates from opting for self-employment. Our 1998 Tracer Study, of the first ISTARN intake, showed that those apprentices who had done carpentry (cost of basic tools Z$ 3 750) were more likely to be self-employed than those who had done welding (cost of basic tools Z$ 6 000).

What "package" are you going to offer?

By "package" here is meant the direct and indirect support offered by the programme to apprentices, both during their apprenticeships, and when they are ready to set up in business themselves.

At least one component of the support will be:

- short-term formal technical training.

It is this support which distinguishes a Traditional Apprenticeship Programme from the traditional practice.

If you do your preparatory work properly, you will also be offering

- an understanding of the market and, hence, a pre-selection of marketable skills/trades.

Among the other possibilities for direct support during the apprenticeship stage are:

- subsistence grants or loans;

- information about what makes for a useful placement;

- guidelines for the EO on what the apprentice should be taken through in the course of the apprenticeship;

- short-term business training.

Among the possibilities for support during the stage when the graduate apprentices are setting up their own businesses are:

- access to loans to participate in a tool hire-to-buy scheme;
- small business advisory services;
- access to other kinds of loans;
- access to cheap raw materials through bulk buying;
- access to marketing support.

These support services can either be offered directly by the implementing agency, or they can be accessed by referrals through the networks of which the implementing agency is part.

As we have already said, ISTARN offered a subsistence grant initially, but later dropped it in attempting to meet the challenges of sustainability and the 10/90 Principle. We did initially attempt to provide guidelines to EOs on what should be covered during the placement, but dropped this as we moved towards less interference in the traditional apprentice/EO relationship.

We continue to offer:

- **guidelines on what makes for a useful placement;**
- **short-term business training;**
- **access to loans to participate in a tool hire-to-buy scheme;**
- **small business advisory services.**

Through our involvement with Informal Sector Associations (ISAs) we can also sometimes help would-be entrepreneurs to access cheap raw materials, and, in Masvingo, we are exploring the process of accessing marketing opportunities.

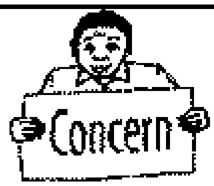
ISTARN has been able to provide this range of support services because it is, itself, an integrated small and micro business support agency, rather than a training agency. In fact, it has not provided training directly itself, but has relied on partners such as NGOs and the technical colleges to do this.

We think the support services are very important in helping to build viable micro and small enterprises. But we also remind ourselves that 90% of successful businesses in the informal sector are run by people who had no support when they started out - what they had was the right attitude, and the most important thing a TAP is meant to do is to help produce the right attitude - the attitude of a winner.

Certification

You will need to decide what form of certification, if any, you will give to apprentices on graduation. You could give a certificate of attendance at the formal training. If you include some form of testing, then you could give a certificate of competence, but then you will need to think through very carefully what you do about those who do not "pass" the testing. Remember that, for this form of vocational skills training, what happens in the workplace is more important than what happens in the classroom.

ISTARN gives a certificate of attendance for the formal part of the training. Past apprentices have said that they find the certificate useful when they seek employment or set up in business because it shows that they have had formal training.



While there is a difference between trade testing and certification of competence, it is quite a gray area and many of those who support TAPs would be very against certification for fear that the emphasis on "passing" a "test" would override the concerns about keeping costs low, and the formal learning process to a minimum.

What time frames are you planning for?

Before you move on to draw up the written plan for your TAP, you need to think about time frames. The two key decisions here are:

- When are you planning to start (your first intake)?

  and

- How long are you going to plan for?

It is unrealistic to think that you can begin planning for a TAP one month, and advertise for your first intake the following month. Our experience suggests that the minimum lead up period is four months, and that six months is more likely. Keep this in mind when you decide on a starting date.

Finally, if you really want to test the potential for a successful TAP, then you probably need to think in terms of a three year pilot phase. This is how long it will take for you to be able to measure impact in a meaningful way.

We have just had the experience of starting up a TAP in the first ISTARN replication phase in Manicaland, Zimbabwe. Even with our experience in Masvingo, it took us four months to get it off the ground.

The initial pilot intake in Masvingo was in March 1996. We are only now, in 1999, reaching the point of being able to assess impact effectively.

Some questions for you to answer?

1. Which skills are you intending to offer in your TAP? I

____
____

2. Do they meet the criteria outlined in the Section above? If not why do you think they are the best skills for you to offer

____
____
____

3. What "package" are you going to offer?

4. Do you have the resources to offer this "package"?

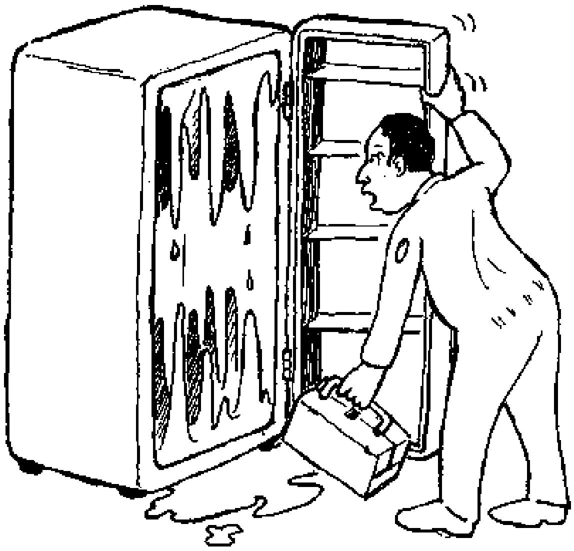
5. If not, how will you access the resources you need?

6. What form of certification, if any, will you offer?

7. When do you plan to advertise for your first Intake

8, What do you have to do before then?

9. How long will you plan for in your initial plan?



SECTION 5: Writing up your plan for implementation of a TAP

You should, by now, have done all your preliminary planning and thinking for your TAP and be ready to write up your implementation plan.

Your implementation plan should answer the following questions:

- What needs to be done?

- By when does it need to be done?

- Who will be involved in doing it?

- What resources are necessary to do it?

- What visible outputs will there be? (Examples of outputs could be: “participant workbooks prepared in each skill/trade”; “advertisements in all local newspapers and on all popular radio programmes”; “at least 30 participants selected”; “two week training sessions run in each skill”; “written progress reports completed on every apprentice”; etc.)

In Part 3 of this manual, we go through the implementation steps in detail. Here we list what your plan needs to cover:

- Preparation for the short-term formal technical training input;
- Recruitment, induction and selection;
- Running the initial short-term formal technical training sessions;
- Monitoring of placements;
- Follow-up short-term formal technical training sessions;
- Evaluation of effectiveness of short-term formal technical training;
- Re-planning for future intakes;
- Providing support services or access to support services;
- Longer-term evaluation - tracer studies;
- Review of TAP - decision whether or not to continue to offer it.

ISTARN has introduced the practice of holding “conventions” of TAP graduates once every year. TAP graduates are invited to a meeting where they can share experiences. This helps ISTARN with its monitoring and evaluation, and also helps to build networks among the graduates themselves.

On the next pages, instead of the usual questions for you to answer, we have provided a schedule for you to complete to help you in planning for the implementation of your TAP. Appendix 1 of this manual provides a format that you could use if you were asked to produce a Business Plan for your TAP.

**If you have worked through this manual systematically,
you should, by now, be ready to think through each step
of the implementation phase in more detail.**

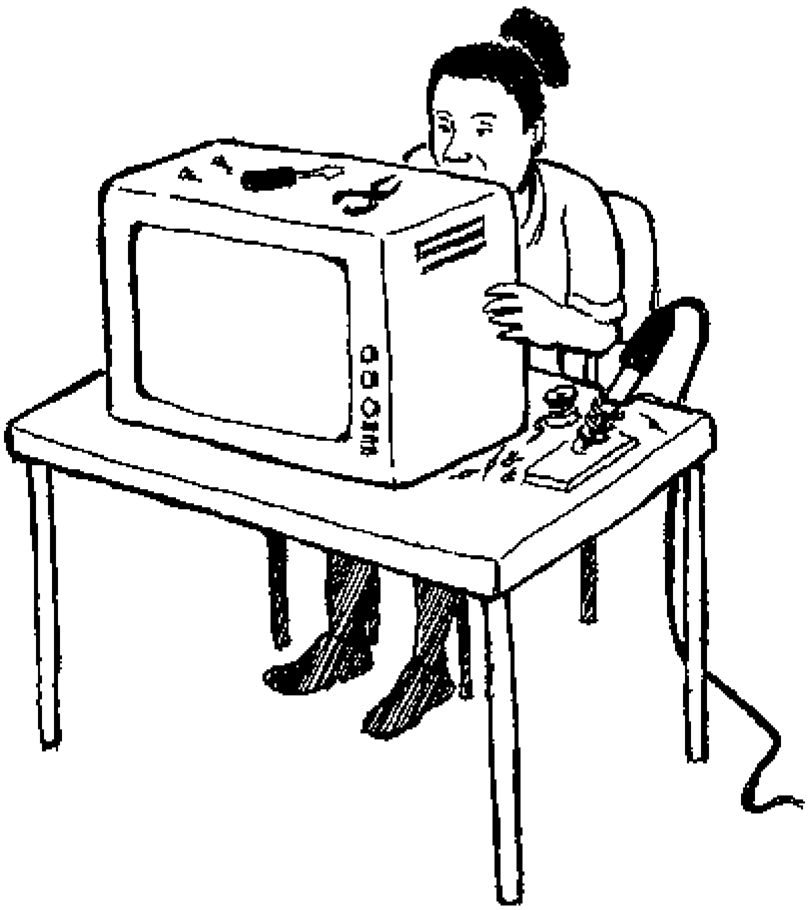
An implementation planning format

PLANNING FOR YOUR TAP

Objective: To set up and run a Traditional Apprenticeship Programme		
What needs to be done?	**Starting Date**	**Target Date**

Questions for you to answer?

Who will be responsible?	What resources are needed?	What outputs will there be?

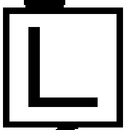


PART 3: IMPLEMENTATION

Implementation of a TAP can be divided into three phases, each of which affects different stakeholders in different ways. The phases are not rigid -in one programme there may be more overlap than in another. For example, for some Phase 1 might end with apprentice induction, while, for another, this might be the beginning of Phase 2. In this manual, we use the outline on the following page. We deal with each phase separately and in what seems to us to be a reasonable chronological order, although, in Phase 3, developments for each stakeholder group are likely to run parallel. As we work through the phases, and the steps within each phase, a reduced version of the plan will highlight for you where we are in the overall implementation process.

The following symbols are used to indicate the particular stakeholder groups that are involved at any particular point:

Implementing agency



Apprentices

Enterprise Owners

After the outline table, you will find a diagram which demonstrates in a more dynamic way what the possible outcomes and routes for a TAP graduate might be.

Implementation and course of a traditional apprenticeship programme

PHASE			1 Preparatory	**Step 1** *Gearing up* for implementation		
	Step 2 *Recruitment* - advertising	**Step 2** *Recruitment* - finding placement	**Step 2** *Recruitment* - approached by apprentice

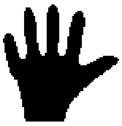
PHASE			
1 Preparatory	**Step 1** *Gearing up* for implementation		
	Step 2 *Recruitment* - advertising	**Step 2** *Recruitment* - finding placement	**Step 2** *Recruitment* - approached by apprentice
	Step 3 *Orientation* - presentation of programme	**Step 3** *Orientation* - decision on whether to participate	
	Step 4 *Selection* - applicants interviewed	**Step 4** *Selection* - interviewed	

PHASE 1: Preparatory Phase

STEP 1: Gearing up for implementation



This step only involves the implementing agency. You have gone through the preliminary steps of finding out about the market and the informal sector in your area, and ensuring that your institution/organisation has the infrastructure and approach necessary to make a TAP succeed. You now **need to gear your institution up to cope with the challenges of this kind of training.**

You need to adapt your skills training approach and re-orient your trainers so that they make the adjustments necessary to train in this new context. If you are using outside trainers or training agencies, then you need to work with them to ensure that you get an appropriate product.

You need a training approach that:

- Identifies the core skills that apprentices need in order to carry out the trade competently, rather than in order to pass an external examination; given the short period of time available, the focus has to be on the essentials that will enable the apprentice to get the most benefit out of the practical experience at the place of attachment.

- Focuses on the use of basic, simple tools, rather than sophisticated equipment.

- Presents theory in a skills-oriented and practical way.

- Provides as many opportunities as possible for practical application.

And you need trainers who:

- Have some understanding of the realities of the workplace in the informal sector.

- Can make the adjustments necessary to the shorter training period, without short-cutting on the essential skills and safety precautions.

- Respect the apprentices and what they are trying to do.

If necessary, you should provide your trainers with training in:

- Self-employment programme planning;
- Training needs identification;
- Training methodologies;
- Assessment of trainees.

Trainers need to be gender sensitive, particularly where they are working with women who are apprentices in trades or skills in which women (...) not traditionally participated.

We did not always get the gearing up right. Here are two quotations from our trainees (both Dressmaking students) about the technical training:

'The lecturers were very patient and also quite understanding. They work very good with people who do not understand too much.'

'Technical training at college was not interesting because the machines were not enough for us all.'

During Step 1, your trainers should be:

- Designing a curriculum;
- Preparing materials.

The team as a whole should be:

- discussing the curriculum;
- giving feedback to the trainers.

You should also be thinking about any follow-up training that is going to be offered, including business training. There needs to be a curriculum for the business training as well. There are products available on the market for teaching of business and entrepreneurial skills.

During 1999 and 2000, ISTARN is planning to produce training manuals in some of the more popular skills training areas.

For business training, ISTARN is now using the Start Your Business package. There are a number of packages on the market and you do not need to "reinvent the wheel".

Some questions for you to answer?

1. What are the essential competencies for each area in which training is? going to be offered?

____
____
____
____

2. What equipment can apprentices in each of the areas realistically expect to find in the workplace?

____
____
____

____

3. What changes will you, or whoever is taking on the formal aspects of the training process, have to make to existing material?

____
____

4. What training materials will need to be produced?

____
____
____

5. What is the time schedule for the development of curricula, writing of materials, editing of materials and production of materials?

____
____
____

6. What business training package will we use?

____
____

7. Will we need to make any adjustments to it? If so, who will be responsible for this?

____

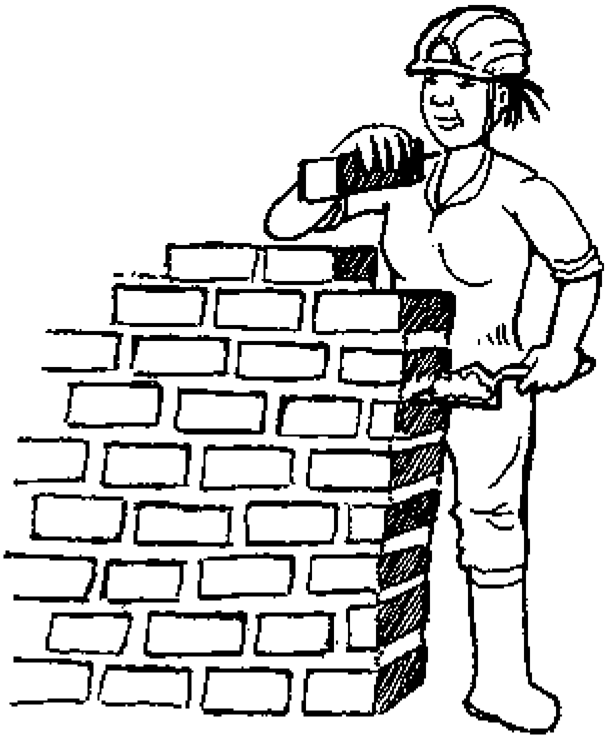
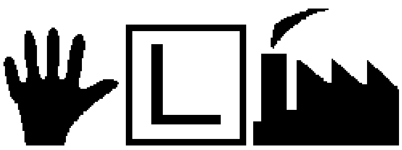
PHASE			1 Preparatory	**Step 1** *Gearing up* for implementation		
	Step 2 *Recruitment* - advertising	**Step 2** *Recruitment* - finding placement	**Step 2** *Recruitment* - approached by apprentice
	Step 3 *Orientation* - presentation of programme	**Step 3** *Orientation* - decision on whether to participate	
	Step 4 *Selection* - applicants interviewed	**Step 4** *Selection* - interviewed	



STEP 2: Recruitment



You have:

- decided what skills you will offer;
- decided what package you will offer;
- prepared the formal part of the training process.

What you need now are participants, and this involves **recruitment** - **letting potential participants know about the programme and how they can be part of it.**

Some of the questions to ask when you deal with recruitment are:

- How do we find the right kind of participants - those who are most likely to be "winners" and to make a success of self-employment?

- Where and how should we advertise our programme?

- What do we expect of would-be apprentices?

The recruitment process is your invitation to people to participate in the programme. Some things to keep in mind about this invitation:

- Your invitation to participate should make the 10/90 Principle clear. This means that your advertisements need to make it clear that participants will be expected to show independence and the ability to overcome obstacles.

- One way to reinforce this message, is to ask participants to find placements before they even come to the orientation meeting where you present the programme in detail. If you decide to go this route, then you should make available some guidelines for the selection of placements (see Appendix 2). Some programmes ask participants to find placements as their first task after the orientation meeting, but before selection.

In the ISTARN TAP we now expect would-be participants to come to the orientation meeting having already found placements for themselves. This is the key "obstacle" they are expected to overcome in order to be accepted for the programme. Apprentices in the more recent intakes indicated that it usually took two or three days to find a placement.

When it comes to advertising your programme, there are a number of options, including:

• Newspaper advertisements;

• Advertising on radio;

• Participating in Career Days at colleges and secondary schools;

• Putting advertising pamphlets on notice boards in public places (such as supermarkets and government offices);

• Networking with organisations which have access to particular groups in the community (such as youth or the unemployed or veterans).

Initially ISTARN recruited through partner organisations. In the replication phase, however, we are using newspaper advertisements and, for the first intake in Manicaland, this worked well.

If you are trying to encourage young women to participate in non-traditional skills, it is useful to get someone like a successful women carpenter *or* auto mechanic to present the programme at a Careers Day or workshop.

There is no one correct way to go about recruitment. You will need to select methods that suit you and your target group.

• Newspapers get to many people, and they provide details in writing so people can think about them, reread them and check them. But not everyone reads newspapers or notices advertisements in newspapers.

• Radio gets to the most people and to people in remote areas, but they may not catch the details and there is no way of "going back" or "replaying" the advertisement.

• Open Days and Careers Days are a good way to get to young people, and they create an opportunity to discuss the programme properly, but you can only get to a limited

number of people this way.

• Pamphlets in public places can catch people's attention, and they will have time to write down the details, but, again, they only get to some people.

• Networking with other organisations is helpful in reaching specific target groups, but, used on its own, limits the number of people who get to hear about the programme.

When you recruit, remember to:

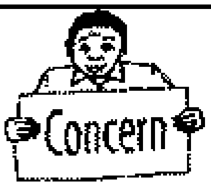
• Advertise in good time (about two months before the proposed starting date) to give people time to make enquiries about the programme and to think about it.

• Choose advertising routes that will get to marginalised groups such as the unemployed or rural people.

• Check that your advertising is clear about:

- who should apply
- by when they should apply
- what is expected of applicants
- the cost
- what a Traditional Apprenticeship Programme is.

Make sure that your advertising (whatever means you choose) particularly encourages women to participate.



We have already mentioned that there are some tensions around the Equity Principle. When, for example, you target rural people in your advertising, keep in mind the problem they may have finding accommodation near their placements and discuss the Issues around some form of subsistence loan with particular reference to their needs. Decide how you are going to reconcile the Equity Principle with the 10/90 Principle.

Some questions for you to answer?

1. What will you do to recruit "winners"? How will they have to prove I themselves?

____
____
____
____

2. How will you encourage women to participate in your programme?

3. Which advertising options do you think will work best with those you are targeting for your programme? Why are these the best?

4. What do you need to prepare for your recruitment campaign?

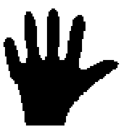
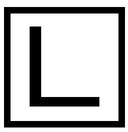
PHASE			1 Preparatory	**Step 1** *Gearing up* for implementation		
	Step 2 *Recruitment* - advertising	**Step 2** *Recruitment* - finding placement	**Step 2** *Recruitment* - approached by apprentice
	Step 3 *Orientation* - presentation of programme	**Step 3** *Orientation* - decision on whether to participate	
	Step 4 *Selection* - applicants interviewed	**Step 4** *Selection* - interviewed	

STEP 3: Orientation



The orientation step is a very important one - it is here that would-be apprentices really come to grips with what a TAP is about. For many of your recruits, it is the first opportunity they will have to hear about the programme face to face and to ask you questions about it. Usually it will take the form of a meeting, organised by the implementing organisation. At this meeting, the TAP team will:

• Explain the programme;

• Emphasise the need for independence and an entrepreneurial approach;

• Emphasise that the programme is intended to lead to self-employment;

• Explain what will be expected of apprentices;

• Explain what is being offered to apprentices, both during the programme, and in support services afterwards;

• Answer any questions the applicants may have.

We have found that a few people are unhappy with the idea of such a **short period of formal training and decide, at this point, not to go ahead. We have also found that it is very important to be clear about expectations, so that the apprentices know exactly what they are getting into. With our first intake in Masvingo, we were not clear enough, and the result was some dissatisfied and unhappy apprentices who complained a lot and expected us to sort out their problems. As one ISTARN staff member said:**

'People convinced themselves of more than we offered.'

At ISTARN, we now hold the orientation meeting after would-be apprentices have already found placements. This means that those who come to the meeting are very serious about the programme, and we can move directly into selection. But it also means that, occasionally, people go to the trouble of finding placements and then discover that they do not want to be part of the Programme.

The meeting could be held before the would-be apprentices go out to look for placements, so that those who do already know exactly what the programme is about and how it works. There would then be a delay before the selection process.

Some questions for you to answer?

1. When will you hold your orientation meeting - before would-be apprentices find their placements, or after? Why do you think this is a better time?

2. Who will do the main presentation at the orientation meeting?

3. What points must be presented?

4. What questions do you think might be asked, and how will you answer them?

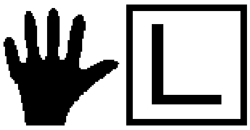
PHASE			1 Preparatory	**Step 1** *Gearing up* for implementation		
	Step 2 *Recruitment* - advertising	**Step 2** *Recruitment* - finding placement	**Step 2** *Recruitment* - approached by apprentice
	Step 3 *Orientation* - presentation of programme	**Step 3** *Orientation* - decision on whether to participate	
	Step 4 *Selection* - applicants interviewed	**Step 4** *Selection* - interviewed	

STEP 4: Selection



Selection is the process **by which you decide who, out of the applicants, will be accepted on to the programme.** As with recruitment, there is no one “right” way to do it, but selection must be related to what you are trying to achieve through the programme. If you are trying to create opportunities for people to become self-employed, then you need to select people who want to become self-employed and who are likely to make a success of it. But you may also have other criteria for selection - you may have decided that you want to give young people particular access to the programme, or that you prefer people who are in “stable” personal circumstances because they are more likely to complete the programme.

We have already talked about the “obstacles” or “tests” that could be used to help in the process of selecting for entrepreneurial aptitude.

The Case Study on the ISTARN TAP quotes a Botswanan programme which expects would-be participants to run mini-businesses over a weekend, producing and/or selling commodities to real customers, using, if necessary, a small loan payable at 30% interest. In other programmes, the implementing agencies have looked for the ability to articulate a rudimentary business plan, to identify finance for the proposed enterprise, or to do some kind of market feasibility plan.

The selection interview is another opportunity to assess the potential of an applicant for running his or her own business, as well as to “score” them on other factors.

In the selection interview, you want to find out:

- the persona! details of the applicants
- why they want to be traditional apprentices
- what their expectations are
- what their personal circumstances are
- why they have chosen a particular trade
- what they hope to do once they graduate
- whether they are likely to cope with the apprenticeship
- whether or not they are independent-minded and problem-solving
- how likely they are to be successful entrepreneurs.

In Appendix 3, we have given an example of a selection interview schedule. You will see that it is prepared in such a way that each applicant can be "scored" for suitability for a TAP. Rather than one person interviewing alone, interview in pairs or teams, compare scores, and agree on them, to give each applicant a fair chance. Those with the highest "scores" are likely to the most appropriate selection for your TAP. The method is not "scientific", but it works well.

Once someone has been selected, the information from the schedule can become the basis of later comparison with tracer studies so that you can assess how successful your selection techniques have been. Did those who scored well on entrepreneurial skills in the selection process make good entrepreneurs?

The successful applicants should also be asked to complete a Personal Data Form (see Appendix 4). Kept in alphabetical order, these forms provide a ready-access set of information on each participant in the programme when it comes to monitoring and evaluation.

The careful selection process followed by ISTARN is seen as important, because "wrong" selection leads to a waste of resources and the discrediting of the programme. However, it is worth noting that selection in the traditional practice is much more ad hoc. Apprentices seek out EOs who select those whom they think will be useful or appropriate to them and whom they think they can trust. One of the EOs in the ISTARN programme said:

'From my experience, you can see people who have direction and people who don't.'

During the selection process, it is very important to keep in mind the issue of gender and other equity issues. Sometimes you may decide to accept a women or a person from a rural are, rather than a man or an urban-based person who may have scored higher, because you want to ensure that there is a reasonable ratio of women on the programme or that rural or other marginalised people are represented. This may mean that you have to provide more support to ensure success, but compromises such as this recognise that certain groups have been historically disadvantaged to a greater degree than others, and so need more encouragement and support in order to "level the playing fields".

Some questions for you to answer?

1. What criteria will you use for selection?

____
____
____
____

2. How will you "test" for entrepreneurial aptitude?

____
____
____

3. What questions will you ask in the selection interview, and how will you “score” them?

4. Will you have “quotas” for marginalised groups such as women and rural people?

5. Who wilt be on the selection team?

6. How will the selection team work together? Will everyone interview, or will you interview in pairs?

7. What information will you include on the Personal Data Form?

At this point, all the necessary elements
should be in place in order to begin the implementation
of the training process.

PHASE 2: Implementation Phase

PHASE			
2 Implementation	**Step 5** Conducting initial *technical training*	**Step 5** Participating in initial *technical training*	
		Step 6 *Placement* - practical skills development	**Step 6** *Placement* - cheap labour, mutual learning

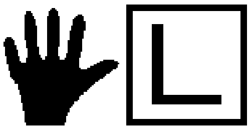
PHASE				Step 8 Conducting *follow-up technical training* - includes *business training.* Usually, but not always, final formal training	**Step 8** Participating in follow-up *technical and business*	

STEP 5: Conducting initial technical training



At this point, you have recruited and selected your intake, and they are ready to begin their training. Either you or your training partners need to present the specially prepared, relevant technical training that is the particular value that a TAP adds to the traditional practice in terms of vocational or skills training.

In order to run the technical training, you need:

• An appropriate venue;
• A curriculum;
• Training tools;
• Trainers;
• Training materials.

At this stage, you should have planned so that all these elements are in place.

It is important to remember that this is likely to be the apprentices first introduction to the trade/skill, and you want it to be as positive as possible. You also want it to be as well-organised and efficient as possible. The time (usually about two weeks) is very short, and none of it should be wasted. This is also an opportunity to model good working habits for apprentices, some of whom may never have worked before. This means being strict about attendance, about starting and finishing times, about work habits, and about attitudes to work. The apprentices will, hopefully, take these attitudes with them into their placements, and so enhance the credibility of the Programme.

The trainers will need to keep records of attendance, and, even if you are only giving certificates of attendance, and not of competence, they should be able to provide the apprentices with feedback on their progress, and their strengths and weaknesses. The training is likely to be in a competency form (with a focus on enabling the apprentices to be able to do certain things competently). Training in a competency format has a number of advantages:

• it is practical;

• it forces trainers to focus on essentials and to be rigorous in what they teach and how they teach it;

• it provides instant feedback on whether the training is working (as measured by the degree of competency participants acquire in skills);

• it lends itself to a “recognition of prior learning” assessment, should participants want to move into a formal training track.

We have already noted that ISTARN is hoping to produce manuals for certain types of training in the near future. It has decided to do this because the availability of existing material that is appropriate is limited. Sometimes, the lack of training material leads to the cancellation of the option. On one occasion at ISTARN, Masvingo, there were four applicants who had found placements as leather workers, but the option was cancelled because there was no formal training available. In the medium-term, it would be useful to build up a range of materials which can be used.

We have talked about the issues related to certification for the technical training. To recap:

- **A Certificate of Attendance provides proof of the apprentice having had formal training, but not of his or her competence.**

- **A Certificate of Competency will help some people to get jobs or generate business, but is it appropriate in a programme where the main part of the learning process is supposed to take place in the workplace?**

- **A focus on certification may lead to more expensive training that is not necessary or relevant to the actual work that will be done by the apprentices.**

In the end, it may be best to leave the decision about whether or not to go for trade testing (or other forms of competency testing) to the apprentice, and to ensure that the technical training provided covers the necessary basics well.

One of the issues that ISTARN confronted at this stage was the need for an indemnity form for indemnifying ISTARN in case of injury during training. At the moment, ISTARN is negotiating with the Zimbabwe Development Fund to get apprentices covered under the national insurance scheme which is administered by government and covers all formal students in tertiary institutions. The students themselves do not contribute anything to the scheme.

We have included a format for an indemnity form as Appendix 7, but it is best to get it checked by a lawyer to make sure that you are covered.

Some questions for you to answer?

1. Are you satisfied with the materials that have been produced for the technical I training?

____

2. Have all necessary arrangements been made for the venue and equipment?

____

3. Are you satisfied that you will cover all the essentials of the introduction to the trade/skill?

____

4. What provision have you made for Keeping track of attendance?

____

5. Are you sure that the planned curriculum is practical enough?

____

6. Are you sure the planned curriculum provides the apprentices with enough theory?

____

7. Do you think you need an indemnity form and, if so, what provision have you made for developing one and getting it approved fry your lawyer?

____
____

8. What still needs to be done?

____

	Step 8 Conducting *follow-up technical training* - includes *business training.* Usually, but not always, final formal training	**Step 8** Participating in follow-up *technical and business training*	

STEP 6: The placement

This step involves the development of the relationship between the Enterprise Owner and the apprentice and, ideally, a mutual transfer of skills. While the apprentice is the main beneficiary, there is the possibility of some innovative technical practices, acquired by the apprentice in the technical training period, being transferred into the workplace as well.

It is during this time that the apprentice will really be able to tell whether or not the placement is suitable for someone wanting to learn skills (both technical and business) which will enable him/her to become self-employed at a later date. In one programme (not ISTARN), the agency running the programme had tested the would-be masters (EOs) for technical competency, and had helped them to design training programmes for their apprentices. This has implications for cost and for the level of “interference” in the traditional practice.

Within the ISTARN context, there have been suggestions that the training partners offer courses to the EOs to upgrade their skills, but EOs would have to pay for this training and we are not sure that they would be prepared to do so.

Initially, ISTARN offered the following services to the Enterprise Owner in exchange for taking on an apprentice for attachment:

- **Free business training.**
- **Free business advisory/consultancy services.**

The Enterprise Owner was also encouraged to join an Informal Sector Association (ISA) so that s/he could benefit from other services offered by ISTARN such as cheap raw materials from the ISA warehouses.

Now ISTARN offers nothing in exchange for the Enterprise Owner taking on an apprentice, except that, if the EO wants business training and business consultancy services, these can be provided at a fee.

The reason for the change was that this practice of giving free business training had the potential to commercialise TAP placements and this would have been a serious interference with the existing practice.

Interviews have shown that some of the EOs approach the skills transfer process with far greater attention than others. They see the process as a fair exchange:

‘I get labour - they grow and develop.’

Some of the EOs have developed quite structured learning practices:

‘I sit down with them once a week and we talk about what they have learned during the week.’

We have also found that the learning opportunities differ in different enterprises, even within the same trade. So, for example, one carpenter may be a craftsman who designs and makes customised pieces. Another may mass produce school furniture. He probably does no special designs and does not even use plans, but he runs a successful business. Clearly the learning opportunities in the two environments are very different.

Given the way in which would-be apprentices find placements, there is a possibility that, once the apprentice is actually in the workplace, what seemed as if it would be an appropriate placement turns out not to be so. The intention should be for the apprentice to make the best of the situation, but sometimes the situation may be unsalvageable and the best option may be for the apprentice to find an alternative place. This might be because the volume of work is just not sufficient for the apprentice to get practical experience, or the EO may simply refuse to let the apprentice do anything that involves using his/her tools, or may not make any effort to transfer skills. This is an area in which the implementing agency can provide support to the apprentice, helping him/her to work out whether or not a change is really needed.

In the ISTARN TAP, we do encourage apprentices to seek alternative placements if they are not developing sufficiently and acquiring skills. However, we have found that this has a negative effect on negotiations for attachments with future apprentices. On the other hand, it also sometimes has positive effects because it serves as a challenge to the EO who then takes stock of how he/she is operating the business and identifies what is lacking in the environment for the apprentice. This can lead to an improvement in the practices in the workplace. So, for example, welding EOs who only use arc welding, and who lose apprentices to neighbouring EOs who offer both arc and gas welding, then improve their equipment to include both.

There are no hard and fast rules about the economic relationship between the EO and the apprentice, and many variations are found, both in the traditional practice and in programmes such as a TAP. Some EOs expect to be paid by the apprentices for the attachment, at least until the apprentice is productive. Others offer food and/or lodging in return for cheap labour. Some EOs expect the apprentices to provide their own tools and raw materials (as, for example, components in the TV and radio repair businesses). It is probably best for the implementing agency to interfere as little as possible in this and to leave it to the EO and the apprentice to sort out an arrangement that suits them.

In a survey commissioned by ISTARN, it was found that it was more common for the EO to make a material contribution to the training than for the apprentice, and that the majority of the contributions were in the form of cash, food and shelter. Some of those being trained had to make a **financial contribution to the training, or they had to pay for materials or stay on for a time after training was complete.**

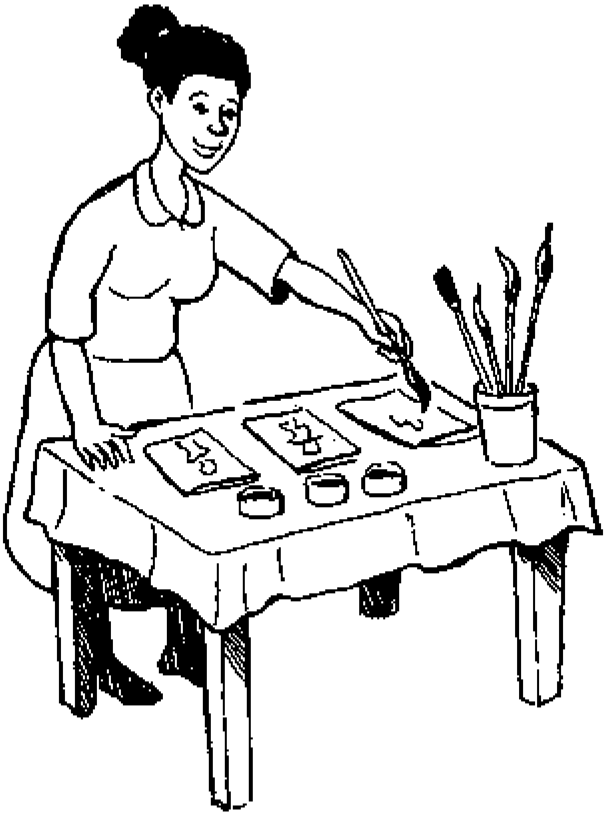
Some questions for you to answer?

1. Do you know what the most common practices are for governing the relationship between the apprentice and the EO in the traditional practice in your area? Make some notes about what you do know.

____
____
____
____

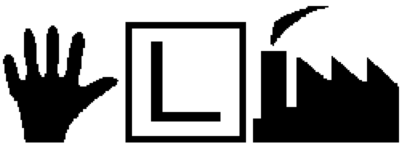
2. Have you thought through how you will deal with apprentice complaints about their EOs? What sort of guidelines will you follow in responding to complaints?

____
____
____
____



PHASE			
2 Implementation	**Step 5** Conducting initial *technical training*	**Step 5** Participating in initial *technical training*	
		Step 6 *Placement* - practical skills development	**Step 6** *Placement* - cheap labour, mutual learning
	Step 7 *Monitoring* - visits and feedback from and	**Step 7** *Monitoring* - feedback to	**Step 7** *Monitoring* -feedback to
	Step 8 Conducting *follow-up technical training* - includes *business training.* Usually, but not always, final formal training	**Step 8** Participating in follow-up *technical and business training*	

STEP 7: Monitoring of placements



Monitoring of placements is a step which can, potentially, benefit all three of the key stakeholders in the TAP.

For **the implementing agency,** it is an opportunity to get feedback on whether the technical training aspect of the programme is, in fact, useful, and to identify any problems that may be making the placement problematic. Depending *on* resources (human and financial), the implementing agency probably needs to visit each workplace once in two weeks, or once a month. The EO is asked to complete a monthly Apprentice Appraisal Form (See Appendix 5 for an example) which the fieldworker from the implementing agency then collects or checks. This gives some indication to the implementing agency that the EO is viewing the apprenticeship as a training period, as well as some indication about how responsibly the apprentice is using the opportunity. The monitoring visits also involve verbal discussions with both the EO and the apprentice, and this is an opportunity to identify problems, either in the placement or in the technical training.

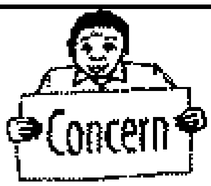
For **the apprentice,** it is an opportunity to discuss the placement with the implementing agency fieldworker, particularly if there are any problems. Once they are in their placements, the apprentices may be quite isolated (particularly if they are the only apprentice in the enterprise), and the fieldworker can provide valuable feedback on whether problems s/he is experiencing are common, require more determination from the apprentice, or are serious enough to require a change of placement.

For **the EO**, it is an opportunity to give feedback about whether or not the programme is meeting his/her needs and what would make it better, and also to make inquires about other services the implementing agency may offer or know about that could be useful to the EO. The fieldworkers may also be able to help with ideas to improve the skills transfer process.

Sometimes the fieldworker may be called upon to play a mediating role between the EO and the apprentice, but here, again, the best rule is to intervene as little as possible and to encourage the two main actors to sort things out between themselves.

We have found the monitoring process useful. Both apprentices and EOs are positive about it, **and it has, at times, given us valuable feedback which we have fed back into the programme. One example of this is mentioned above - the complaints from EOs doing fancy dressmaking that only basic skills were included in the dressmaking technical training. Initially, the visits tended to invite complaints from the apprentices, but this has been less the case since the 10/90 Principle has been more firmly explained and implemented.**

The literature on TAPs suggests that women, particularly those in non-traditional trades, may need more support than men and the monitoring process provides an opportunity to give this additional support, and to identify any special problems that may be making the placement difficult for the apprentice - anything from sexual harassment to problems with childcare or negative EO attitudes.



Often the monitoring process is not recorded anywhere except in the fieldworker's head. It is important that fieldworkers write reports which encompass the experience from the perspectives of the implementing agency, the EO and the apprentice. This provides a record of learnings which cart be used in the future - even if the fieldworker leaves the agency or gets run over by a bus!

Some questions for you to answer?

1. What form will your monitoring of placements take?

____
____
____

2. Who will do the monitoring?

____

3. Have you prepared an Appraisal Form? If not* who will do so, by when?

____

4. Now will feedback from the monitoring process be recorded for future reference and use?

____
____
____

5. How will feedback from the monitoring process be fed into the process of planning generally, and planning for the next technical training input specifically?

____
____

6. What will be done to provide particular support for women during the monitoring process?

____
____
____

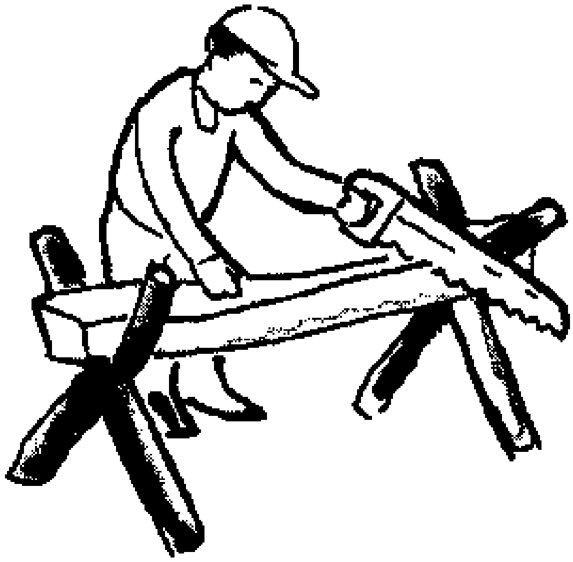
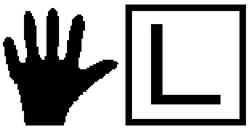
PHASE			2 Implementation	**Step 5** Conducting initial *technical training*	**Step 5** Participating in initial *technical training*	
		Step 6 *Placement* - practical skills development	**Step 6** *Placement* - cheap labour, mutual learning
	Step 7 *Monitoring* - visits and feedback from  and 	**Step 7** *Monitoring* - feedback to 	**Step 7** *Monitoring* -feedback to 
	Step 8 Conducting *follow-up technical training* - includes *business training.* Usually, but not always, final formal training	**Step 8** Participating in follow-up *technical and business training*	



STEP 8: Follow-up technical training and evaluation



In most cases, this will be *the final technical input, and will also provide an opportunity for the trainers to evaluate the development of the apprentices' technical skills. In the ISTARN programme, this is now also the time when business training is specifically given.*

In some trades, it may be necessary to offer more than the two formal technical inputs, over a three to six month period. This will only be for those trades which are more technically complex and which are, therefore, not likely to be included in a TAP in most cases. One exception is motor mechanics, which does require more formal technical training sessions (over what is likely to be an 18 month apprenticeship), and which has been a successful TAP area for ISTARN.

For most trades, this training will be the final input of the TAP process, and will probably be another two week session. With regard to the technical training, this is an opportunity for the trainers to assess how much has been learned through the practical experience in the workplace, and to provide any additional training required to make the apprentices competent in the field. Ideally, it will be a rounding off of skills, rather than teaching of totally new skills. The training time also provides an opportunity for the apprentices to ask questions about the technical process which their EOs have been unable to answer. If the monitoring process has worked well, the fieldworkers will have fed back to the trainers any comments about gaps in the initial training and, if necessary, this is an opportunity to address them. Again, the emphasis should be on what is relevant and necessary to enable the apprentice, soon to graduate, to provide a complete service or product at the relevant level.

We have not always got this right, as these quotations from our trainees indicate:

'I did not enjoy the theory lessons because the lecturers did not explain some things. They assume we know it from our attachment place, while we do not. At the attachment place they also assume you know it from college.'

'It is like our lecturers are hammering on lighter things that could not help us because we expected them to forward us other than keeping on doing things we did the previous time.'

We believe that this final training period is the right opportunity to introduce business skills as a formal package. By now the apprentices should have been exposed to business practices in the workplace. They should be familiar with the practices related to getting raw materials and to negotiating with customers. They should have a sense of how a business works, of the importance of cash flow and, if they have been very fortunate in their EOs, to the importance of financial record keeping. The business skills programme provided at this point serves to formalise what they have learned and to fill in the gaps of what they have not learned.

ISTARN used to offer the Township Management of Business Activities (TMBA) training package, but we are now using the Start Your Business (SYB) package.

Some questions for you to answer?

1. What will be covered on the technical side during the follow-up technical i training?

____
____
____

2. How will apprentices be assessed for practical skills and competence?

____
____
____

3. How wilt you build in the opportunity for the apprentices to ask questions and get answers on technical areas they are unsure about?

____
____
____

4. What business skills framing will you provide?

____
____
____

The training process has now been completed.

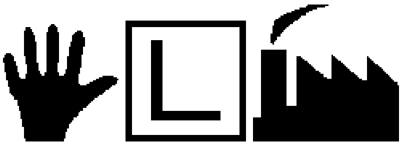
This does not necessarily mean that the learning process has been completed, and, in fact, it will probably be carried forward in some way in all the stakeholder groups.

PHASE			
3 Post implementation	**Step 9** *Evaluating training* for appropriateness	**Step 9** *Possible routes:* • Journeyman • Self-employed • Different employer • Trade testing	**Step 9** *Possible options:* • Keep on -journeyman • Take on new apprentice • No apprentice
	Step 10 Providing ongoing *support* - for self-employment route	**Step 10** If self-employed - option of accessing *support*	
	Step 11 *Reviewing* and *replanning* of whole process		
	Step 12 Longer-term *evaluation* -tracer studies		

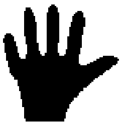
PHASE 3: Post Implementation

In the post-implementation phase, each stakeholder group follows its own track so that the process becomes parallel rather than integrated. The following steps are, at times, therefore, presented separately for each stakeholder group.

STEP 9



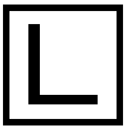
There is an immediate step after the implementation for all three stakeholder groups.



Evaluating the training for appropraiteness

For the implementing agency, this is the point at which there needs to be a *review of the training process.* This should have already begun through the monitoring process. What is required now is a full evaluation in which the fieldworkers and trainers together look at the input that has been received from the apprentices and the EOs, and at the observations made by the trainers in the formal training sessions. The process should:

- collect all the feedback received on the formal training;
- identify problem areas;
- plan how to avoid them in the future.



Selection of possible routes to follow for the apprentices

At this stage, the apprentice may *choose one of three options:*

- a Journeyman position with the EO where s/he has trained
- a Journeyman position with another EO
- Self-employment.

When we use the term “journeyman” we are referring to someone who has completed his/her apprenticeship, and can function as a skilled and fully productive employee.

The other possibility, and obviously not a desirable one, is that none of these options will be open to the graduate apprentice, and that s/he will be unemployed.

The tracer study of the first two ISTARN, Masvingo intakes of apprentices (all welders and carpenters), done in 1998 reached 88% of the graduate apprentices. Of these:

- **56.9% were self-employed**
- **29.2% were employed**
- **13.8% were unemployed.**

International literature on traditional apprenticeship-type programmes sees one third of graduates self-employed after six months as success.

The other thing that can happen at this stage, in addition to any one of the listed options, including unemployment, is that the graduate apprentice can decide to try for trade testing in his/her particular trade (where trade testing is offered). The pros and cons of this have been discussed above. It does provide a way for the graduate moving from informal training, to a form of formal accreditation. The implementing agency can provide support here by finding out what is involved in the trade testing and informing graduates. Any costs incurred, however, should be paid by the graduate apprentice.

Some of ISTARN's motor mechanic apprentices have gone the route of first level trade testing and have generally done well in the test.

Possible options for the enterprise owner

Post implementation, the EO can opt to:

- keep on the apprentice as a journeyman;
- take on a new apprentice;
- decide not to have an apprentice or a journeyman.

There is always the possibility that the EO will decide to seek further help in developing his/her business from the implementing agency, and you should be able to provide the support or to refer the EO appropriately. If things work out as the best possible scenario, the EO will also have gained from the experience and will have a more productive business, with the possibility of taking on more apprentices. However, after this, the EOs involvement in the TAP formally ceases, unless s/he decides to take on more TAP apprentices.

Some questions for you to answer?

1. How will you go about evaluating the technical training for appropriateness?

2. What will your approach be to the issue of trade testing?

3. What have you to offer if the EO asks you for further assistance?

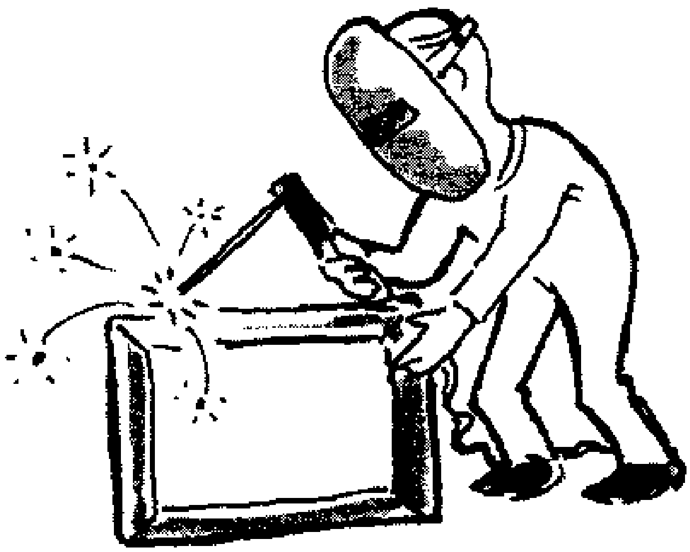
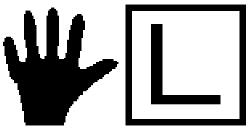
PHASE			3 **Post implementation**	**Step 9** *Evaluating training* for appropriateness	**Step 9** *Possible routes:* • Journeyman • Self-employed • Different employer • Trade testing	**Step 9** *Possible options:* • Keep on - journeyman • Take on new apprentice • No apprentice
	Step 10 Providing ongoing *support* - for self-employment route	**Step 10** If self-employed - option of accessing *support*	
	Step 11 *Reviewing* and *replanning* of whole process		
	Step 12 Longer-term *evaluation* - tracer studies		



STEP 10: Provision of ongoing support



This step applies to the situation where *the graduate apprentice moves into self- employment and the implementing agency offers ongoing support.* This can take place immediately after the completion of the apprenticeship, or at any stage thereafter.

Usually, the implementing agency will have made it clear what support it is able and willing to offer at the beginning of the programme. The support will be the same kind of support that is offered to small and micro enterprises by most small and micro business advisory services. It may not be direct support, but could be in the form of a referral to an appropriate agency. The purpose of the support is to give the new business the best chance of surviving and becoming viable. **The best case scenario here is that the graduate apprentices will themselves become enterprise owners, and will be willing and able to take on apprentices themselves.**

The "aftercare" support services offered by ISTARN are all aimed at helping the newly self-employed graduate to make a success of his/her business. They include access to a tool hire-to-buy loan scheme, access to business advisory services, and invitations for inclusion in events such as the Small Business Expo.

Special ongoing support for a woman may include, for example, speaking to her family when she wants to practice a "non-traditional" trade, so that they are more supportive instead of discouraging her.

Some questions for you to answer?

1. What ongoing support can you offer to graduates who become self- employed?

____
____
____
____

2. What useful referrals can you offer such graduates?

____
____
____
____

3. How will you remind graduates who do not become self-employed immediately about the support services they entitled to?

____
____

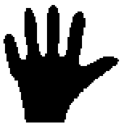
PHASE			3 Post implementation	**Step 9** *Evaluating training* for appropriateness	**Step 9** *Possible routes:* • Journeyman • Self-employed • Different employer • Trade testing	**Step 9** *Possible options:* • Keep on - journeyman • Take on new apprentice • No apprentice
	Step 10 Providing ongoing *support* -for self-employment route	**Step 10** If self-employed - option of accessing *support*	
	Step 11 *Reviewing* and *replanning* of whole process		
	Step 12 Longer-term *evaluation* - tracer studies		

STEP 11: Reviewing and replanning



The process is still not complete for the implementing agency. In addition to evaluating and improving on the technical and business training aspects of the programme, the implementing agency *needs to review the whole process* from choice of trades onwards. At this stage, you will be in a position to:

- review the trades chosen and decide whether to change them or add others
- review the recruitment process and make changes if necessary
- review the orientation programme and make changes if necessary
- review the selection process and make changes if necessary
- incorporate the changes agreed to for the technical training aspect
- review the monitoring process and make changes if necessary
- review the ongoing support offered and make changes if necessary.

ISTARN has used this review process very productively to look at issues to do with the 10/90 Principle, Sustainability and Equity. On this basis it has made changes to both the preparatory and the implementation stages over time, as well as to the provision of ongoing support.

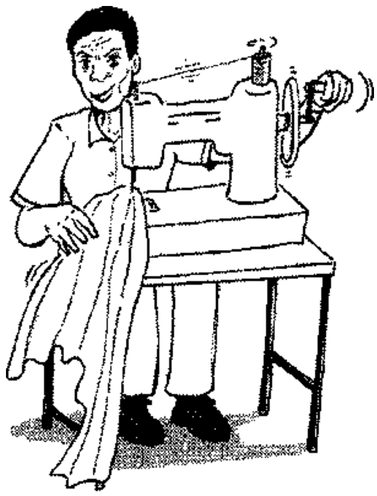
Some questions for you to answer?

1. When will you review the whole process?

____
____

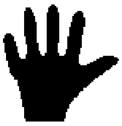
2. Who will be involved in this review?

____
____



PHASE			
3 Post implementation	**Step 9** *Evaluating training* for appropriateness	**Step 9** *Possible routes:* • Journeyman • Self-employed • Different employer • Trade testing	**Step 9** *Possible options:* • Keep on - journeyman • Take on new apprentice • No apprentice
	Step 10 Providing ongoing *support* -for self-employment route	**Step 10** If self-employed - option of accessing *support*	
	Step 11 *Reviewing* and *replanning* of whole process		
	Step 12 Longer-term *evaluation* - tracer studies		

STEP 12: Long-term evaluation



About three months after the completion of the programme by the graduates (up to Step 8), the *tracking process* needs to begin. This involves either sending out questionnaires, or going out and doing tracer study interviews. (For an example of a Tracer Study Questionnaire, see Appendix 6.) This process needs to take place about once every six months for three years in order to get meaningful results. The purpose of the tracer studies is to measure the impact of the TAP. What you will be interested in in your tracer studies will be related to why you decided to implement a TAP in the first place. If the TAP was intended to create self-employed entrepreneurs, then the information you gather will focus on what graduates are doing, whether they are self-employed and, if so, how viable their businesses are. If your only concern was that these particular participants find some form of employment, then the focus of your tracer studies will be different.

The tracer studies also provide an opportunity to collect further information about the relevance and impact of the programme, because you can also ask questions about the usefulness of the technical and business training, whether support services were accessed and, if so, how useful they were, what would make the programme more useful, and so on.

For those who need to "sell" the TAP in order to get apprentices, or to access funds, or to prove that money has been well spent, some information about what happens to graduates provides very good evidence.

ISTARN has conducted regular tracer studies and they have shown that there has been a high success rate with regard to graduates becoming self-employed. Because the tracer studies have been fairly comprehensive (getting to over 80% of the graduates), it has been possible for us to use the results to work out such figures as the cost of the training (in other words, the cost to the programme) required to create one job. For the first intakes, the cost to ISTARN for each employed or self-employed welder was Z$ 7 542 (with a subsistence allowance), and for each employed or self-employed carpenter, it was Z$ 3 286 (with a subsistence allowance). To this (for those who went the self-employment route) needs to be added the cost of setting up in business (usually the price of the tools), in order to get a picture of the cost of creating a job in the informal sector through a TAP. In 1996, we estimated that it would cost about Z$ 4 500 to set up in carpentry, so the cost of creating a job in carpentry was Z$ 7 786. This compares very well with the estimated Z$ 80 000 to Z$ 100 000 required to create a job in the formal sector (without training).

The impact of development programmes on the welfare of women Is seen as a key indicator of their success. The tracer studies provide an excellent opportunity for following up to see whether there are differential (...)s of success between men and women, and for identifying the causes such differentials and taking remedial action if necessary.

There are pros and cons to investing in tracer studies.

• They cost money and require time and effort from staff who may well be overworked in other areas.

• If they are not carefully thought through and if the questions asked are not useful, they may not yield very useful information.

• They can provide crucial information which makes it possible to assess whether a programme is worth the resources (financial and human) invested in it.

• They can provide evidence which can be used to "sell" the concept to potential apprentices, donors and government departments.

ISTARN has introduced the practice of holding annual TAP Conventions. All the graduates of the programme are invited to a workshop. The objectives of a Convention are to:

- **give graduates the opportunity to share experiences**
- **do some joint problems solving through sharing experiences**
- **give feedback to ISTARN about the programme from a more long-term perspective**
- **provide recommendations on how the programme can be improved**
- **help ISTARN assess the impact of the programme on the direct beneficiaries.**

The Convention usually coincides with the Annual Small Business Expo. Graduates who have started up their own businesses are encouraged to bring their products for display at the Expo and the stand is paid for by ISTARN.

Some questions for you to answer?

1. Will you conduct tracer studies?

____

2. Who will be responsible for the tracer studies?

____

3. What form will the tracer studies take?

____
____

4. How often will you do the tracer studies?

____

5. What will you try to find out in the tracer studies?

____
____

6. How will you use what you find out from the tracer studies?

____
____

If you work through this manual, and then plan and implement your TAP to this stage, then you will probably know as much about TAPs as we do.

If you think there is anything we can help you with, then please give us a call.

Our details are included in the inside front cover.

We look forward to sharing your learnings about Traditional Apprenticeship Programmes in the future, and developing best practice together.

APPENDIX 2: Suggested Guidelines for Apprentices in Selecting a Placement

Most of your learning will take place at the work site where you negotiate a placement. Here are some guidelines to help you when you are looking for a placement.

- The enterprise owner (EO) must have enough work on a regular basis to keep you (the apprentice) busy.

- The work should be of a varied enough nature so that you can learn all aspects of the trade/skill.

- The EO must be experienced enough and skilled enough so that you can learn from him/her.

- The EO must be willing to pass on skills in running a business, as well as in the trade.

- The EO must have tools for you to use, and these should be hand tools, rather than heavy machinery. When you set up your own business, you will only be able to afford hand tools.

- The EO should be willing to give feedback to our programme so that we can improve it.

It is also best if you like and trust the EO, and s/he likes and trusts you. The relationship between you is very important. Once you have found the right place, it is up to you to negotiate a contract with the EO. We will provide you with an initial two weeks of technical training before you begin your placement, and a further two weeks towards the end of your placement.

APPENDIX 3: Example of a Traditional Apprenticeship Selection Interview Schedule

Name of candidate: ____
Trade: ____

1. Age

Age	16-20	21 -25	26-30	31 -35	36 and above
Score	5	4		2	1

2. Marital status

Married	3
Single	2
Divorced	1

3. Organisation recommending apprentice: ________________________

4. Name and address of enterprise where placement found:

____
____

5. Why do you want to be attached as a Traditional Apprentice?

Answer rated:

Very good	4
Good	3
Fair	2
Poor	1

6 What are your expectations from this programme?

Answer rated:

Very good	4
Good	3
Fair	2
Poor	1

7. Number of dependants in the family

Number	1-2	3-4	5-6	7-8	More
Score	1	2	3	4	5

8. Period of unemployment

Period	7 months - 1 year	1.5 - 2 years	2.5 - 3 years	3.5 years or more
Score	1		3	4

9. Source and amount of income/support during period of unemployment
(Most reduced circumstances gets the highest score on a scale of 1 to 5.)

Source: _______________________
Amount: ______________________
Score: ________________________

10. Why did you select your chosen trade?

Answer rated:

Very good	4
Good	3
Fair	2
Poor	1

11. What do you know about your chosen trade?

Answer rated:

Very good	4
Good	3
Fair	2
Poor	1

12. Other areas of development pursued: ___________________________________

____

____

13. Why did you fail in these areas?

Answer rated:

Very good	4
Good	3
Fair	2
Poor	1

14. What do you hope to do once you have completed your apprenticeship?

Answer rated:

Very good	4
Good	3
Fair	2
Poor	1

For the following questions, make brief notes on the answer, and give a score of 1 - 5, where 5 is a very good answer.

15. What will you do in the event of a lack of raw materials or inadequate tools at the enterprise where you will be attached?

____

____

____

Score:....................

16. What do you think your contribution should be during your period of attachment?

____

____

____

Score:....................

17. Have you ever worked under difficult and strenuous circumstances? Explain.

____
____
____

Score:....................

18. How do you regard self-employment as an option for earning a living?

____
____
____

Score:....................

19. If you have an accident at work, during your attachment, who will be responsible?

____
____
____

Score:....................

20. What obstacles do you think you might encounter if you were to try to start your own business?

____
____
____

Score:....................

21. How would you try to overcome these obstacles?

____
____
____

Score:....................

22. Have you ever been employed? If so, what happened that resulted in you losing the job?

____
____
____

Score:....................

TOTAL SCORE: ....
Total possible score: 86

APPENDIX 6: Example of a Tracer Form

1. Name: ____

2. Postal address:____

3. Physical address:____

4. When were you apprenticed? (Please give months and year)_______________

5. Please tick appropriate box:

Are you: ☐ Employed (formal sector) ☐ Employed (informal sector)
☐ Self-employed ☐ Unemployed

6. **Personal Details**

Marital status: ______________ Number of dependants:____________________
Age: ______________________ Gender: ☐ Male ☐Female
Highest academic qualification:____
Other post school training:____

7. What were you doing before you enrolled for the Traditional Apprenticeship Programme? (Tick appropriate box)

☐ At school ☐ Employed (say for how long)_____________
☐ Unemployed (say for how long)_____________________
☐ Self-employed (say for how long)____________________

8. Was your participation in the Traditional Apprenticeship Programme useful? (Tick appropriate box)

☐ Not useful ☐ Useful ☐ Very useful

9. Please tell us why you think it was not useful/useful/very useful:

____
____
____

10. Do you think the technical training you got at ____________ was useful? (Tick appropriate box)

☐ Useful ☐ Not useful

11. What skill did you get training in? ___________________________________

12. Has the certificate you got after your training been useful? (Tick appropriate box)

☐ Very useful ☐ Useful ☐ Not useful

If it has been useful, in what way has it helped you? ____________________
____
____

13. Do you have any suggestions for improvement in the programme you attended?

____
____

14. Is there a demand for your trade in your area? (Tick the appropriate box)

☐ Yes ☐ Some, but not a lot ☐ No

15. Would you recommend to others that they do a programme similar to the one you did?

☐ Yes ☐ No

Questions 16 to 22 to be answered by those who responded to Question 5 by saying they were employed.

16. Please give the name and address of your employer: _________________
____
____

17. How long did it take you to find your current job? ____________________

18. Is your current job a new position, or did you take over from someone else? (Tick appropriate box)

☐ New position ☐ Position occupied by someone else before

19. At which of the following are you employed? (Tick appropriate box)

☐ Urban Business Centre ☐ Rural Service Centre
☐ Urban home ☐ Rural home

20. Are you finding any problems with your current job? (Tick appropriate box)

☐ Yes ☐ No

21. If yes, please describe your problems: ____________________________
____

22. What is your average income? ________________________________
____

Questions 23 to 32 to be answered by those who responded to Question 5 by saying that they were self-employed.

23. Please give the name, address and type of your business: ___________
____
____

24. How many people, other than yourself, do you employ? ___________

25. Who helped you to set up your business? (Tick appropriate box)

☐ Family ☐(Name of implementing agency) ☐ Other
☐ No-one

Please give details to explain your answer: _________________________
____

26. How long after your TAP apprenticeship did it take you to start your own business?
____

27. Did you do anything in between? (Please specify)___________________
____

28. What problems are you currently facing? (Tick appropriate box or boxes)

☐ Tools ☐ Capital ☐ Working space
☐ Other (specify): ________________

29. How do you think the problems should be solved? ___________________
____

30. Have you approached anyone with your problem(s)? (Tick appropriate box)

☐ Yes ☐ No

31. If yes, whom have you approached and what was their response? ________
____

32. What is your average income (profit) per month? ______________________

Questions 33 to 36 to be answered by those who responded to Question 5 by saying that they were unemployed.

33. Have you ever been employed or self-employed since doing the TAP? (Tick the appropriate box)

☐ Employed ☐ Self-employed ☐ Neither

34. What do you think are the reasons why you are unemployed even though you went through the TAP?
____
____

35. What other options do you think are available to you?_________________
____

36. What are you intending to do to solve the problem of your unemployment?
____
____

Questions 37 to 39 to be answered by all respondents.

37. Would you be interested in being informed about other opportunities that may arise from our programme? (Tick appropriate box.)

☐ Yes ☐ No

38. Would you be interested in joining a tool hire-to-buy scheme? (Tick appropriate box)

☐ Yes ☐ No

This manual is intended to provide guidelines and support to those interested in setting up their own Traditional Apprenticeship Programme (TAP).
It takes the form of a workbook to guide implementers in making choices and decisions about their particular TAP.

This manual should help interested institutions and organisations develop a TAP Programme using the experiences of GTZ-ISTARN as a foundation. However, this manual is not a blueprint, which should be followed slavishly, it has been produced to provide guidelines based on what is thought to be best practice.

This manual has a complimentary first volume entitled
'Is a Traditional Apprenticeship Programme an Option for You?' which describes what a TAP is. Both manuals are seen as an aid to replication and to the implementation of technical training programmes for the informal sector in different circumstances and locations.

INTRODUCTION: What is ISTARN?

The Informal Sector Training and Resources Network (ISTARN) is a Zimbabwe-based programme. It is a joint venture between the Zimbabwean and German governments, and receives financial and technical support from the German government through the Deutsche Gesellschaft f r Zusammenarbeit (GTZ). The project was initiated in 1995 in Masvingo, Zimbabwe, where a number of interventions were piloted, all of them aimed at assisting in the creation of jobs in the informal sector, in order to address the problem of unemployment which is endemic in Zimbabwe.

ISTARN has tried to develop an integrated approach to strengthening the informal sector, and its interventions have included a Small Business Advisory Programme, a Marketing Support Programme, and a programme to develop and strengthen Informal Sector Associations. The selection of interventions is intended to create an integrated package for the informal sector which will result in more, stronger and bigger businesses, creating sustainable jobs.

Among the initiatives piloted was a Traditional Apprenticeship Programme (TAP). This used a traditional practice of skills transfer to increase the potential for people learning skills through apprenticeships in the informal sector to set up and succeed in their own informal businesses. The intention of the TAP was to add value to the traditional practice, without excessive interference.

Initially piloted in 1995, the programme has shown very encouraging results, and has generated much interest. ISTARN is now in its replication phase, with Manicaland, Zimbabwe as the first site of replication. The TAP is being piloted here in different forms, with different host agencies.

As part of the replication process, ISTARN has produced a set of two manuals, under the title of Adding Value. The first describes what a TAP is and what is needed in order to set one up. The second provides guidelines for implementation. By reading the first manual, we hope that decision-makers in organisations and institutions that are potential hosts for a TAP -training colleges, vocational training centres, business associations, non-governmental organisations (NGOs) and private training institutions - will get enough background and information to enable them to decide whether a TAP is the right option for them. Once they have decided to go ahead, then the second manual should provide a useful guide on what to do, when to do it and how to do it.

The manuals are not blueprints. They are intended, rather, as guides so that, as development workers, we are able to build on one another's experience and learnings. We look forward to hearing from you about your TAP experiences.

The ISTARN Team

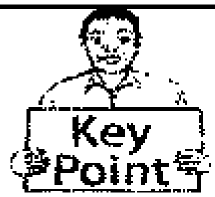
CONTENTS

SECTION 1: What is a TAP?

A Traditional Apprenticeship Programme (TAP) is a development intervention aimed at providing vocational skills training which is cost-effective, relevant and accessible to relatively large numbers of people. It is particularly appropriate in countries where there is a high rate of unemployment, and an established informal sector, and is based on a traditional practice which has been taking place world-wide for many centuries.

In the traditional practice, a person with an informal business, based on a marketable skill, takes on an apprentice who, while working for the business owner, learns the skill, as well as the practice of business. Traditionally, apprentices find their own attachments, and either pay the business owner a small sum for the training, or are given some form of subsistence support only (e.g. a place to stay and a meal a day). The practice is cost effective because of the practical orientation of the work and the productivity of the apprentice during training. It is particularly effective because the apprentices learn not only the trade skill, but are also inducted into a business culture and business networks.



A Traditional Apprenticeship Programme (TAP) is a development intervention aimed at providing vocational skills training. It is cost- large numbers of people and is particularly effective where there is high unemployment and an established informal sector.

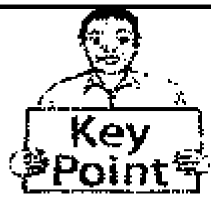
A TAP is based on a traditional practice which has existed world-wide for many centuries and which has been shown to be widespread in southern Africa.

Once the apprentice is sufficiently skilled, she has the possibility of setting up her/his own business. While the practice is not that different from a formal apprenticeship scheme, it does not involve long-term formal training or high level educational levels for entrance, apprenticeships are usually shorter than in the formal schemes and are not bound by rigid, inflexible regulations, and the training is geared to the informal sector market and self-employment, rather than to formal sector wage employment.

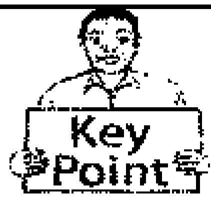
While there is an international literature on the traditional apprenticeship practice, there was a lack of documented information on the subject in southern Africa in general, and Zimbabwe in particular. ISTARN commissioned research into the practice in Zimbabwe, which not only found that it existed, but provided many guidelines for an attempt to replicate the existing practice.

A TAP is an attempt to add value to the traditional practice, without interfering excessively and ruining it. By "adding value" we mean that graduates of the development intervention, as opposed to the traditional practice, will have a greater likelihood of succeeding in creating jobs for themselves, and, possibly, for others.

Using and adding value to existing traditional systems ensures that approaches that have worked over long periods of time can continue to work within complex social, economic and cultural environments and can be continuously adapted to the demands of an ever-changing economic environment.



A TAP adds value to the traditional practice by interventions that mates it more likely that the graduates of the programme will be successful in creating jobs for themselves and, possibly, for others.



In a typical TAP, based on the ISTARN model:

participants come from the ranks of the unemployed, selection is based on entrepreneurial aptitude, the major site and vehicle of skills transfer is the workplace, appropriate skills Involve manufacturing or service, value id added through short-term technical training, utilising existing facilities and training capacity, and by providing short-term business training and support.

In a typical Traditional Apprenticeship Programme, based on the ISTARN model:

• Participants are recruited from the ranks of the unemployed, and are usually, but not always, young people who do not have marketable skills.

• They are selected on the basis of their entrepreneurial aptitude, as the intention is that, in the absence of jobs, they should, after completion of the programme, be able to become self-employed, the most common practice in the informal sector.

• The major site and vehicle of the skills training is the workplace - usually the workshop of a business owner who has agreed to take the participant on as an apprentice. Attachments (placements) are usually for a short time period - three to six months is common, but this depends to some extent on the nature of the skill. A carpentry attachment will be considerably shorter than a motor mechanic placement.

• The kinds of skills most appropriate are manufacturing skills (such as carpentry, welding, dressmaking, building) or service skills (such as hairdressing, motor mechanics, fixing of appliances). Ideally, the capital costs of setting up one's own business should be as low as possible.

• The TAP adds value through organising for apprentices to have initial short- term technical training, and, where necessary, short-term follow- up training. Short-term here means something like two weeks, but this varies, depending on the complexity of the skills involved. This training, as far as is possible, utilises existing training facilities and spare training capacity (such as that available at a technical college or training centre). The technical training component needs to be as short as possible, but as long as is necessary. The point of departure is that a trainee must gain all (but only) that knowledge and skills required and needed to perform competently those sets of tasks needed to be self-employed or to secure employment (most probably in the informal sector).

• The TAP also adds value by providing short-term business training, and support to those who take the initiative to set up their own businesses. This support could, for example, take the form of access to credit, or specifically for credit to buy tools for their trade (a tool hire- to-buy scheme), or access to business advisory services.

A TAP has been shown to be a cost effective way of addressing the need for vocational training, linked to entrepreneurial development, in the developing world.

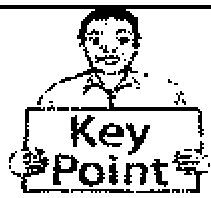
ISTARN has carried out regular tracer studies of graduates of its pilot TAP and these have shown encouraging results. Of the first five intakes, comprising 317 graduates, 89% were employed in some way, and the over-whelming majority of these were self-employed.

SECTION 2: Why start a TAP?

A A TAP tries to address one of the major problems of our time - the ticking time bomb of increasing unemployment and the poverty to which it leads. These are factors that threaten stability, family support systems and individual survival. A TAP creates an opportunity for unemployed breadwinners to earn an income again, and for young people to enter the economy productively for the first time, albeit via "the backdoor".

Very conservative estimates of the percentage of the labour force that is unemployed in Zimbabwe range between 35% and 50%. In 1997 it was estimated that more than 90% of those who sat the "O" level examinations in 1996 were still unemployed.

In a society where the formal sector is able to provide employment for the great majority of its citizens, a TAP would not be an appropriate intervention. In most developing countries, where the reality is shrinking formal sector employment, the informal sector offers an option, and a programme such as a TAP offers a route to making that option as viable as possible. Increasingly, the informal sector has become the default route into the economy, but formal vocational skills training has not made the transition necessary to keep it relevant to the needs of this sector. A TAP is a low cost way of addressing unemployment through relevant vocational skills training.



A TAP is particularly suited to the current conditions in most developing countries, where there is high unemployment, a shrinking formal economic sector, and a growing informal sector.

So, in answer to the question: Why start a TAP?, we suggest the following reasons:

• Unemployment has been identified by the International Labour

• Organisation (ILO) as a long-term persistent trend affecting up to 30% of the global labour force, or some 820 million men and women. The trend is being exacerbated by Structural Adjustment Programmes (SAPs) currently being implemented widely in the developing world.

• The World Bank estimates that the informal sector comprises up to 60% of the labour force in the urban areas of many sub-Saharan African countries. By the year 2020 this could rise to 95% in some parts of Africa!

• A programme which aims to create employment opportunities in the informal sector in developing countries through an innovative approach to skills development training, meets the need for relevant skills training head-on.

• Graduates of formal technical training courses are failing to find employment in the formal sector and their training has not been geared to self-employment and entrepreneurship. These graduates are contributing to the swelling numbers of the unemployed.

• The formal courses traditionally offered as technical training are not only no longer relevant to the needs of the market, but they are very costly at a time when budgets available for skills training are increasingly tight. A TAP is a low cost route to relevant training because it emphasises the workplace as a site of learning, and provides the apprentice with the basic skills to be productive in the workplace almost from the very word go.

The informal sector in Zimbabwe employs 1.6 million people, compared with 1.2 million employed in the formal sector.

Formal vocational training institutions assume that opportunities for formal employment exist when they do not. A tracer study of engineering students at Masvingo Technical College, Zimbabwe, in 1996, revealed that, out of 105 responding graduates (of a total of 138) of the Engineering Division who graduated in mid-1995, only 32.4% had found formal employment a year later. A tracer study carried out in 1999 of the Commerce and Engineering Divisions' graduates of 1997 at the Mutare Technical College, Zimbabwe, revealed that only 20.4% had secured formal employment.

• The training is directly related to goods or services that are going to be sold and the apprentice is taught on what the customer has ordered or requested. The whole process is, therefore, market-oriented, and grounded in the actual realities of the business world in terms of equipment, expectations, access to raw materials, and so on. The apprentice learns to provide services and goods at an appropriate level and cost.

• It is relatively easy and cheap to set up a TAP because it utilises existing infrastructure and the spare capacity of existing training institutions. So, for example, the infrastructure and staff capacity of technical colleges can be effectively utilised during vacations and evenings.

• The cost of creating one job in the informal sector, from training through to actual self-employment, through a TAP, is about one tenth of the estimated cost of just the training involved in creating a formal sector job.

In the ISTARN pilot programme, the average cost per trainee in the TAP, as estimated in 1997, including basic training, technical evaluation, administrative costs, business training and tool kit, was Z$ 5 608.83 (US$ 486.80). In 1998, the average cost per trainee in the TAP, right through to setting up in business, was Z$ 12 771.31. The increase in Zimbabwean dollars was largely due to the higher costs of some of the trades introduced, such as Refrigeration, Radio and TV Repairs, Motor Mechanics and Solar Electric Installations.

• A TAP meets the challenge of equity because it does not exclude those who lack relatively high levels of formal education (basic literacy skills are usually sufficient).

• Because there are not many regulations in the informal sector, there is flexibility of entry and exit. So, for example, a retrenched person can use the TAP as a route to self-employment until such time as employment opportunities in the formal sector exist again. The costs involved in setting up the kind of micro businesses towards which a TAP is geared are usually very low.

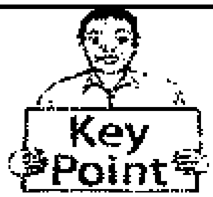
• A TAP has the potential to strengthen the informal sector in terms of productivity and quality because the technical training which the apprentice receives injects new ideas into the enterprise. Research has shown that one of the drawbacks to the traditional practice is that it is seldom innovative. A TAP adds value not only by creating learning opportunities for the apprentice, but also for the business or enterprise owner.

• A TAP addresses the need to develop an entrepreneurial spirit in struggling communities.

• And finally, and most importantly, our experience shows that a TAP can work by creating employment and self-employment opportunities!

A tracer study done on the Masvingo pilot TAP graduates in April 1998 showed the following for the 87.8% of graduates who were reached:

- 56.9% were self-employed
- 29,2% were employed by someone else
- Only 12.2% were unemployed.



Why start a TAP? Because:

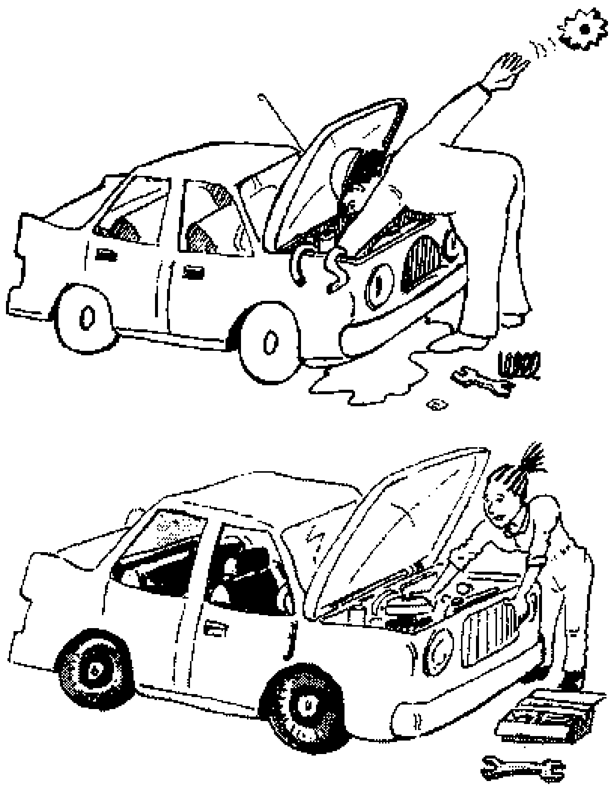
- The trend towards increased unemployment in the formal sector is accelerating.

- The informal sector is Increasingly becoming a more significant site of employment than the formal sector in sub-Saharan African countries.

- The TAP offers an innovative approach to skills development training that is relevant to the informal sector and cost-effective in terms of the input required to create an employment opportunity.

- The TAP does not require entrants with relatively high level educational qualifications and so meets the challenge of equity.

- The TAP adds value to the existing traditional practice by injecting innovative practices, through the technical training component, into sector that is notoriously conservative. Both quality and productivity can, thus, be improved.



SECTION 3: Why is ISTARN producing this manual?

The ISTARN TAP has generated interest locally and within the sub-region. A number of local institutions have shown a keen interest in starting a similar programme. Development practitioners, governments at all levels, training institutions and organisations, and struggling communities are all looking for options that can help to address some of the most troublesome problems of the developing world.

Through the pilot TAP in Masvingo, ISTARN has developed and tested the model sufficiently to conclude that it is a useful training approach, and a productive intervention in the informal sector. It:

- Creates jobs through self-employment
- Skills people so that they are employable and get employment
- Achieves impact at a reasonable cost
- Adds value to the traditional practice

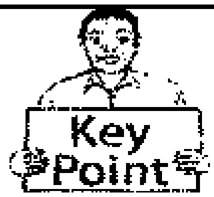
We see this manual, and its companion manual which deals with how to go about setting up a TAP, as an aid to replication, and to the implementation of TAPs in different circumstances and locations. The two manuals should help interested institutions and organisations:

- Assess their capacity and suitability to start similar programmes.

- Develop similar programmes, using the learnings of ISTARN as a foundation. While adaptations will need to be made, institutions and organisations interested in implementing TAPs will not need to start from scratch.

The manuals are intended to provide guidelines, based on ISTARN's "best practice" experience. They are not, however, blueprints which should be followed slavishly. Each experience will be different, something we ourselves are discovering as we move further into replication. Because of this, the second manual has the format of a workbook, to allow implementers to think about the ISTARN experience of best practice in the light of their own circumstances.

We suggest that those of you who are responsible for making the decision about whether or not to go ahead with a TAP read Manual 1 carefully. Once you take the decision to go ahead, you need to take a look at Manual 2, before passing both manuals on to those who will be required to implement the programme.

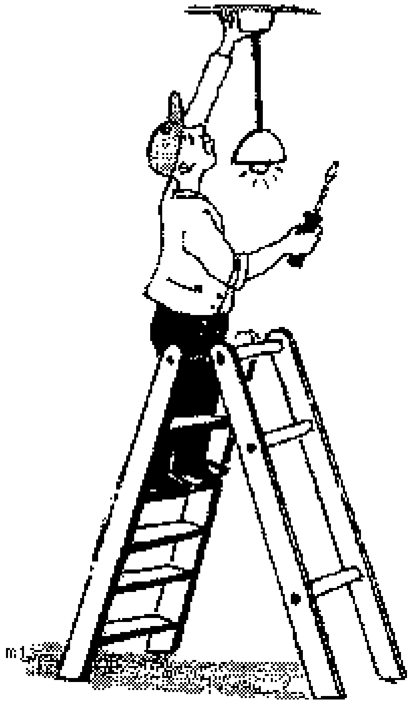


The manuals are intended to provide guidelines and support to those interested in setting up their own TAPs. Through them ISTARN hopes to reach a wider audience than would be possible through direct contact

Manual 1 provides the information and explanations that should enable decision-makers to decide whether or not a TAP is appropriate for their context.

Manual 2 takes the form of a workbook to guide implementers in making choices and decisions about their particular TAP.

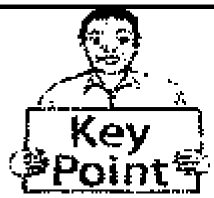
Through the manuals we hope to reach a wider audience than is possible through direct contact, and to provide some support to other initiatives even when we cannot meet directly with those involved in them.



SECTION 4: When is it a good idea to start a TAP?

We believe that any organisation or institution with the right approach, support systems and networks can set up a traditional apprenticeship programme. However, in order for there to be the best possible chance of your TAP being a success, it is important that you give careful consideration to:

• the environment in which the TAP will be operating; and
• the culture and capacity of your own organisation.



It is a good idea to start a TAP when the external environment is appropriate and when the culture and capacity of your organisation enhance the likelihood of success.

What is a suitable environment for a TAP?

While there are no hard and fast rules about this, our experience has led us to believe that a TAP is most likely to flourish when:

• there is ongoing high unemployment and a low capacity in the formal sector to absorb or even retain workseekers there is an existing informal sector, playing a significant role in the local economy

• there are concentrations of business activity in certain nodal points, providing markets for informal sector outputs

• there is already a traditional practice of informal apprenticeships

• the approach of government, at the local, regional and national levels, to the informal sector is at least constructive, even if restrictive regulations are in place.

In deciding whether your particular environment is suitable for starting a TAP, you need to think about issues such as unemployment, the role and robustness of the informal sector, the existing practices of informal training, and the government's attitude to the informal sector.

• In Zimbabwe, estimates of the unemployment rate range between 35% and 50%.

• The Economic Structural Adjustment Programme has led to shrinking formal employment.

• The informal sector employs more people than the formal sector.

• There was a well-established traditional practice before the ISTARN intervention.

• There has been some deregulation in relation to the informal sector, but a number of restrictive regulations are still in place. Nevertheless, government rhetoric towards the informal sector is positive.

In the ISTARN experience in Zimbabwe, a positive factor was the relatively high level of education of the unemployed population. Between 70% and 80% of the unemployed in Zimbabwe have at least an "O' Level Certificate. As the TAP intervention includes a formal training component, it is helpful if the participants have a good enough educational and literacy base to make the most of the opportunity.

Do you have the appropriate organisational culture and capacity?

There is probably no one organisation that is "exactly right" in every respect to set up a traditional apprenticeship programme. However, our experience at ISTARN and the extensive literature on similar interventions suggest that the following is a list of "ideal characteristics" for an organisation or institution that wants to set up a TAP.

- Clarity about the problem or issue it is addressing - knowing what the programme is supposed to achieve

- A carefully researched and thought through project concept which anticipates, to the degree possible, potential problems - although there is general agreement that there will always be problems no-one has anticipated!

- Sufficient staff with experience and skills appropriate to vocational training for the informal sector

- An established administrative and co-ordinating infrastructure (but not necessarily a physical infrastructure, as training facilities belonging to other organisations and institutions can be used)

- A business and market-related orientation

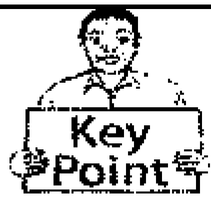
- Flexibility and creativity in both decision-making and implementation

- Participation in a network of programmes involved in support to the informal sector

- Flexible funding, linked to careful costing - in other words, costs should be kept low, but some funding needs to be available to be used flexibly as the needs of the programme become clearer

Good monitoring and evaluation systems

Even if you do not already have these characteristics, if you are looking at the option of setting up a TAP, then you should begin to look at the internal developments your organisation or institution will need to make it a suitable "home" for a TAP.



To give your TAP the best possible chance of success, you need to develop an appropriate culture and sufficient capacity within your organisation or institution.

ISTARN did meet these criteria in certain ways, but it was by no means perfect.

In its favour were:

- **Clarity on the problem, which it defined as unemployment**

- **Some basic research around a clear programme concept, and ongoing research related to it - the concept was the creation of employment through skilling people to be successful informal sector entrepreneurs**

- **Staff with an understanding of the informal sector and growing skills and expertise in the area**

- **An increasingly businesslike and market-related orientation**

- **Flexibility and creativity**

- **Contact with others working in the field**

- **Flexible funding**

- **Good related support services**

- **Administrative and co-ordinating capacity**

- **Ongoing efforts at monitoring and evaluation**

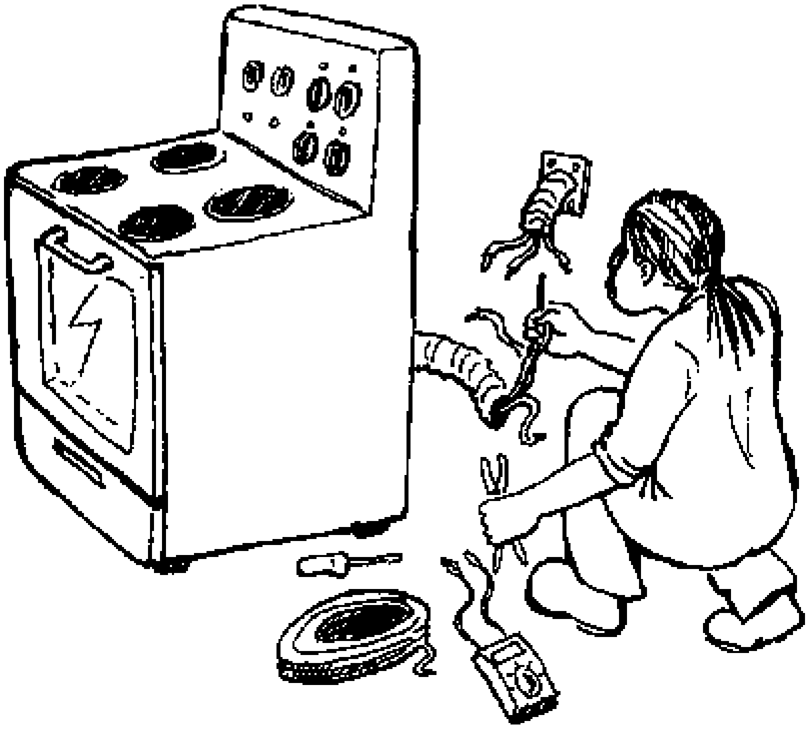
There were, however, gaps:

- **Staff were over-stretched and under-resourced - at one stage, well into the programme, there was one full-time person assigned to the Programme and he had access to 20% of one vehicle!**

- **There was sometimes confusion about how the success of the TAP should be measured - was it enough for graduates to be employed, or did they have to be self-employed?**

- **We did not always pay enough attention to costing and the implications of costing.**

- **Initially, we did not put enough emphasis on business-orientation - so, for example, we gave participants living subsidies, which not only made them more dependent on ISTARN, but also interfered with the traditional relationship between the Enterprise Owner (EO) and the apprentice in a way which did not add value.**



SECTION 5: What would you need to start a TAP?

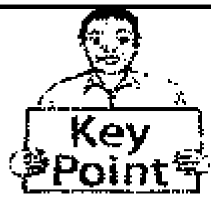
The second manual in this set deals in detail, step-by-step, with how an organisation or institution committed to setting up a TAP would go about the task. Here we include a summary of what would be involved so that you can make an informed decision about whether or not to get involved in such a programme. Although you yourself may not be implementing the programme, you will need to be 100% behind the staff who are, and this means having an understanding of the implementation process.

There are three key sets of stakeholders in any TAP:

- The organisation or institution that is the "home" of the TAP and which is often also the provider or co-ordinator of the formal training element of the programme

- The apprentice - the person who wants to acquire a skill

- The enterprise owner (EO) who, in other contexts, might be called the apprentice's "master" - the person who has the skills that need to be transferred



There are three key sets of stakeholders in any TAP - the implementing agency, the apprentice and the enterprise owner.

Involvement in a TAP means different things for each of these, and all these different types of involvement need to be taken into account when you Implement a TAP.

For the **organisation or institution implementing** a TAP, once the decision to go ahead has been taken, the process involves:

- Setting up a team to plan, implement and monitor the programme.

- Ensuring that the environment is understood and is as appropriate as possible to implementing a TAP (this may require some basic research, including surveying the existing informal sector).

- Gearing the organisation or institution up to be able to implement the programme (this may involve raising money, finding appropriate staff, re-orientating staff to the new approach, and so on).

- Taking key decisions on what skills to offer, what package to offer, how to recruit and select, whether to have gender targets, what geographical area to cover, and so on.

- Drawing up a plan for implementation.

- Preparing appropriate training for the formal part of the programme.

- Recruiting, and selecting participants.

- Conducting the first formal training and any subsequent formal training that has been agreed on (if the implementing organisation or institution is not a training agency, it will have to ensure that training partners are found, and that they offer a quality service).

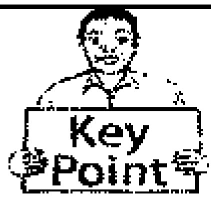
• Monitoring the progress of the apprentice, the suitability of the placement (the workshop site) and the appropriateness of the formal training.

• Providing some form of support to the apprentices when they move on to self-employment (this will depend on the "package" offered and may simply involve referrals to appropriate agencies for loans, access to tools, business advice etc, or direct provision of these).

• Tracking the progress of graduates.

• Evaluating success against goals.

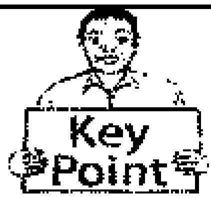
• Replanning in the light of learnings gained.



The implementing agency has to plan, implement and monitor, as well as gear up for implementation. It also has to recruit and select appropriate participants, ensure that the formal training part of the process takes place, monitor the placement and progress of the apprentice, provide some form of support to those who choose a self-employment option, and then track the progress of graduates to ensure that the programme is "working".

A note on monitoring and evaluation:

A traditional apprenticeship programme is a way of providing cost-effective, relevant skills training so that participants, usually drawn from the ranks of the unemployed, end up in employment of some kind. Unless you track the progress of graduates, you will not be able to say whether or not this goal has been reached. Without evidence that a TAP is a successful intervention, it will be difficult to "sell" it to prospective apprentices, or to donors or government departments.



Apprentices, once they have decided that this is the sort of vocational training they want, need to find and negotiate an appropriate placement, attend the formal training sessions, and participate in and learn from, the activities of the work site. Once they are graduates, they may choose wage employment (in the formal or informal sectors) or self-employment.

For the **apprentices,** the process involves:

• Deciding whether or not this form of vocational training is appropriate for you.

• Finding an appropriate placement in the skill and location of your choice, and negotiating with the enterprise owner about the conditions of the apprenticeship.

• Attending the formal training sessions.

• Participating in and learning from the activities of the workshop site.

• Co-operating with the implementing agency and the enterprise owner to ensure that the placement is as productive as possible.

• Selecting a career path which could involve continued employment with the enterprise owner, employment elsewhere (in either the formal or informal sector), or self-employment. In each of these instances, there may also be a possible option to convert the certificate of attendance that goes with the informal training to a formal certificate of competence through, for example, trade testing.

• Accessing the support offered through the implementing agency for those choosing the self-employment option.

A note on trade testing:

Some development experts believe that the trade testing option "corrupts" the traditional apprenticeship process, making it more costly, both in terms of training costs, and in terms of the services that are subsequently offered - a motor mechanic who has successfully completed the first level of trade testing may expect to be able to charge more for his/her services, reducing the size of the market able to access his/her services. We do not take a purist position on this, and believe that this should be a decision taken by the apprentice, but that, where possible, the training process should make the option possible.

For the **enterprise owners,** the process involves:

• Deciding that taking on an apprentice is worthwhile for you as an enterprise owner - because it is a way of acquiring cheap labour, because you believe you might learn something in the process, or even simply because you want to make a contribution to your society by handing on your skills.

• Negotiating a contract with the would-be apprentice that suits you and satisfies him/her.

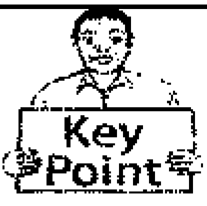
• Providing a working environment that encourages the development of both the practical skills of your trade, and business skills,

• Providing feedback to the implementing agency on the usefulness of the formal training and the progress of the apprentice.

A note on why EOs agree to participate in a TAP:

EOs give many reasons for participating in a TAP, including access to a cheap form of labour, profit from fees (which some EOs charge), increasing manpower, and "patriotism" which seems to mean fulfilling an obligation to society.

It is important that any implementing agency take all three of these stakeholders into account when thinking about what would be involved in starting a TAP.



Enterprise owners take on apprentices for a variety of reasons, and, once they have negotiated a contract with the would-be apprentice, must provide a working environment that encourages the learning process, both in the trade and in business skills, as well as providing feedback to the implementing agency.

• ISTARN commissioned a study of existing practice in traditional apprenticeship in Masvingo Province in 1995 which showed that there was a strong traditional practice in the area. In 1997, it commissioned an extensive survey of informal sector enterprises in the sector which generated useful information.

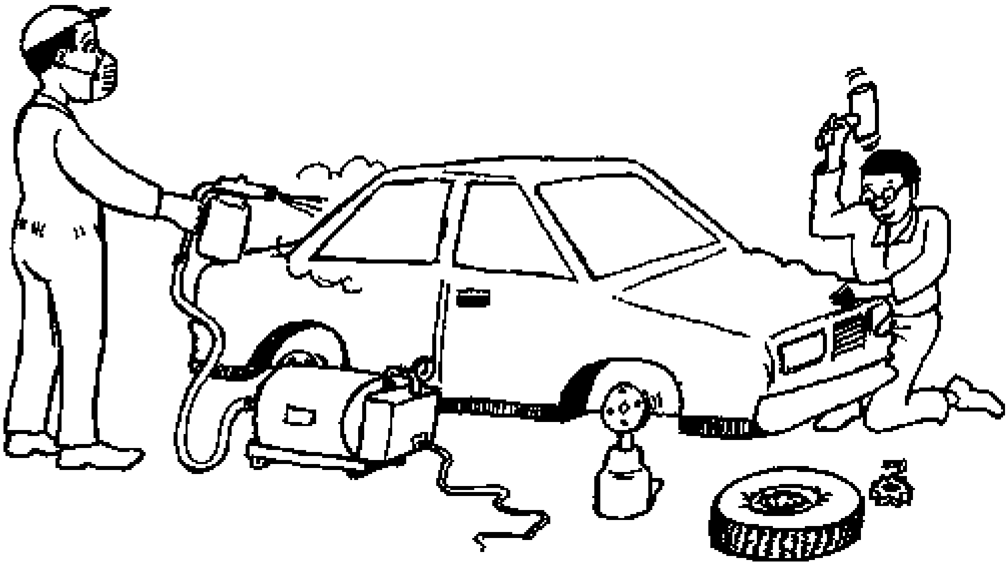
• The ISTARN pilot TAP did not itself offer training, but relied on training partners.

• Currently, the ISTARN TAP offers a "package" which consists of the formal training and, for those who go the self-employment route, access to a Tool-Hire-to-Buy Scheme and to business training.

• ISTARN intends to track graduates for three years after the completion of the apprenticeship process.

• ISTARN-linked apprentices in the motor mechanic trade have written the first level trade test and have done well in it. Apprentices are required to pay the cost of such testing themselves.

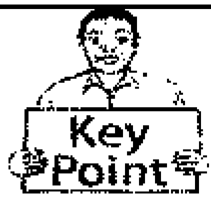
• An evaluation of the ISTARN TAP found that, in many cases, EOs prefer to take on ISTARN apprentices who have had some formal training. Reasons given included the cost of damage to tools and wasted material in the early days if people come in "raw" and the fact that apprentices with some prior theoretical knowledge learn more quickly.



SECTION 6: Who should start a TAP?

We have already said that almost any kind of organisation or institution could start a TAP, provided it was flexible enough and informed enough to design and implement such a programme successfully.

Depending on the kind of organisation or institution you are, you will face different challenges in planning and implementing a TAP.



If you meet the criteria for an organisation with an appropriate culture and sufficient capacity, operating in an appropriate environment, then, no matter what kind of organisation or institution you are, you could consider starting TAP.

In the table below we have summarised some of the possible starting points, but there could well be others

KIND OF ORGANISATION	ISSUES SPECIFIC TO THAT KIND OF ORGANISATION	ADVANTAGES	DISADVANTAGES
NGOs	A TAP would have to fit in with the aims and objectives of the NGO. A decision about initiating such a programme would have to come from the Board. The impact would need to be monitored to ensure that it contributed to the greater good of the society.	NGOs tend to be flexible and have the potential to be creative without being tied up in the slow wheels of bureaucracy. NGOs have the freedom to test models which can then be replicated by other organisations and institutions.	Long-term sustainability may be a problem as the survival of an NGO may be donor-dependent.
Technical Colleges	These have not been traditionally orientated towards the informal sector, and a TAP will require them to change their approach in almost all areas of operation - management, lecture format, equipment orientation, goals and purposes, forms of recognition (certification), and market approach.	Facilities and staff exist. They are geared towards student intakes. They are geared to the procurement of training consumables. They may have access to student subsidies.	They are often training-driven, at the expense of market orientation - they have a tendency to offer the training they have, rather than that demanded by the market. They may be too bureaucratic and regulation- controlled to make them suitable for a programme that requires flexibility.

KIND OF ORGANISATION	ISSUES SPECIFIC TO THAT KIND OF ORGANISATION	ADVANTAGES	DISADVANTAGES
Vocational Training Centres	As these are often run by community representatives, and the intention is that, at least partially, they will be run by financial contributions from the community (fees), the community would need to buy into the idea of a TAP as a credible alternative form of vocational skills training.	They are accessible to people in rural areas. They are more flexible than technical colleges, and less concerned with formal qualifications, but they are still geared to training. While they may have facilities, they are more concerned with the programme offered and are willing to use the facilities of other institutions.	TAP placements in more modern skills (such as fixing electrical appliances) may be limited in more rural areas. Placements in general may be more limited in rural areas, and those in urban areas more difficult to access for people who come from the rural areas, particularly if they have no way of finding accommodation.
Private training institutions	These provide a service in return for payment. They survive on, and exist for, the profit generated from selling training. They may specialise in one skill or offer a number of different skills. There are at least 100 such institutions in Zimbabwe.	They have a built-in market orientation. They are geared to offering low cost training in a cost-effective way.	They tend to be orientated towards the classroom, rather than the workplace. There may be a reluctance on the part of potential students to pay profit-related fees for a course that does not provide a "proper" qualification. They are not necessarily impact-oriented (but would have to be able to "prove" results if they wanted to go on getting students).

• Initially, ISTARN was an NGO which used the training expertise and facilities of other NGO training partners or of the Technical College which housed it.

• Now ISTARN is experimenting with different starting points, including Vocational Training Centres and Technical Colleges.

SECTION 7: What are some of the issues you need to consider?

If you decide to go ahead and implement a TAP, there will be many issues which you need to consider and about which you will need to make decisions. In Manual 2 we provide more information on these, but here we want to list some of them and describe them briefly, so that, as decision-makers, you can be aware of the kinds of complexities and dilemmas that your implementation team will face.

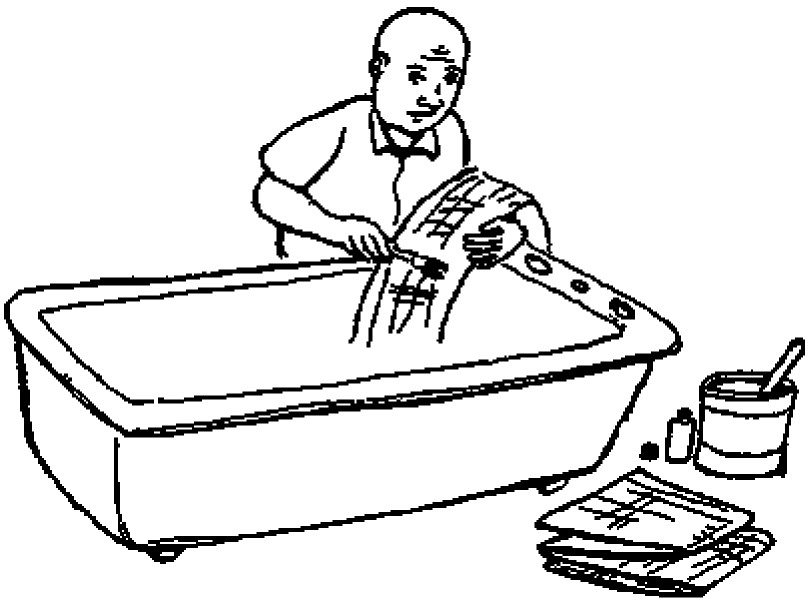
As decision-makers, you need to be aware of some of the key issues and dilemmas that will need to be dealt with in the implementation phase. Among these are:

- **choice of trades/skills to offer - the Importance of selecting trades and skills which are marketable in the context of the informal sector**
- **gender - particularly the inclusion of women in the programme**
- **the 10:90 Principle which states upfront the need for participants to match the 10% input from the implementing agency with their own effort as the remaining 90% input**
- **selecting winners - those most likely to make a go of their own businesses in the medium- to long-term**
- **formal certification and qualifications - where they fit in and the problems they raise**
- **monitoring and evaluation - their purpose and their usefulness**
- **outreach - getting to significant numbers of people.**

Choice of trades/skills to offer

The growth of urban areas and the introduction of modern products and technologies has opened up many new opportunities for small-scale enterprises, thus extending the potential of the traditional practice. This is important because it means that a TAP can offer training in a variety of skills. An over-focus on any one skill in a particular geographical area might lead to saturation of the market. An understanding of the informal sector market and existing enterprises will help you to make market-related choices about what to offer.

In a TAP, other considerations when deciding what trades/skills to offer would include the availability of training expertise in the skill, the availability of apprentice placements and the willingness of EOs to take on apprentices, the length of time it is likely to take for someone to become sufficiently skilled in the particular trade/skill, and the likely capital cost of setting up one's own business.



In 1997, ISTARN commissioned a study of the informal sector in Masvingo Province and, through this, identified a range of potential trades/skills which could be incorporated into the TAP. Initially only carpentry and welding were offered, but later intakes were offered the additional options of dress-making, radio and TV repairs, motor mechanics, refrigeration and solar electric installation.

Of these, motor mechanics is the one that requires the longest training (about 18 months) and the greatest investment of capital to set up a business (about Z$ 12 000). Although purists would probably exclude it as an option on these grounds, and it is likely that apprentices will end up having to work longer before they can set up their own businesses, it has been a successful area for the ISTARN TAP.

In the studies done in Masvingo it was found that hairdressers were reluctant to take on apprentices because their experience was that, as soon as apprentices had some skills, they left and set up businesses in competition with them. The reason for this was the very low capitalisation cost of setting up a hairdressing business.

Gender

Gender is a major consideration in any development work, and, for those of you who have a more profit-oriented approach, women are often a market that has not been fully penetrated. Studies have shown that women tend to occupy positions at the lower end of the informal sector - so they are more likely to be street vendors than to be involved in manufacturing, for example. Research has also shown that women usually experience more problems than men in setting up and sustaining their own businesses. One of the implications of this is that a TAP, which adds value by providing ongoing business support, may have an important role to play in changing the profile of women in the informal sector.

In addressing the issue of women in a TAP, there are two approaches: the one is the inclusion of women in traditionally male-oriented trades, and the other is the inclusion of trades in the programme which are more "women-friendly".

If gender equity is a concern for you and your organisation or institution, then you probably need to set targets for how many women (as a percentage of all apprentices) you aim to include, and work consciously towards meeting the targets.

ISTARN has always had gender equity-related targets, and has gone both the route of encouraging women to work in traditionally male dominated trades, and the route of including "women-friendly" occupations. In the first two intakes at Masvingo, when only welding and carpentry were offered, only one woman was recruited. She did carpentry and is now successfully self-employed. In the third intake, which was of motor mechanics, there were two women, but they both dropped out. In the fourth intake, there were attachments in dressmaking, but women also chose to do welding and carpentry.

The 10/90 Principle

We believe that this principle is fundamental to the success of a TAP. Put simply, the principle is that, in an intervention such as a TAP, where success is so dependent on the mind-set of the participant, the implementing agency offers an opportunity which is 10% of the input, but, in order for the opportunity to be maximised, participants are expected to input 90% in effort.

This principle needs to be presented upfront to participants, and to be stressed throughout the process. It has many implications which include the need to encourage independence from the implementing agency from the start, and to ensure that "support" is not interpreted by either the implementing agency or the participants as "hand holding"; and; the need to select carefully and to make sure that participants understand the principle and are willing to put in the required effort.

ISTARN learned the importance of this principle by experience. Initially, for example, we offered a subsistence allowance, and negotiated placements for the apprentices. The first intake had unrealistic expectations and many complaints at the beginning of their placements. Now participants are expected to find their own placements and negotiate directly with the EO, and a subsistence grant is no longer offered. We found that when apprentices were offered a subsistence grant or a down payment on the tool hire-to-buy scheme instead, most chose the latter, indicating that they could survive without the subsistence grant.

Selecting "winners"

This issue is linked to the "10/90 Principle", but refers specifically to the fact that, if you want people to become self-employed and, possibly, set up businesses which can employ others (job creation), then you select those who are most likely to become successful entrepreneurs, whether in the short- or the long-term. One way of doing this is to maintain the barriers to selection that approximate the traditional practice, making selection for the programme conditional on would-be apprentices finding their own placements, and being able to find their own accommodation and food.

ISTARN found that, once it was clear that it did not intend to subsidise apprentices, the committed ones generally sorted themselves out, even if it meant moonlighting (working at night) to make money for their subsistence. A word of warning here: once you have begun the practice of offering a subsistence grant, it is much more difficult to stop it than it would have been never to offer it in the first place.

Formal certification and qualifications

In the ISTARN TAP model, all apprentices get certificates of attendance on completion of their attachments. Apprentices are given the option to write trade tests, where these exist, but they pay for them themselves. This is the point at which the informal and formal systems of education have the potential to meet. With moves towards formal recognition of prior learning and experience, the options of moving from informal to formal levels of qualification are likely to increase. In education and training terms, this creates important opportunities. In the informal sector, however, it is an option that needs to be treated with care. While establishing "test standards" may increase the quality of work apprentices produce, quality is not a sufficient predicator of success in itself and needs to be defined in relation to the target market - what it wants and needs in terms of quality. If accreditation and certification result in higher prices for goods and services in the informal sector, then the training that leads to them may become as irrelevant as that offered currently in formal technical training courses.

ISTARN staff believe that anything but the most basic trade testing level will have the effect of making past apprentices too costly for their target market which would rather use someone with sufficient skills at a **lower cost, than someone with many skills at a higher cost.**

Monitoring and evaluation

Monitoring and evaluation enable an implementing agency to track the progress and success of a TAP. Monitoring takes place during the process and enables the implementing agency to take remedial action where necessary. So, for example, if monitoring of placements shows that a particular placement is inappropriate because the EO cannot provide a suitable environment for the transfer of skills, then the apprentice can be encouraged to seek an alternative placement. Monitoring might show that the technical training input is not sufficiently relevant to the needs of the workplace, and then adjustments could be made to subsequent technical inputs.

Evaluation is more long-term and relates to whether the programme is achieving its intended goals or impact. In a TAP, this would be that graduates end up self-employed, or, at the very least, employed. This requires tracer studies of graduates. Evaluation is clearly very important for programmes funded from public money (government or donor) which are required to demonstrate that such money is being well-spent. It is also important for private training institutions who can only expect to recruit fee-paying trainees if they can demonstrate that the programme leads to some form of employment.

ISTARN has gone to some trouble both to monitor and evaluate its TAP. The monitoring process has led to some adjustments to the technical training, based on workplace needs. The evaluation, through tracer studies, has been able to show that the ISTARN TAP is, indeed, achieving its goal of creating jobs through self-employment, at a credible rate, by international comparison.

Outreach

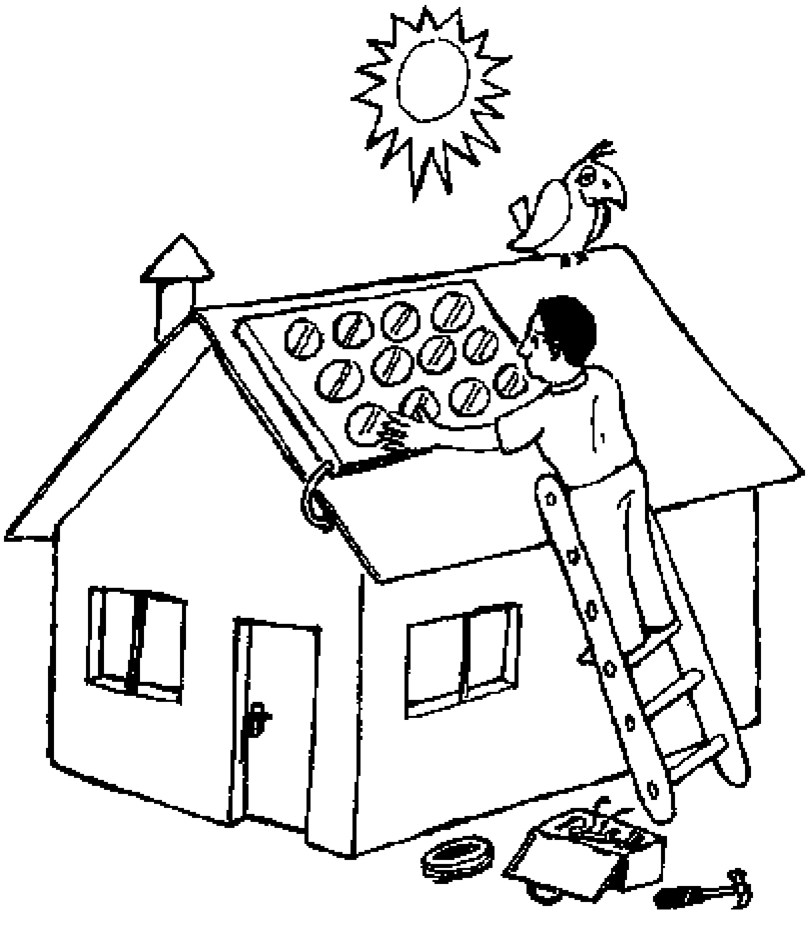
By this we mean that a TAP needs to reach significant numbers of people to make it as cost-effective administratively as possible, as well as to ensure that it makes some degree of significant impact on the problem of unemployment. This means that there need to be regular intakes (probably three to six monthly) of a reasonable size (your early intakes might be smaller - in the region of 30 to 40 apprentices - but as your experience grows you will be looking at numbers of between 40 and 100).

The first ISTARN intake at Masvingo was 40, and the second 39. The most recent intake in Mutare, from where the replication phase of ISTARN is being directed, was 87. The 1998 intake in Masvingo was 120.

Cost recovery versus Equity

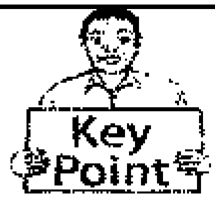
The issue here relates to skills training where recovery costs on the formal training are prohibitively high. A case in point is the training of motor mechanics. If, in the interests of sustainability, and, in line with the 10/90 Principle, the programme insists on the participants paying full fees, this may exclude people who cannot afford the fees. The Principle of Equity (that the option for participation should be open to all, particularly the most needy) is then compromised.

ISTARN is investigating the possibility of establishing a **scholarship fund for those who are not able to pay full fees.**



SECTION 8: Who should be involved in implementing a TAP and how should you involve them?

Effective implementation of a TAP requires a team approach. The team needs to include decision-makers and hands-on implementers, although the day-to-day involvement of the different levels may vary. The team also needs to be excited by the idea of a TAP, and keen to see it succeed.



Successful implementation of a TAP requires the enthusiastic involvement of a TAP team.

WHO SHOULD BE ON THE TAP TEAM?

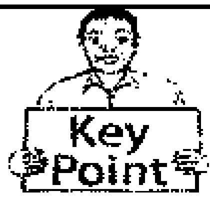
Ideally the team should include **someone who has the power to make decisions** about the use of the budget, so that it can be used flexibly and appropriately. This person may not be involved on a day-to-day basis but will attend team meetings and provide advice and support when it is needed.

The main implementing role should be played by the **TAP Co-ordinator or Manager** who should have the responsibility for planning, scheduling, coordinating the internal team and any outside stakeholders, implementing, monitoring and evaluation. This is the person who should be ensuring that adequate records are kept, that reports are written, experiences are shared and networks and contacts are established and maintained. This is the frontline person, responsible for marketing the programme and keeping on the cutting edge of developments in the field of vocational training for the informal sector.

Training providers, whether internal to the implementing agency, or brought in from other institutions or organisations, also need to be part of the team. They have the responsibility for developing appropriate curricula and materials and for ensuring that the technical training is of a high quality and relevant content.

Depending on the size of the programme, one or more **fieldworkers,** able to go out into the field and assess placements and apprenticeship process, as well as the relevance of the training given, will also be needed. Some of this can be done by the Co-ordinator, but if you are intending to have 100 or more apprentices on the programme at any one time, then s/he will probably need help.

This team should be meeting regularly to plan, review and reflect on learnings emerging from implementation, share decision-making, make adjustments to plans and processes where necessary, and provide support to one another, particular in the early stages of planning and implementation. The team should probably plan to meet weekly initially, and once a fortnight thereafter.



Ideally the TAP team will be made up of:

- **Someone with the power to make key decisions, particularly in relation to the use of the budget**

- **The TAP Co-ordinator or Manager with overall responsibility far planning, Implementation and monitoring and evaluation**

- **Training providers, whether internal or external partners**

- **One or more fieldworkers to support the Co-ordinator/Manager.**

Initially, in the pilot phase, the ISTARN team consisted of the Advisor appointed by the donor (GTZ) who had decision-making power in relation to the budget and the programme, and the Co-ordinator. There is now an additional staff member who has remained in Masvingo, while the Coordinator is running the programme and the replication initiatives in Mutare. There were times when the programme was under-staffed and the single dedicated staff member struggled to meet all his commitments. Even now, when the host College for the replication phase (Mutare Technical College) is taking far more responsibility for the programme, and has its own team, there are sometimes capacity problems.

HOW DO YOU GET TEAM MEMBERS TO BUY INTO THE TAP PROCESS?

If this manual has convinced you that the TAP is a real option for your institution or organisation, then we suggest that you give it to those who are likely to be responsible for implementing the TAP in your institution or organisation, and ask them to read it and think about it. Then you need to sit down together and talk about what a TAP would mean for you, and whether it is really a viable option for your institution or organisation. Suggest they read Manual 2 as well, and look at it yourself. The degree of success of your TAP will depend to a large extent on the degree of enthusiasm with which it is implemented. It is not enough to tell team members they "must" implement a TAP; they also need to "want" to implement it.

Some suggestions for getting the team to buy into the idea:

- Be clear about why you think it is a good idea for your institution or organisation to start a TAP.

- Communicate your enthusiasm for the idea, but

- Don't present it as a "have to do", rather

- Present it as an idea that has a lot of merit and which those who might be involved need to discuss together.

- Provide encouragement and support.

- If you are expecting someone to take on TAP responsibilities, make sure you discuss what responsibilities they will be relieved of.

- Make sure that the whole organisation or institution is aware of the new venture, what it is meant to achieve, why it is important, and who will be working on it.

- Give the team an opportunity to share its plans, learnings and achievements with the whole organisation or institution.

Don't impose the idea on those who will have to implement it - rather motivate, encourage and support them to buy into the idea.

SECTION 9: Where can you get support for your efforts to start a TAP?

It is important for you to remember that you are not being asked to reinvent the wheel here - there is extensive international experience in traditional apprenticeship programmes in various forms, and there is also the ISTARN experience, as reflected in these manuals, for you to draw on.

We have included a short bibliography at the end of this manual, so that, if you are interested, you can read more about TAPs.

Our contact details are to be found in the inside front cover of this manual. We look forward to hearing about other attempts to set up TAPs, and are able to offer:

- a consultancy and advice service, based on our own experience of starting TAPs; and, in the near future,

- a set of training modules related to some of the more common trades/skills that feature in TAPs.

All that remains to do is for you to make the decision:

When Are you Going to Start Your TAP?

BIBLIOGRAPHY

This list is intended to guide you to a few additional sources of information about TAPs. We have selected readings we found particularly useful and interesting. The list is by no means comprehensive.

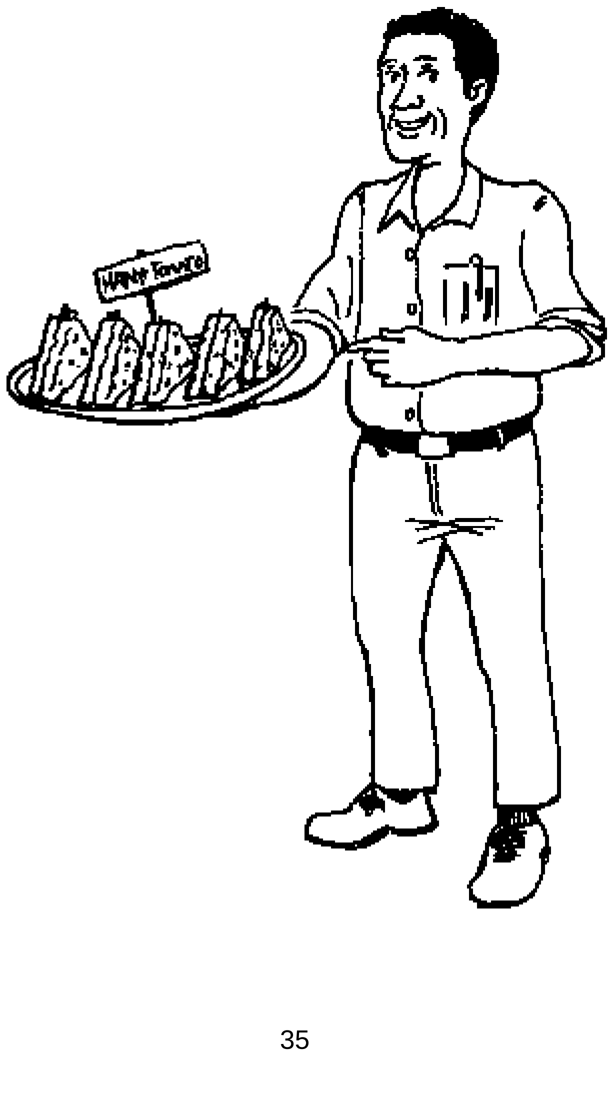
FLUITMAN Fred (1992) Traditional Apprenticeship in West Africa: Recent Evidence and Policy Options. ILO.

GRIERSON John P (1997) Where There is No Job: Vocational Training for self- Employment in Developing Countries. Swiss Centre for Development Co-operation in Technology and Management; The Centre of African Studies, the University of Edinburgh; and the Swiss Agency for Development and Cooperation, Switzerland.

KWASHIWA Daglus, MALCOLM Rosie and CARLTON Andy (1997) Report of a Survey of Informal Sector Enterprises Carried Out by ISTARN. GTZ-ISTARN, Zimbabwe.

MAVUNDUSE Donald (1995) The Existence and Nature of Traditional Apprenticeship in the Informal Sector of Masvingo Province, Zimbabwe: An Assessment of the Credibility of Traditional Apprenticeship as vehicle for Further Training. A Report for the GTZ ISTARN Project, Zimbabwe.

NELL AND SHAPIRO CC (1998) Adding Value: A Formative Case Study of the Traditional Apprenticeship Programme (TAP) of the Informal Sector Training and Resources Network (ISTARN), Masvingo Province, Zimbabwe. Prepared for ISTARN, Zimbabwe.



This manual describes what a Traditional Apprenticeship Programme (TAP) is and what is needed to set one up. It provides information and explanations that should enable decisions makers to decide whether or not a TAP is appropriate in their context.

It is designed for development practitioners and decision makers in organisations such as training colleges, vocational training centres, business associations, non-governmental organisations (NGO's) and private training institutions.

By reading this manual interested institutions and organisations should be able to assess their capacity and suitability to start similar technical training programmes for the informal sector.

If an institution or organisation should decide to go ahead and implement a TAP then it should study the complimentary second manual entitled 'How to set up and run a TAP'.

TECHNISCHE MATHEMATIK METALL

Hermanns- Klemmstein

Besondere Merkmale:
Alle Aufgaben sind textfrei. Die vorhandenen Bilder, Symbole und Zahlen erfordern keine Übersetzungen.
Während in der Lehrerfassung noch Überschriften und Fachwörter erscheinen, tragen die Schüler die vorkommenden Begriffe handschriftlich in die Leerzeilen der Schülerversion ein. Der Unterricht findet in der lokalen Umgangssprache statt.

Auf den **INFORMATIONSBLÄTTERN** zeigt ein Schlüsselbild das neue Thema jeweils in einem typischen Anwendungsbeispiel. Daraus ist eine Formel abzuleiten, die als Regel wörtlich festgehalten wird. Darunter zeigen Rechenbeispiele die wichtigsten Anwendungsvarianten. Abschließend ermöglichen leichte Testaufgaben eine erste Erfolgskontrolle in kürzester Zeit.

Die **AUFGABENBLÄTTER** bieten Probleme mit unterschiedlichem Schwierigkeitsgrad, wobei die Grundformel oft umgestellt werden muß.

Curriculare Anpassung:

Je nach Aufbau der lokalen Lehrpläne sollte die Themenwahl dem lokalen Bedarf angepaßt werden. Diese projektadäquate Auswahl ist vor Ort zu vervielfältigen.

Zur Erinnerung:
Beachten Sie möglichst folgende methodischen Hinweise!

- Fragen Sie die Schüler nach der möglichen Bedeutung des Schlüsselbildes und der darin verschlüsselten Regel!
- Beteiligen Sie möglichst viele Schüler am Lösungsprozeß bei den Aufgaben!
- Geben Sie den Schülern das Resultat der Hausaufgaben, aber kontrollieren Sie das Verständnis des Lösungsweges!
- Benutzen Sie die beiliegenden Modellösungen der Lehrerfassung zum Vergleich!

LEARNING WITHOUT LANGUAGE BARRIERS

TECHNICAL MATHEMATICS FOR METALWORKING

Hermanns - Klemmstein

Special features:

None of the exercises have written instructions. The pictures, symbols and figures do not have to be translated. Whereas the teacher's copy contains headings and subject terminology, the pupils are required to enter terms by hand as they occur, in blank spaces provided in their copies. Teaching takes place in the local vernacular.

On the **INFORMATIONS SHEETS**,a key picture shows a typical application of the new topic. From this, a formula is derived and expressed in words as a generally valid rule. Underneath this, specimen calculations illustrate the principal variations of the application concerned. In conclusion, easy test exercises permit a rapid initial check on success.

The**EXERCISE SHEETS** provide problems of varying degrees of difficulty, often requiring the basic formula to be re-arranged.

Adapting to curriculum:
Depending on the structure of local curricula, the choice of topics should be suited to local needs. The selection deemed appropriate for the project must be duplicated locally to produce the number of copies required.

Reminder:
Whenever possible, comply with the following instructions concerning method:

- Ask pupils about the possible meaning of the key picture and the rule it symbolises!
- Obtain the participation of as many pupils as possible in the process of solving the exercises!
- Inform pupils of homework results, but check that they have understood the correct solution procedure!
- Use the accompanying specimen solutions in the teacher's copy as a means of comparison.

APPRENDRE SANS BARRIERE DE LANGUE

MATHEMATIQUES TECHNIQUES - METAL

Hermanns - Klemmstein

Particularitês:

Aucun exercice n'est accompagnê de texte. Les figures, les symboles et les chiffres ne nêcessitent pas de traduction.
Alors que les exemplaires destinê aux enseignants comportent encore des titres et des termes techniques, les êlêves inscrivent eux-mêmes dans les espaces prêvus â effet les expressions qui se prêsentent. L'enseignement se fait dans la langue du pays.
Sur les **FICHES D'INFORMATION**, le nouveau sujet abordê est annoncê par une figure-clê, dans un example typique d'application. Il faut en dêduire une formule que l'on retient littêralement comme règle. Plus bas, des exemples de calcul prêsentent les applications possibles les plus importantes. Ensuite, des exercices faciles permettent d'effectuer três rapidement un premier control de rêsultats.
Les **FICHES DE PROBLEMES** offrent des exercices de degrês de difficultê divers, obligeant souvent â transformer la formule fondamentale.

Rappel:
Respectez dans la mesure du possible les indications suivantes concernant la mêthode d'enseignement:

- Demandez aux êlêves la signification de la figure-clê et de la rêgle qu'elle reprêsente.
- Faites participer le plus grand nombre possible d'êlêves â la recherche des solutions de ces problêmes.
- Donnez aux êtudiants la solution des exercices qu'ils font â la maison. mais vêrifiez s'ils ont compris le raisonnement.
- Contrôlez en comparant avec les solutions types jointes â l'exemplaire pour enseignants.

MATEMATICAS EN LA TECNICA DEL METAL

Hermanns - Klemmstein

Características:

Todos los ejercicios se presentan sin texto. Los gráficos, símbolos y números del ejercicio no necesitan traducción alguna.
Mientras que en el ejemplar destinado al personal docente aparecen títulos y denominaciones técnicas, los alumnos escriben a mano las denominaciones que vayan apareciendo en las líneas en blanco que se encuentran en al ejemplar destinado al alumno. Las clases tienen lugar en el lenquaje corriente local.
En las **HOJAS INFORMATIVAS** se muestra a través de un gráfico clave el nuevo tema, en un ejemplo típico de aplicacíon. De allí habrá que deducir una fórmula, la cual se resumirá generalmente de modo verbal. Más abajo se presentan en ejemplos de cálculo las variantes más importantes de aplicación. Por fin, se consique en breve tiempo a través de problemas fáciles la verificación de resultados.

Las **HOJAS DE TRABAJO** presentan problemas de dificultad diferente, para los cuales habrá que adaptar frecuentemente la fórmula básica.

Atencion:

Procuren atenerse a las siguientes observaciones de carácter metódico:

- Pregunten Uds. a los alumnos por el posible significado del gráfico clave y de la regla impolicada en el mismo.
- Procuren que participe el mayor número posible de alumnos en la solución de los problemas.
- Comuniquen a los alumnos los resultados de las tareas de casa pero controlen si han comprendido el proceso de cálculo hasta llegar a la solución.
- Utilicen a título comparativo las soluciones modelo adjuntas del ejemplar para el personal docente.

	Nombre de dents		Nūmero de dientes
	Diamètre primitif de référence		Diámetro del cīrculo primitivo
	Empattement		Distancia entre ejes
	Roues menantes		Ruedas de tracciōn
	Roues menées		Ruedas traccionadas
37	Circonférence primitive de référence	37	Perīmetro del cīrculo primitivo
	Trajectoire de la crémaillère		Via de la cremallera
	Roue vis		Rueda helicoidal
	Nombre de spires		Nūmero de filetes
39	Longueur de cône	39	Longitud del cono
	Angle de cône		Angulo del cono
	Angle de mise au point		Angulo de ajuste
	Différence de diamètre		Diferencia de diām.
40	Force maximale	40	Fuerza máxima
	Superficie de la coupe transversale		Superficie de la secciōn transversal
43	Section de cisaillement	43	Superficie de corte

(1) a) $48 - x = 19$

$x = 48 - 19$

$x = 29$

b) $1,5 = 4,83 - x$

$x = 4,83 - 1,5$

$x = 3,33$

(2) a) $30,48 - 12,44 - x = 9,92$

$x = 30,48 - 12,44 - 9,92$

$x = 8,12$

b) $x - 13,64 - 12,8 = 96,4$

$x = 96,4 + 13,64 + 12,8$

$x = 122,84$

(3) a) $4x + 12 = 32$

$4x = 32 - 12$

$4x = \frac{20}{4}$

$x = 5$

b) $80 - 2x = 68$

$2x = 80 - 68$

$x = \frac{12}{2}$

$x = 6$

(4) a) $420 - 44,28 = 280,1 + l$

$l = 420 - 44,28 - 280,1$

$l = 95,62$

b) $100,2 - L = 88,6$

$L = 100,2 - 88,6$

$L = 11,6$

(5) a) $\frac{5''}{8} + x = \frac{9''}{12}$

$x = \frac{9''}{12} - \frac{5''}{8}$

$x = \frac{1''}{8}$

b) $42\frac{3}{4}\,\text{ft} - x = 39\frac{2}{3}\,\text{ft}$

$x = 42\frac{3}{4}\,\text{ft} - 39\frac{2}{3}\,\text{ft}$

$x = 3\frac{1}{12}\,\text{ft}$

(6) a) $422,82\,\text{mm} - 2x = 311\,\text{mm}$

$2x = 422,82\,\text{mm} - 311\,\text{mm}$

$x = \frac{111,82\,\text{mm}}{2}$

$x = 55,91\,\text{mm}$

b) $x - 39,9\,\text{mm} = 60,21\,\text{mm}$

$x = 60,21\,\text{mm} + 39,9\,\text{mm}$

$x = 100,11\,\text{mm}$

(7) a) $\frac{d_1}{2} + \frac{d_2}{2} = a$

$\frac{d_1}{2} = a - \frac{d_2}{2}$

$d_1 = 2a - d_2$

b) $V = V_1 - V_2 + V_3$

$V_3 = V - V_1 + V_2$

(8) a) $a = \frac{d_1}{2} + d_2 + \frac{d_3}{2}$

$d_2 = a - \frac{d_1}{2} - \frac{d_3}{2}$

b) $A = A_1 + A_2 - A_3$

$A_3 = A_1 + A_2 - A$

2.2

(1) a) $\frac{5}{3}x = 12$

$x = \frac{12 \cdot 3}{5}$

$x = 7,2$

b) $9 = \frac{4x}{18}$

$x = \frac{9 \cdot 18}{4}$

$x = 40,5$

(2) a) $120 = \frac{4 \cdot 12}{x}$

$x = \frac{4 \cdot 12}{120}$

$x = 0,4$

b) $\frac{5}{x} = \frac{12}{18}$

$x = \frac{5 \cdot 18}{12}$

$x = 7,5$

(3) a) $100 = \frac{20 \cdot h}{3}$

$h = \frac{100 \cdot 3}{20}$

$h = 15$

b) $300 = \frac{A_m \cdot 50}{3}$

$A_m = \frac{300 \cdot 3}{50}$

$A_m = 18$

(4) a) $628 = \frac{d \cdot 3,14}{2}$

$d = \frac{628 \cdot 2}{3,14}$

$d = 400$

b) $\frac{1}{v_1} = \frac{5}{36}$

$v_1 = \frac{36}{5}$

$v_1 = 7,2$

(5) a) $v = d \cdot \pi \cdot n$

$n = \frac{v}{d \cdot \pi}$

b) $s = m \cdot z \cdot \pi$

$m = \frac{s}{z \cdot \pi}$

(6) a) $F \cdot 2\pi\, r = F_{ax} \cdot P$

$r = \frac{F_{ax} \cdot P}{F \cdot 2\pi}$

b) $i = \frac{z_2 \cdot z_4}{z_1 \cdot z_3}$

$z_1 = \frac{z_2 \cdot z_4}{i \cdot z_3}$

(7) a) $\frac{a}{b} = \frac{h}{l}$

$a \cdot l = h \cdot b$

$b = \frac{a \cdot l}{h}$

b) $W = \frac{F \cdot s}{t}$

$F = \frac{W \cdot t}{s}$

(8) a) $a = \frac{m}{2}(z_1 + z_2)$

$m = \frac{2a}{z_1 + z_2}$

b) $A = \frac{a + b}{2}\, h$

$a + b = \frac{2A}{h}$

$a = \frac{2A}{h} - b$

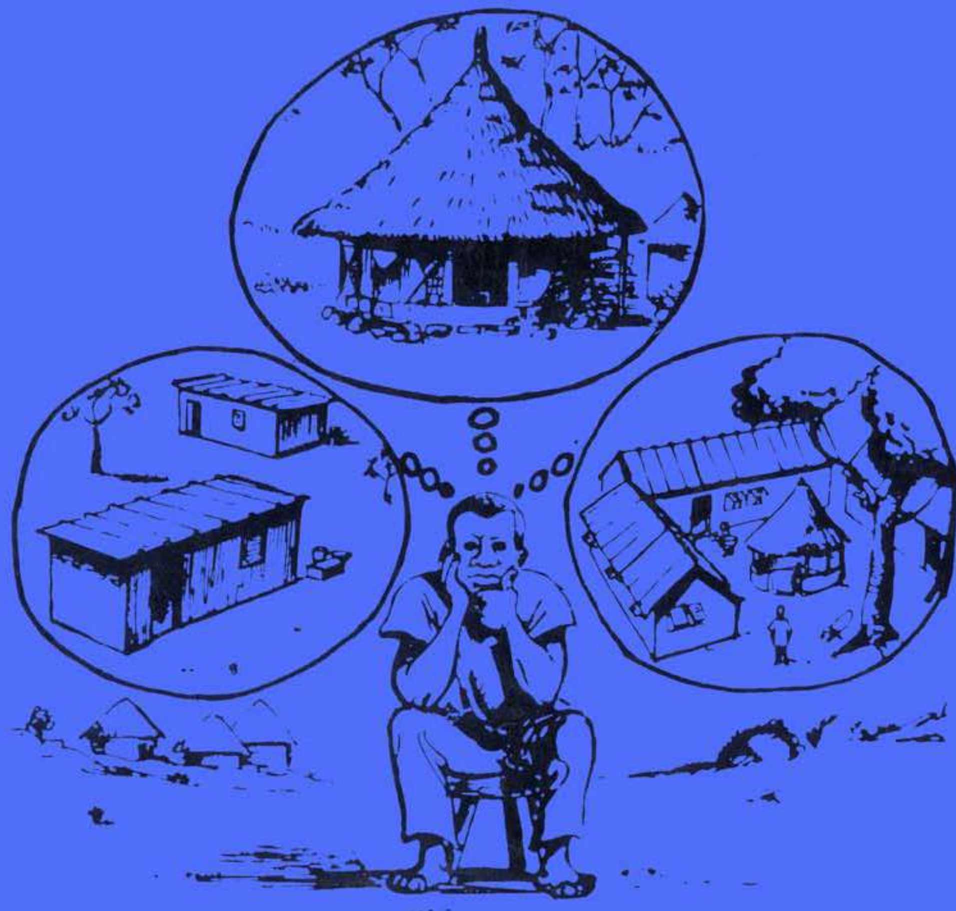
RURAL BUILDING



DRAWING BOOK

PREFACE

This official text book is designed purposely to meet the needs of trainees who are pursuing rural building courses in various training centres administered by the National Vocational Training Institute.

The main aim of this book is to provide much needed trade information in simple language and with illustrations suited to the understanding of the average trainee.

It is the outcome of many years of experiment conducted by the Catholic F.I.C. brothers of the Netherlands, and the German Volunteer Service instructors, in simple building techniques required for a rural community.

The National Vocational Training Institute is very grateful to Brothers John v. Winden and Marcel de Keijzer of F.I.C. and Messrs. Fritz Hohnerlein and Wolfram Pforte for their devoted service in preparing the necessary materials for the book; we are also grateful to the German Volunteer Service and the German Foundation For International Development (DSE) - AUT, who sponsored the publication of this book.

We are confident that the book will be of immense value to the instructors and trainees in our training centres.

DIRECTOR: National Vocational Training Institute, Accra

INTRODUCTION TO A RURAL BUILDING COURSE

Vocational training in Rural Building started in the Nandom Practical Vocational Centre in 1970. Since then this training has developed into an official four year course with a programme emphasis on realistic vocational training.

At the end of 1972 the Rural Building Course was officially recognised by the National Vocational Training Institute. This institute guides and controls all the vocational training in Ghana, supervises the development of crafts, and sets the examinations that are taken at the end of the training periods.

The Rural Building programme combines carpentry and masonry, especially the techniques required for constructing housing and building sanitary and washing facilities, and storage facilities. The course is adapted to suit conditions in the rural areas and will be useful to those interested in rural development, and to farmers and agricultural workers.

While following this course, the instructor should try to foster in the trainee a sense of pride in his traditional way of building and design which is influenced by customs, climate and belief. The trainee should be aware of the requirements of modern society, and the links between old and new techniques, between modern and traditional designs -- and how best to strike a happy medium between the two with regard to considerations like health protection, storage space, sewage, and the water supply. The trainee should be encouraged to judge situations in the light of his own knowledge gained from the course, and to find his own solutions to problems; that is why this course does not provide fixed solutions but rather gives basic technical information. The instructor can adapt the course to the particular situation with which he and the trainee are faced.

This course is the result of many years of work and experimentation with different techniques. The text has been frequently revised to serve all those interested in Rural Development, and it is hoped that this course will be used in many vocational centres and communities. It is also the sincere wish of the founders of this course that the trainees should feel at the completion of their training that they are able to contribute personally to the development of the rural areas, which is of such vital importance to any other general development.

We are grateful to the Brothers F.I.C., the National Vocational Training Institute, and the German Volunteer Service for their support and assistance during the preparation of this course.

Bro. John v. Winden (F.I.C.)

LAY-OUT OF THE RURAL BUILDING COURSE

The Rural Building Course is a block-release -system course, which means that the trainee will be trained in turn at the vocational centre and at the building site. The period of training at the centre is called "off-the-job training", and the period on the building site is called "on-the-job training". Each will last for two years, so that the whole course will take four years and will end with the final test for the National Craftsmanship Certificate.

BLOCK RELEASE SYSTEM

YEAR	TERM 1	TERM 2	TERM 3
1	X	X	X
2	O	O	O
3	O	X	O
4	X	O	X

X = OFF-THE-JOB TRAINING
O = ON-THE-JOB TRAINING

The total "off-the-job" training period lasts approximately 76 weeks, each week 35 hours. During this training about 80% of the time is spent on practical training in the workshop. The remaining 20% of the time is devoted to theoretical instruction.

The total "on-the-job" training period lasts approximately 95 weeks, each week 40 hours. During this period the trainee does full-time practical work related to his course work. In addition some "homework" is assigned by the centre and checked by the instructors.

A set of books has been prepared as an aid to the theoretical training:

- Rural Building, Basic Knowledge (Form 1)
- Rural Building, Construction (Forms 2, 3, 4)
- Rural Building, Drawing Book (Forms 1, 2, 3, 4)
- Rural Building, Reference Book

All these books are related to each other and should be used together. The whole set covers the syllabus for Rural Building and will be used in the preparation for the Grade II, Grade I, and the National Craftsmanship Certificate in Rural Building.

SYLLABUS FOR RURAL BUILDING DRAWING

FORM I

FORM II

FORM III

FORM IV

BOOK INTRODUCTION

The drawing book is divided into four sections, corresponding to the four forms in the Rural Building curriculum.

The lessons are planned to last approximately 90 minutes, during which the instructor should spend some time going over mistakes made in the drawings from previous lessons. Then the instructor can give the introduction to the new lesson, following this by a discussion of the how and why of the lesson. At the end of the session, the instructor should furnish the trainees with the technical data for the new drawing they are assigned for that week. Assignments should be handed in a few days before the next lesson so the instructor has time to correct them and make himself acquainted with the general difficulties which appear as a result.

Tests should be given at intervals. The drawings should then be made within the time specified in the book. The instructor can write the necessary technical data on the blackboard.

In the first part of the book much emphasis is put on the techniques for oblique and orthographic drawings. This kind of drawing has to be mastered early for the trainee to be able to understand drawings made on the blackboard during lessons. Sketching is important because during practicals many explanations are made with the aid of sketches. Plenty of time should be allowed for these exercises, and it is only at the end of the first year that the trainee should attempt drawings of simple frames. The instructor can add other drawings or sketches as needed to help the trainees to understand.

The last three parts of the book are oriented towards the course content for Rural Building. In these parts the trainee will find the lay-out of a whole building from the foundations to the roof construction, with the plans, elevations and cross sections; and building design is discussed as well. Here too, the instructor should feel free to change the sequence of the lessons if necessary to fit them together with the practicals in the workshop. During the lessons the instructor is advised to visit building sites with the trainees so that they can compare the drawings with the actual structures.

Ability to read drawings is also very important and ample time should be spent to help the trainees master this. It is helpful at times to have the trainees exchange drawings and correct each other's work.

DRAWING EQUIPMENT

DRAWING BOARD

A drawing board should be made from well seasoned wood or good quality plywood. One edge of the board -- usually the left edge -- should be very straight so it can be used with the T-square.

T-SQUARE

T-squares are rulers with a cross piece or stock fixed on one end to form the letter "T". The stock is either glued or attached to the blade by screws. Like drawing boards, T-squares should be made from materials which do not warp easily.

SET SQUARES

Set squares are triangular shaped tools which are used with the T-square. Two angles are available; 45 degrees and 60 degrees.

RULERS

Rulers used for drawing have 30 centimetre (cm) scales, subdivided into 300 millimetres (mm).

PENCILS

Pencils used for drawing are usually 2H, 3H, or 4H. The higher the number, the harder the lead. Sharpen pencils with a pocket knife. Cut the wood at a low angle to expose about 7 mm of lead, then sharpen the lead by carefully rubbing it on a piece of sandpaper.

Pencil lines must be fine, light and clear. It is a good habit to rotate the pencil as you draw a line, to keep a sharp point on the lead. When drawing lines follow the instructions on page 3.

DRAWING PINS

Drawing pins are used to fix paper to the board. The pins should have short fine points so that they don't make large holes in the drawing board. The pins should have large flat heads so that they can be removed easily. Because drawing pins can damage the T-square, various types of adhesive (sticky) tapes are often used instead of pins.

THE COMPASS

The compass is a precision instrument used to draw circles. One of the legs has a pointed end; this point must be thin and sharp so that it makes only a small hole in the paper. Especially when drawing small circles, make sure that the pencil point is the same length as the steel pin.

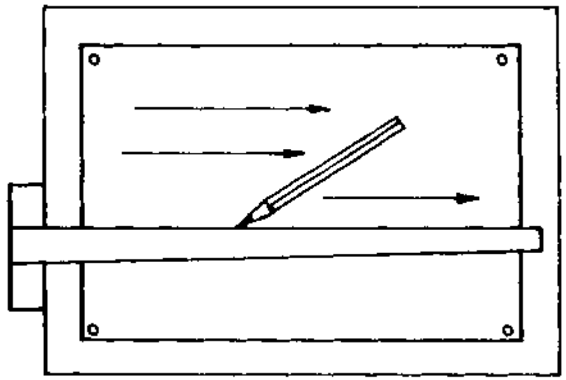
ERASERS

An eraser should be soft and of good quality so it does not damage the paper. The eraser should be used very little, and only with great care. If the corners of the eraser are rounded, it is a good idea to cut one end sharp again if you need to erase very exactly.

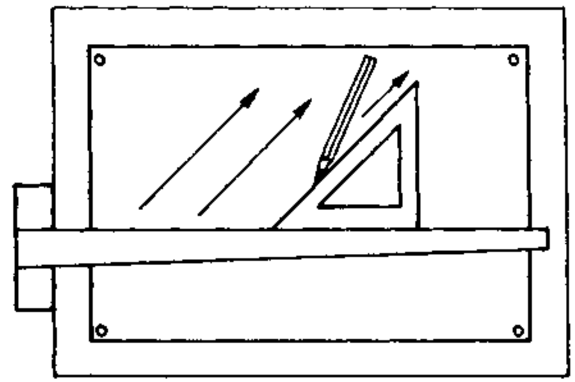
DRAWING PAPER

Drawing paper is special paper and it is cut to standard sizes.

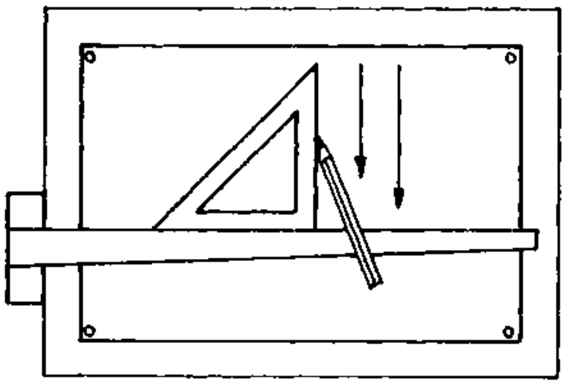
ALWAYS "DRAG" THE PENCIL ---------- NEVER "PUSH" IT



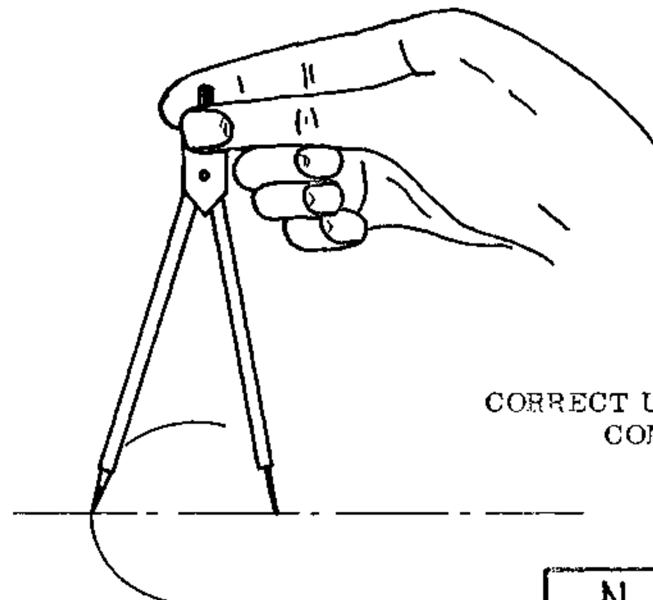
HORIZONTAL LINES



SLANTING LINES



VERTICAL LINES



CORRECT USE OF THE COMPASS

N.P.V.C.

3.

LETTERING

Any writing which is done on a drawing is always in the form of lettering and never in ordinary writing. Make sure that all the lettering on a drawing is the same height, with the exception of the title, which may be in larger capitals.

GUIDELINES

Guidelines are made to show the height and proper alignment of the letters on a drawing. They should be ruled very faintly with a sharp pencil so that they can be erased easily. For pencil lettering use an H or HB pencil.

TYPES OF LINES

Various types of lines are used on drawings; these are shown in the examples on the right.

A- FAINT LINES: These should stand out very fine and clear.

B- VISIBLE OUTLINES: These are bold continous lines and they should stand out clearly.

C- HIDDEN OUTLINES: These are chains of short, sharp lines.

D- SECTION LINES: These show the plane on which an object is cut for the section view.

E- DIMENSION LINES: These lines always have a number on them, giving the length of a part of the object.

F- CENTRE LINES: These show the centre line of an object and are usually used in sketching.

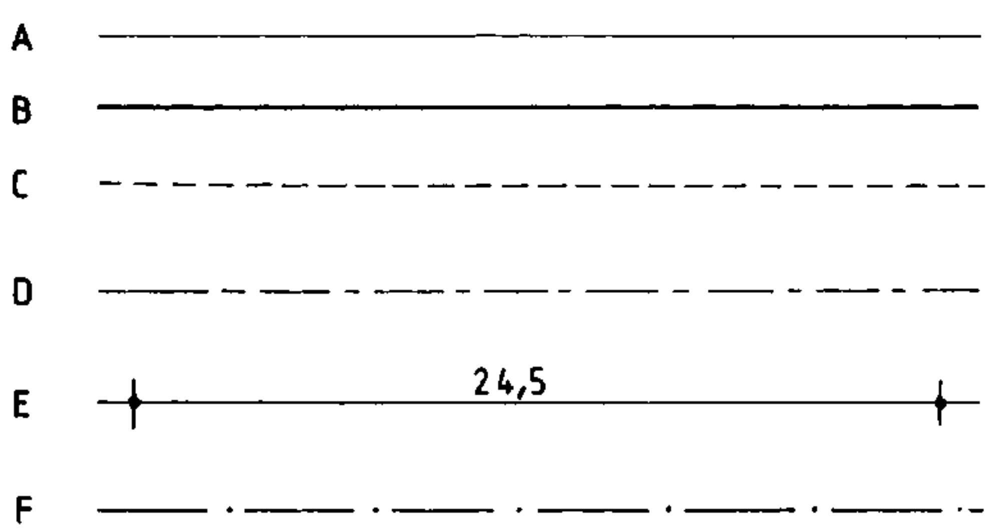
G- RADIUS AND DIAMETER LINES: In drawing circles, two lines are particularly important; these are the radius and diameter of the circle.

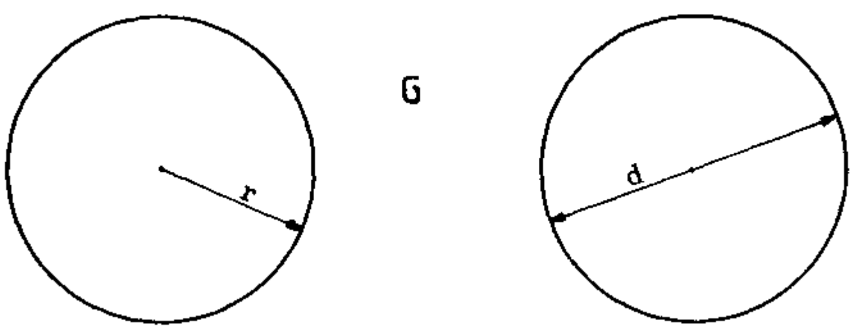
WHICH KIND OF LINES DO YOU SEE IN DRAWINGS 1, 2, AND 3?

ABCDEFGHIJKLMNOPQRSTUVWXYZ

123456789

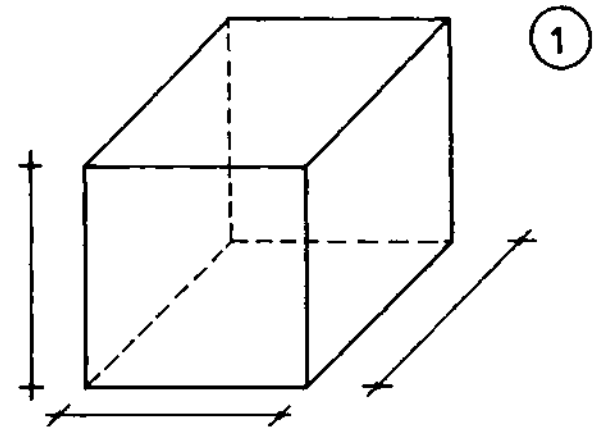
ABCDEFGHIJKLMNOPQRSTUVWXYZ

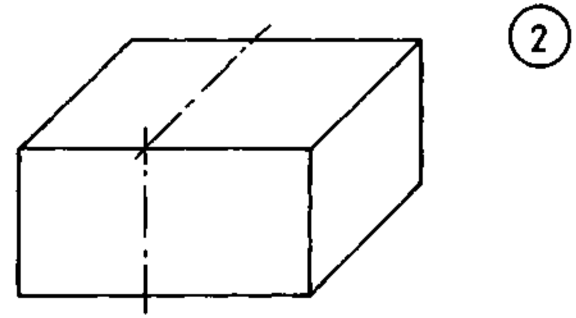


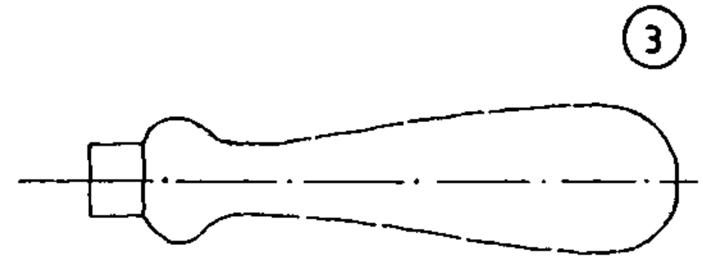


r = RADIUS

d= DIAMETER







N . P . V . C .

5.

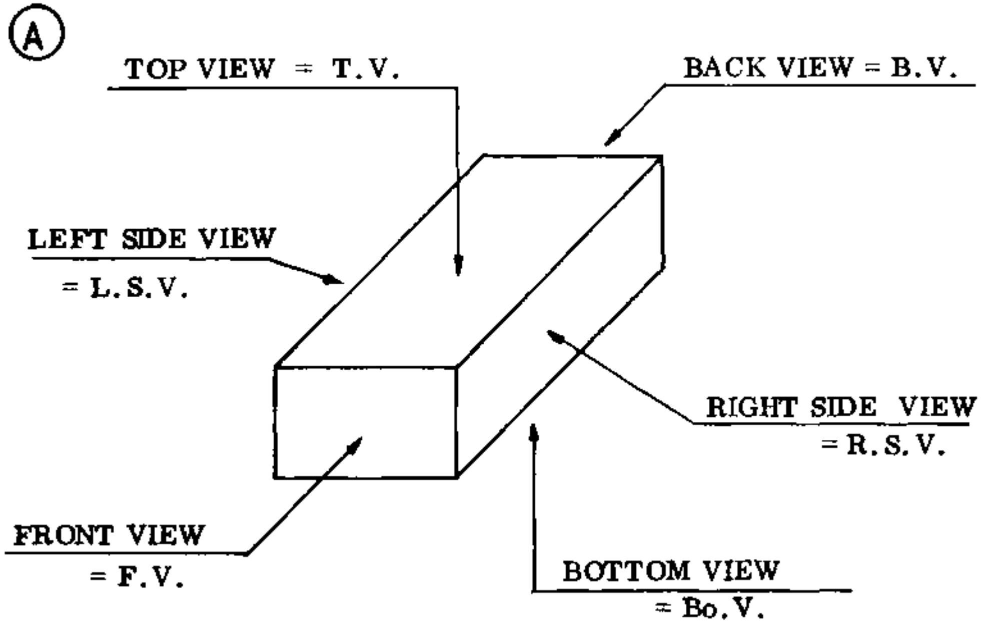
ORTHOGRAPHIC DRAWING

An orthographic drawing shows an object by means of a number of different views. Each view shows one side of the object as it is seen if looked at straight on. The diagram here shows a rectangular solid (A) along with an orthographic drawing of it (B).

- If a certain view will be the same as another view, you need draw only one of the views (compare the left side view and right side view from A).
- If certain measurements on one view are the same as measurements on another view, you should not label these measurements on both views. It is better to arrange the views so it is clear that the measurements are the same. The drawings on the right show how this is done (B & D).

In making an orthographic drawing, it is necessary to first choose the "front view". Any side can be choosen as the front view (even the top!) although it is usual to choose the most important side of the object.

- THE IMPORTANT POINTS TO REMEMBER IN MAKING AN ORTHOGRAPHIC DRAWING ARE:
  - Space the views an even distance apart.
  - Make accurate measurements.
  - Make clear lines. Make sure that the outlines are darker than the dimension lines.
  - The scale, in cm or mm, should be mentioned in the title block of the drawing (see page 9).
  - The lettering must be uniform and clear.
- STUDY: Look at solid A and orthographic drawing B. You need only three views for the drawing. Why is this?
  Look at solid C and orthographic drawing D. Why do you need more views in orthographic drawing D?
- DRAW: Make an orthographic drawing of solid C with side X as the front view.



A
TOP VIEW = T.V.
BACK VIEW = B.V.

ORTHOGRAPHIC DRAWING

N.P.V.C.	
30 MIN.	7.

SETTING OUT THE DRAWING

When you set out the different views of an object on the paper, make sure that they are evenly spaced. Never squash them all on one side. Leave enough space for the necessary titles, sub-titles, and descriptions.

The name of each view should be written on the lower right side of the view. Abbreviations of the view names can be used:

F.V.	= front view	B.V.	= back view
T.V.	= top view	Bo.V.	= bottom view
L.S.V.	= left side view	R.S.V.	= right side view

MARGIN LINE

A margin line should be drawn around the paper, 1 cm from the edge.

DIMENSIONS

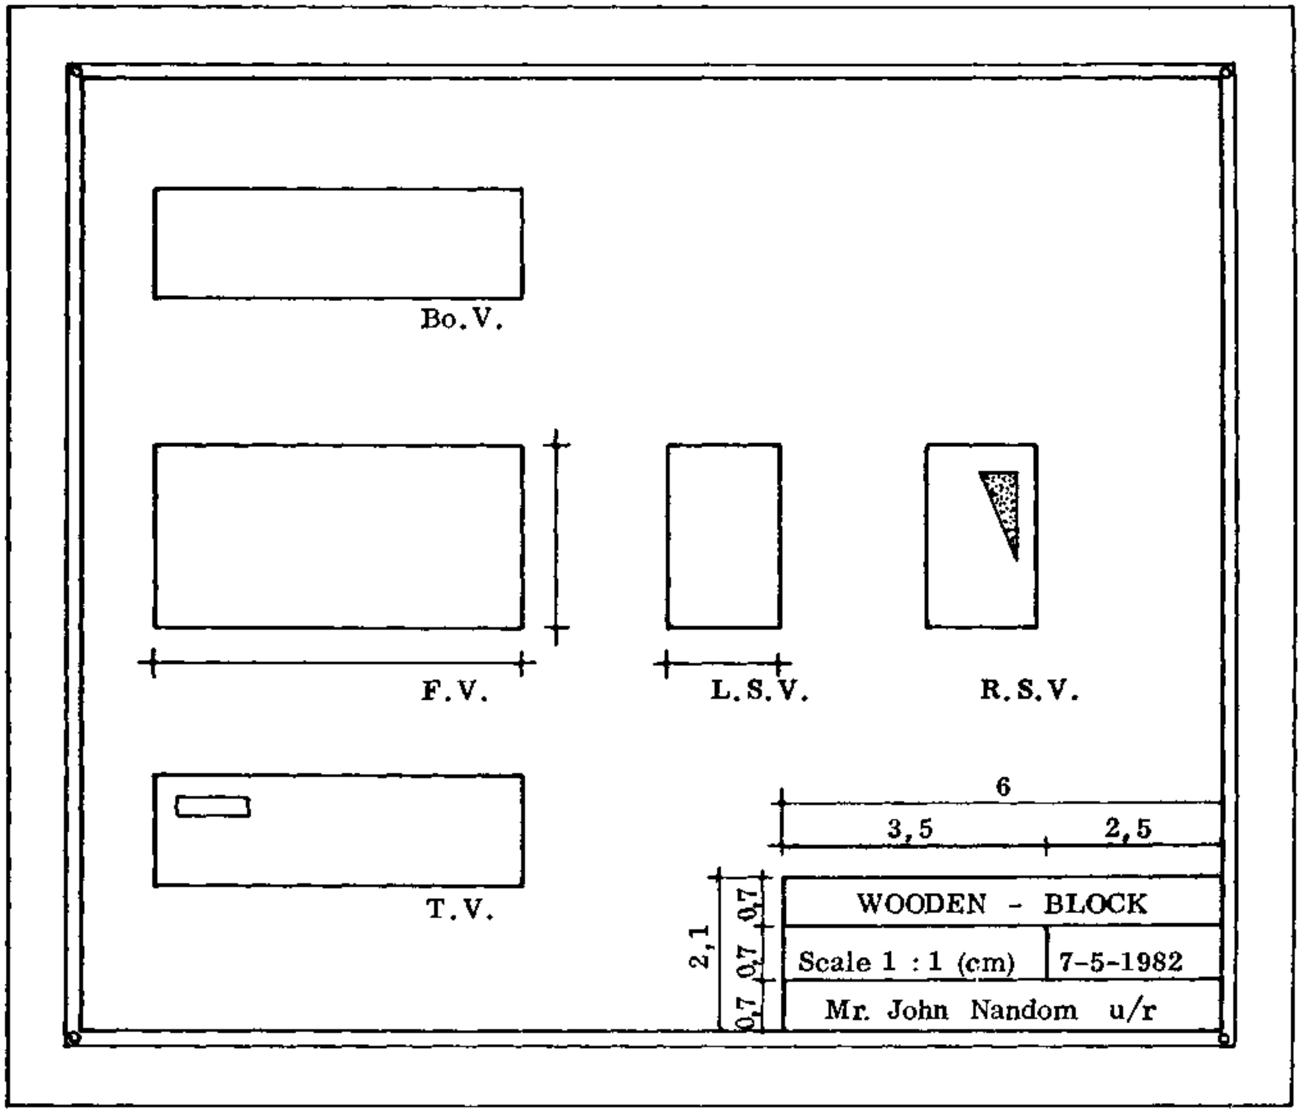
No drawing is complete unless the dimensions or lengths of all the sides are given. The illustration on the right shows how dimensions are given on a drawing. Make sure that no dimensions are left out or repeated.

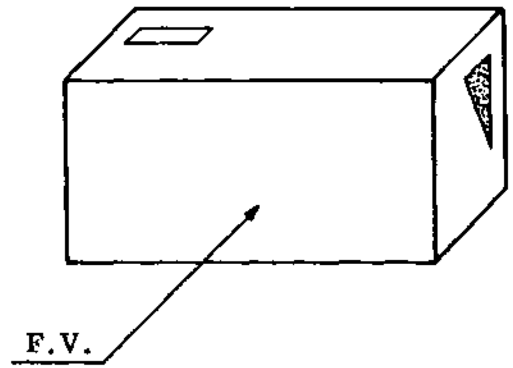
TITLE BLOCK

When the drawing is complete, the last thing that has to be done is to make a title block in the bottom right corner of the paper. The title block gives the title of the drawing, the scale used, the date on which it was drawn, and who drew it. The standard size of the title block is given in the drawing on the right.

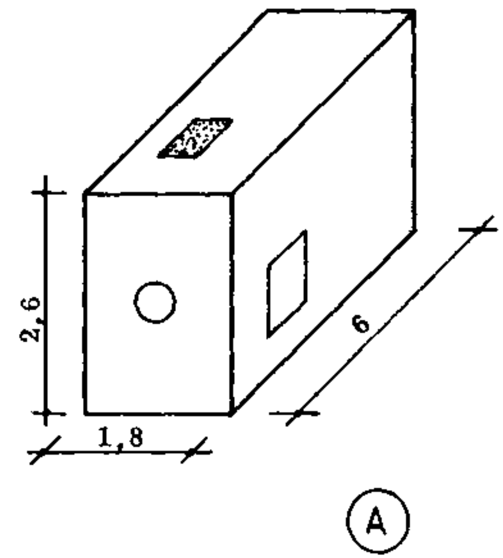
- DRAWING: Make an orthographic drawing of solid A.

CORRECT SPACING OF THE VIEWS





OBLIQUE EXAMPLE



○ = FRONT VIEW

MAKE AN ORTHOGRAPHIC DRAWING OF THIS SOLID.

N . P . V . C .	
40 MIN.	9.

OBLIQUE DRAWING

An oblique drawing is a pictorial representation of an object. The difference between oblique and orthographic drawings is that in oblique drawings the object appears as a single drawing and looks like it does in real life. It is important that you be able to understand both types of drawing and be able to turn one type of drawing into the other.

In oblique drawing one face of the object is drawn in its true shape. This face is always the front view. The rest of the drawing is then built up using three "axes" or directions. One axis is always horizontal (A); another axis is always vertical (B); but the third axis (C) can be at any other angle. It is usual, however, to have the third axis at 45 degrees. These are shown in the illustration on the right.

Oblique drawing can be done step by step.

1 - Choose the front view. Draw it faintly on your paper.
2 - Draw the oblique lines at 45 degrees. Make sure that they are all the same length.
3 - Connect the oblique lines together using vertical lines or horizontal lines as needed.
4 - Erase all unnecessary lines.
5 - Mark all dimensions.
6 - Redraw the outline of the object with an HB pencil to make it darker.

CURVED OBJECTS

An object with a curved surface can easily be shown in an oblique drawing. To do this, draw the shape of the curve in the front view, so that the curve appears in its true shape. Finish off by drawing the oblique lines etc. as usual (see below).

	11.

TECHNIQUES IN OBLIQUE DRAWING

There are some techniques and conventions that you need to know to make good oblique drawings. The most important of these is choosing the best view of the object. The best view is the one that gives you the most information about the object. A good rule to follow is: the best view is the one that is the hardest to draw.

On the next page you can see four different drawings of the same object. They all have the same front view but they are all projected in different directions. You should see that they all give different amounts of information about the object (A).

- Which view gives you the most information?
- Which view is the hardest to draw?

The answer is "B", for both questions.

- CONVENTIONS: All types of drawing have their own conventions. At first the conventions may seem unnecessary, but you will soon find that they all help you to understand a drawing better. One of the most important conventions in oblique drawing is the marking of dimensions. The drawing here (B) shows how this should be done. Remember that the dimensions are given simply as numbers on the drawing itself, and that the unit (cm, mm, etc.) is given in the title block.

  For example: if the length of a block is 6 cm, the dimension in the drawing is given as "6"; and the unit "cm" is recorded in the title block.

- DRAW: Draw or sketch several solids, as in the following pages. Judge which side should be the front view. Decide upon the position in which the solid will be drawn.

SCALE DRAWING

Before you start to make any kind of workpiece, it is necessary to make a drawing showing how it should be made. This drawing is usually called the "layout". When making a layout it is important to use the correct scale. The scale tells you how much bigger or smaller the actual object is, compared to the drawing.

- Large objects have to be drawn smaller than they actually are: in this case you have to use a REDUCED SCALE.
- Very small objects have to be drawn larger than they actually are so that all the details can be seen. In this case you have to use an ENLARGED SCALE.
- If the object is neither very large nor very small, it may be drawn as it actually is. In this case you use FULL SCALE.

SCALES

The scale affects the size of every side of the object in the drawing. Make sure that you draw all lengths, widths, and to the correct scale.

- EXAMPLES OF SCALE: A scale of 1 : 5 (mm) tells you that 1 mm on the drawing represents 5 mm in real life. In other words, the drawing shows the object as 1/5th of its real size, with all dimensions in millimetres.

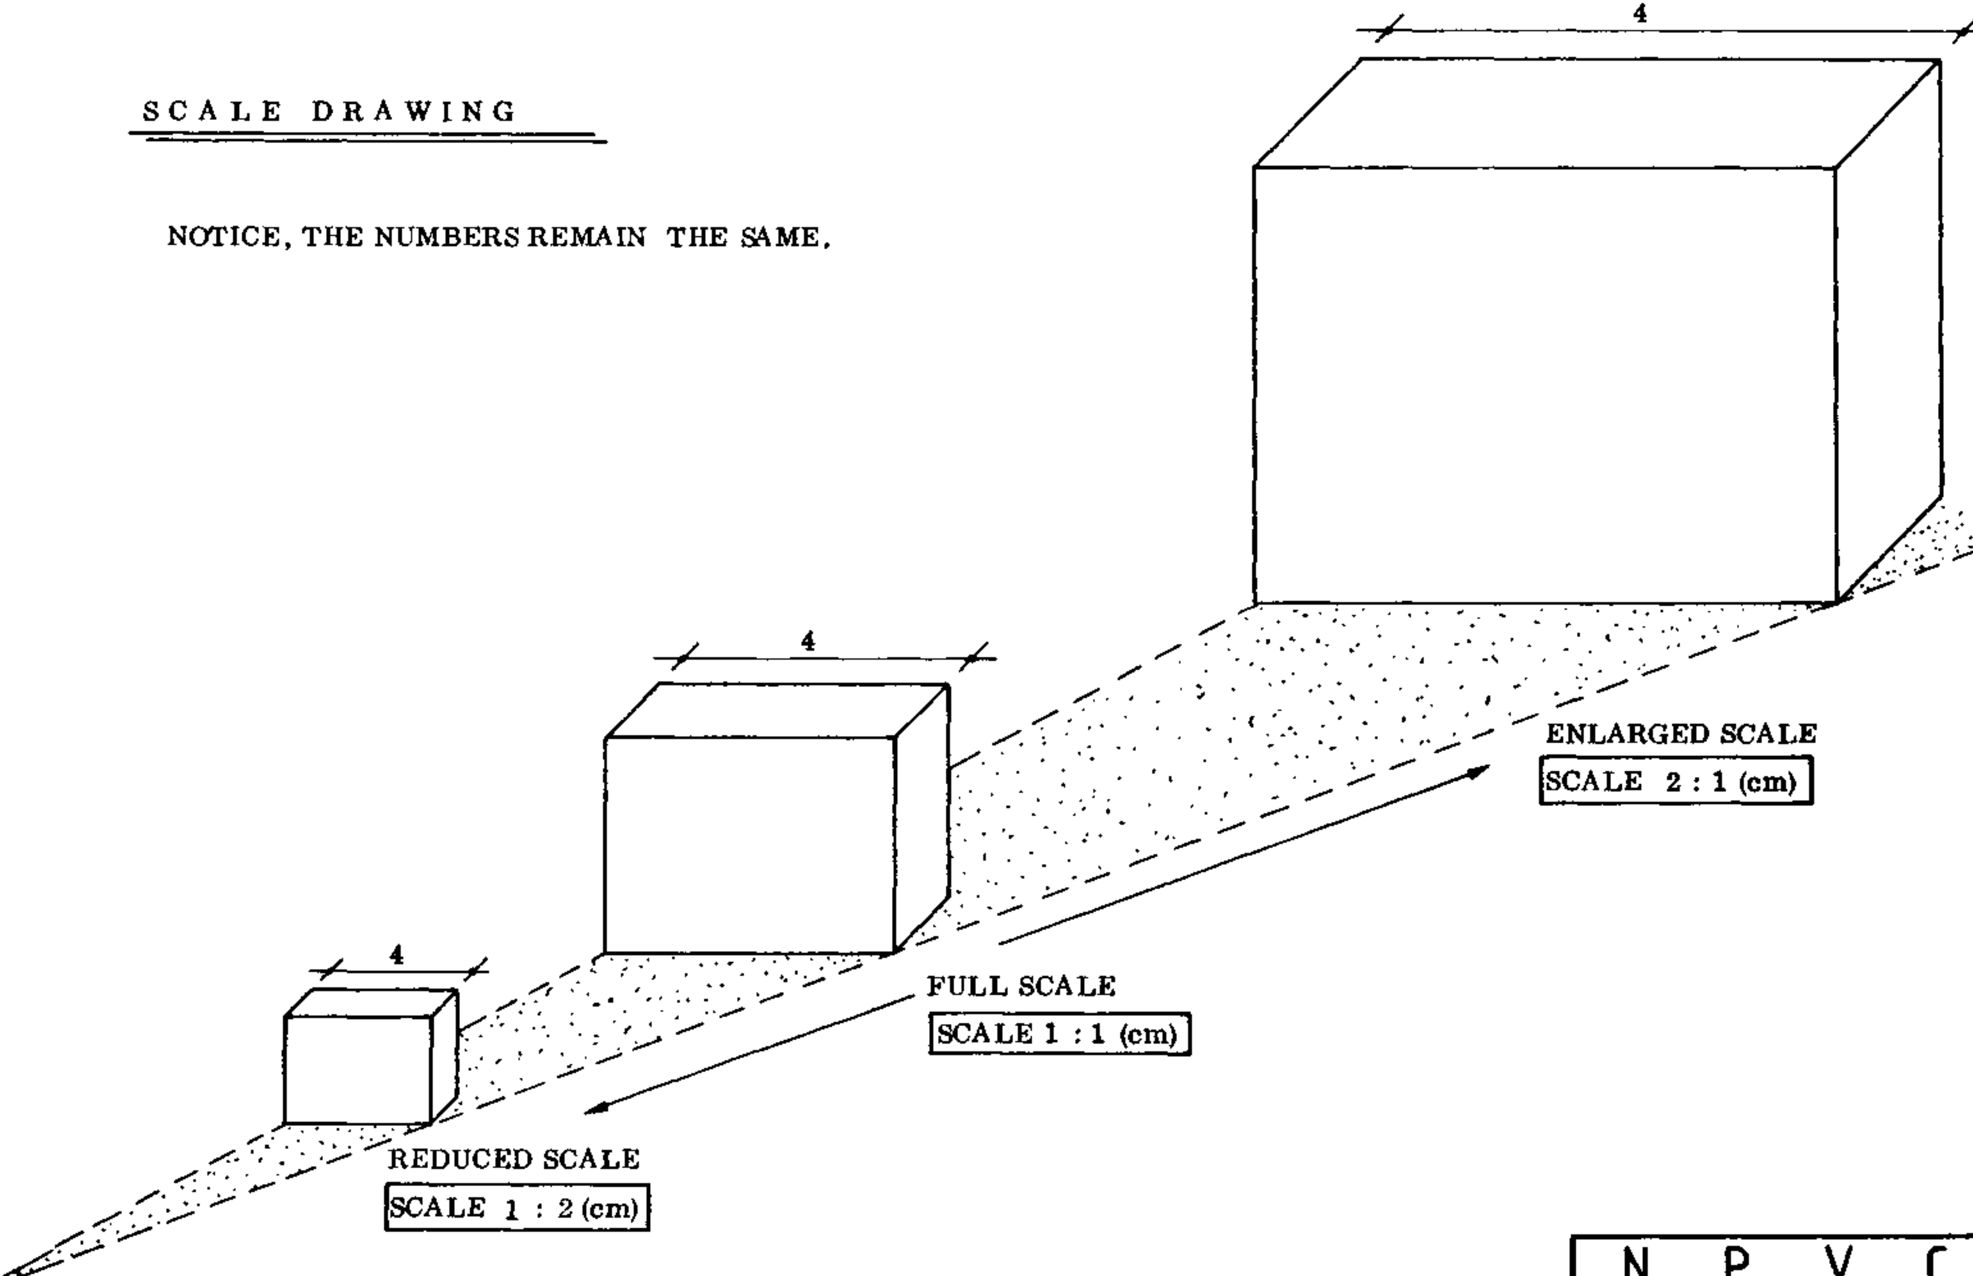
  A scale of 2 : 1 (cm) tells you that 2 cm on the drawing represents 1 cm in real life. In other words, the drawing shows the object as twice its actual size, and all the dimensions are in centimetres.

  What do the scales 1 : 10 (m) and 5 : 1 (cm) tell you?

- COMMON SCALES: Some commonly used scales are 1 : 2; 1 : 5; 1 : 10; 1 : 20; and 1 : 50.

SCALE DRAWING

NOTICE, THE NUMBERS REMAIN THE SAME.



INSIDE AND OUTSIDE DIMENSIONS

If you measure the inside of a box, you will find the measurements are smaller than the outside measurements. This is because of the thicknesses of the sides of the box. Look at the drawing on the next page (A) and note that the outside length of the box is equal to the inside length plus TWICE the thickness of the walls. The same applies to houses: the outside dimensions of a room will always be larger than the inside dimensions.

- EXAMPLE: A box has inside dimensions of 30 x 55 cm and is made of boards which are 3 cm thick. What are the outside dimensions of this box? (see A).

FRAMES

Many articles such as windows and doors can be bought as ready made pieces. These have certain sizes. Both doors and windows usually need a frame around them, and this has to be taken into account when the plans are made for the house.

Figs. B and C on the next page show some ready made articles. Below each you see the same article with a frame around it. In both cases the frame is 6 cm thick.

Fig. B shows a single article such as a casement. The frame goes all the way around the casement, which means that the window opening in the wall must be 12 cm longer and 12 cm higher than the casement itself, so that there is room for the frame.

Fig. C shows a pair of casements. In this case the frame goes all the way around the casements and also between them. This means that the window opening in the wall must be 18 cm longer and 12 cm higher than the casement itself.

EXERCISE: IN AND OUTSIDE DIMENSIONS

N. P. V. C.

DESIGNING FROM SKETCHES

You will often have people coming to you with a rough sketch of something they want you to make, for example a set of casements. In order to make the frame around the casements and to know the size of the opening which has to be made in the wall, there are two important things to notice about most rough sketches:

- The dimensions are the outside dimensions of the casements.
- The thickness of the frame has been left out.

Someone may come to you with a rough sketch of a complicated box with many partitions. In order to be able to construct the box, you have to notice two important things about the sketch:

- The dimensions are the inside dimensions of the partitions.
- The thickness of the partitions and the sides of the box has been left out.

As a craftsman you have to turn these types of sketches into good plans. The plans you draw should have inside and outside dimensions, as well as the thicknesses of the members of the frame or partitions.

- BUILD UP YOUR PLAN IN THE FOLLOWING WAY:
  - Draw two planning lines, one vertical and one horizontal (lines A and B).
  - On line A, start at the left and mark the thickness of the frame member; then the width of the casement. Next mark the thickness of the central frame member and then the width of the right casement. Finally mark the thickness of the right frame member.
  - Starting from the bottom, do the same thing on line B. Your marks should indicate in order: frame; casement; frame; casement; frame; casement; frame.
  - Transfer lines A and B onto your drawing paper so that they form a right angle (page 28).
  - You should now be able to finish the drawing as shown on page 29.

In the original sketch here, it looks as though the large space at the top of the sketch was 259 cm long. On your final drawing you will see that it is 269 cm long. Can you see why?

SKETCHING

You will often find that you will have to make a rough drawing in which accurate dimensions are not really necessary. In this case it is usually best to make a sketch. To sketch means to make a drawing without using drawing instruments like rulers, etc. You will find that this type of drawing is much quicker than technical drawing with the drawing instruments. However, sketching is probably harder than technical drawing, especially at first. It requires a steady hand, a sense for proportions, and an appreciation of detail.

Sketching is the art of putting ideas into pictures and is especially useful for understanding technical drawings and making rough plans.

The only equipment you need for sketching is an H pencil, an eraser, and some paper. Use plain paper for sketching.

- TECHNIQUE: Practice makes perfect. Practice drawing straight lines and curves. After a while you will find that your straight lines look almost as if they were drawn with a ruler! On the next page you can see the best way to draw horizontal, vertical, and inclined lines, and the best way to draw a circle.

- REMEMBER:

  - Take your time while sketching, be careful.
  - Don't try to draw long lines with one motion.
  - Rest only the side of your hand on the paper.
  - Don't turn the paper while you are sketching. You should be able to draw all your lines with the paper in the same position.

KEEP YOUR WORK BOLD , CLEAR AND CLEAN
THIS BOOK WILL BE YOUR PRIDE , AND GUIDE TO ALL
YOU'VE LEARNT AND SEEN .

FORM 2: GENERAL BUILDING INFORMATION

The important rules for a Rural Builder to remember in general are:

- PLAN CAREFULLY EVERYTHING THAT YOU MAKE OR BUILD.
- DRAW ALL IDEAS OUT ON PAPER FOR THE BENEFIT OF THOSE WHO WILL HAVE A PART IN THE PROJECT BEFORE, DURING AND AFTER CONSTRUCTION.
- ALWAYS TAKE INTO ACCOUNT MATERIALS WHICH ARE LOCALLY AVAILABLE, AND WHEN POSSIBLE USE THESE RATHER THAN EXPENSIVE IMPORTED MATERIALS.
- TAKE INTO ACCOUNT THE SIZES OF READY-MADE MATERIALS WHEN YOU ARE PLANNING THE BUILDING.
- BE AWARE OF THE REQUIREMENTS OF THE ENVIRONMENT AND THE LOCAL CUSTOMS.

Drawings should be precise and clear and should take account of the sizes of all the ready-made materials, so as to avoid unnecessary waste. It is therefore important to be informed about all the materials which are available for Rural Building, and their sizes. These can be found in the Reference Book, Materials and Products sections.

Remember that a building is an investment and the construction should be long-lasting. Proper construction, using good materials, will avoid unnecessary expense, inefficiency, and dissatisfaction.

As a rule, mistakes in design or construction are costly, obvious, and permanent.

SCALE

When you draw a plan of a building on paper you will find that you have to use a scale, to make the plan small enough to fit on the paper. Scales were explained earlier, but here are some examples to help you remember how to use them.

- EXAMPLES: A scale of 1:50 (cm) tells you that 1 cm on the drawing represents 50 cm in real life. In other words all the dimensions on the drawing are 1/50th of their real size and all the dimensions are in centimetres.

  A scale of 1: 500 (cm) tells you that all the dimensions on the drawing are 1/500th of their real size and that all the dimensions are in centimetres.

  Both of these scales make the drawing smaller than the actual building size. These types of scales are called "reduced scales".

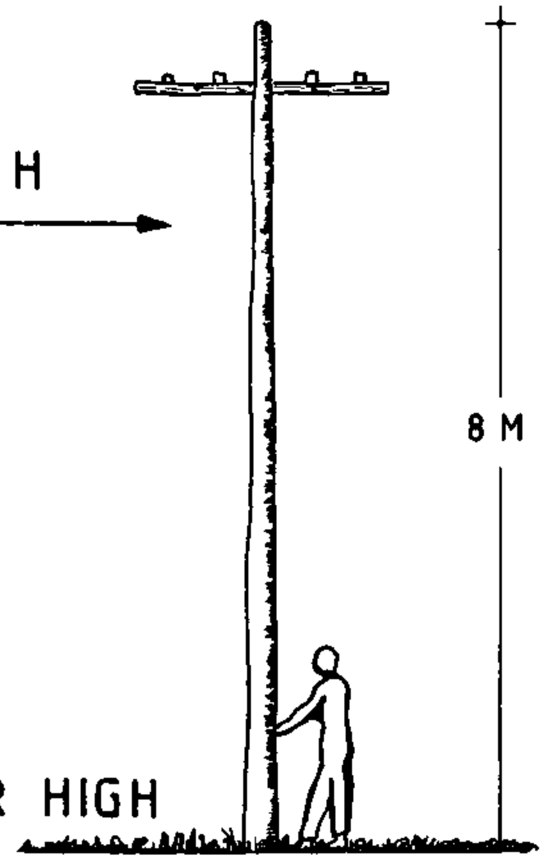
  The man you see on the next page is making a scale drawing of an electricity pole. The pole is 800 cm high and the man is using a scale of 1 : 100 (cm) which means that his drawing will be 8 cm high. The 8 cm on the drawing represents 800 cm in real life.

  If the crossbar on the pole is 150 cm long, how long will the man draw it on his paper?

All building drawings are made in reduced scale. Here are some examples of drawings used in building, and the scales commonly used with them:

- LOCATION PLAN	1 : 500
- DESIGN DRAWING	1 : 100
- FINAL DRAWING	1 : 50
- DETAIL DRAWING	1 : 20; 1 : 10, or 1 : 5

Always remember to include the UNITS of the scale you have used; these are usually "cm" or "mm".



IF THIS POLE IS 8 METER HIGH

AND

IS DRAWN

8 CENTIMETER HIGH

THEN THE POLE IS DRAWN

SCALE 1:100 (cm)

WORKING DRAWINGS

Three different types of drawings are needed to show the builder exactly how the building should look, on the inside and the outside. These include the elevations and sections, as well as the plans. Here we describe the different types of plans which have to be made: the foundation plan, floor plan, and roof plan.

- FOUNDATION PLAN: A foundation plan, along with its sections, shows the builder how deep the foundations should be laid and gives all the dimensions for the foundation and the footings. Sometimes the corners of the rising walls are indicated on the footings.
- FLOOR PLAN: This plan should show the builder the size of the building and the verandahs, the thickness of the walls, and where to place the doors and windows. It also shows which way the doors are meant to open.
- ROOF PLAN: Roof plans are made to show the builder what shape the roof should be and how it is to be built. The roof plan should contain such information as the angle of the roof, the shape, and the materials to be used.

The drawing here illustrates the types of plans and what it is they show to the builder.

Elevations and cross sections are of course essential parts of the working drawings. These are examined in detail after some further examples of plans in the next pages.

N . P . V . C .	
1 ½ HOURS	58.

ELEVATIONS

A special type of drawing is used to show what a building will look like from the outside. These drawings are called "elevations" and they show what you would see if you looked straight on at the side of the house. Of course a house has more than one side, and so there are always a number of elevations. There are as many elevations as there are sides of the house. Houses usually have four sides and so there are usually four elevations.

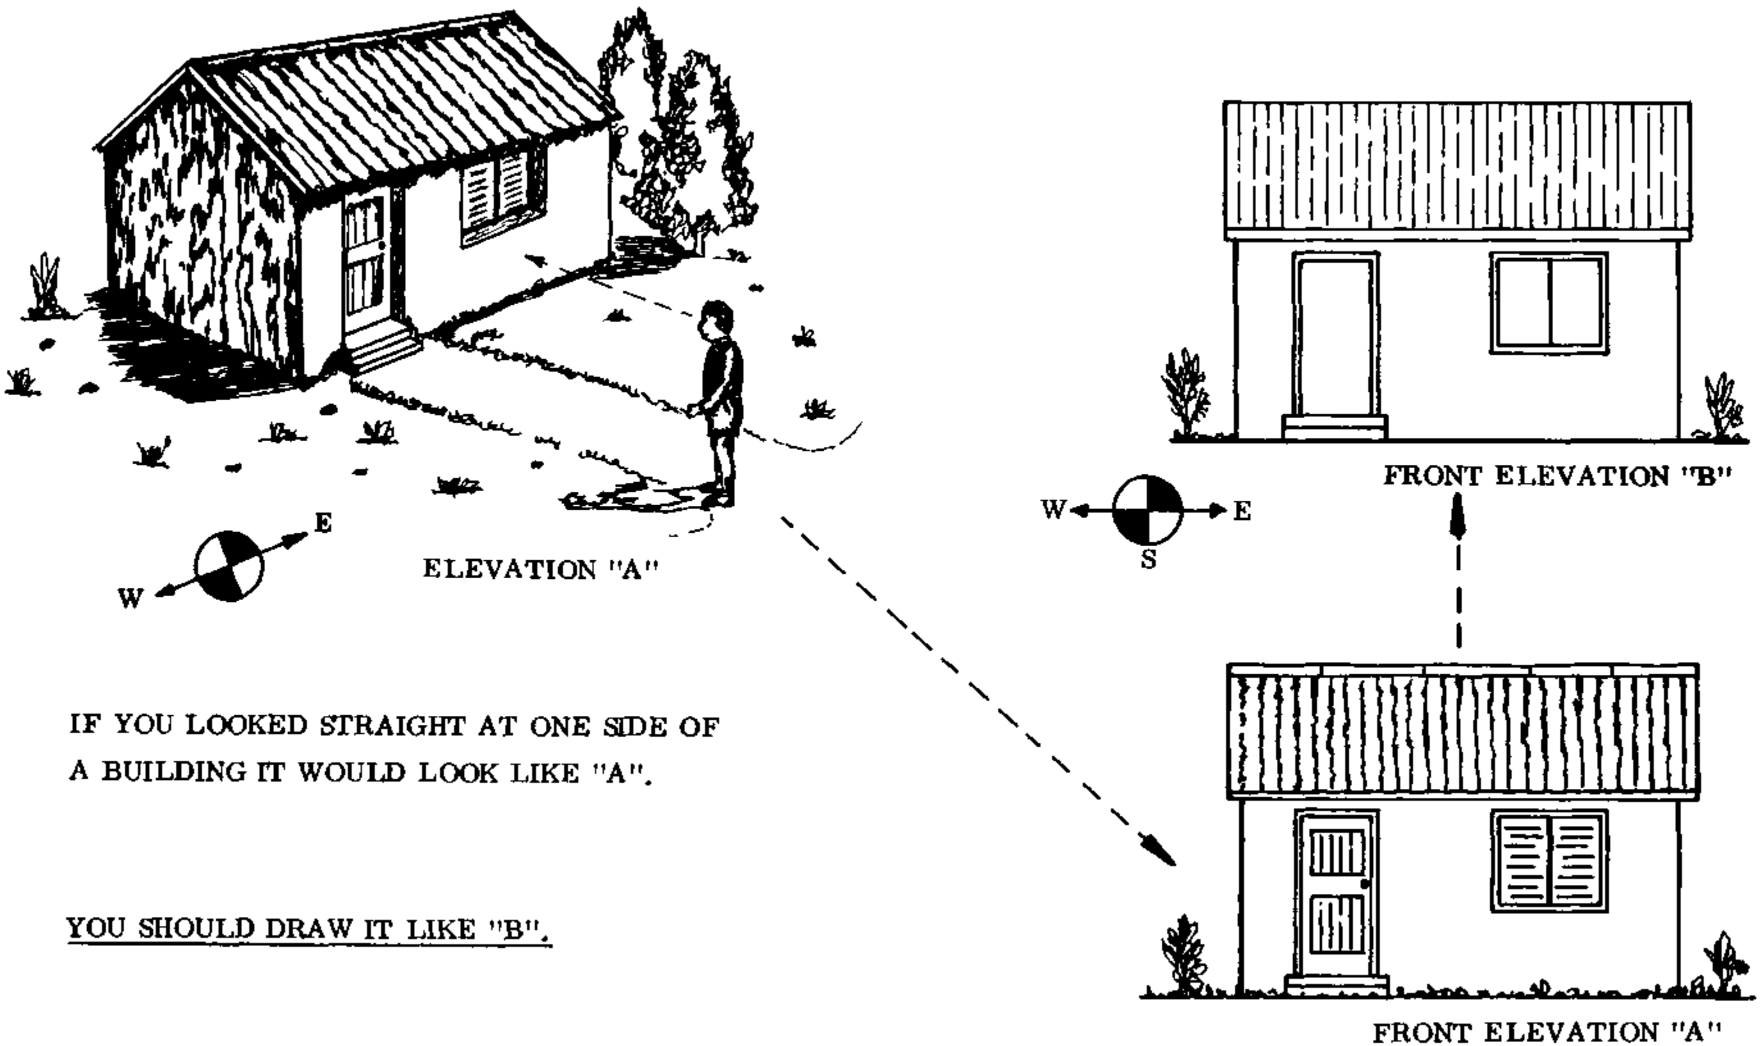
It is not always necessary to draw all the possible elevations of a building, especially if some of the sides look very similar to each other.

The drawing here shows the front elevation of a small house. You should notice that the sides of the house are not drawn. This is because if you stand directly in front of the house you cannot see the sides. The front elevation shows the sizes and positions of the doors and windows as well as the height and length of the house itself.

The building shown on the next page faces south. The front elevation is therefore called the "south elevation". The other three elevations are the east elevation, the north elevation, and the west elevation.

In general only main features are shown on the elevations. Small details of the doors, windows, etc. are given in the detail drawings.

ELEVATIONS



IF YOU LOOKED STRAIGHT AT ONE SIDE OF A BUILDING IT WOULD LOOK LIKE "A".

YOU SHOULD DRAW IT LIKE "B".

N . P . V . C .	
	60.

SECTIONS

Suppose you were able to cut right through a building and then take away one part. What you would see would look something like the diagram on the next page (1). If you now look at the building straight on, you will see a "cross section" of the building (2). The cross section shows the insides of the roof and the room as well as the footings and foundations.

Sections are useful because they give a lot of information about the building which is not found in the elevations and the plans. For example, on a section you can see the height of a room inside the building, the thickness of the ceiling, and the floor and roof construction. You can also see the thickness and width of the foundation, which is not given in the plans and elevations.

- CHOOSING SECTIONS: You will usually find it necessary to take at least two sections through the building. You can take any section through any part of the building, but of course the best sections are the ones which are the hardest to draw! When you take a section through a building, you have to mark on the plan exactly where you have "cut" and the direction from which you look at the section.

  On the right page you can see the conventional way of doing this. The place where the building is cut is marked by a broken line which has arrows at its ends to show which way the section faces. All sections should be marked on the plan, and you should label each end of the line with a letter. On the plan here, the section has the letter "A" at each end. When this cross section is drawn, it is labelled as "cross section A-A". The next section would be "cross section B-B" etc.

BUILDING DESIGN

You have some general technical information about building. Now you can try to make your own designs, with the aid of the basic outlines on the next pages. Keep in mind all that you know about building, and follow a policy of design:

GENERAL POLICY

Plan for the future in your design. Perhaps it may not be possible to build the entire building at once; it may be completed section by section as funds become available. The building can be planned as a whole, properly constructed piece, and then built up over the years. It is better to design what is actually needed than to design something which is not adequate and have to change it, or even abandon it when it cannot be changed into the desired structure.

Remember that a building is a lasting structure. Try to think ahead and lay out the site and the building with the future requirements in mind. Also keep in mind the points listed on page 96. Think about how people do these daily things and design around their needs.

NOTES:

DESIGN POLICY

- EFFICIENCY: This is so that the whole structure will function as it is meant to do. There should be sufficient room for all the activities and for furniture and whatever equipment is needed. Provide ventilation, privacy, protection against insects, and pay attention to water and sewage problems.
- DURABILITY: The building should withstand the stresses of its own weight, and the outside forces such as wind. It should be as protected as possible against attack from weather, dampness, insects, and the normal wear and tear of use. Keep in mind the climate and its influences, and choose your materials with some thought to their durability.
- ECONOMY: Design and erect buildings economically. Plan ahead and have the materials ready to go through with whatever section has been planned. Knowledge about materials, their quality and durability prevents much waste.
- FINISH: Finish the whole as attractively as possible. Finishes not only improve appearance, but they are usually preservatives as well. Appropriate colours make the building pleasant as well as cooler.

NOTES:

LOCATION PLAN

The illustration on the right page shows a piece of land as it looks from the ground, and how it would look if you were above it in an aeroplane looking down. The view you would see from the plane resembles the plan.

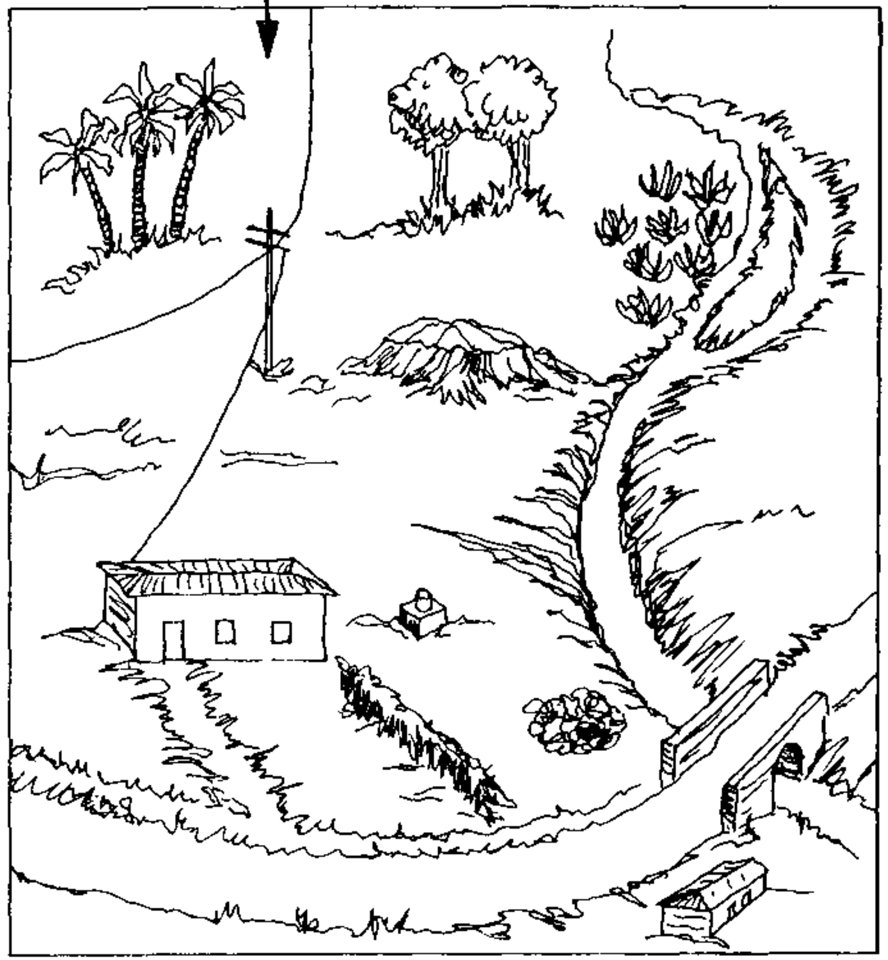
A plan tells you all the things which are on the site such as buildings, trees, roads, streams, bridges; and where all of these are located. The plan also shows the orientation of all these features with respect to directions: north, south, east and west; and how the surface of the ground slopes.

It is impossible to properly plan a building without a great deal of knowledge about the land on which it is to be built. The plan is essential to help the builder to design a building which will fit into the surroundings in the most economical and convenient way.

If a building is planned without taking into account the basic information contained in the location plan, it may turn out to be the wrong shape to fit the site. It may be more costly to build because it is not placed correctly along the "contours" of the land. It may be uncomfortable to live in if it is facing into the hot afternoon sun. It may be hard to reach if there is not a good entrance way from the road.

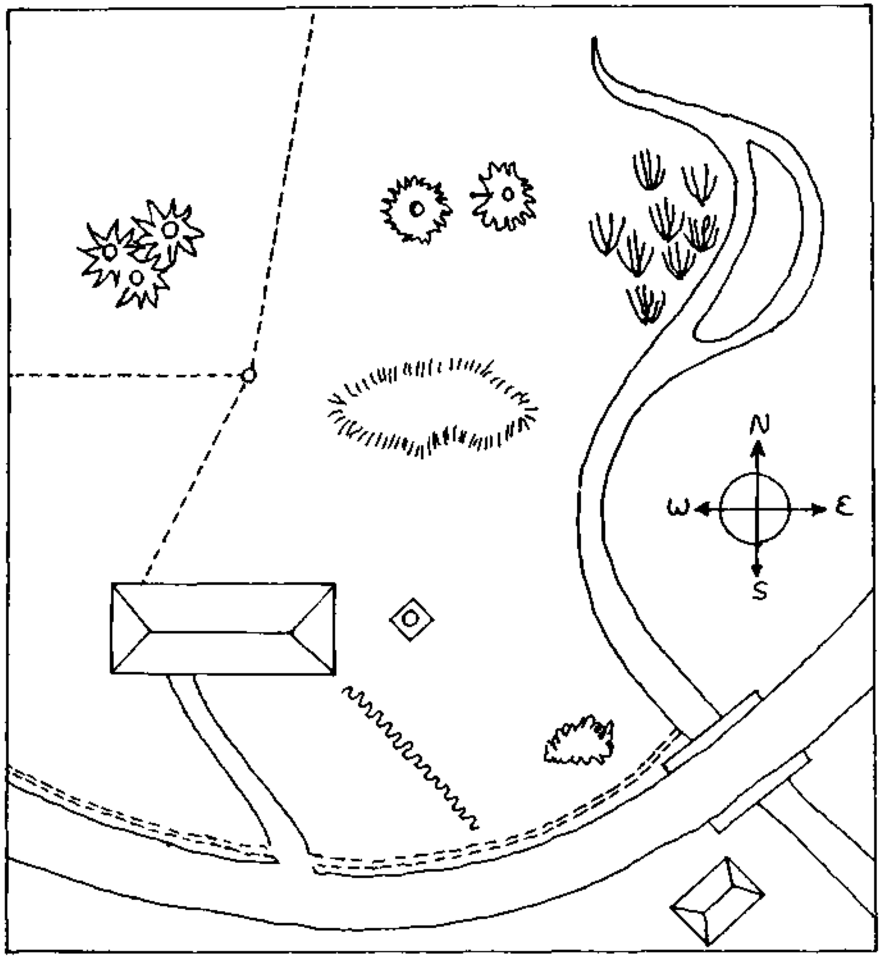
The following pages contain some information about the factors which need to be considered about the site when you are planning a building. These include the measurements of the site and plot, the building regulations and restrictions, the direction of the breeze and of storms, the slope of the site, the direction of the sun's rays at different times of day: all of these need to be considered when planning so that the building will be comfortable to live in and economical to build.

IF YOU LOOK DOWN FROM AN AEROPLANE:



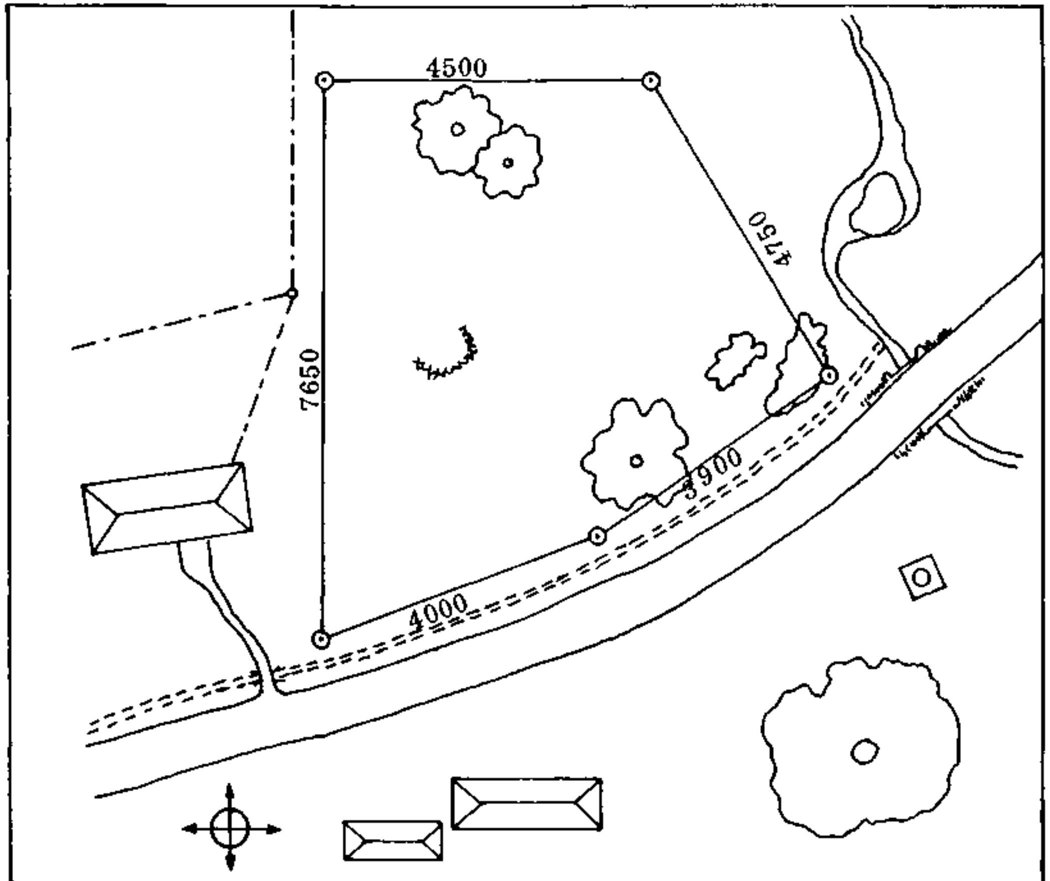
PICTORIAL VIEW

YOU WOULD SEE ONLY THE ROOFS OF THE BUILDINGS AND THE TOPS OF THE TREES, SO THE VIEW YOU WOULD SEE IS LIKE THIS:

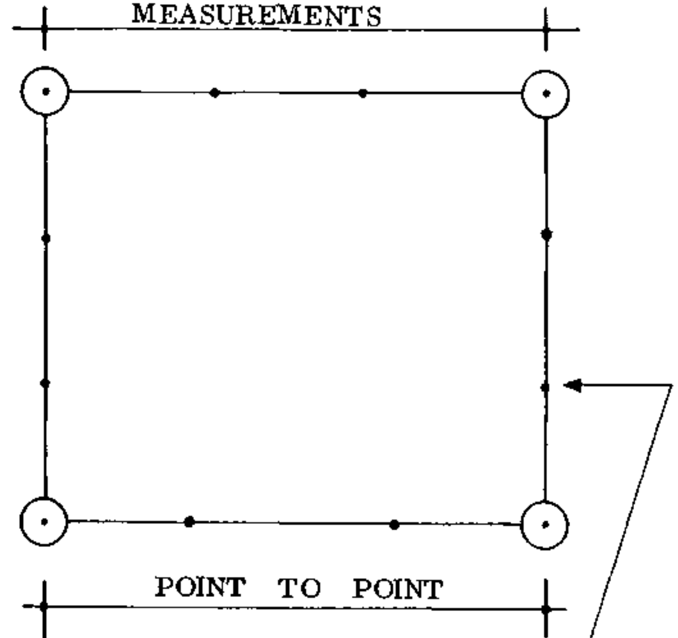


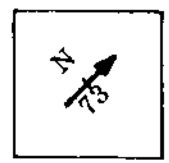
THIS VIEW IS A PLAN OF THE LAND AND MAY BE CALLED A MAP OR SURVEY PLAN.

BOUNDARY LINE



SCALE : 1 : 1000 (cm) PLAN No 145 - B



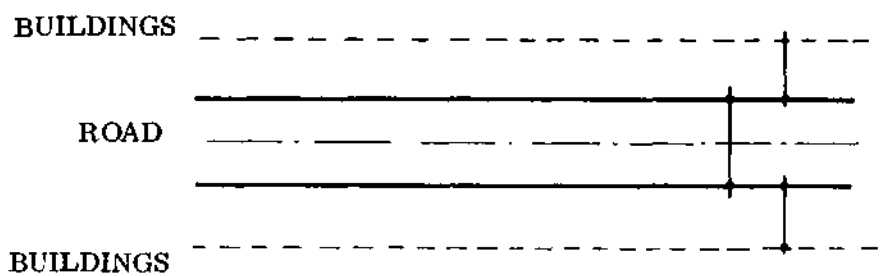


"BOUNDARY STONE". THE ARROW IS FACING THE NORTH. THE NEXT STONE IS 73 METRES AWAY.

SITE PLANS HAVE THE LENGTHS WRITTEN ALONG THE BOUNDARIES SO THAT THE EXACT LOCATION OF THE PLOT IS KNOWN.

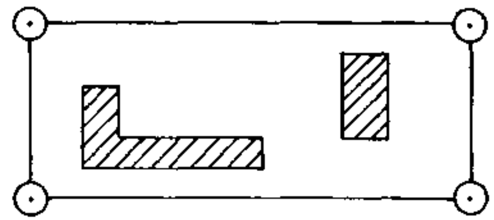
N.P.V.C.	
101.	

BUILDING LINE



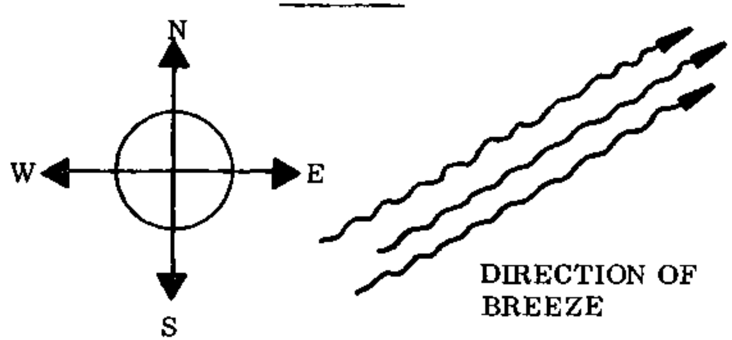
IN PLANNED TOWNS NO BUILDING IS ALLOWED TO REACH TO THE EDGE OF THE ROAD: A BUILDING HAS TO BE A CERTAIN DISTANCE AWAY FROM THE ROAD TO ALLOW FOR FUTURE ROAD WIDENING AND SO THAT THERE IS ENOUGH SPACE BETWEEN BUILDINGS.

SITE COVERAGE



IN SOME TOWNS THERE ARE RULES ABOUT HOW MUCH LAND CAN BE BUILT OVER: FOR SO MANY SQUARE METRES OF LAND, THE BUILDINGS CAN TAKE UP ONLY A CERTAIN AMOUNT OF THE SPACE. IN ADDITION, THE BUILDINGS USUALLY HAVE TO BE A CERTAIN DISTANCE AWAY FROM THE PLOT BOUNDARIES. THIS IS TO MAKE SURE THAT THE BUILDINGS WILL HAVE PLENTY OF LIGHT AND AIR SO THEY ARE HEALTHY TO LIVE IN.

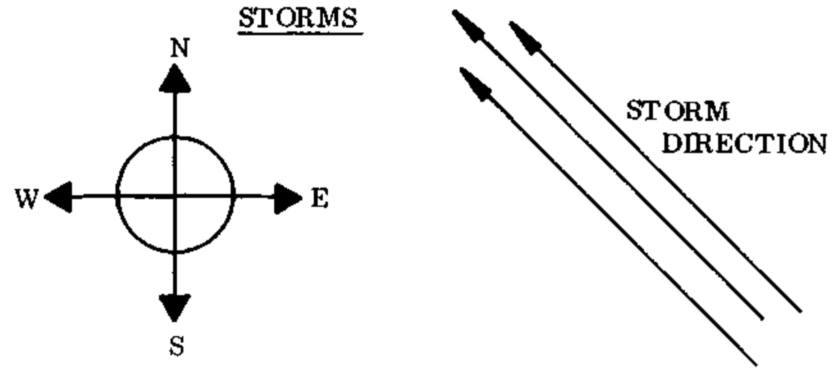
BREEZE



IN HOT WET CLIMATES, IT IS IMPORTANT TO HAVE A BREEZE BLOWING THROUGH THE BUILDING SO THAT THE PEOPLE INSIDE ARE COOLER.

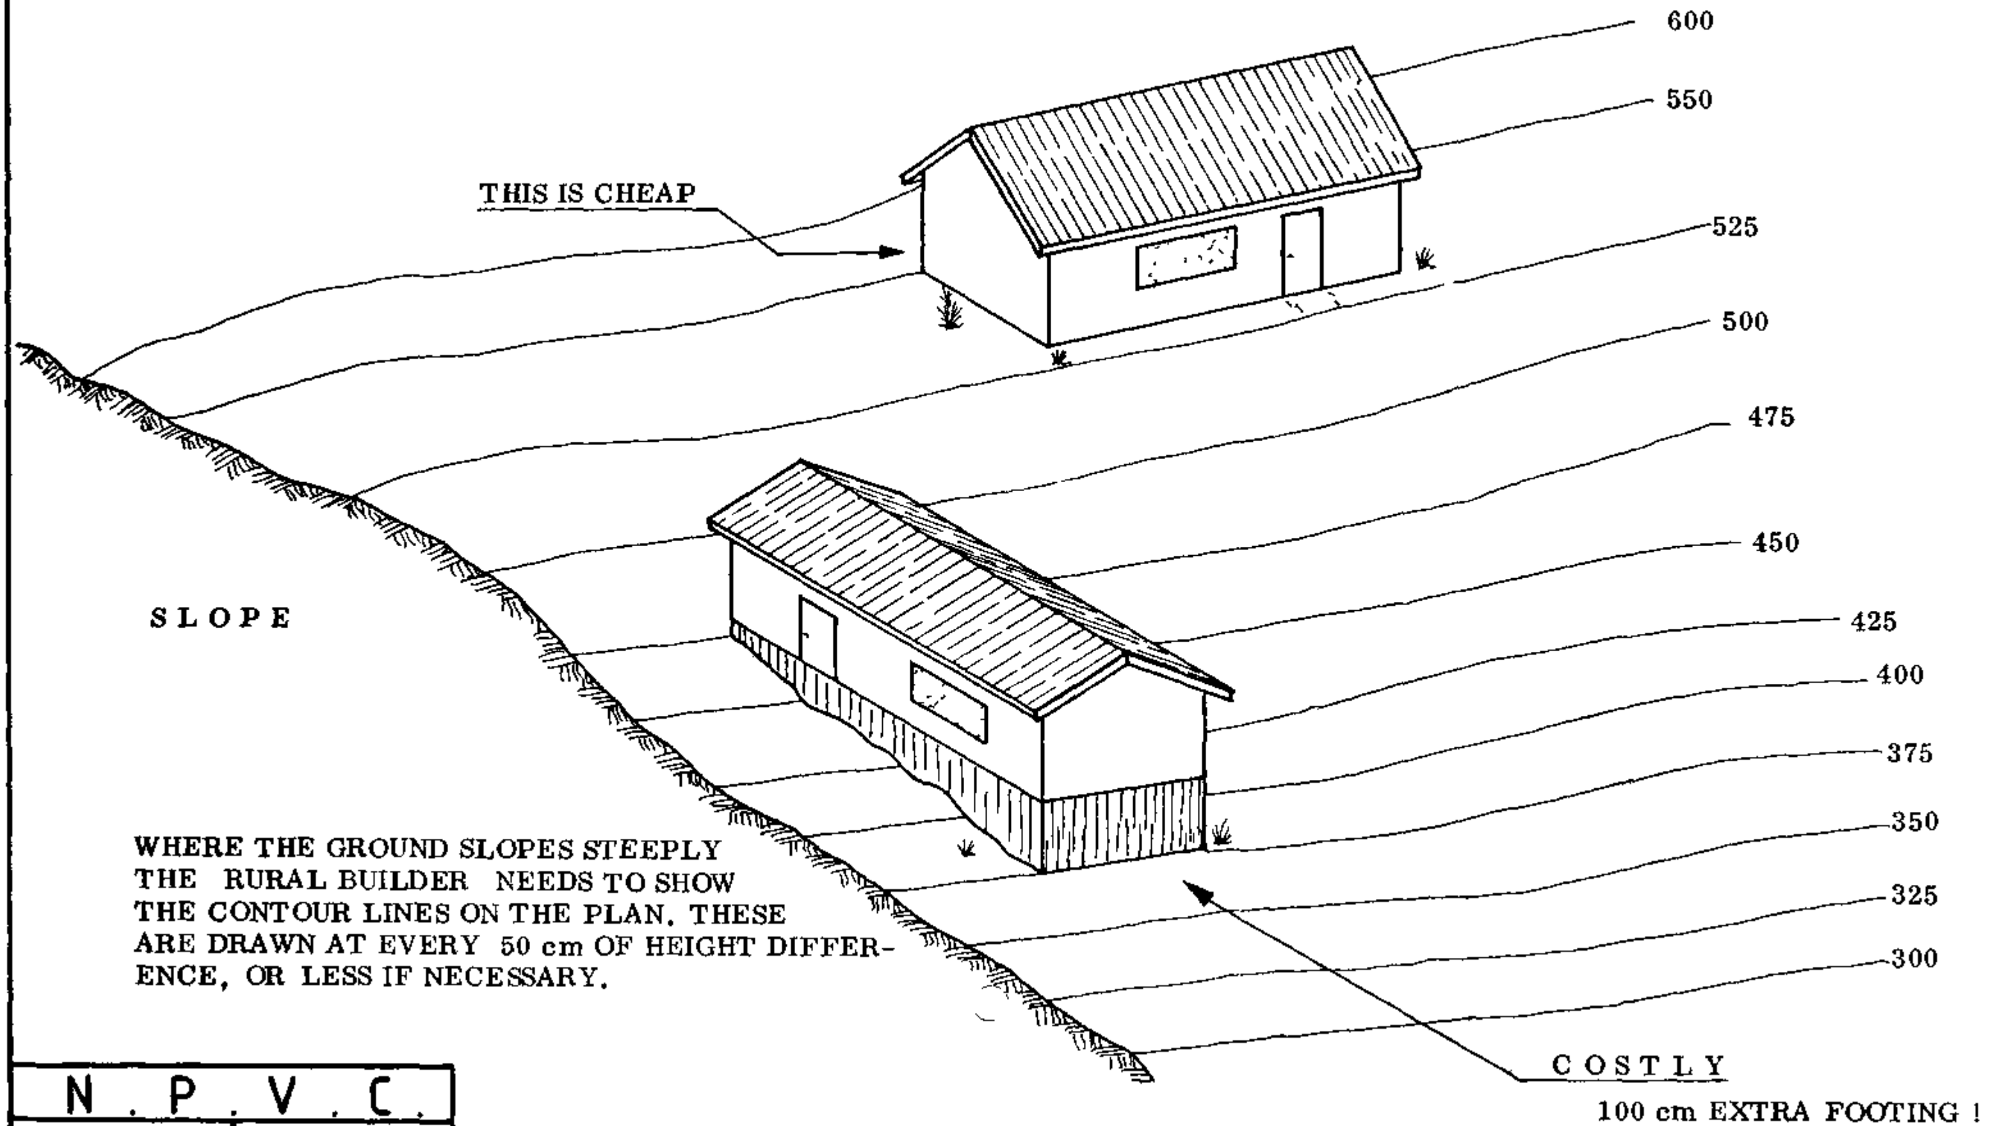
THE DIRECTION OF THE PREVAILING BREEZE (THE USUAL DIRECTION THE BREEZE COMES FROM) IS MARKED ON THE PLANS.

STORMS

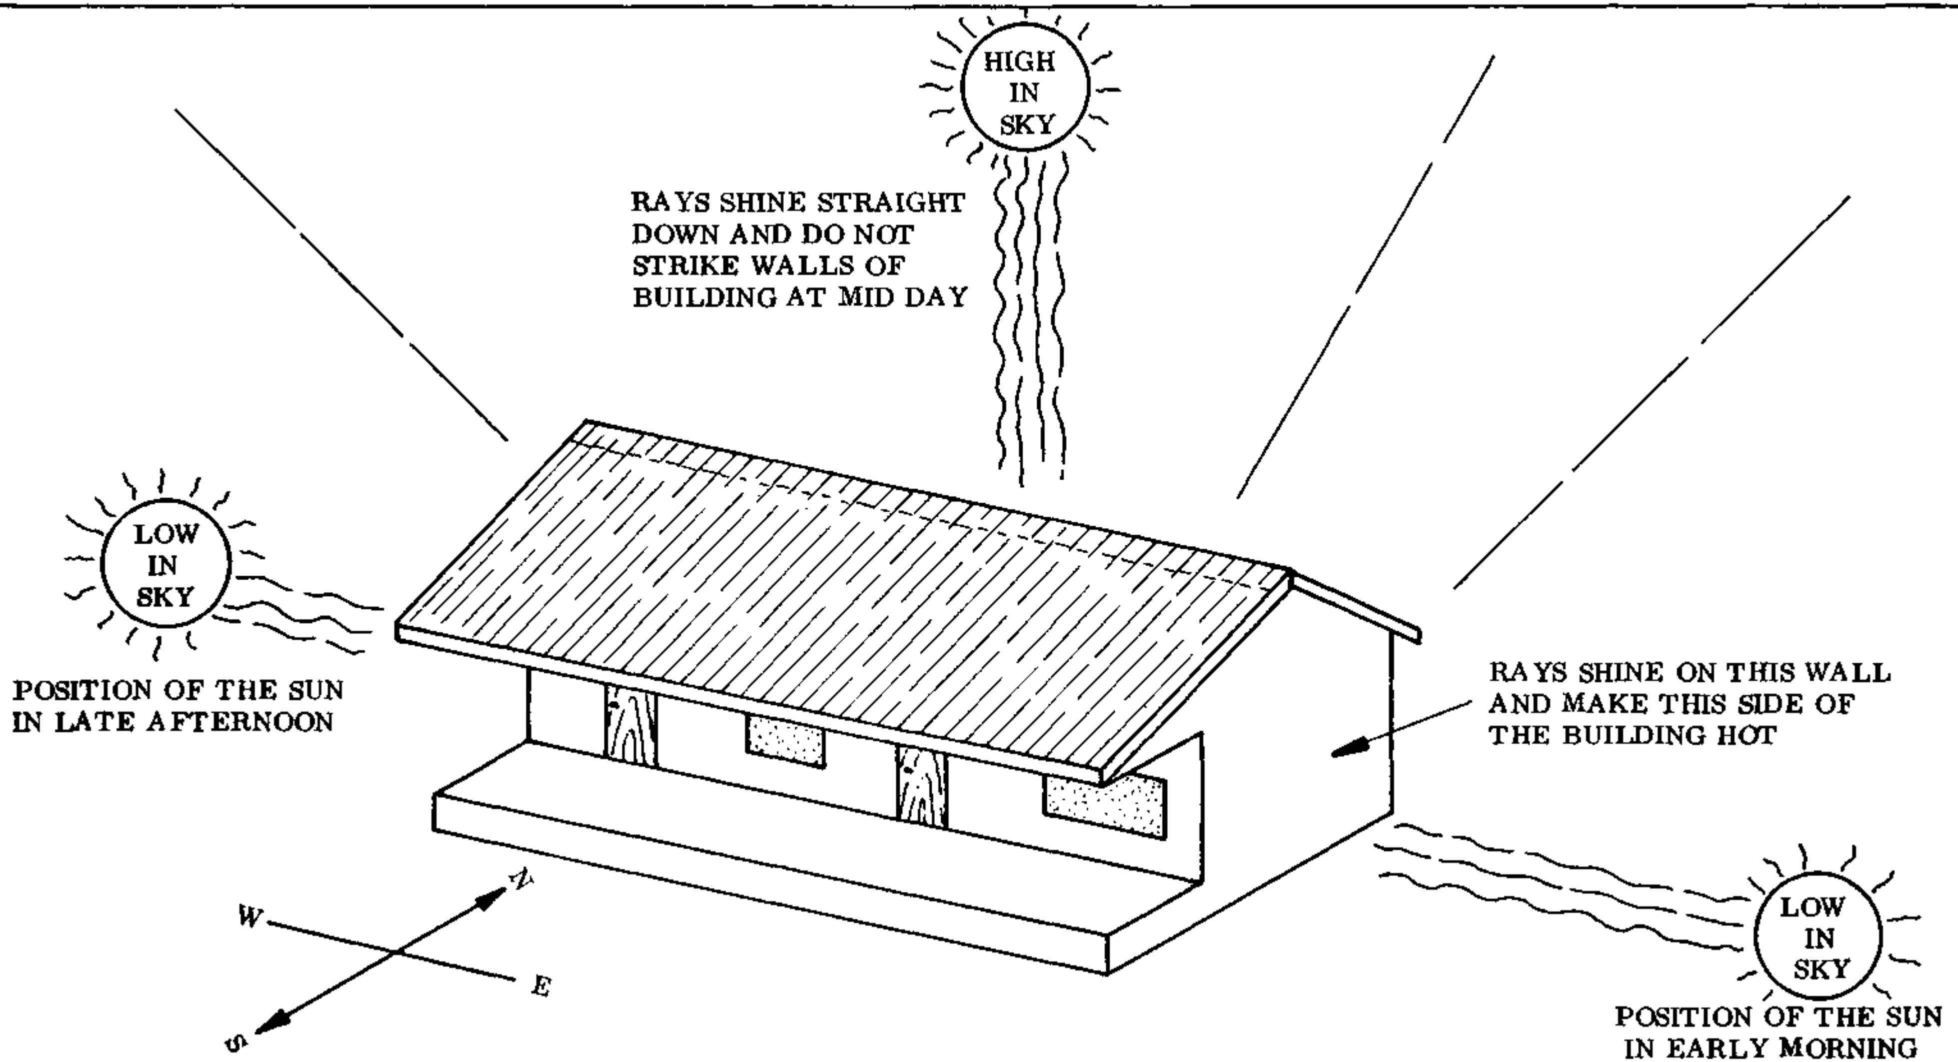


IN AREAS WHICH GET BAD STORMS, THE RURAL BUILDER WILL PLAN THE BUILDING SO THAT THE OPENINGS WHICH FACE THE STORM ARE PROTECTED.

BUILDING ALONG THE CONTOURS



WHERE THE GROUND SLOPES STEEPLY THE RURAL BUILDER NEEDS TO SHOW THE CONTOUR LINES ON THE PLAN. THESE ARE DRAWN AT EVERY 50 cm OF HEIGHT DIFFERENCE, OR LESS IF NECESSARY.



BUILDINGS WHICH HAVE THE LONG SIDES FACING NORTH AND SOUTH AND HAVE A VERANDAH ARE COOLEST AND MOST COMFORTABLE IN HOT COUNTRIES BECAUSE THE SUN SHINES ON THE SHORT SIDES ONLY.

N.P.V.C. 104.

DESIGNING BUILDINGS TO WITHSTAND STRONG WINDS

Many buildings are not strong enough to resist the forces of very strong winds. They may be destroyed and the people inside can be injured or even killed. The guidelines here aim to help the Rural Builder to design and construct buildings so that such occurrences are reduced in the future. The point of these guidelines is to reduce the force of the wind against the building, and to make the building more resistant to wind forces. The following points are illustrated on the right.

A - Take advantage of natural windbreaks such as trees or hedges when deciding on the site for the building. Such a location can reduce the force of the wind.

B Sites on hills and near hilltops can have much higher windspeeds.

C - Valleys can funnel winds and create higher windspeeds.

D - The pitch of the roof is very important. This should be between 15 and 20 degrees.

E - A hip roof resists wind forces better than a gable roof.

F - Avoid making large overhangs, even if they are supported by columns. Locate verandahs away from the direction of the strongest winds.

G - A parapet around the roof helps to reduce the wind force along the roof edges.

H - Avoid making large openings such as doors or windows near the roof line or near the corners of walls. These tend to weaken the structure if they are located where the loads are greatest.

I - Make sure that every part of the building is secured: the roof parts to each other, the roof itself to the walls, the walls to the other walls, the walls to the floors, the floor to the foundations. The foundations should rest on firm soil if possible.

- REMEMBER: Whatever the form of roof construction, the parts of the roof must be securely tied together. Anchor the whole structure to the building. Ignoring this precaution means that the roof will almost certainly be damaged in any strong wind.

RURAL BUILDING

CONSTRUCTION

PREFACE

This official text book is designed purposely to meet the needs of trainees who are pursuing rural building courses in various training centres administered by the National Vocational Training Institute.

The main aim of this book is to provide much needed trade information in simple language and with illustrations suited to the understanding of the average trainee.

It is the outcome of many years of experiment conducted by the Catholic F.I.C. brothers of the Netherlands, and the German Volunteer Service instructors, in simple building techniques required for a rural community.

The National Vocational Training Centre is very grateful to Brothers John v. Winden and Marcel de Keijzer of F.I.C. and Messrs. Fritz Hohnerlein and Wolfram Pforte for their devoted service in preparing the necessary materials for the book; we are also grateful to the German Volunteer Service and the German Foundation For International Development (DSE) - AUT, who sponsored the publication of this book.

We are confident that the book will be of immense value to the instructors and trainees in our training centres.

DIRECTOR: National Vocational Training
Institute, Accra

INTRODUCTION TO A RURAL BUILDING COURSE

Vocational training in Rural Building started in the Nandom Practical Vocational Centre in 1970. Since then this training has developed into an official four year course with a programme emphasis on realistic vocational training.

At the end of 1972 the Rural Building Course was officially recognised by the National Vocational Training Institute. This institute guides and controls all the vocational training in Ghana, supervises the development of crafts, and sets the examinations that are taken at the end of the training periods.

The Rural Building programme combines carpentry and masonry, especially the techniques required for constructing housing and building sanitary and washing facilities, and storage facilities. The course is adapted to suit conditions in the rural areas and will be useful to those interested in rural development, and to farmers and agricultural workers.

While following this course, the instructor should try to foster in the trainee a sense of pride in his traditional way of building and design which is influenced by customs, climate and belief. The trainee should also be aware of the requirements of modern society, the links between the old and new techniques, between traditional and modern designs - and how best to strike a happy medium between the two with regard to considerations like health protection, storage space, sewage and the water supply. The trainee should be encouraged to judge situations in the light of his own knowledge gained from the course, and to find his own solutions to problems; that is why this course does not provide fixed solutions but rather gives basic technical information. The instructor can adapt the course to the particular situation with which he and the trainee are faced.

This course is the result of many years of work and experimentation with different techniques. The text has been frequently revised to serve all those interested in Rural Development, and it is hoped that this course will be used in many vocational centres and communities. It is also the sincere wish of the founders of this course that the trainees should feel at the completion of their training that they are able to contribute personally to the development of the rural areas, which is of such vital importance to any other general development.

We are grateful to the Brothers F.I.C., the National Vocational Training Institute and the German Volunteer Service for their assistance and support during the preparation of this course.

Bro. John v. Winden (F.I.C.)
Wolfram Pforte (G.V.S.)
Fritz Hohnerlein (G.V.S.)

LAY-OUT OF THE RURAL BUILDING COURSE

The Rural Building Course is a block-release-system course, which means that the trainee will be trained in turn at the vocational centre and at the building site. The period of training at the centre is called “off-the-job” training, and the period on the building site is called “on-the-job” training. Each will last for two years, so that the whole course will take four years and will end with the final test for the National Craftsmanship Certificate.

BLOCK RELEASE SYSTEM

YEAR	TERM 1	TERM 2	TERM 3
1	X	X	X
2	O	O	O
3	O	X	O
4	X	O	X

X = OFF-THE-JOB TRAINING
O = ON-THE-JOB TRAINING

The total “off-the-job” training period is approximately 76 weeks, each week 35 hours. During this training about 80% of the time is spent on practical training in the workshop. The remaining 20% of the time is devoted to theoretical instruction.

The total “on-the-job” training period is approximately 95 weeks, each week 40 hours. During this period the trainee does full-time practical work related to his course work. In addition some “homework” is assigned by the centre and checked by the instructors.

A set of books has been prepared as an aid to the theoretical training:

A - Rural Building, Basic Knowledge (Form 1)
B - Rural Building, Construction (Forms 2, 3, 4)
C - Rural Building, Drawing Book (Forms 1, 2, 3, 4)
D - Rural Building, Reference Book

All these books are related to each other and should be used together. The whole set covers the syllabus for Rural Building and will be used in the preparation for the Grade II, Grade I, and the National Craftsmanship Certificate in Rural Building.

CONTENTS

BOOK INTRODUCTION

Rural Building Construction is your main construction book. It is built up in the same logical way that a house is built up: starting with the preliminaries of setting out and ending with the roof construction, hanging the doors, and the finishing.

Because of the structure of the training course, it might sometimes be necessary for the instructors to rearrange this sequence and treat certain working methods either earlier or later in the course (for example, plastering is done late in the construction of a building, but it might have to be treated quite early in the actual Centre training). In any case the instruction should follow the current Rural Building syllabus, and the instructor should pick out the chapters which need to be covered according to the syllabus.

There is room for the instructor to add his own ideas, knowledge and experiences concerning the local ways of building, and to adapt the lessons to the local circumstances. The trainee should be able to adapt the knowledge he has gained to the requirements of the rural areas.

In order to work with this text book, you should be familiar with drawing techniques so that you can understand the sketches and drawings. Don't be afraid to make notes and sketches in the book: the notes made here can be helpful to you again and again in your future building career.

- The tools and materials mentioned in this book are described and explained in the Rural Building Reference Book. Some figures essential for the Rural Builder are given in the Tables of Figures at the end of the Drawing Book.

- All measurements, figures and constructions given and explained in this book are made in accordance with the standard sizes of timber, steel, etc. which are commonly used in Ghana.

The appendix gives some basic designs and construction information for water filters, wells, sanitation systems, and a silo for improved grain storage.

BUILDING PRELIMINARIES

Site selection

When choosing the location of the planned building, the responsible builder will strongly advise his client to avoid building on valuable farm land, if possible.

Most Rural Builders come from farming communities; they are building for farmers, and they also do farming themselves. Thus they are very conscious of the land and know that good land should never be wasted by building on it.

Moreover, the Rural Builder is aware that there are a number of advantages in building on higher, stony areas not suitable for farming.

Some of the advantages are:

- The higher the building is situated, the healthier and more comfortable it will be to live in, because of the better ventilation and the reduced danger from dampness rising from the ground.

- Building materials such as stones and laterite are often available on the spot, and do not need to be brought from far away.

- The soil in higher areas is more likely to be the desired type to form a firm base for the house. This makes the construction of the foundations easier, and reduces the amount of building materials required, keeping the costs lower.

Location plan

When building a house or any other structure one must have certain information available, in order to arrive at the best and most economical result.

The most basic information is the location, size and nature of the plot. This is contained in the location plan, which shows the plot and the immediate surroundings in scale. The scale can be from 1:200 up to 1:1000, depending on the size of the project.

The plan outlines the shape of the plot and the dimensions of its boundaries, as well as the location of the future building. It should also show the nature of the area, because it is very important to know whether the site is sloping or if the ground is uneven.

Roads, drive ways and the positions of the bigger trees are also marked on the location plan (Fig. 1).

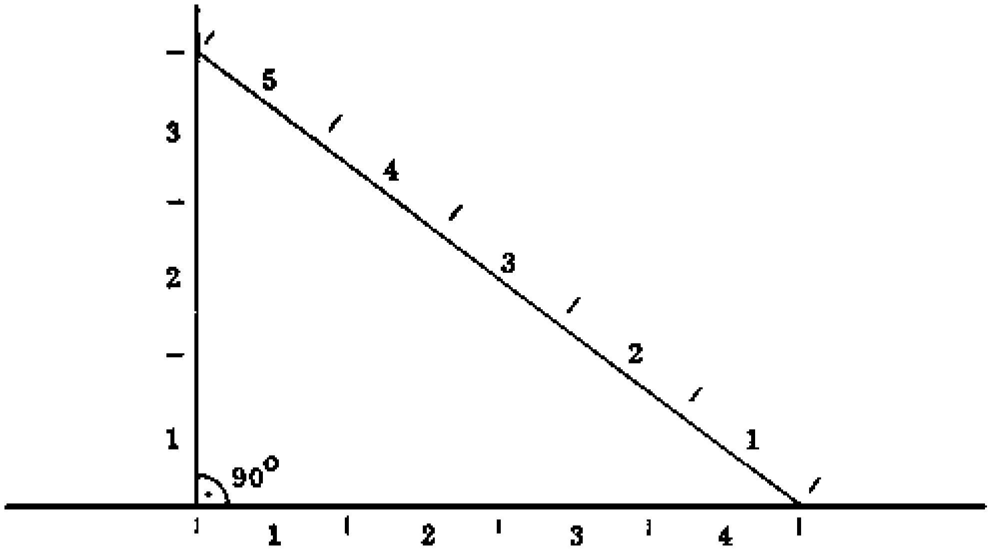

Fig. 1

In Rural Building, location plans are often not available, so in order to get the necessary information, both the client and the builder have to examine the plot thoroughly. Important matters such as the best position for the future building are discussed and decided on the spot.

When the site has been examined thoroughly and all the measurements and particulars have been obtained, the drawings for the house can be prepared.

- NOTE: Before the building can be started, all the required drawings have to be ready, and at the disposal of the foreman. Before you can prepare any drawings, you need to have all the particulars of the site.

NOTES:

Working drawings

The working drawings are the drawings which the builder uses before the construction starts and during the construction; to plan for materials requirements, to plan the work; and finally to carry out the construction according to the directions contained in the drawings.

The drawings include “plans”, “cross sections”, “elevations”, and “detail drawings”. They are all prepared in scales which are suitable to the particular drawing. The first three types of drawing have a scale of between 1:50 and 1:20.

- PLANS: A plan is a view that shows a certain layer or horizontal section of a building as if it were looked at from above (see Drawing Book, page 55). The plans usually include the “floor plan”, which shows the walls, positions of the doors and windows, etc. (Drawing Book, page 54); the “foundation plan” gives the dimensions of the foundations and footings; and the “roof plan” which shows the shape of the roof and its dimensions. The floor plan and the foundation plan are often combined into one drawing.

- CROSS SECTIONS: A cross section is a drawing which shows the inside of the structure, as if the building were cut into two (see the Drawing Book, pages 61 and 62). The exact position where the cross section is taken has to be shown on the plan.

- ELEVATIONS: These are the views of the building as it would look from the outside (see pages 59 and 60 in the Drawing Book).

- DETAIL DRAWINGS: These show members or portions of the structure in a larger scale than the other drawings; such as 1:10, 1:5, 1:2,5, etc. Detail drawings are made when:

  - There is not enough space in the other drawings to clearly indicate all the required measurements.

  - The member of the structure is too small to be properly shown in the other drawings.

  - The member has a complicated shape and more views or cross sections are needed to explain it (see Drawing Book, page 84).

  - Important construction hints have to be pointed out.

  - The member is built up from several different materials.

The working drawings have to show the various materials used in the structure (see Drawing Book, pages 49 to 50). This enables the builder to make a list of the materials that will be required and the amount of each material (see the Reference Book, Tables of Figures, pages 234 to 240.

When this is done the builder can estimate the cost of the building and order the materials he will need. Ordering materials has to be done in advance so that the materials are there when they are needed.

Plot and site clearing

Once the planning work has been completed, the plot and site both have to be prepared for the setting out. The location plan shows exactly from which areas the trees, bushes, grass and stones must be removed. The ground is levelled. The part of the plot which is cleared will be the actual site that the future building will occupy, including a space of about 5 m all around the building.

One very important measure is to remove all the tree roots from the site area. If the roots remain, they will sometimes grow again and might damage the structure. This is particularly true with the roots of the neem tree.

Clearing does not mean that all the trees on the whole plot are removed. Beyond the 5 m clear space, as many trees as possible should be allowed to remain, because they will provide shade for the people using the building or living there.

Site organization

The first step in organizing the site is deciding where to make the driveway.

Next, choose the area where the building materials will be stored and arrange the storage facilities. Certain materials like sand and stones may have to be located, excavated, and transported to the site. This can be done as soon as the storage areas are located.

The building materials should not be stored too far away from the working place, nor should they be too close.

Space has to be provided for making blocks, and for mixing concrete and mortar. This also should not be too close to the future building.

The same applies to any temporary work sheds or storage sheds that are erected.

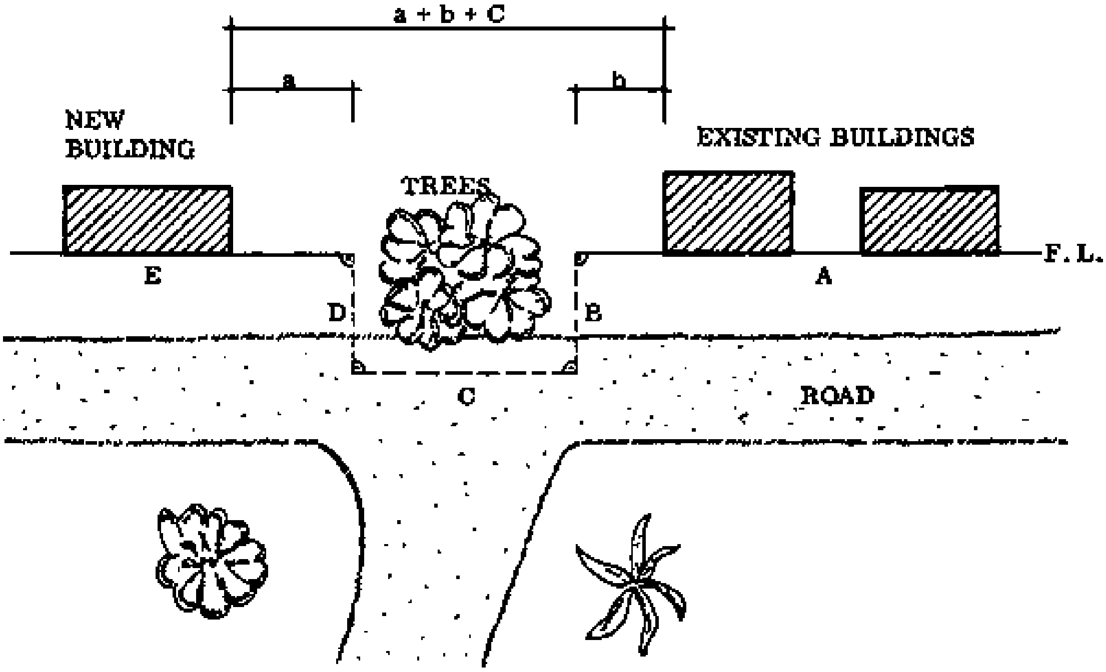

Fig. 2

NOTES:

Water supply

Any kind of building would be impossible without water. Therefore one of the main tasks of the builder is to provide a guaranteed supply of clean water.

Usually piped water is not available, so it is advisable to build a simple water tank, or else dig a well if this is possible (see the Appendix, pages 277 to 281).

The water tank should be located so that after construction is completed it can be used to store rain water collected from the roof. The best site will be close to either gable end of the house so that the rainwater from the gutters can be fed into the tank directly.

Investigate the possibilities for digging a well, as this would eliminate the need to transport water and thus cut down on unnecessary effort and cost.

SETTING OUT

Once the plot and site clearing is completed, the setting out can be done: first mark the frontline of the building and from there mark all the other lines using the 3-4-5 method described in the Basic Knowledge book, page 142.

However, not all sites are conveniently flat and level, and the Rural Builder will frequently face more difficult situations. While the construction of a right angle remains the same, the measurement of distances and the determination of directions might sometimes be difficult.

There is also the case where there are trees or other buildings which should remain, but which are in the way when we are making a particular measurement.

Interfering objects

Provided that you have mastered the 3-4-5 method, it is relatively easy to by-pass interfering trees or buildings in setting out: it only requires a bit more time to construct the additional angles (Fig. 1).

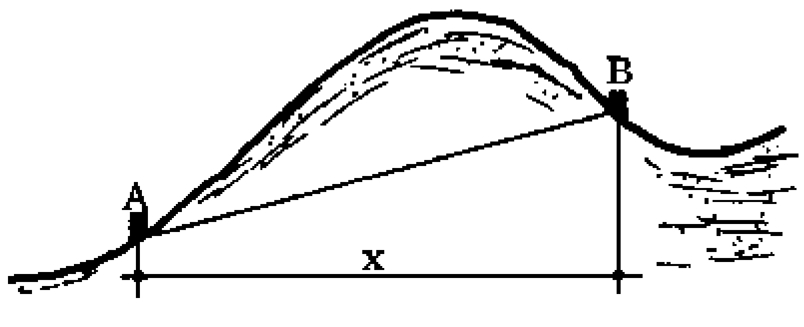

Fig. 1

Fig. 2 illustrates an example: the frontline of the existing buildings must be maintained in the new building, but it is difficult to set out directly because there are trees which are in the way. Rather than cut the trees down, we can by-pass them.

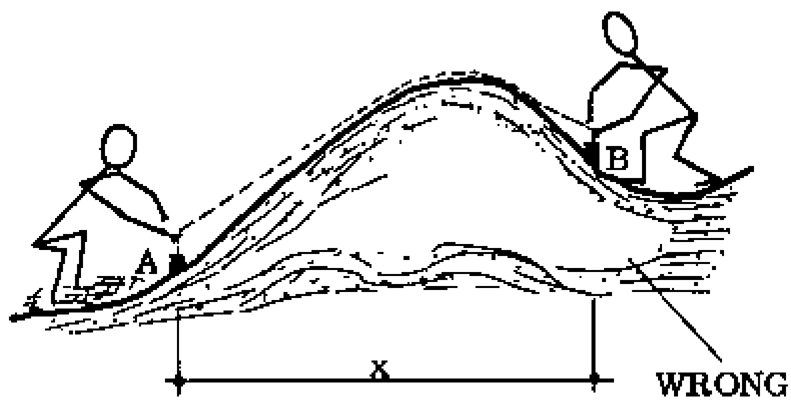

Fig. 2

From the frontline of the existing buildings (line A), set out line B, using the 3-4-5 method, perpendicular to line A. Then construct lines C and D using the same method, followed by line E which is the front line of the new building. Check that line C plus the distances “a” and “b” all add up to the total planned distance between the new building and the existing buildings (Fig. 2).

Uneven ground

Setting out on uneven ground, and particularly measuring distances, requires you to apply some simple geometry.

When we measure distances in setting out, we are actually looking for the horizontal distance between two points (Fig. 1, x). We don't measure the distance along a slope, because the house we want to build will not slope; it will have level floors and walls.

Since the ground is not flat, and the points are at different heights (point A is lower than point B), the horizontal distance between them has to be measured indirectly.

Fig. 2 shows two men trying to measure the distance between pegs A and B along uneven ground. Their result cannot be correct because the line they are holding is neither straight nor is it horizontal (measure "x" and compare it to the length of their line).

The men in Fig. 3 also fail to get the correct measurement. Their line is stretched taut and is therefore straight, but it is still not horizontal (measure "x" and compare it to the length of their line).

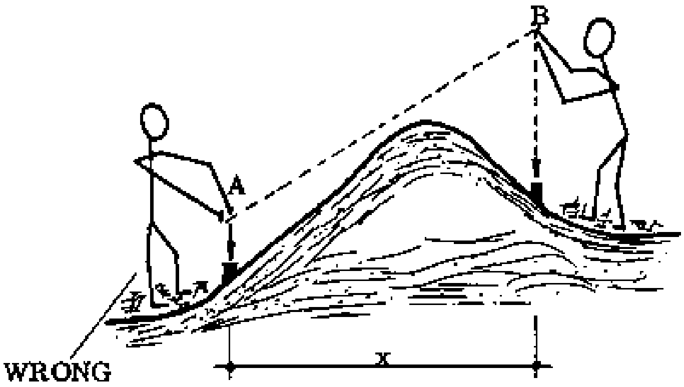

Fig. 3

In order to find the true horizontal length "x", the line or tape measure has to be held horizontally and stretched taut so it is straight. Both ends of the line are kept vertically above the pegs A and B by means of plumb bobs (Fig. 4). This method as shown is a good rough method for short distances.

If a larger distance has to be measured, the work is carried out in intermediate steps of suitable lengths (Fig. 4).

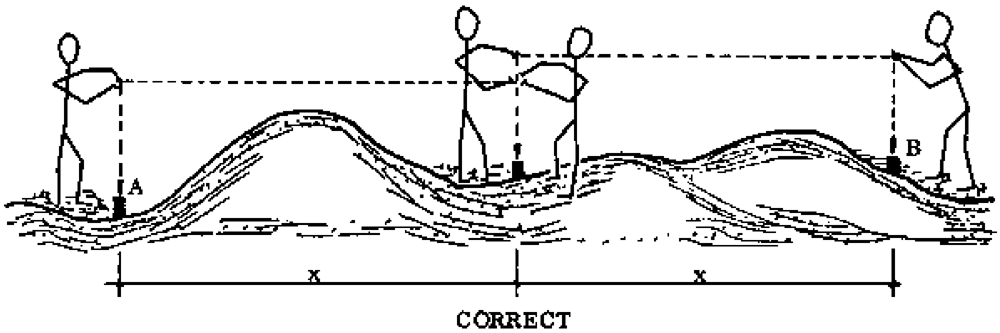

Fig. 4

For very large distances, the use of boning rods (Reference Book, page 25) can help to make sure that the different steps are in line and the total length measured is straight (Fig. 5). With the boning rods and a water level (Reference Book, page 25) you can also make sure that the whole distance is horizontal.

Use the water level to level between two boning rods; then any points in between can also be levelled by simply sighting along the boning rods (Fig. 5).

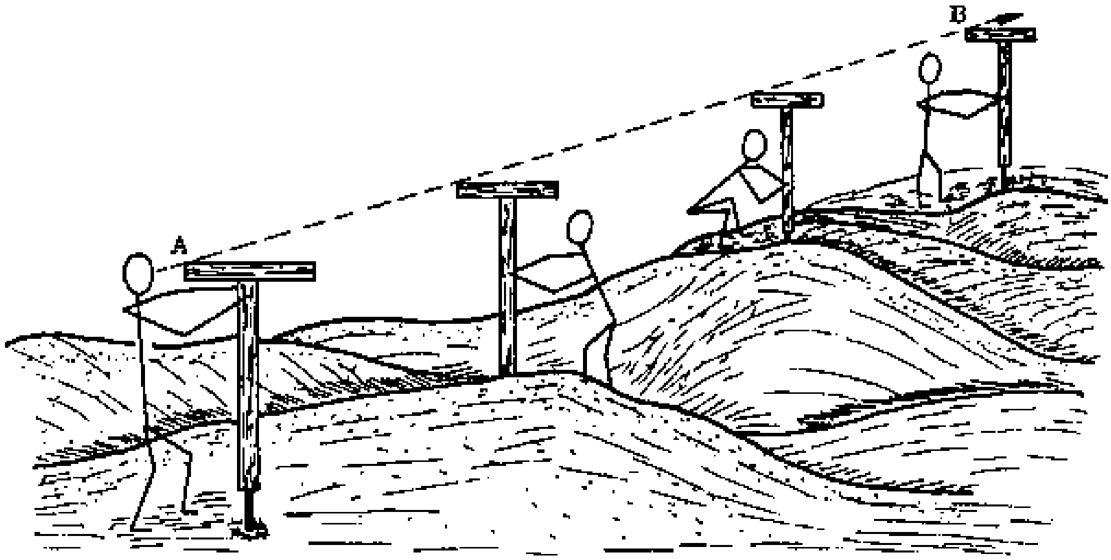

Fig. 5

NOTES:

Sloping sites

Setting out and measuring distances on sloping sites is simply the same procedure as explained in the section on uneven ground.

The work is carried out in steps (Fig. 1), with the line always held horizontally when measurements are taken.

The length of each section depends on how steep the slope is. The steeper the slope, the shorter the section, while slightly sloping areas allow longer sections (Fig. 1).

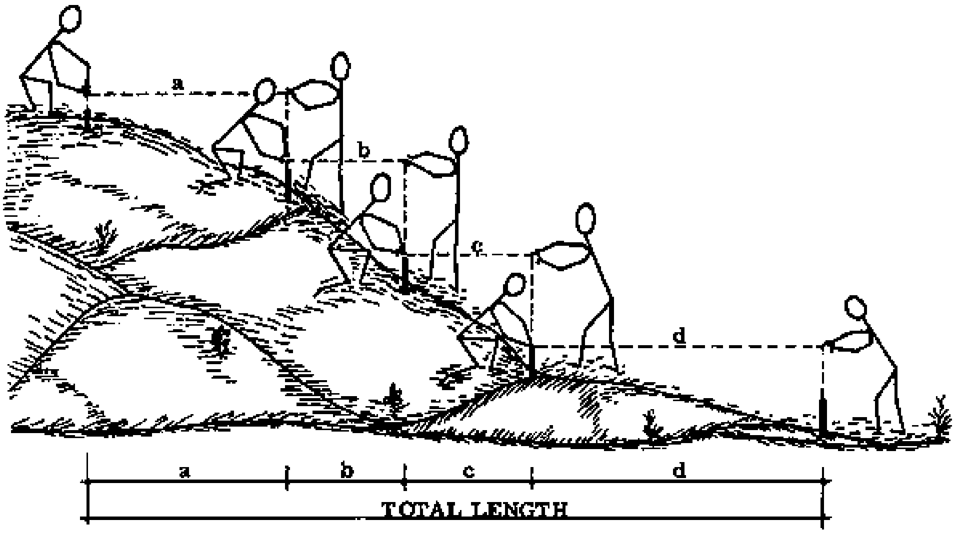

Fig. 1 MEASURING A DISTANCE ON A SLOPING SITE

The construction of a right angle according to the 3-4-5 method is the same on a slope, as long as all the lines involved are straight. To see that this is true, take your try square and turn it around in your hands. You will observe that whatever the position of the try square, the angle is always the same, because the sides of the try square remain straight.

Even on a site which slopes in two or more directions (Fig. 2) it is possible to construct a right angle as long as the lines are straight and do not touch the ground. The pegs may have to be different lengths, in order to keep the lines off the ground.

Keep in mind that on sloping sites all lines stretched between the pins do not represent the horizontal length (unless they are also levelled) but only the future positions and directions of the walls, etc. (Fig. 2, see also Figs. 1 to 4 on the previous page).

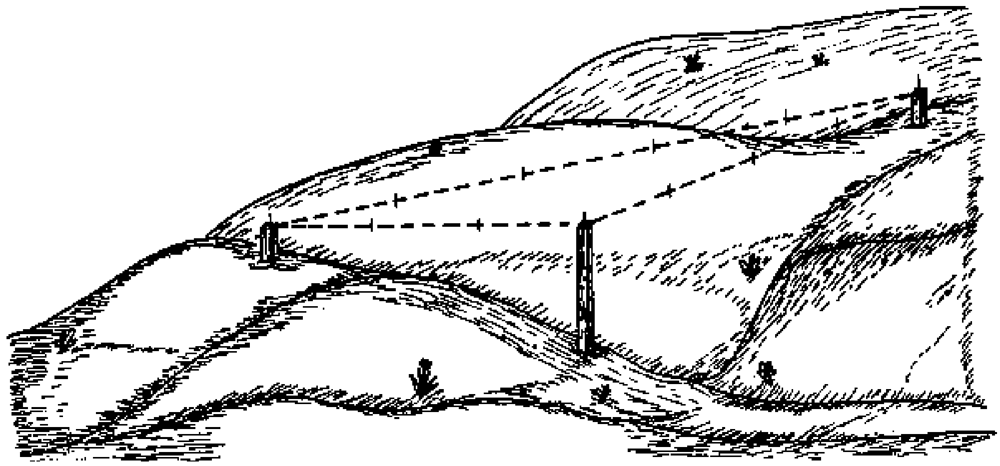

Fig. 2 3-4-5 METHOD ON A SLOPING SITE

The Rural Builder knows that the decision to build on a sloping site can have expensive consequences. There are some advantages such as easier sewage disposal, but the disadvantages are usually greater (Drawing Book, page 103).

NOTES:

Profiles

When the positions of the corners of the building are known, and the distances between them, then we can mark the positions and widths of the foundations as well as of the footings and plinth course.

This marking should be carried out in a relatively permanent way, so that it is accurate for a longer period. We do this by using profiles. A profile is a simple, temporary structure which maintains the correct locations of the various marks.

The profile consists of a board nailed flatwise on top of two pegs which are set in the ground, at a height of about 60 cm (Fig. 1). This height is necessary to lift the line well above the footings, so that later the plinth course can be marked from the profile.

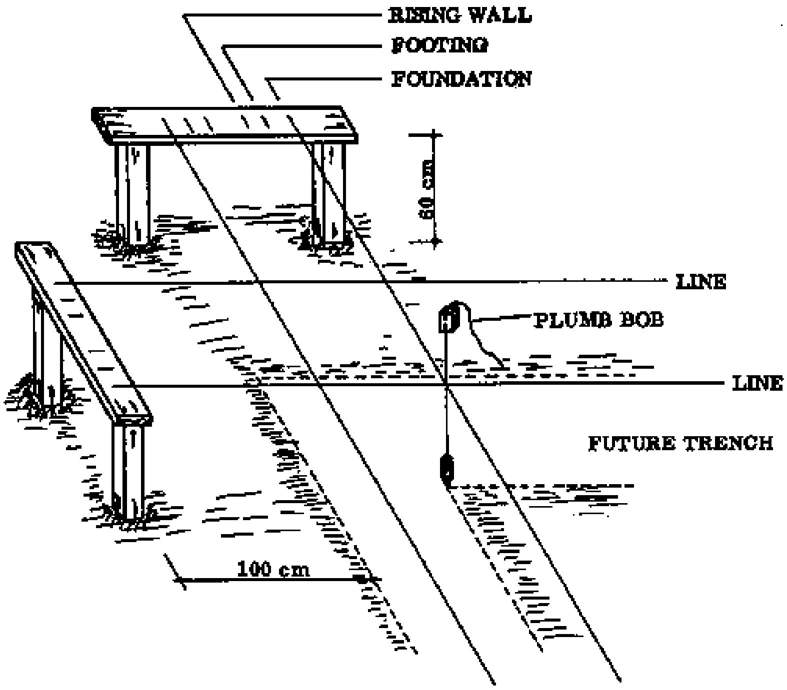

Fig. 1 MARKING THE POSITION OF THE FOUNDATION ON THE GROUND

If the soil is too hard to drive the wooden pegs into, then specially made iron pegs designed to receive a profile board can be used (Fig. 2). If these are not available, plain iron rods can be used, although they are less accurate since the lines are fixed directly onto the rods.

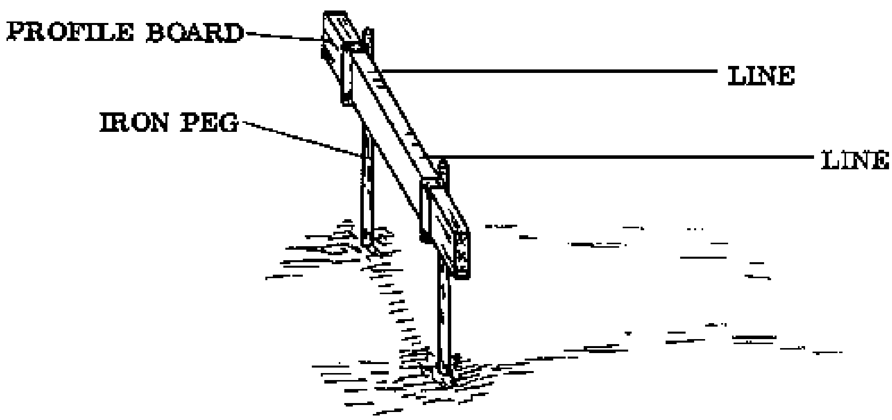

Fig. 2

At the corners of the building, two boards are used, to mark in two directions (Fig. 3). To mark off the dividing walls, one board is used at each end of the future wall (Fig. 3).

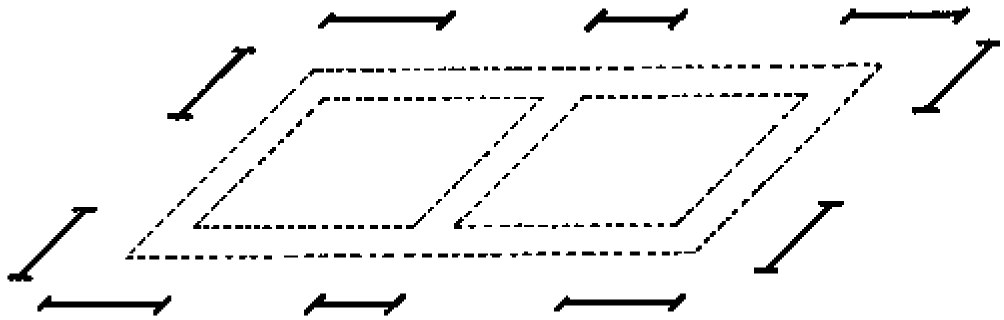

Fig. 3 POSITIONS OF THE PROFILE BOARDS

The profiles are erected at a distance of about 1 m from the outside edge of the foundation (Fig. 1). Permanent divisions are marked on the boards to indicate the width of the foundations and the thicknesses of the footings and rising walls. The marks may be either saw-cuts or short nails, so that lines can easily be fixed to them as they are needed.

The positions of the foundations are then marked on the ground by plumbing down from the lines stretched between the profiles (Fig. 1).

FOUNDATIONS

The stability of all buildings depends largely on the load-bearing capacity of the ground under them. As far as Rural Building is concerned, all hard soils are suitable for building. Soft soils, and those soils which become very soft and turn into mud when wet, are not suitable.

If a building is erected on the wrong kind of soil or if the foundations were constructed incorrectly, the building might settle unevenly, tilt or slide, or even collapse.

This can be avoided by selecting the right site for the building and by adapting the foundation construction to the soil conditions and the nature of the building.

Types of foundations

The most common forms for foundations in Rural Building are:

- SINGLE FOUNDATION: This is for columns, pillars and poles, if they are detached from the building (Fig. 1).

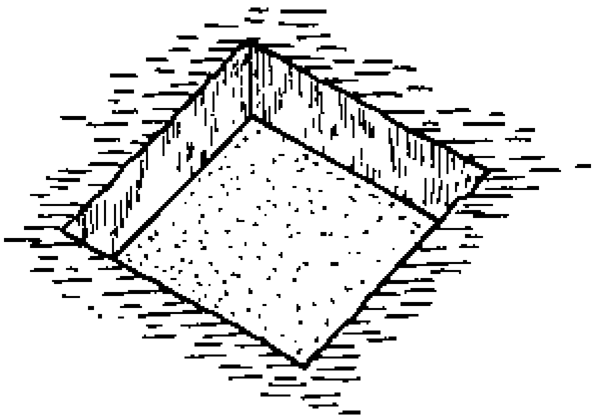

Fig. 1

- STRIP FOUNDATION: This is the most widely used foundation for walls (Fig. 2).

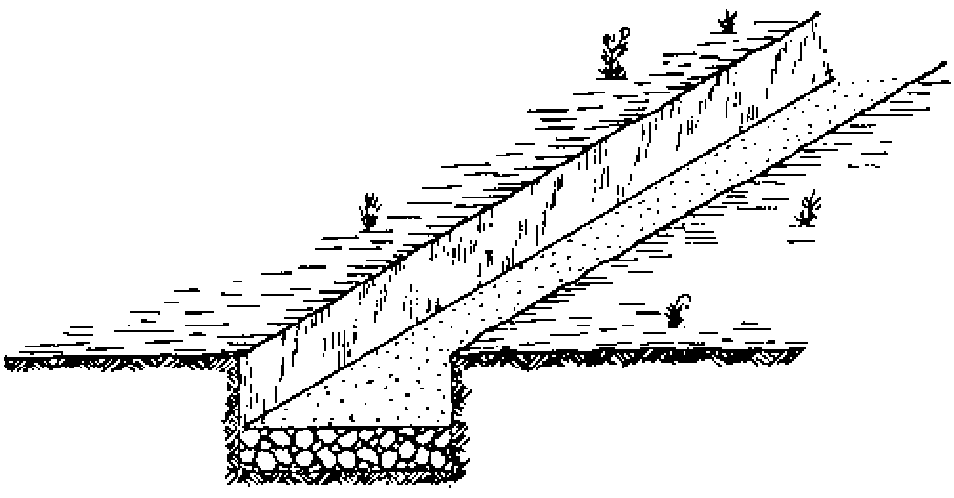

Fig. 2

- SLAB FOUNDATION: This is used for water tanks and septic tanks (Fig. 3).

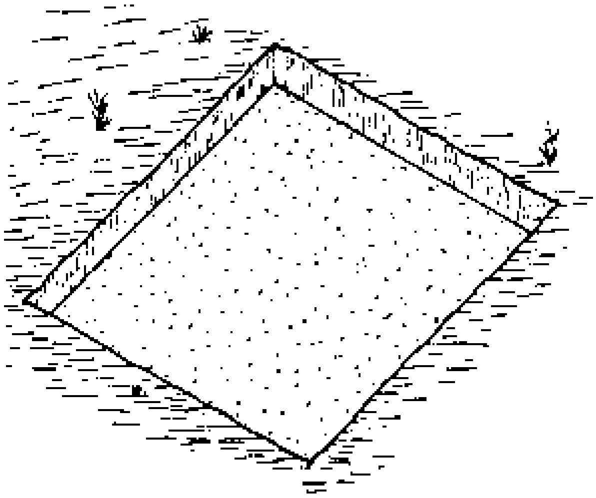

Fig. 3

- STEPPED FOUNDATION: On sloping sites the so-called stepped foundation must be used, which is in fact just a special form of the strip foundation (Fig. 4).

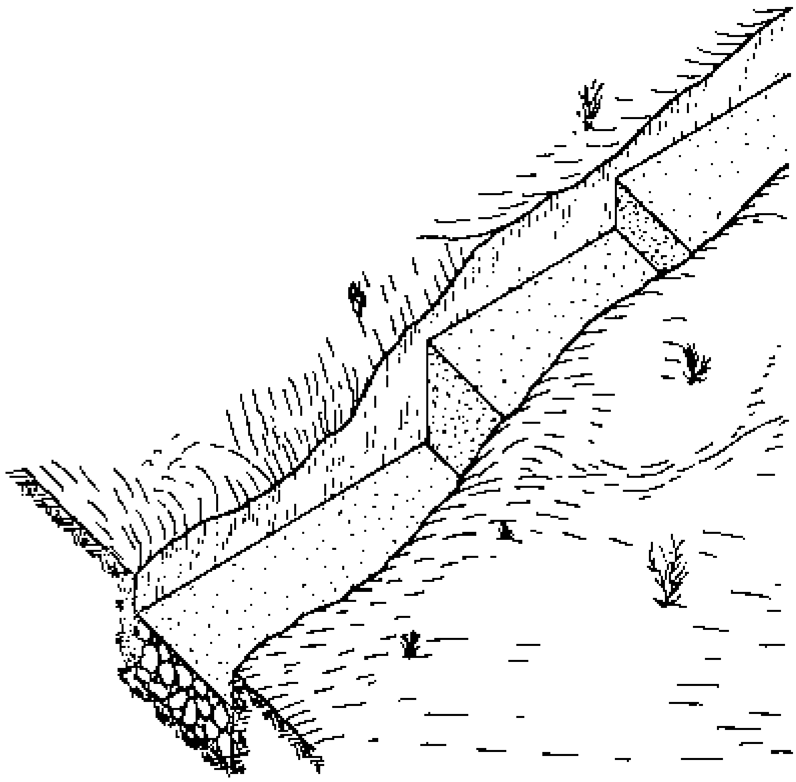

Fig. 4

NOTES:

Functions of the foundation

A foundation has to be constructed in a way that it can fulfill the demands that the building structure places on it. These are:

- To provide a solid, level base for the building
- To receive loads from the structure above
- To distribute the loads onto the ground over a larger area
- Thus, to prevent uneven settling of the building.

The above demands are met through the correct choice of dimensions, materials, and constructions for the foundation.

Dimensions for strip foundations

Many years of building experience in northern Ghana have proven that the dimensions for concrete foundations shown in Fig. 1 are sufficient, provided that the structure consists of only a ground floor and it is built upon firm soil.

A simple rule is: the depth of the foundation should be no less than the thickness of the rising wall; while its width should be no less than 3 times the thickness of the rising wall (Fig. 1).

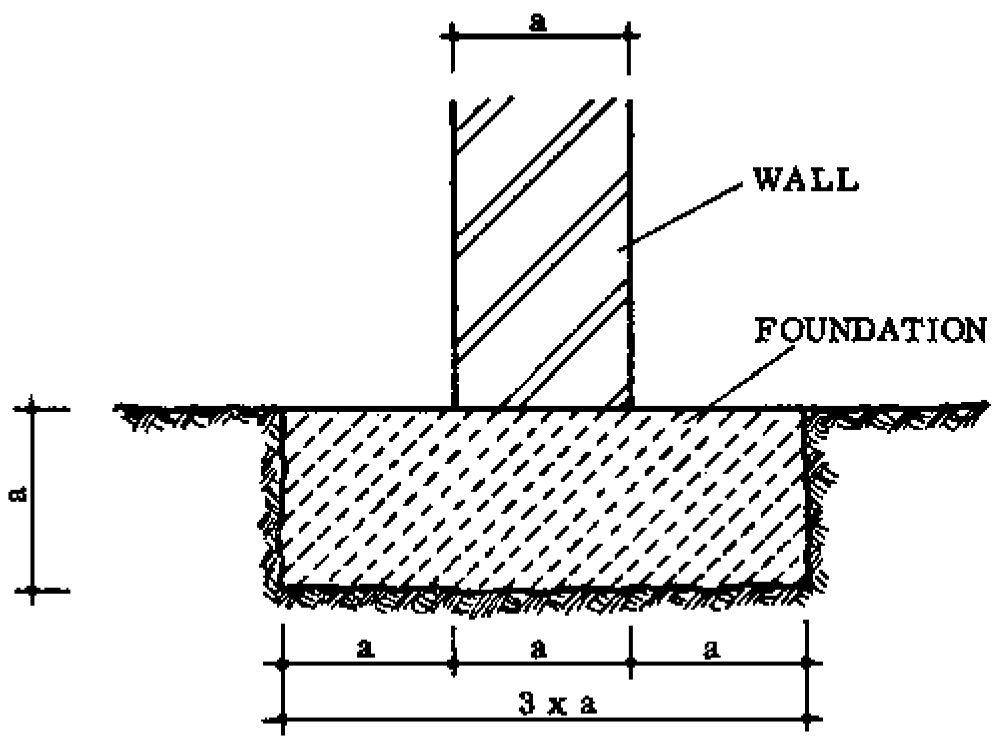

Fig. 1

Lower walls (not exceeding 2 m in height) which do not carry loads can be built on smaller foundations; these should be at least 30 cm wide and 15 cm deep (Fig. 2).

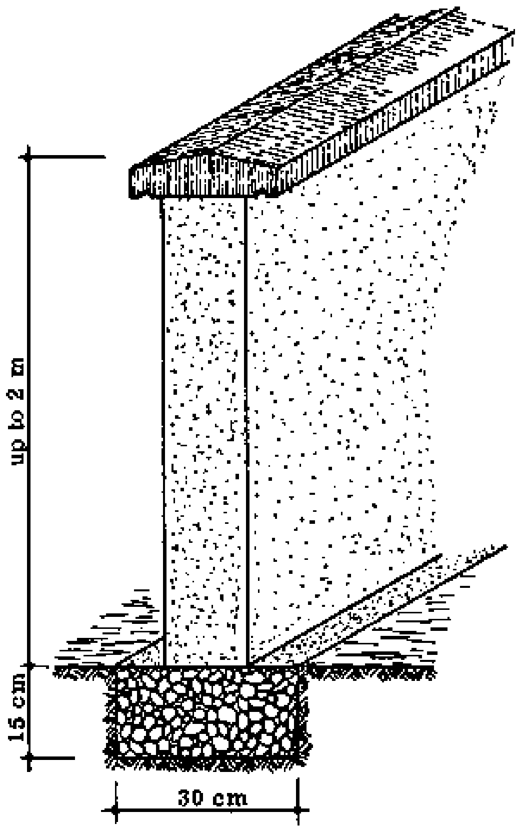

Fig. 2

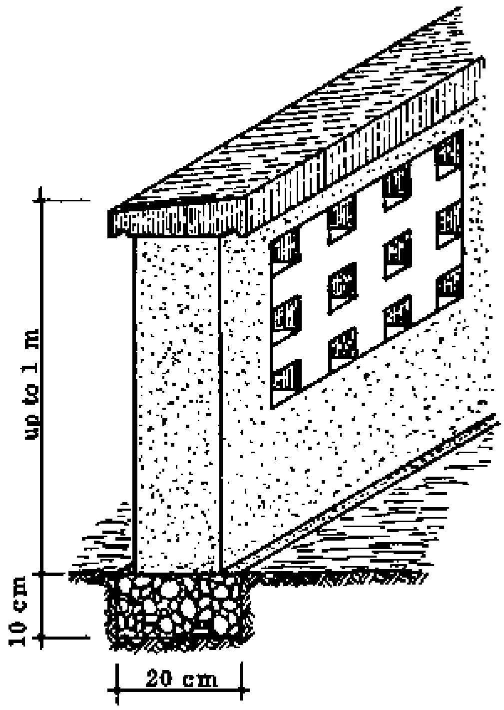

Fig. 3

Foundations which carry very low walls (less than 1 m high) such as decorative openwork screen walls enclosing verandahs, may be reduced to no less than 20 cm wide and 10 cm deep (Fig. 3).

NON-CONCRETE FOUNDATIONS

Although most foundations in Rural Building are made of concrete, there are situations where the choice of another material would be practical and economical. Some of the common alternatives to concrete foundations are:

- Rubble and boulder foundations
- Ashlar masonry foundations
- Laterite rock foundations
- Artificial stone (brick and sandcrete block) foundations.

In certain areas of the world, the first two types of masonry were formerly widely used: not only foundations but also footings, plinths and even rising walls were made out of stones. Due to the increased use of cement worldwide, and the improved concrete technology, stone masonry became uneconomical to build with because it takes more time and labour. Eventually the use of some of these types of masonry disappeared.

However, cement can be very expensive and it makes sense to return to the use of local materials when possible.

Rubble and boulder foundations

This kind of foundation is preferred on stony sites where rubble, rocks and boulders are found in large quantities, and where the soil is firm enough to permit its use.

This foundation saves building materials such as cement and timber for formwork, but it takes more time to construct and requires some skill.

As shown in Fig. 1, as far as possible very large stones are used, and the spaces that remain between them must be filled up with spalls. Spalls are smaller stones used to fill up the voids left in boulder masonry, in order to save cement mortar.

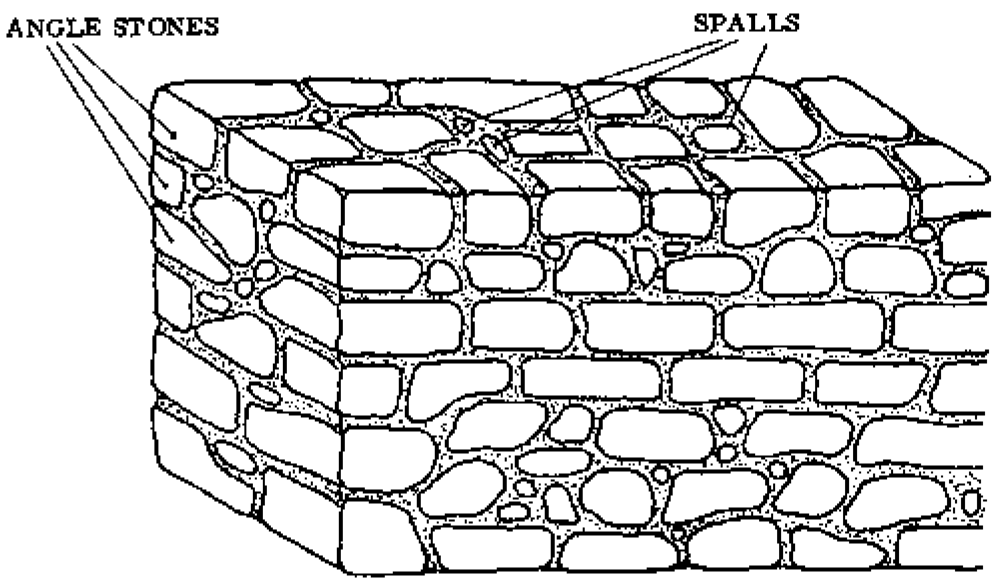

Fig. 1

The stones are used in their raw state, but the boulders forming the quoin should be shaped a bit more regularly to form a secure corner bond. The first course is laid in mortar, not directly onto the bare ground. It is usually impossible to construct regular courses because of the irregular shapes of the stones.

If the foundation is made of a porous rock like laterite rock, it is advisable to plaster both the inside and outside faces to prevent dampness from penetrating. Otherwise only the outside face is plastered.

The excavation for the trench is made a little wider than the foundation (Fig. 2) so that the plaster can be applied right down to the bed of the first course. Coarse gravel or broken stones can be used later to refill the space when the plastering is finished. This prevents the erosion of soil along the foundations, especially under the eaves of an overhanging roof.

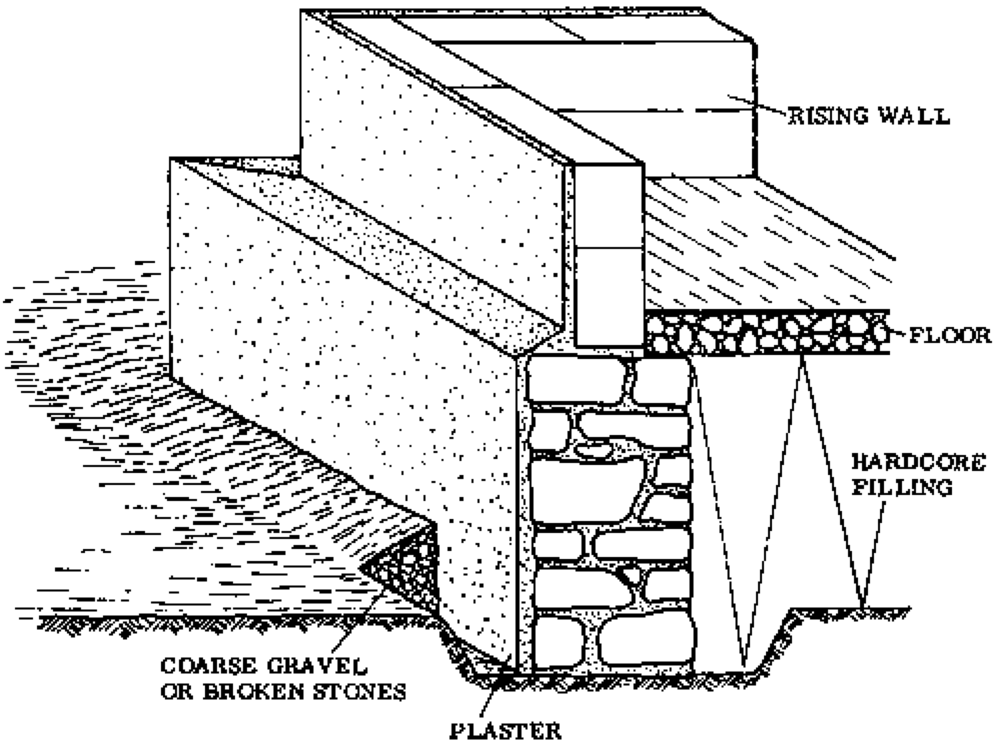

Fig. 2

NOTES:

Ashlar masonry foundations

In this type of masonry, the stones are “dressed” before they are used in the structure. To dress stone means to cut and shape it, and it is done to make the stones fit together better. There are four different types of ashlar masonry, depending on how much dressing is done and how the stones are put together. These are:

- Rough stone masonry
- Hammer-dressed ashlar masonry
- Broken range masonry
- Range masonry.

These are listed according to the increasing amounts of stone dressing and stone arrangement required for each method.

- ROUGH STONE MASONRY: This sort of masonry consists of natural stones which are shaped only slightly along their bed faces, or not shaped at all. As in boulder masonry, regular courses are not seen because of the irregularly shaped stones (Fig. 1).

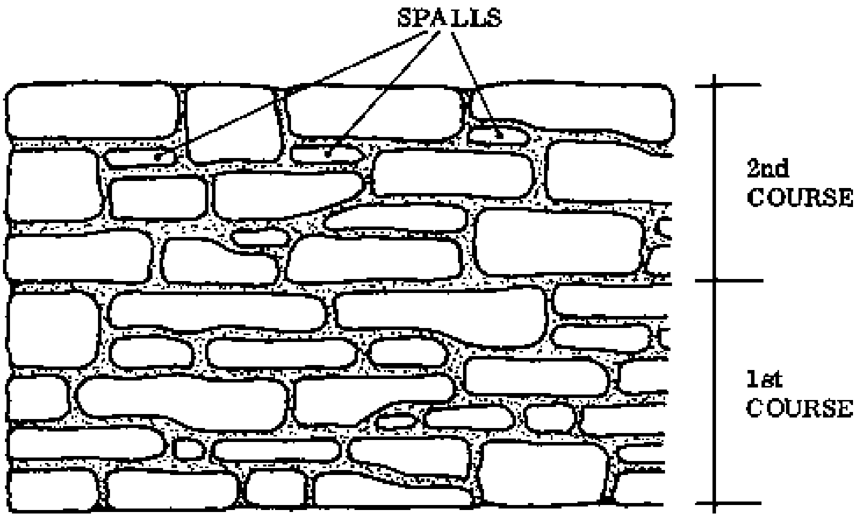

Fig. 1 ROUGH STONE MASONRY

- HAMMER-DRESSED ASHLAR MASONRY: As the name implies, the stones used for this type of masonry are roughly shaped with a hammer, so that the stretcher and header faces are approximately square to each other.

The stones are laid in regular courses but the thickness of the stones may vary within one course (Fig. 2).

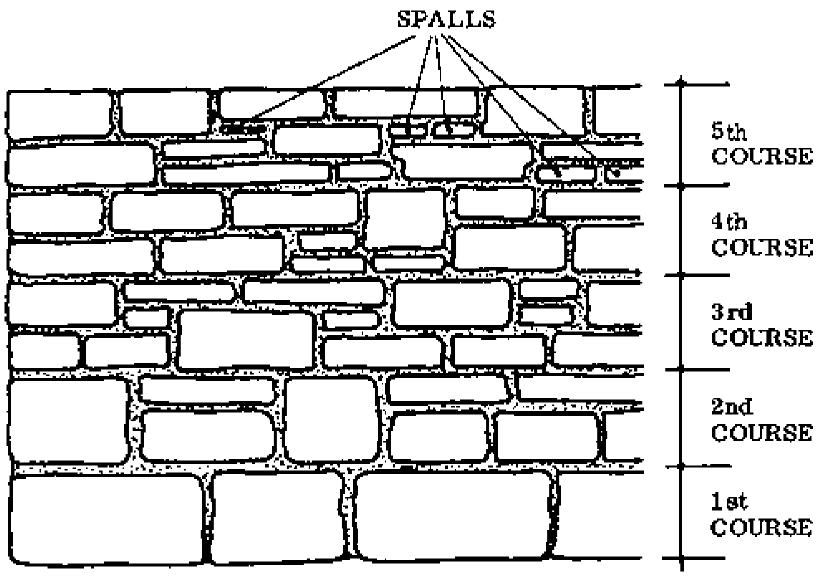

Fig. 2 HAMMER-DRESSED ASHLAR MASONRY

NOTES:

- BROKEN RANGE MASONRY: The stones of this masonry are accurately shaped with the club hammer and cold chisel (Reference Book, page 15) so that all the faces are square to each other. The bond should not contain joints more than 3 cm thick. The height of the stones may vary within a course, and the height of the courses may also vary, with the result that the courses are continuous for only short distances (Fig. 1).

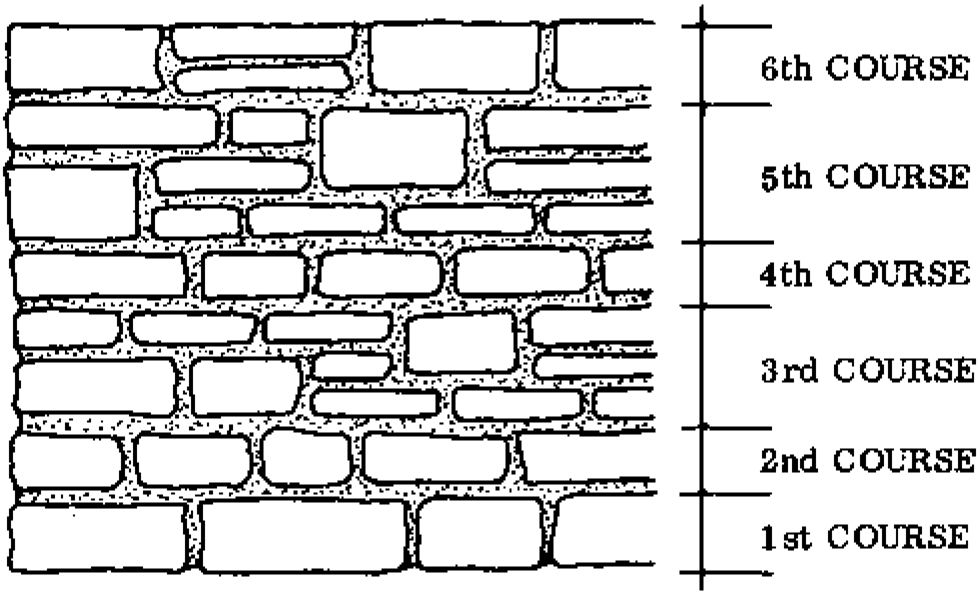

Fig. 1 BROKEN RANGE MASONRY

- RANGE MASONRY: The accurately squared stones are laid in courses, and each course is uniformly thick throughout its length. However, the courses are not all necessarily all the same thickness (Fig. 2).

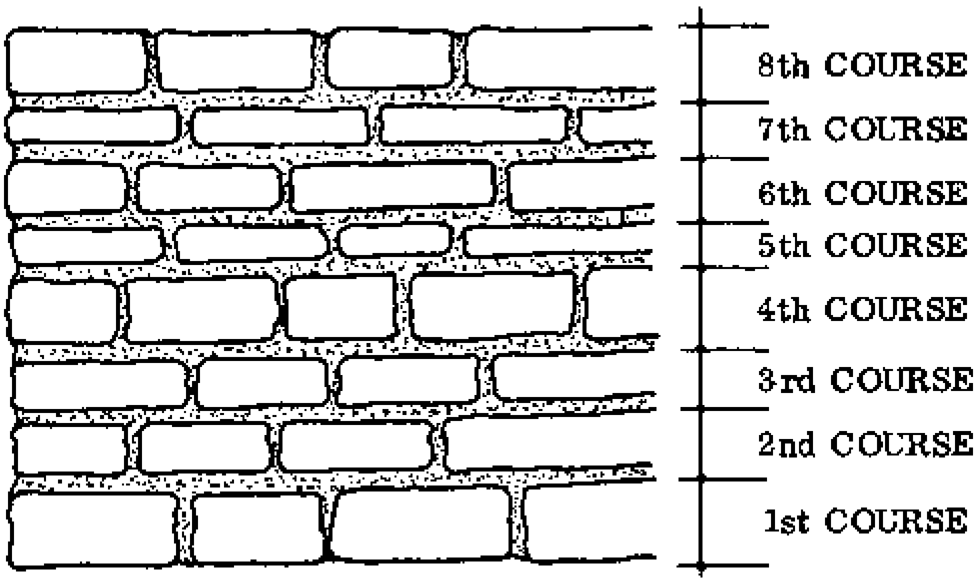

Fig. 2 RANGE MASONRY

Bonding principles

The following rules are observed for all four ashlar masonry techniques, regardless of how much dressing is done on the stones.

- Observe the structure of the rock, and if possible lay the stone in the way it has “grown”. For example, if the stone appears to have horizontal layers, it should be laid so that the layers are flat.

- Never lay stones edgewise.

- The stones should overlap each other as far as possible; avoid making any continuous cross joints between two courses (Fig. 3).

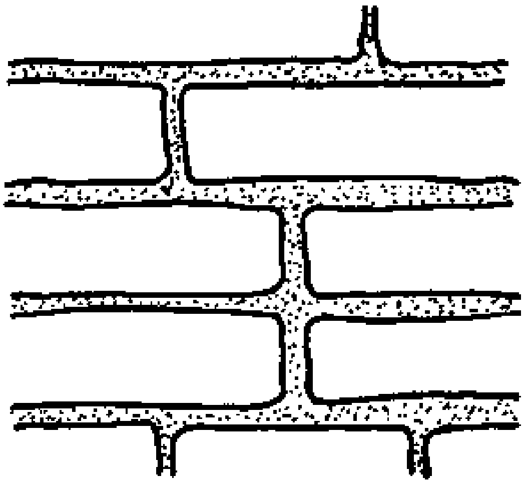

Fig. 3 WRONG!

- Also avoid making a group of continuous cross joints in one course (Fig. 4), as this creates an unpleasant appearance and an impression of a separation. A better arrangement is shown in Fig. 1.

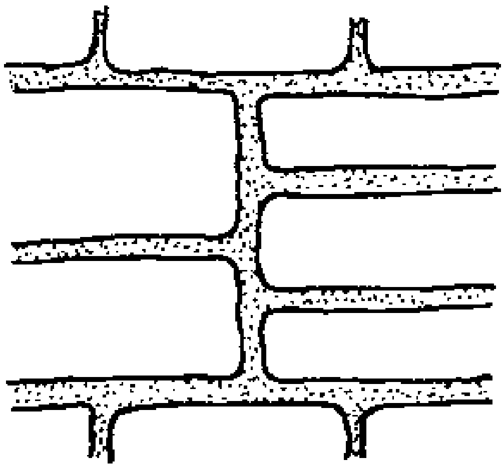

Fig. 4 WRONG!

- Fill up the bigger voids between stones with spalls, to save mortar.

- If ashlar masonry is used as a foundation, the first course is always laid in mortar, not directly on the ground.

- In case the foundation is combined with the footings and the plinth course, all ashlar masonry must be coursed and levelled at a height not exceeding 1,5 m, and preferably every 50 cm.

NOTES:

Laterite rock foundations

Many areas of northern Ghana offer the opportunity to work with a highly suitable building material; namely laterite rock.

In structure and colour it appears similar to laterite soil, and although it is rather porous and comparatively soft when freshly dug from the earth, it gradually becomes hard and rock-like when it is exposed to the air.

Laterite stone has been used for many sorts of masonry because it is readily available, easily shaped, and strong.

Its only disadvantage compared with concrete is that it takes time to excavate the stone and shape it into blocks.

However, taking all the factors into consideration, there are some cases where laterite rock represents the most economical choice for building material.

Although the stone can be given any convenient shape, the dimensions of blocks made from laterite stone should preferably be 14 x 30 x 46 cm, which allows proper bonding with all sorts of masonry. Accordingly, the dimensions of half-blocks are 14 x 30 x 22 cm; for 3/4 blocks, 14 x 30 x 34 cm; and for 1/4 blocks, 14 x 30 x 10 cm (Fig. 1).

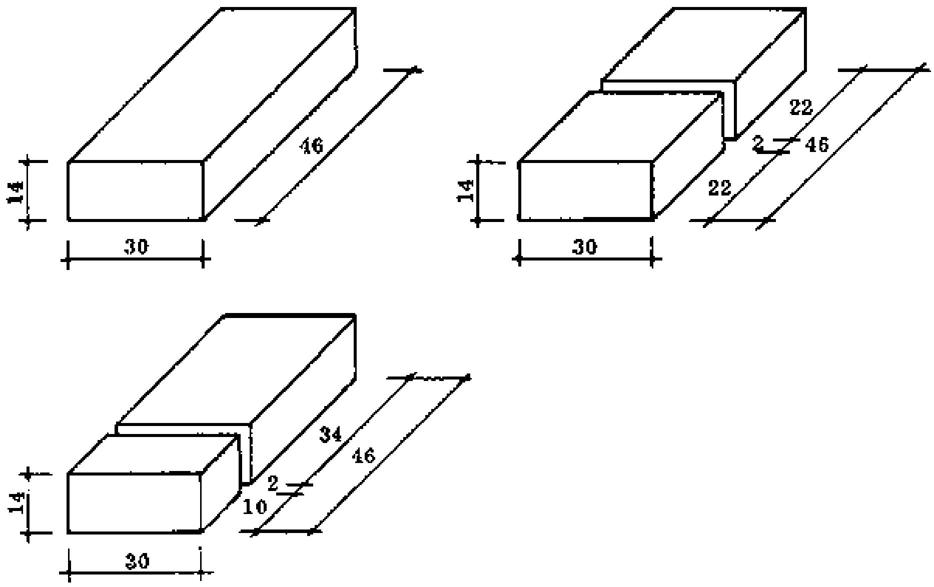

Fig. 1

When blocks of laterite stone are used for footings, they are laid in stretcher bond, flatwise, which results in a footing which is 30 cm thick instead of 23 cm when sandcrete blocks are used (Fig. 2).

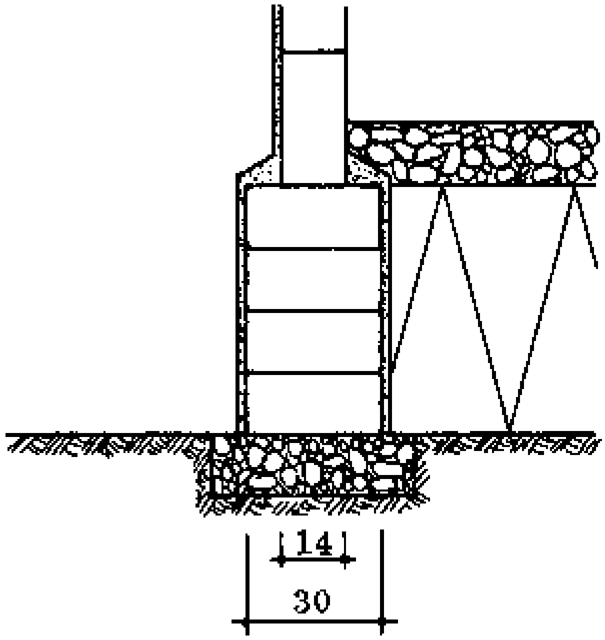

Fig. 2

Foundations can be built out of laterite stone blocks; the blocks are laid in header bond, with a minimum of two flatwise courses (Fig. 3). Foundation and footings can be combined as shown in Fig. 4, which allows the erection of stronger outside walls.

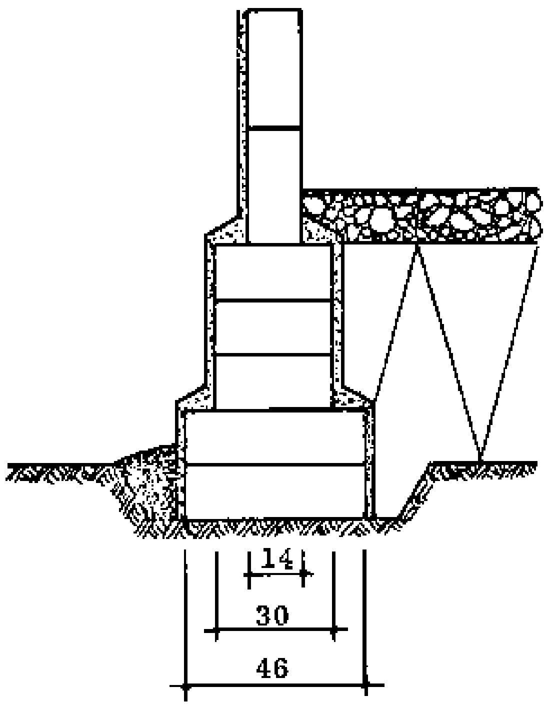

Fig. 3

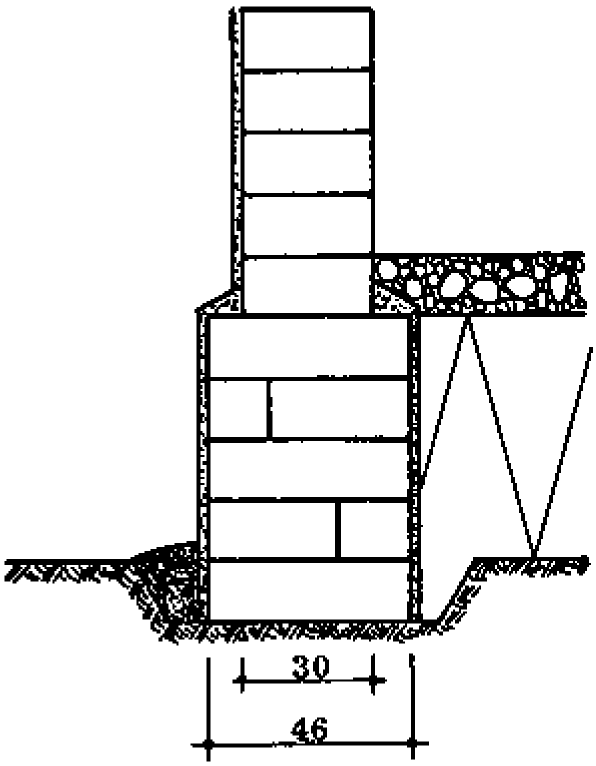

Fig. 4

Since the laterite stone is porous, the foundations should be plastered on both the inside and outside faces.

NOTES:

Artificial stone foundations

As far as Rural Building is concerned, there are only two artificial stone products of importance for foundations: bricks and sandcrete blocks.

Both products are seldom used for foundations in northern Ghana. We don't use bricks because, while the clay is available to make them, it would take too much firewood or other fuel to fire the bricks. Concrete or laterite stone blocks are usually more economical to use than sandcrete blocks.

- BRICK FOUNDATIONS: Brick is one of the oldest known artificial stones; it is made from clay which is shaped, dried, then fired in a kiln. The usual dimensions of a brick are 7,1 x 11,5 x 24 cm, a size which results in a masonry containing many joints, but which allows the construction of most complicated bonds.

Foundations made out of bricks must be at least 5 courses high and carefully laid in cross bond or English bond (Fig. 1). Note the different arrangements of the alternating courses.

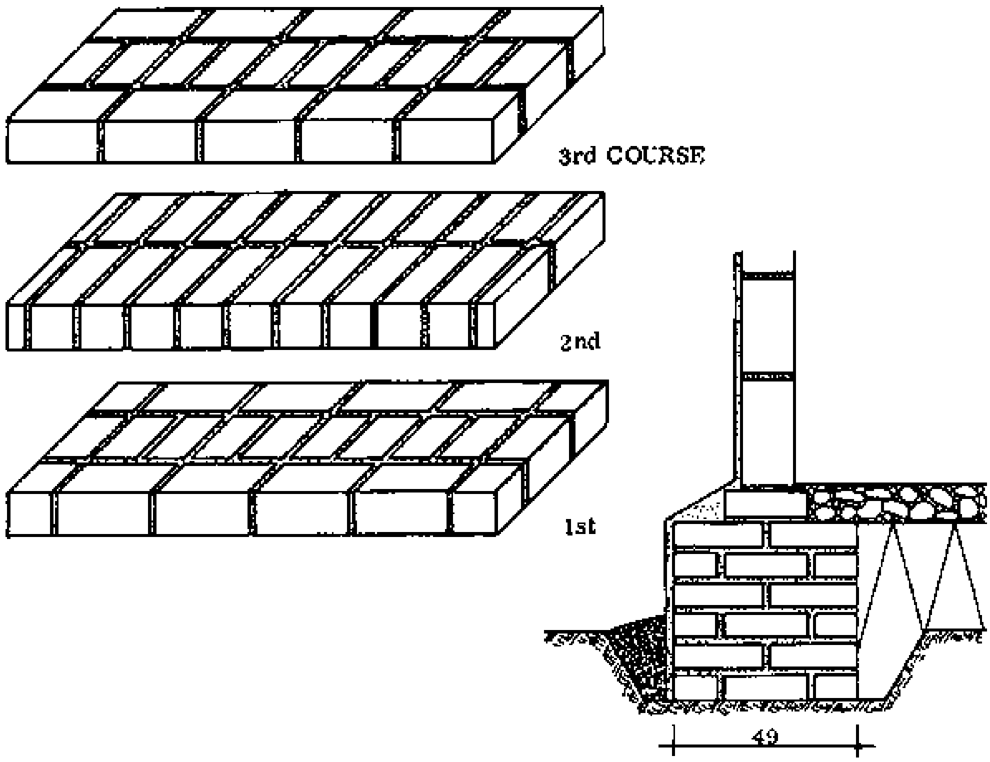

Fig. 1 BRICK FOUNDATION

- SANDCRETE BLOCK FOUNDATIONS: In an area where there is a lot of sand available but no broken stones, gravel or laterite rock, etc., one may be forced to use sandcrete blocks to build the foundations. The mix proportion for these blocks should be no less than 1:8, and the blocks themselves should be laid in header bond, as seen in Fig. 2.

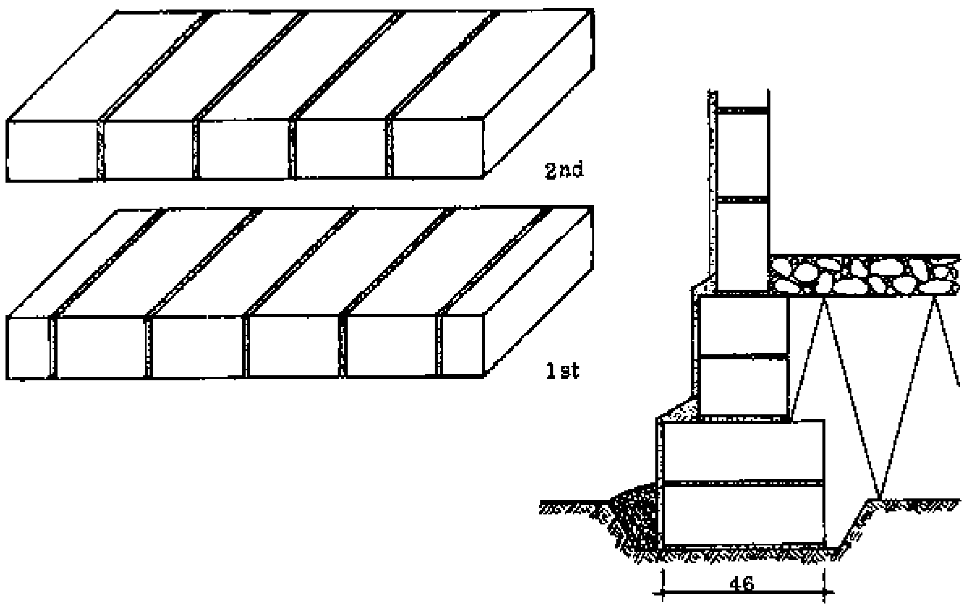

Fig. 2 SANDCRETE BLOCK FOUNDATION

NOTES:

CONCRETE FOUNDATIONS

Excavating the foundation trenches

After the setting out is complete, including marking the positions and widths of the foundations on the ground, the lines are removed from the profiles or pins and the excavation work is started.

All the topsoil and as much as possible of the soft soil and light soil is removed, and brought to a place where it can either be used immediately or kept for a future dry season garden.

In most cases soils of a firm consistency and good load bearing capacity are found at depths ranging from 15 to 25 cm, which is deep enough for the construction of foundations for a rural dwelling place (Fig. 1).

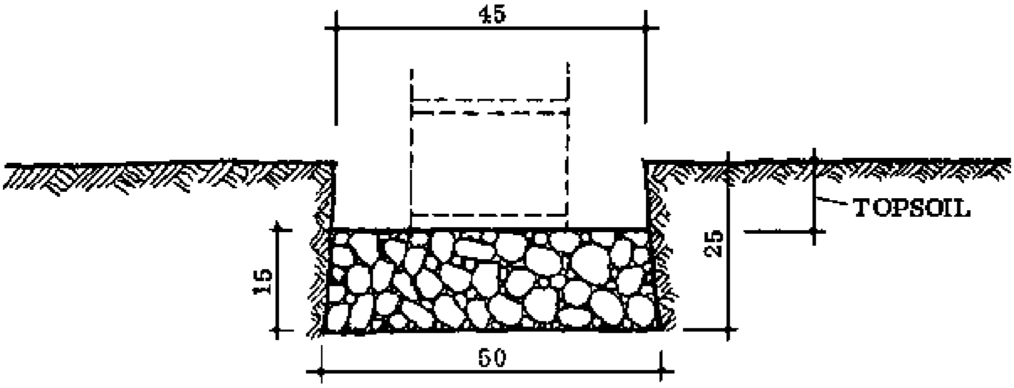

Fig. 1

There are of course exceptional cases where the rock is close to the surface, or even at the surface, which makes the work easier; or the opposite situation of very deep soft soil, which is a problem.

In areas where there is light or heavy rock close to the surface, the thickness of the foundation can be reduced, but to no less than 5 cm thick. The surface of the rocks should be roughened if necessary to provide a good grip, and cleaned before the concrete is cast. These areas are usually rich in stones, so one should check out the possibility of making boulder foundations. The boulder foundations can also be carried out as a stepped foundation if necessary, following the contours of the rocky surface (Fig. 2).

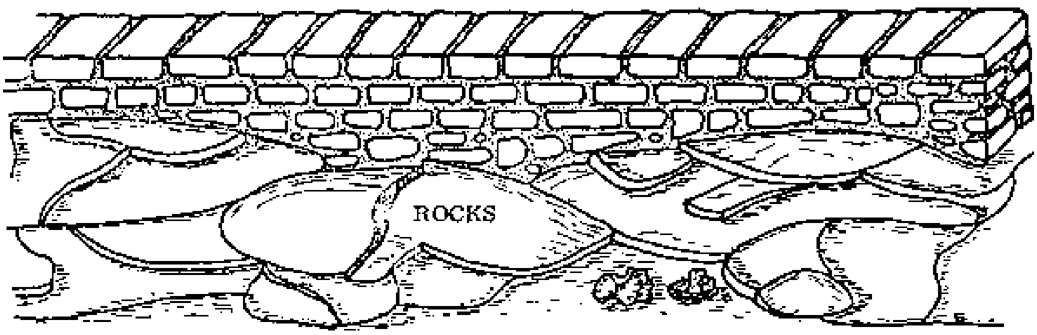

Fig. 2

Very deep soft soil is a problem, and it requires special measures. In general, all excavations should be continued until a layer of good firm soil is found. When a depth of 60 cm is reached and the soil is still too soft, the excavation work is stopped.

Instead of digging deeper, widen the trench to at least 60 cm. This increases the total area on which the structure rests, with the result that the pressure on the soil underneath is distributed over a wider area.

Fig. 3 shows that the thickness of the widened foundations must be increased to 30 cm, because of how the foundation material distributes the pressure of the wall above.

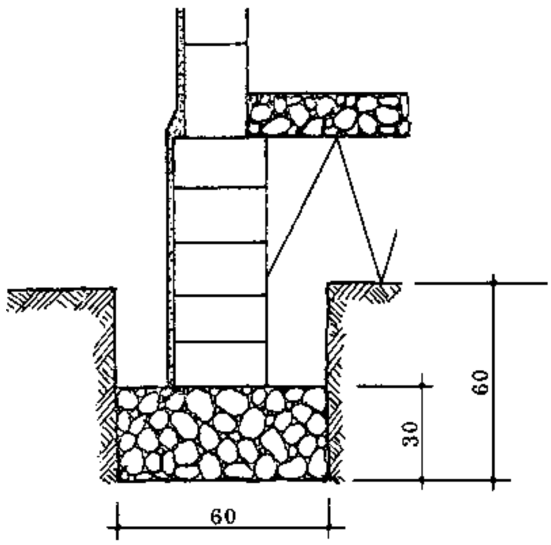

Fig. 3

In order to save concrete, put bigger stones, rubble or boulders into the foundation; it should preferably be flush to the ground surface (Fig. 4).

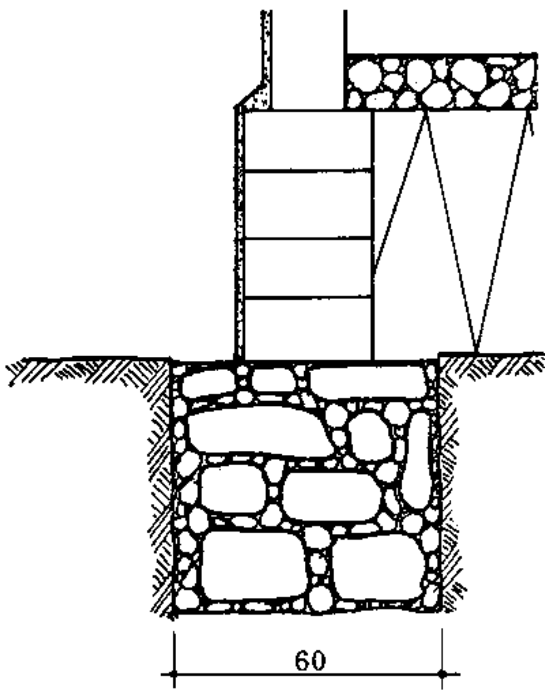

Fig. 4

- SOFT POCKETS: During the excavation work it sometimes happens that the character of the soil changes unexpectedly: spots or pockets of soft soil are found in the firm soil. These may be natural deposits or man-made holes that have gradually filled in. The load bearing capacity of the soil is reduced in these places.

If the area is relatively small and runs across the trench, it is advisable to reinforce the concrete foundation covering the pocket with a network of crossed iron rods (Fig. 1). The rods should be long enough to bridge the soft part and project past it on both ends to anchor securely in the foundation which is supported by firm soil.

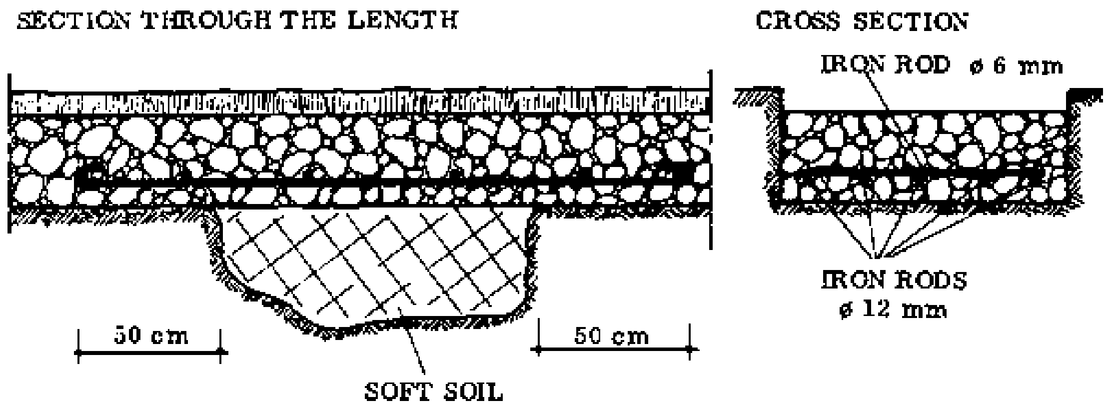

Fig. 1

In case the area is too wide to be reinforced in this way, the soft soil is removed and the hole is refilled with compacted layers of boulders, stones, and sharp sand; or with concrete, thus improving the load bearing capacity (Fig. 2).

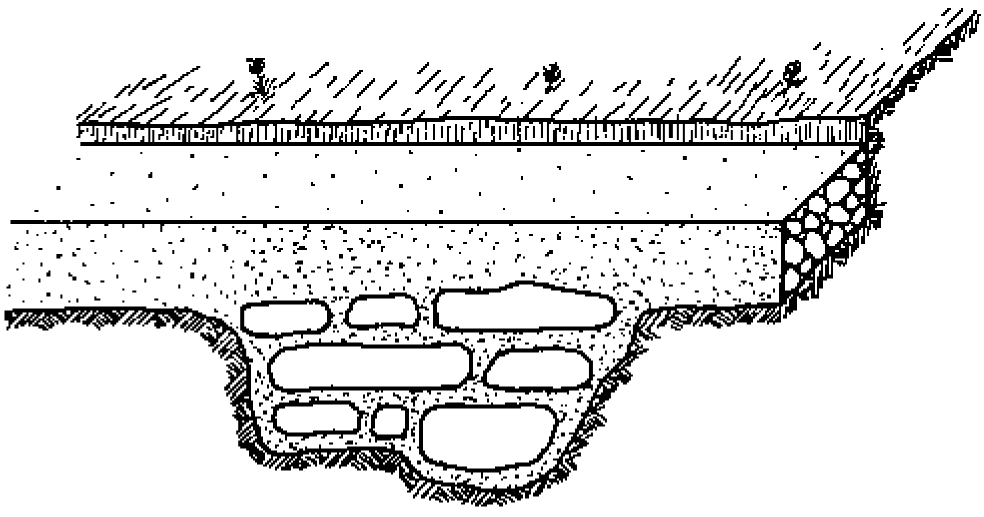

Fig. 2

When the foundation has to cross a very wide section of soft soil, that section of the foundation has to be made wider and deeper than the rest (see the previous page).

- SHAPE OF THE TRENCHES: Although it is generally accepted that the ideally shaped foundation trench has walls that are at right angles to the levelled bot tom of the trench (Fig. 4), it is often observed that unskilled or even skilled workers tend to dig trenches which are incorrectly shaped. Special attention should be given to this problem during excavations in harder soils, because the more difficult the digging, the more likely it is that incorrectly made trenches will result (Fig. 3).

Fig. 3

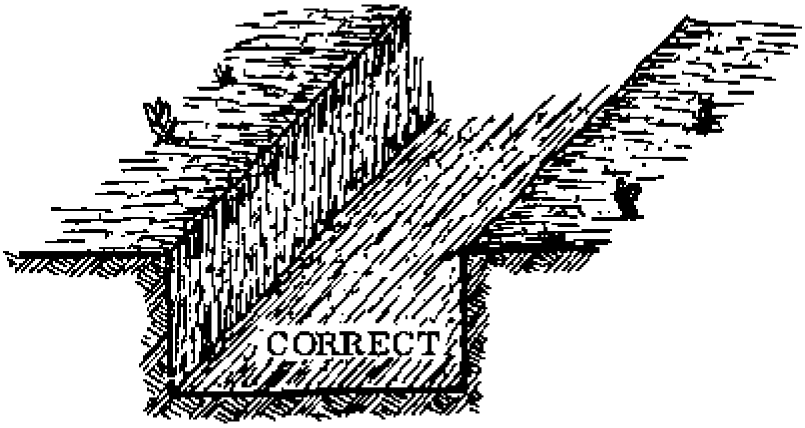

Fig. 4

Experience has shown that it is best to ask the workers to make the trenches a bit wider at the bottom, to ensure that the minimal width of the foundation is maintained everywhere (Fig. 5).

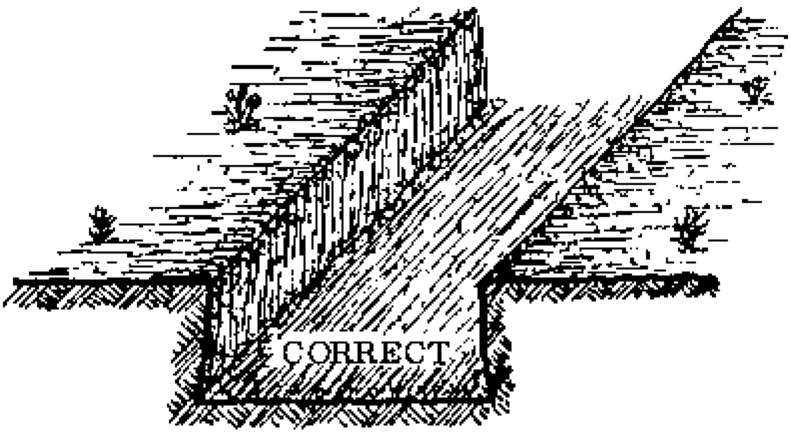

Fig. 5

NOTES:

Measurements of stepped foundations

The number, length and height of the steps in the foundation depend on the shape and steepness of the ground contours. To make it easier to construct the footings later and to save materials, the skilled builder will adapt the length and height of the steps to fit with the type of blocks that will be used for the footings.

Fig. 1 shows a common stepped foundation made of concrete, and footings built of sandcrete blocks. It can be seen that the concrete thickness is 15 cm throughout, while the steps are different lengths.

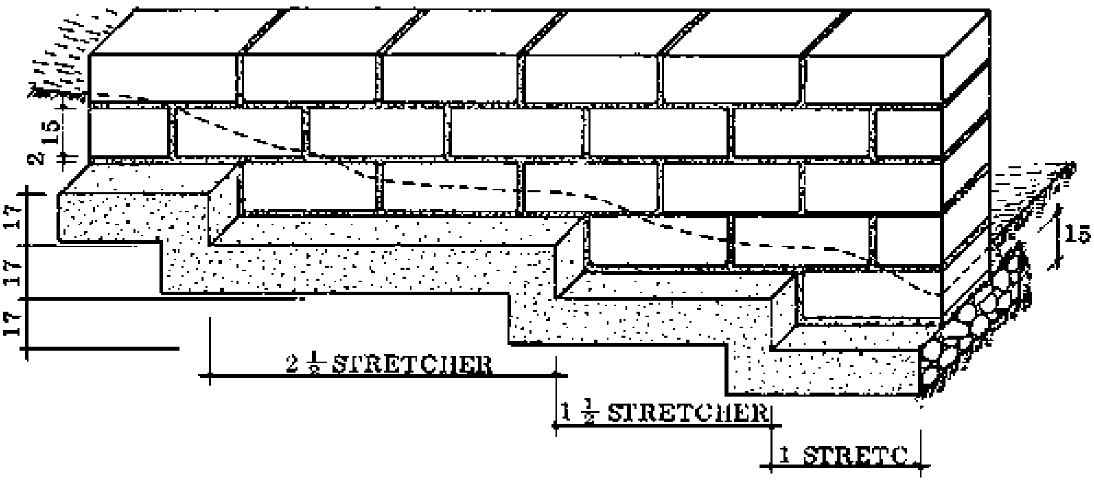

Fig. 1 STEPPED FOUNDATION WITH SANDCRETE FOOTING

- HEIGHTS OF THE STEPS: The height of each concrete step is always the thick ness of a sandcrete block, plus the thickness of the mortar bed; making 15 cm plus 2 cm equals 17 cm.

In case the steps have to be steeper, the height of the step is always a full multiple of 17 cm: 34, 51 cm, etc. so that 2 or 3 courses of sandcrete blocks can fit on the step (Fig. 2).

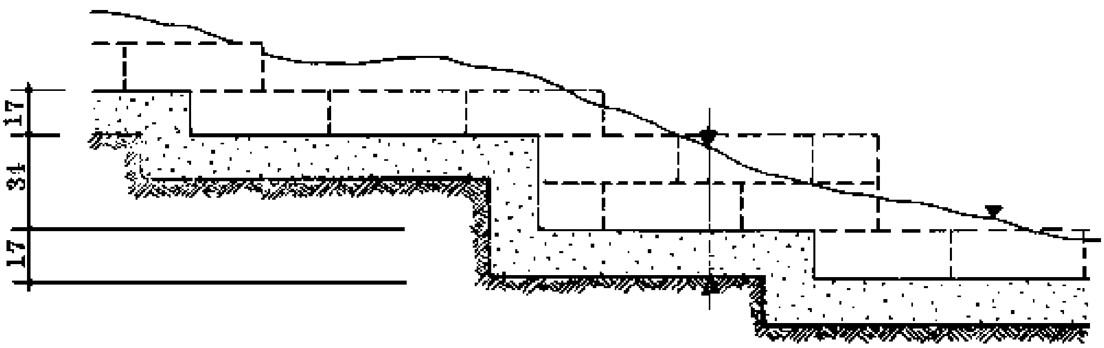

Fig. 2 STEPPED FOUNDATION WITH 2 COURSES ON ONE STEP

- LENGTHS OF THE STEPS: All masonry is supposed to be built in half-block bond. Accordingly, the minimum length of a step is half a block plus the joint: 22 cm plus 2 cm equals 24 cm; or for longer steps, a full multiple of this: 48 cm, 72 cm, 96 cm and so on.

If the foundation is to be constructed with laterite stone blocks (Fig. 3), the height of one step is reduced to 16 cm, that is 14 cm for the block plus 2 cm for the joint. The lengths of the steps are the same as for sandcrete blocks.

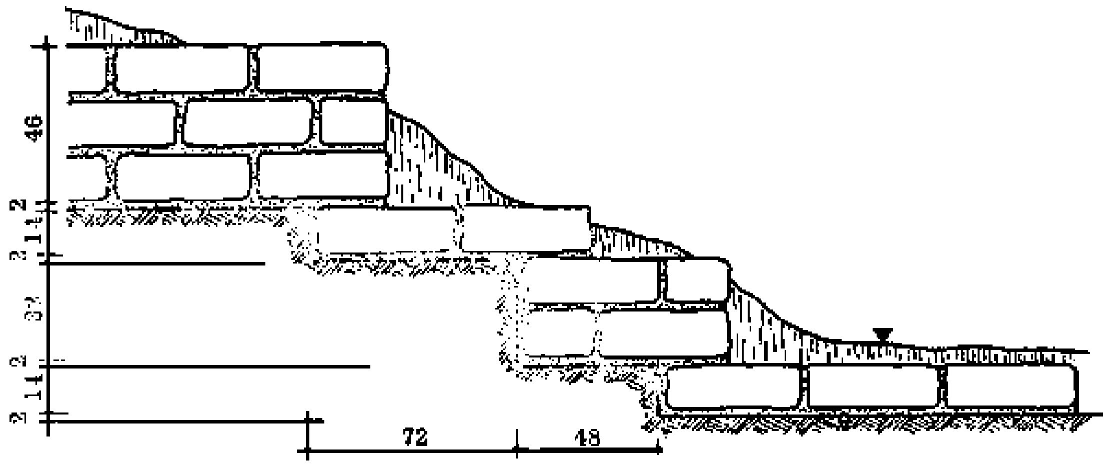

Fig. 3 STEPPED FOUNDATION WITH LATERITE STONE

The actual construction of a stepped foundation and its footings must always be started from the lowest step, to prevent bonding mistakes.

NOTES:

Levelling the trenches and marking the foundation depth

The bottoms of all foundation trenches must be perfectly level, not only in the length but also across the width. Otherwise the building may settle unevenly, which can cause cracks in the structure or even a complete collapse.

This is why a foundation on a sloping site must be constructed in steps (Fig. 1) instead of taking a course parallel to the slope of the ground.

An improperly constructed foundation can result in a building that is a danger to the people living in it, and also a possible loss of valuable property.

When the trench has been excavated and roughly levelled, the next step is to determine the depth of the foundation concrete and at the same time, to level the bottom of the trench more exactly.

This is done by inserting iron or wooden pegs in the trench so that they project from the bottom by a distance equal to the depth of the foundation (Fig. 1). The distance between the pegs should be no further than the straight edge can bridge, so that it is possible to level between them using the straight edge and spirit level. Trenches can be levelled more accurately over longer distances by using the water level.

The triangular pattern of the pegs is necessary to obtain a level surface: if the distances A-B and B-C are level, then A-C must also be level (Fig. 1).

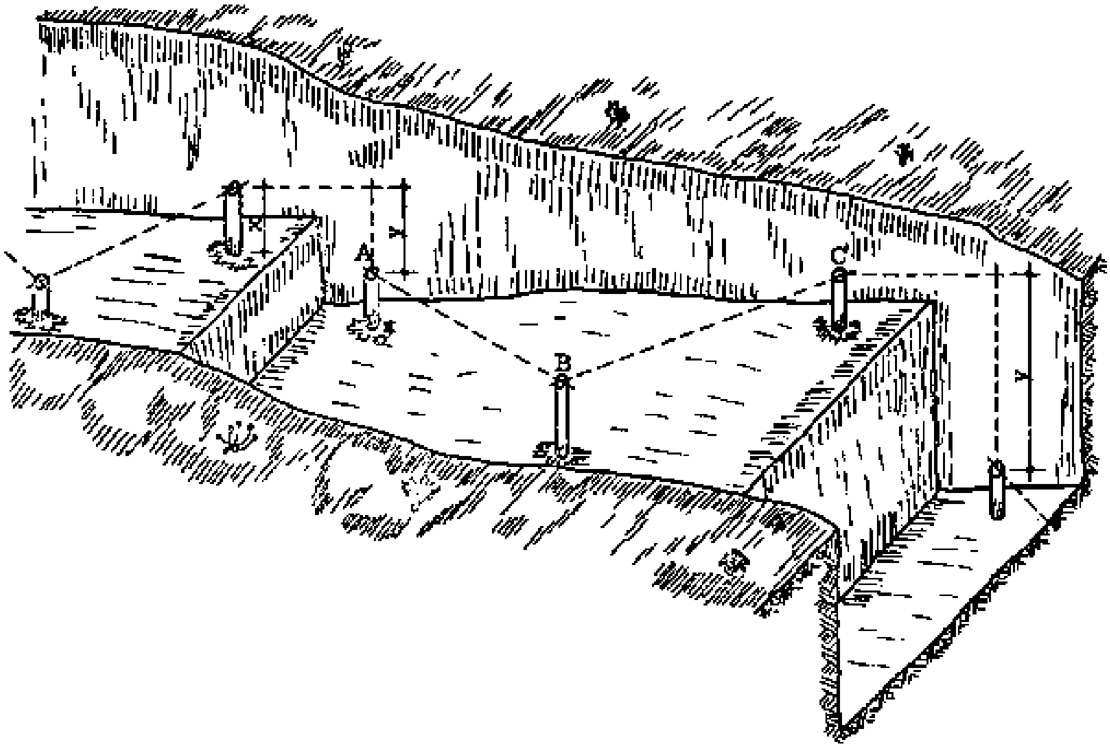

Fig. 1

x = DEPTH OF FOUNDATION CONCRETE
y = HEIGHT OF STEPS (BLOCK PLUS JOINT)

NOTES:

When the tops of the pegs are level, we can measure how far each peg sticks out from the bottom of the trench, and thus check whether the trench bottom is also level. High areas are skimmed off with a shovel, while hollows are filled with concrete. Never refill hollow areas with excavated soil, as this might lead to uneven settling of the foundation.

NOTES:

Mix proportions

The correct mix proportions for foundation concrete should generally be determined through the calculations of an engineer. Since this is usually not possible in Rural Building, the Rural Builder can decide the mix proportion with the help of the Tables of Figures, Reference Book, page 234. The data given there and the following hints are approximate values and are intended as a guide. The general range for the mix is from 1:10 to 1:15.

- For small projects like single dwellings, stores, etc., a mix proportion of 1:15 is sufficient because the total weight on the foundation is not so great.

- Bigger buildings like two-storeyed houses, halls or churches require a better mix proportion of 1:12.

- Elevated water storage tanks, bell-towers and other large heavy structures should be based on foundations mixed in a proportion of 1:10.

Preparations before casting

If the ground is dry, the foundation trenches have to be wetted down before the concrete is cast. This helps to reduce the absorption of moisture from the concrete by the soil. Take care that the sides of the trenches are also thoroughly wetted.

After the foundation concrete is mixed (Reference Book, pages 161 to 163), it has to be transported to the trenches, either in buckets, headpans or wheelbarrows. All transportation of the concrete has to be done without too much delay or vibration, as this could lead to the aggregates becoming separated. If wheelbarrows are used, the paths should be covered with boards to reduce vibration and to make it easier to push the wheelbarrows.

It is a good idea to provide a wheel stop (Fig. 1) beside the trench. This helps to ensure that the concrete is emptied right in the middle of the trench and does not take along dust and dirt from the sides of the trench. A board can be used to protect the opposite side of the trench (Fig. 1). This is not necessary when the concrete is picked up with a shovel from the wheelbarrow.

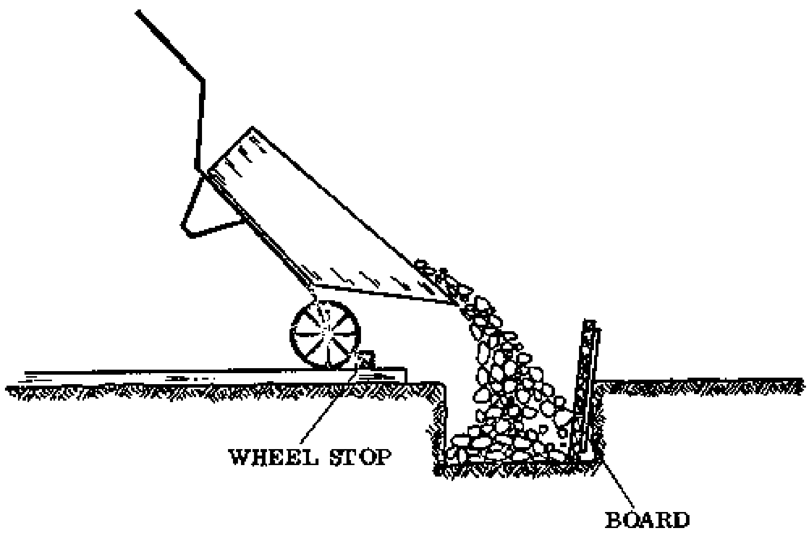

Fig. 1

NOTES:

The containers in which concrete is transported should be kept wet, so that no concrete sticks to the container when it is poured.

NOTES:

Casting

The concrete must be cast systematically so that the compacting and levelling follow immediately after it is poured in the trench. The headpan loads or wheelbarrow loads are deposited in an orderly way, not just dumped anywhere in the trench (Fig. 1).

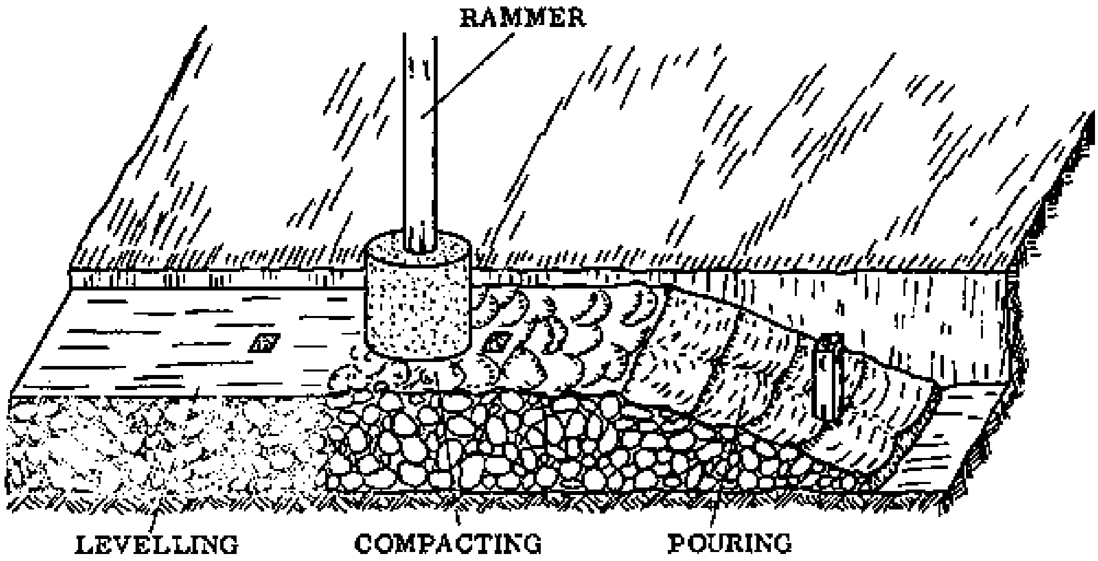

Fig. 1

Do not cast foundation concrete in sections with spaces in between, as this can lead to disturbances of the hardening process when the gap is filled up later. Always start from the far end of the trench and work your way closer to the mixing area. Two groups of workers can cast foundations on different sides of the building at the same time.

- COMPACTION: The concrete must be well compacted so that no air voids re main. Since foundation concrete has a rather stiff consistency, to compact it requires the use of heavy rammers (Reference Book, page 19).

The concrete is applied in layers no more than 15 cm deep, and each layer is compacted with the rammers. Pay special attention to compacting the corners and the outside edges. Stiff concrete should be compacted until its surface becomes wet.

Do not be tempted to compact the concrete just roughly, or to add water to ease the work. The production of a good foundation is a hard job, but only hard work will result in a good quality foundation.

- STEPPED FOUNDATION: In casting the vertical parts of a stepped foundation, pieces of board are used as shown in Fig. 2. These are fitted into recesses cut in the side of the trench. The width of the board is the same as the height of the step (Fig. 2).

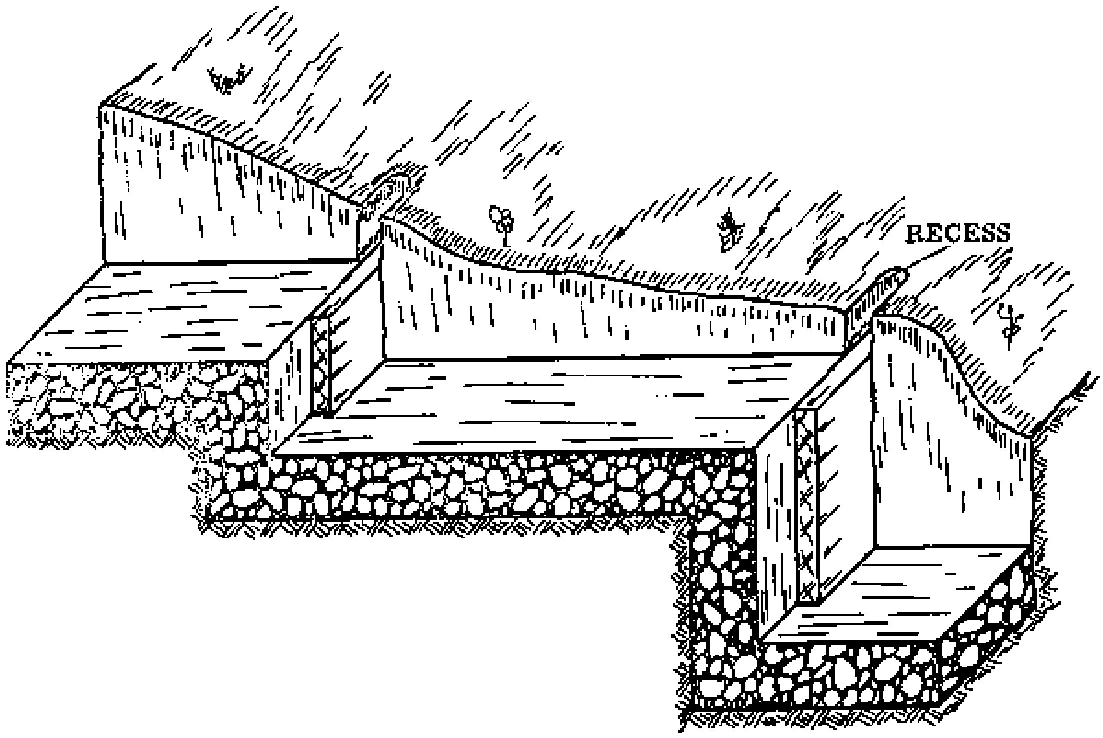

Fig. 2 CASTING A STEPPED FOUNDATION

NOTES:

Levelling the foundations

As soon as the foundation is compacted, the top has to be levelled flush with the top of the pegs. For this purpose a strike board is used.

If the compaction has been carried out correctly, the levelling should be fairly easy as there is not much concrete left to strike off.

All wooden pegs have to be removed and the holes filled with concrete, while the iron pins may remain if these were used.

As soon as the hardening process starts, as can be seen by the dull and dry looking surface, the area where the footing course will be set must be slightly roughened with the blade of a trowel, to provide a good grip for the mortar (Fig. 1).

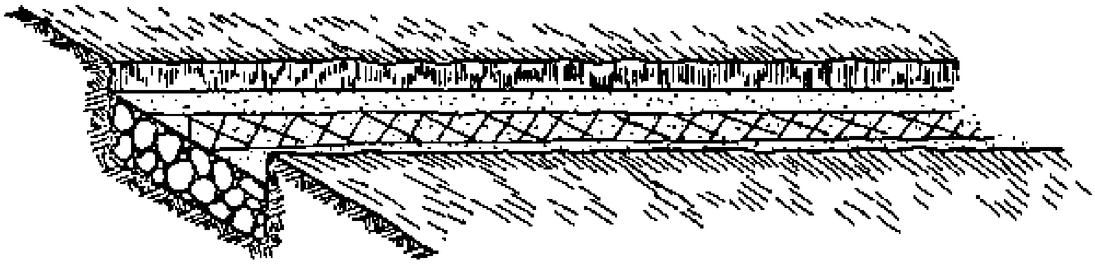

Fig. 1

Curing

If the concrete is disturbed during the hardening process, serious defects may be produced.

Freshly cast concrete must therefore be covered with empty cement bags, straw, mats, boards or moist sand to protect it against:

- The rain, which can wash out the cement paste, leaving the non-bound aggregate behind (Fig. 2).

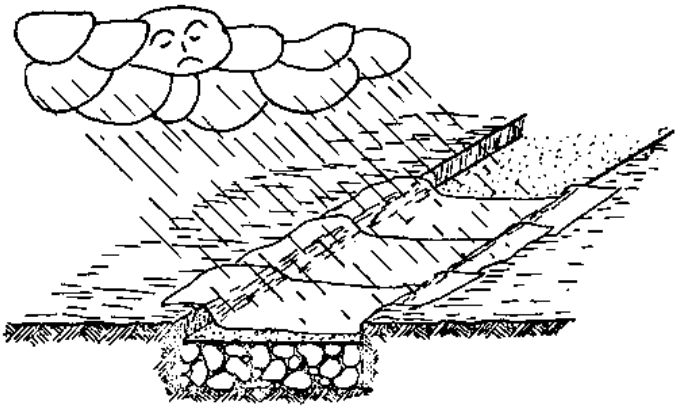

Fig. 2

- The sun, which can "burn" the surface of the concrete, so that although the concrete looks cured, under the surface it has not set hard enough (Fig. 3).

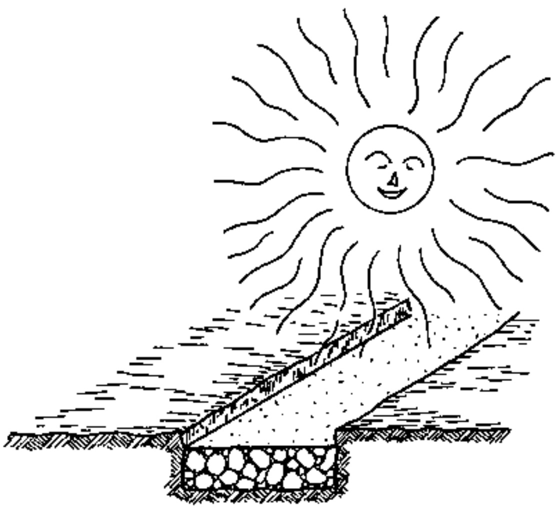

Fig. 3

- The wind, which can dry up the surface, resulting in cracks due to excessive dryness and shrinkage: especially during the harmattan season (Fig. 4).

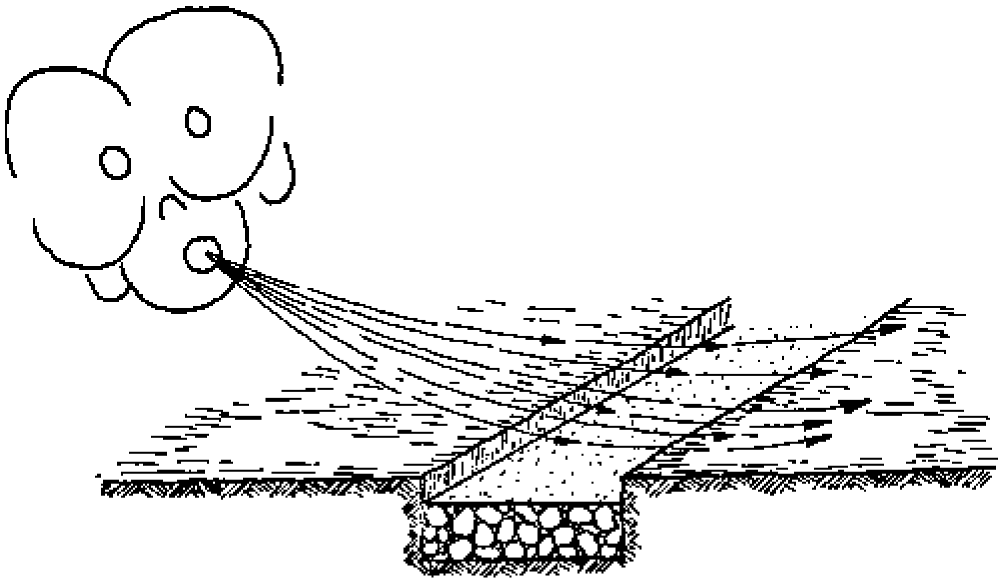

Fig. 4

- The dirt, which may get on the surface and interfere with the grip of the footings.

Any vibration near the hardening concrete could cause cracks and destroy the internal structure of the concrete. Don't continue with any excavation work, etc. near the just-completed foundation.

Once the surface has set sufficiently hard, the concrete must be wet down and kept wet for three days.

NOTES:

FOOTINGS

The projecting courses at the foot of a wall, between the rising wall and the foundation, are called the footings. If there is no wider concrete foundation, the combination foundation/footing is called a footing (see Foundations, page 25).

Functions of the footings

Since the footings form the link between the rising wall and the foundation, the demands on them are similar to those set on the foundations. These are:

- To provide a solid, level base for the walls
- To receive loads from the structure above
- To distribute the loads onto the foundation (or the ground).

In addition, the footings have to:

- Raise the floor high enough above ground level to prevent moisture from rising through to the floor, and to keep the landcrete blocks of the rising wall dry.

As far as Rural Building is concerned the last function is the most important one.

Materials and measurements

The most common material used for footings is sandcrete blocks, laid flatwise in a half-block bond. The courses are 23 cm thick and 17 cm in height, and they are laid in the centre of the foundation strip.

In order to effectively prevent moisture penetration, three courses should be laid above ground level, thus raising the soffit of the floor to a height of 51 cm above ground level. This is the minimum for all bedrooms and living areas.

Only in cases where the building is not to be used as a dwelling place for people, for example a store or a shelter for animals, may the footings be built to a lower level.

The use of boulder or laterite rock masonry is preferred as this can save considerable amounts of cement. The dimensions of such footings will be the same as those of sandcrete footings, when the laterite rock blocks are cut to the same dimensions as sandcrete blocks.

- COMPARE: Fig. 1 shows a building with no footing. The floor is at ground level and water can easily enter. The building in Fig. 2 rests on a footing and the floor is raised above ground level, so it will be drier and thus healthier to live in, and also less likely to collapse since the mud walls are kept drier.

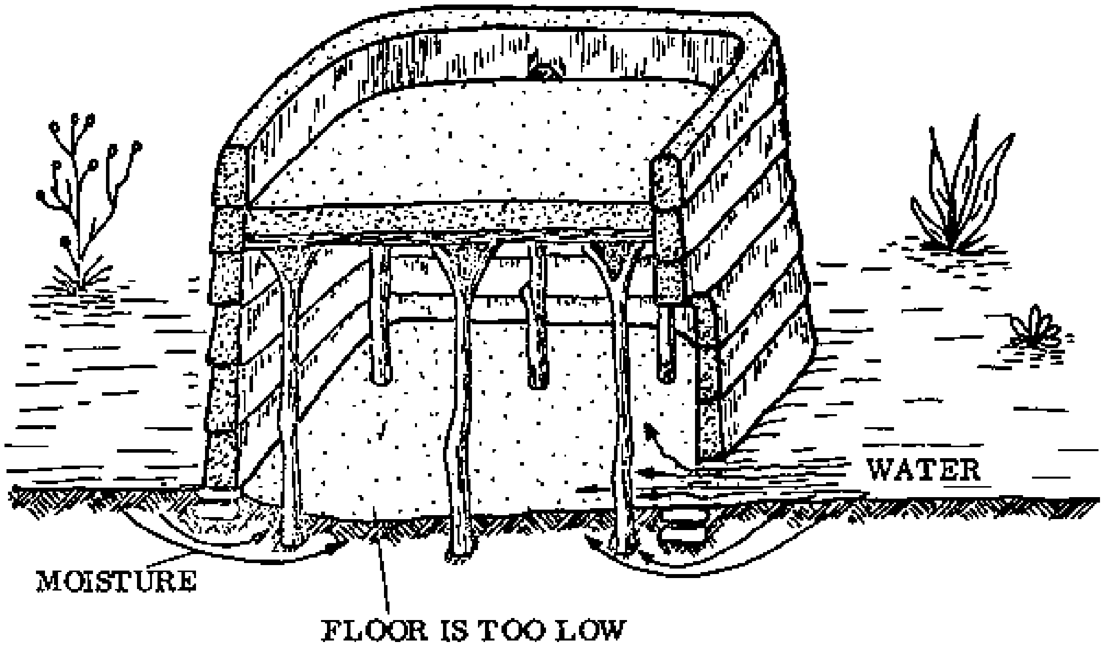

Fig. 1 BUILDING WITHOUT FOOTING

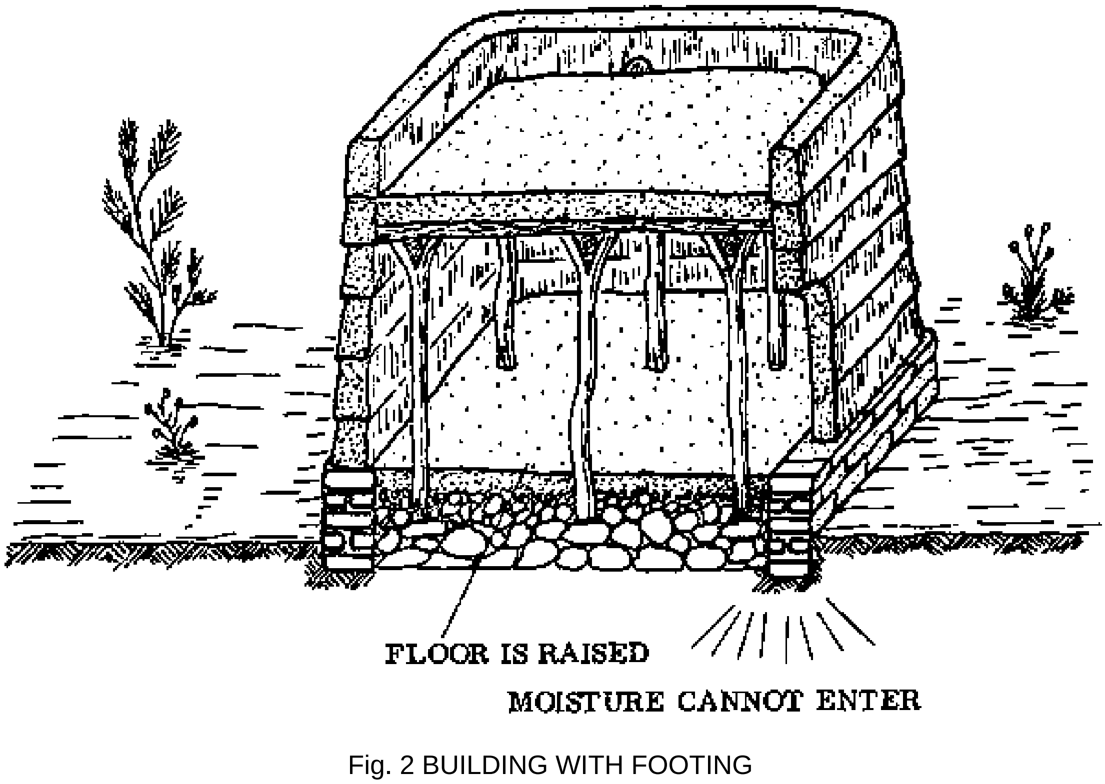

Fig. 2 BUILDING WITH FOOTING

SPECIAL BONDS

Special bonding problems occur at quoins, T-junctions and cross junctions where walls of different thicknesses meet. These situations are frequently found in connection with the footings. They may also occur in other masonry.

An example where footings with different thicknesses meet is in the construction of a verandah. This is because the footing courses under verandahs are laid edgewise instead of flatwise, in order to save material. This is possible because there are no great loads on the verandah footings.

The bonding problem arises from the fact that the dimensions of common sandcrete blocks make it difficult to form a bond between the edgewise courses and those laid flatwise. Fig. 1 shows that two courses laid edgewise do not exactly correspond with three courses laid flatwise: there is a 1 cm difference in height.

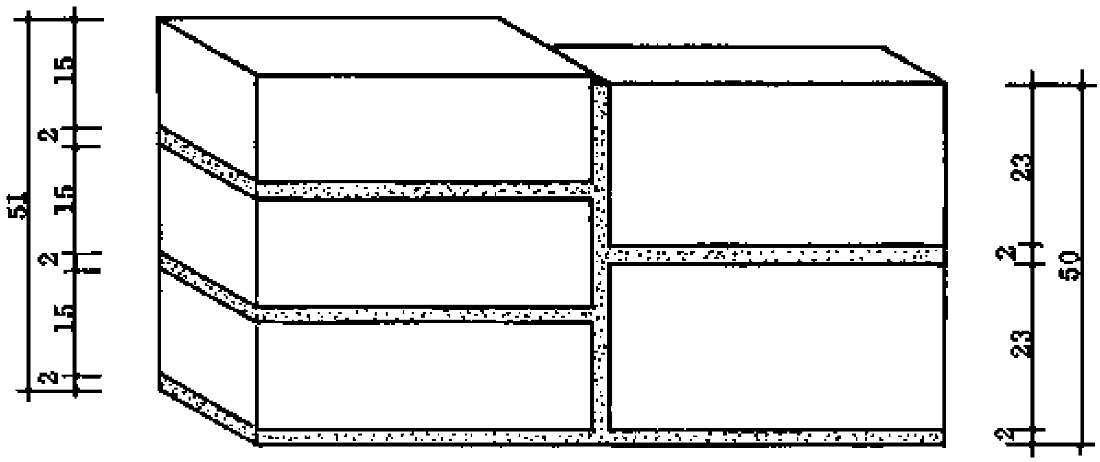

Fig. 1

Footing blocks can be specially made to dimensions that will show a better correspondence, so that bonding is easier and less block-cutting is needed to make the bonds. Fig. 2 shows four flatwise courses of specially made blocks, 10,5 cm thick, which correspond perfectly with two courses laid edgewise. Thus bonding is made easier.

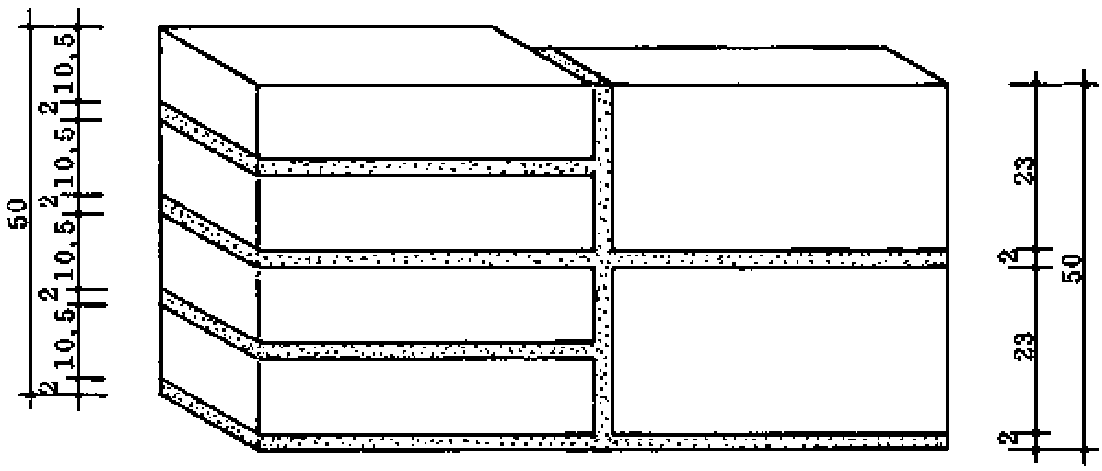

Fig. 2

The verandah footing may be kept in line with the outside face of the wall footing (Fig. 3), or in line with the rising wall (Fig. 4) which results in a recessed footing (see Drawing Book, pages 65, 66, and 90).

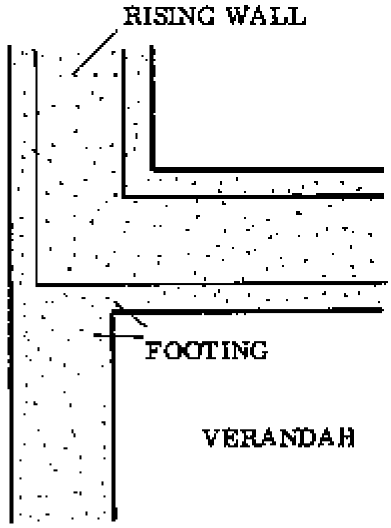

Fig. 3

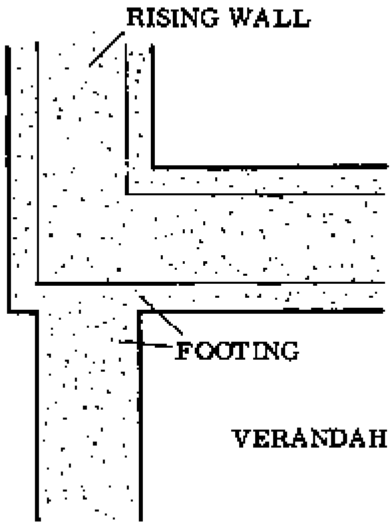

Fig. 4

Each type of block can be used with either a recessed footing or a flush footing. Therefore there are four possible situations:

- Common sandcrete blocks in a flush footing
- Common sandcrete blocks in a recessed footing
- Specially made sandcrete blocks (10,5 cm thick) in a flush footing
- Specially made sandcrete blocks in a recessed footing.

NOTES:

Different wall thicknesses at a quoin

This situation occurs when a verandah is closed at one end with a wall, or where a “loggia” is made. A loggia is a room which has one side open to the courtyard, garden, etc. (Fig. 1). The footings which carry walls have to be regular flatwise footings, while the footing on the open side can be constructed with the blocks edgewise, since it does not carry any wall.

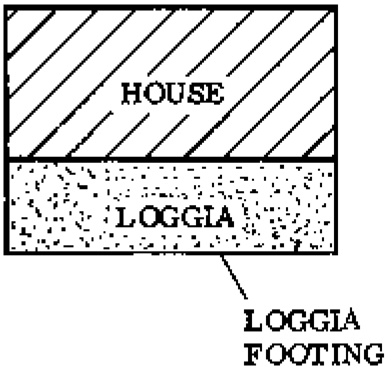

Fig. 1

- COMMON BLOCKS, FLUSH TO OUTSIDE: Fig. 2 shows that both quoin stretchers of the edgewise courses (blocks A and C) have to be cut to an odd shape to fit together with the flatwise quoin header of the second course (block B). In order to maintain the half-block bond, block B has to be cut to a length of 39 cm.

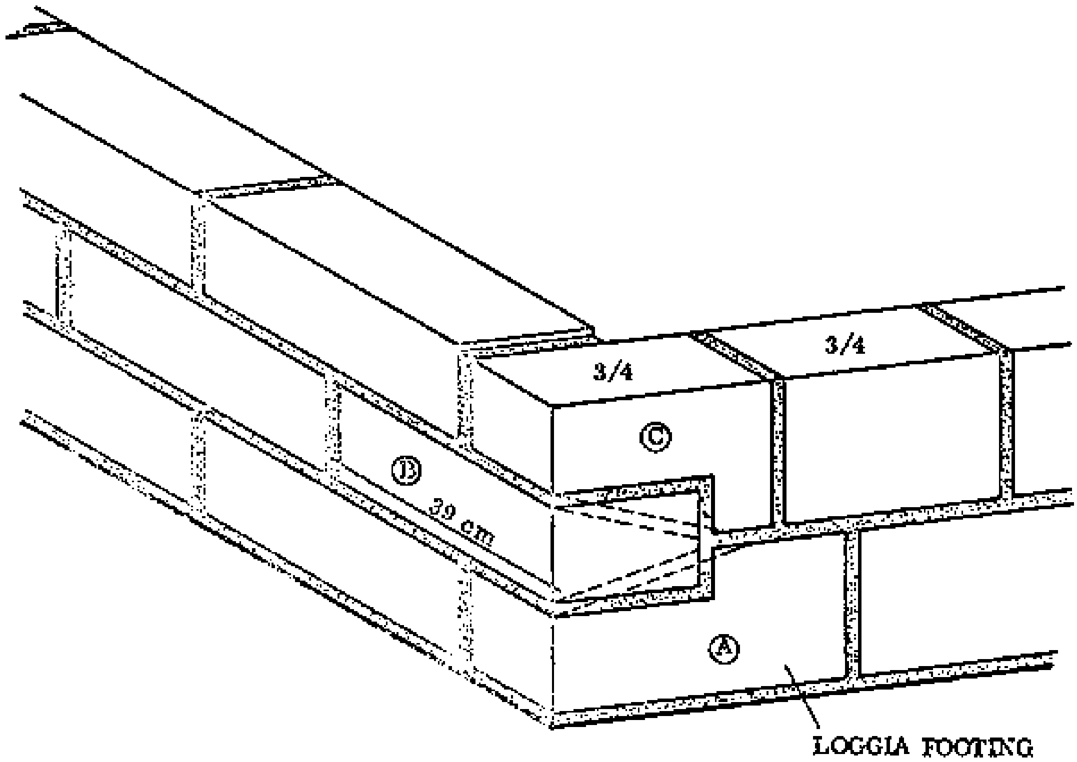

Fig. 2

- SPECIALLY MADE BLOCKS, FLUSH TO OUTSIDE: If specially made blocks are used, it is not necessary to cut them to odd shapes, and the bond is easy to make as well as more economical (Fig. 3).

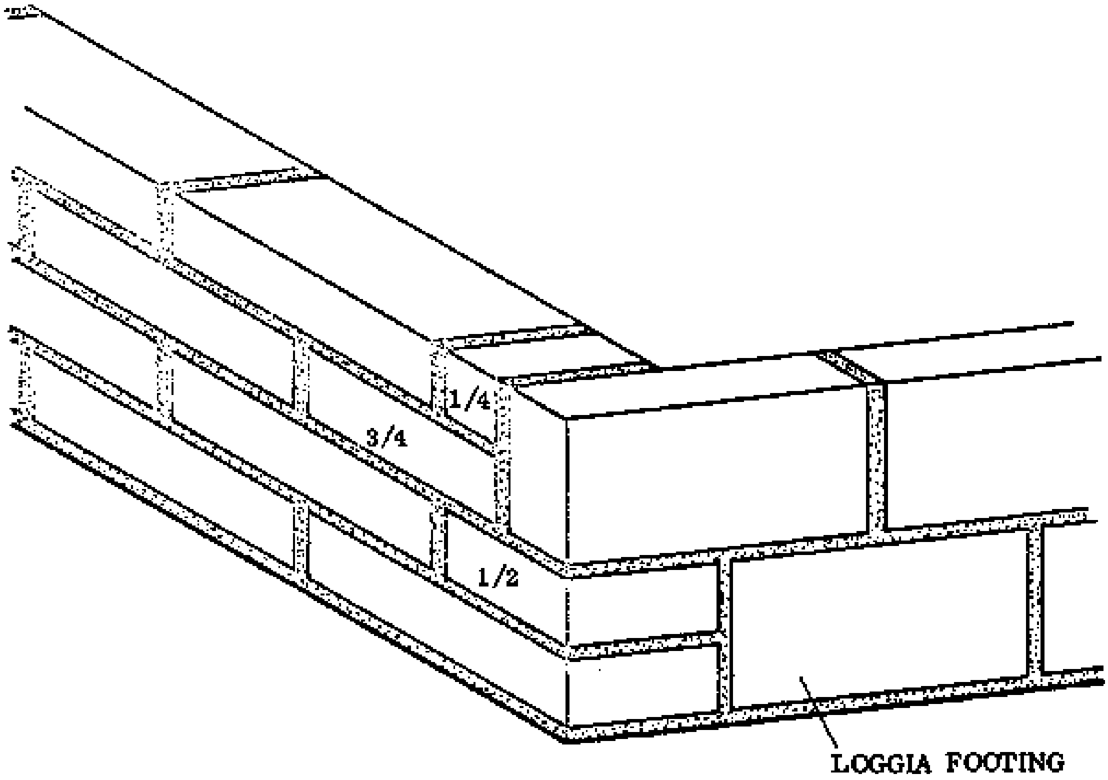

Fig. 3

A corner bond in which the edgewise courses are set back (recessed) in order to be in line with the outside of the rising wall does not make sense and it is therefore not shown here. It is best to apply one of the arrangements above, or to make the whole structure stronger by laying all the corner blocks flatwise (Fig. 4, below).

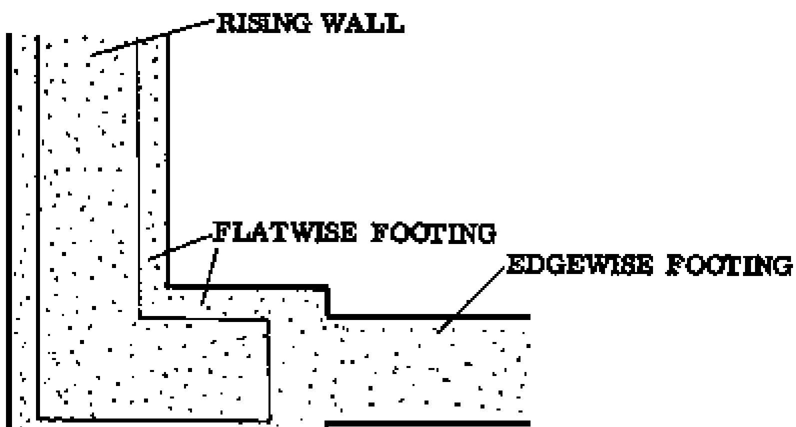

Fig. 4

- NOTE: It is best to avoid making these bonds with common blocks: use specially made blocks instead if possible, because it is extremely difficult to cut the odd shaped blocks (Fig. 2, blocks A and C) to the ideal shape without breaking them. If specially made blocks are not available, the common blocks can be given a wedge shape where they intersect, as indicated in Fig. 2 by the broken lines. This shape is easier to cut without breaking the blocks.

Different wall thicknesses at a T-junction

In Rural Building we are mostly concerned with those T-junctions in which a course of edgewise blocks meets either a corner (“A” below) or a wall (“B” below) of flatwise blocks.

Situation “A” occurs for example when a verandah is built flush with the corner of the house; while situation “B” will occur if the verandah meets the wall of the house away from the corner.

There are also possible situations where a flatwise course meets a corner or wall of edgewise blocks, but these situations are not common in Rural Building.

Here we discuss four methods which can be used in situation “A”, depending on the type of blocks available and on whether the edgewise course will be recessed or flush to the outside of the flatwise courses. Two methods are given to deal with situation “B”.

- SITUATION “A”, COMMON BLOCKS, OUTSIDE FLUSH: As with the corner bond using common blocks (previous page), this bonding problem can only be solved by shaping the first blocks of both courses of the thin wall so that the second course of the thick wall can be bonded (Fig. 1). This requires precise and careful cutting.

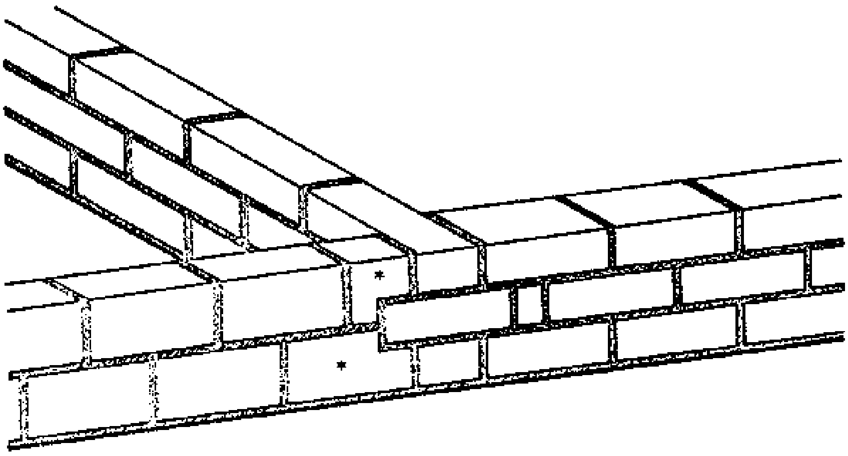

Fig. 1 SITUATION “A” - COMMON BLOCKS, OUTSIDE FLUSH

- SITUATION “A”, SPECIALLY MADE BLOCKS, OUTSIDE FLUSH: Bonding be comes simpler and more economical when these blocks are used. Fig. 2 shows that there is no material wasted since the 1/4 block which is left from cutting the 3/4 block will be used in the fourth flatwise course.

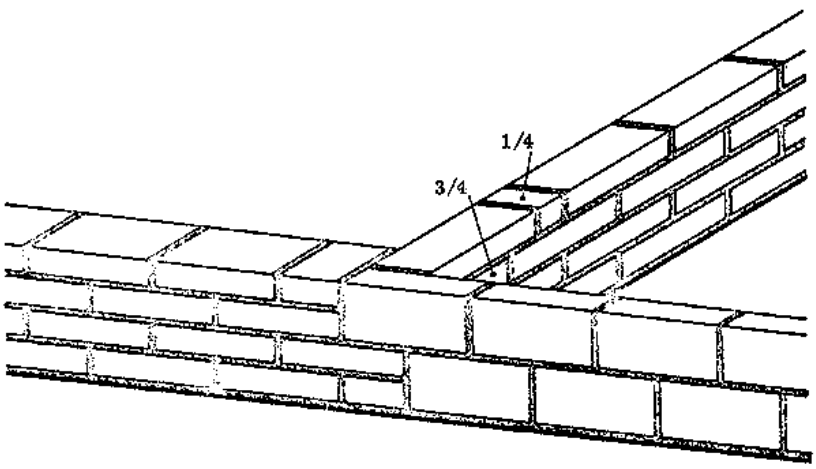

Fig. 2 SITUATION “A” - SPECIALLY MADE BLOCKS, OUTSIDE FLUSH.

SITUATION “A”, COMMON BLOCKS, RECESSED: This bond is almost the same as the first method above, except that the stretcher of the second flatwise course projects on both sides in the direction of the thin wall (Fig. 3, broken lines). After the mortar has set hard, the projecting corners are chiselled off.

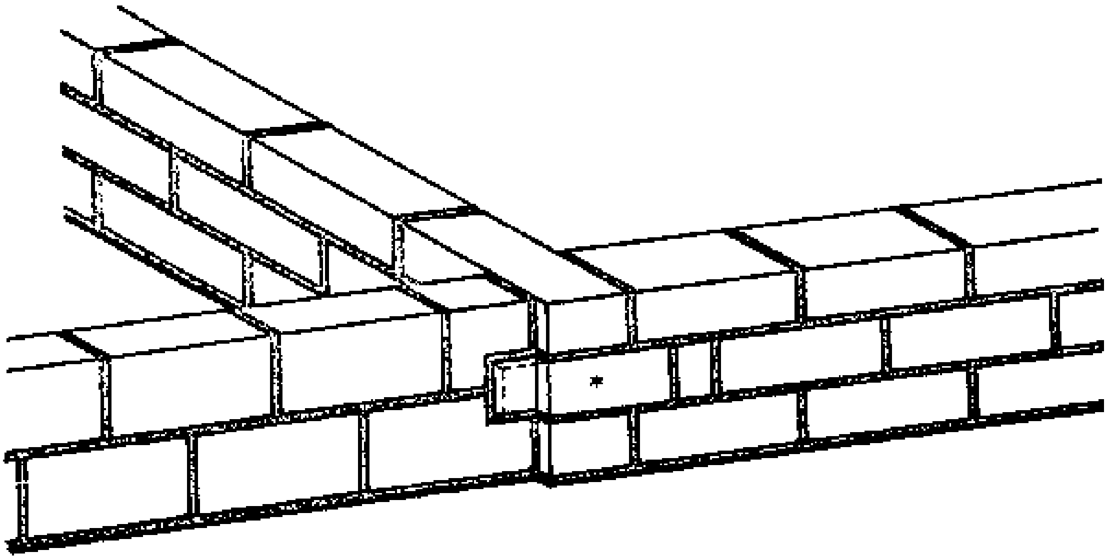

Fig. 3 SITUATION “A” - COMMON BLOCKS, RECESSED

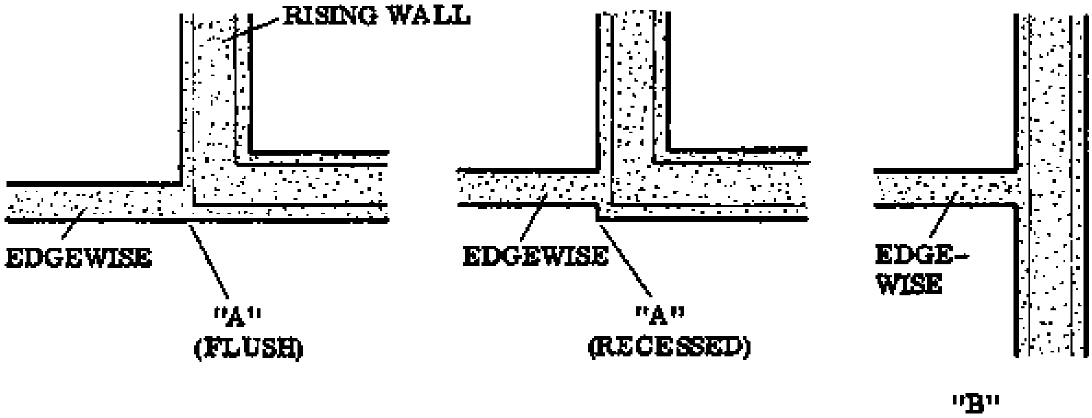
- SITUATION “A”, SPECIALLY MADE BLOCKS, RECESSED: In this case we can use the same bond as in the second method (Fig. 2, last page). The 3/4 block and the full block above it have to be shortened by 4 cm. This will reduce the in side overlap of the junction, but that cannot be helped.



- SITUATION “B”, COMMON BLOCKS: Again, here it does not make sense to talk about making a recessed thin wall: as at a quoin, the edgewise course will always be flush with the outside face of the flatwise footing course.

Fig. 1 shows that here again we find the same problem which always arises when common blocks are used in a bond between different wall thicknesses. The first blocks of the two edgewise courses have to be cut to odd shapes.

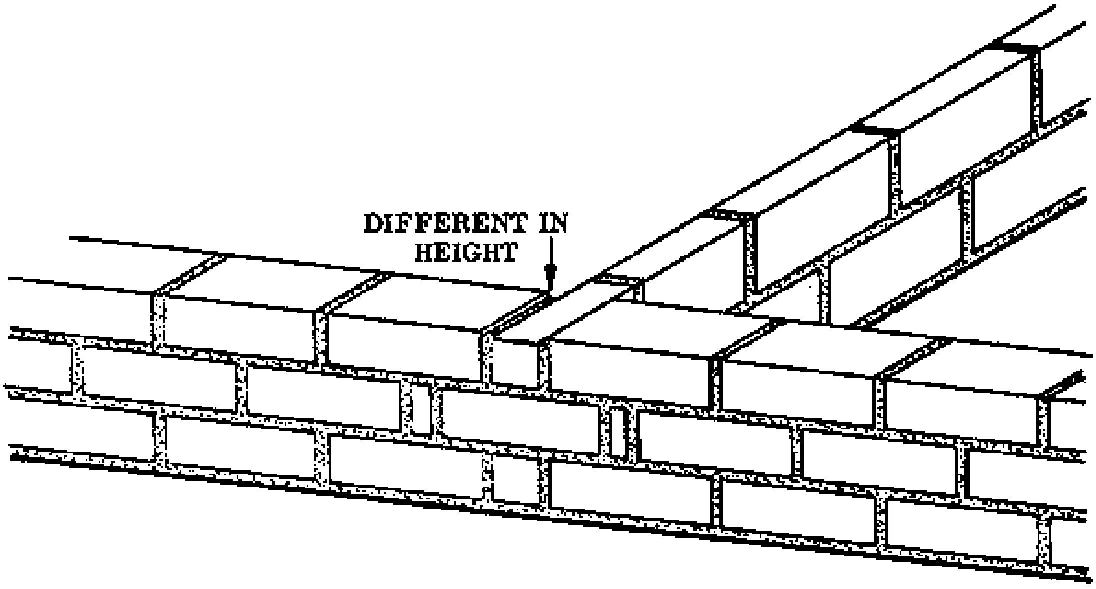


Fig. 1 SITUATION “B” - COMMON BLOCKS

- SITUATION “B”, SPECIALLY MADE BLOCKS: When this bonding method (Fig. 2) is compared with the last method, it is clear that once again the specially made blocks are the best choice.

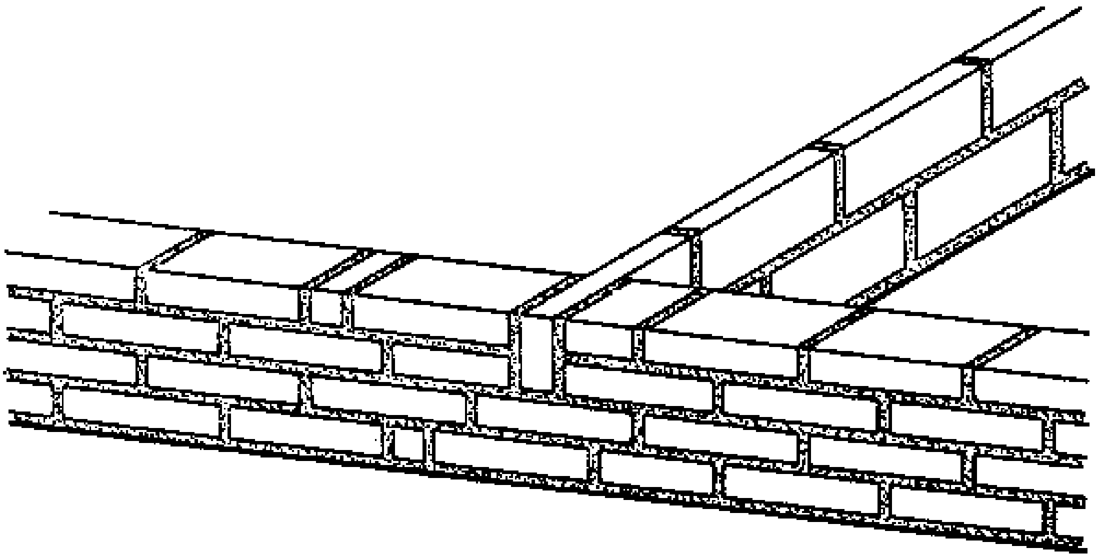

Fig. 2 SITUATION “B” - SPECIALLY MADE BLOCKS

NOTES:

Different wall thicknesses at a cross junction

There are four possible situations for a cross junction with different wall thicknesses. The one which is described here is the most common in Rural Building. This situation occurs when the end of a verandah joins the wall of the house and is in line with an inside wall (Fig. 2, below). This means that the footing blocks are laid flatwise in three directions, and edgewise in one direction.

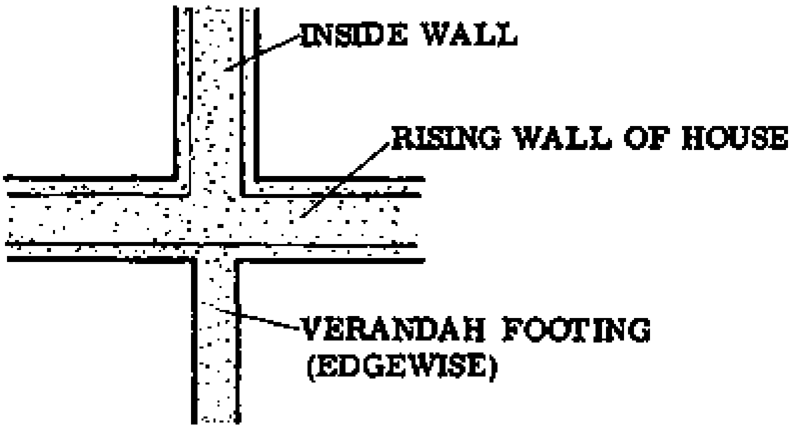

Fig. 2

- COMMON BLOCKS: The first course of the thin wall is bonded into the thick one by a 3/4 block (block A) which must be shaped in such a way that the second course of the thick wall can overlap it (block B). Block A is followed on one of its stretcher sides by a 1/2 block, while all other directions are continued with full blocks (Fig. 1a shows the first courses).

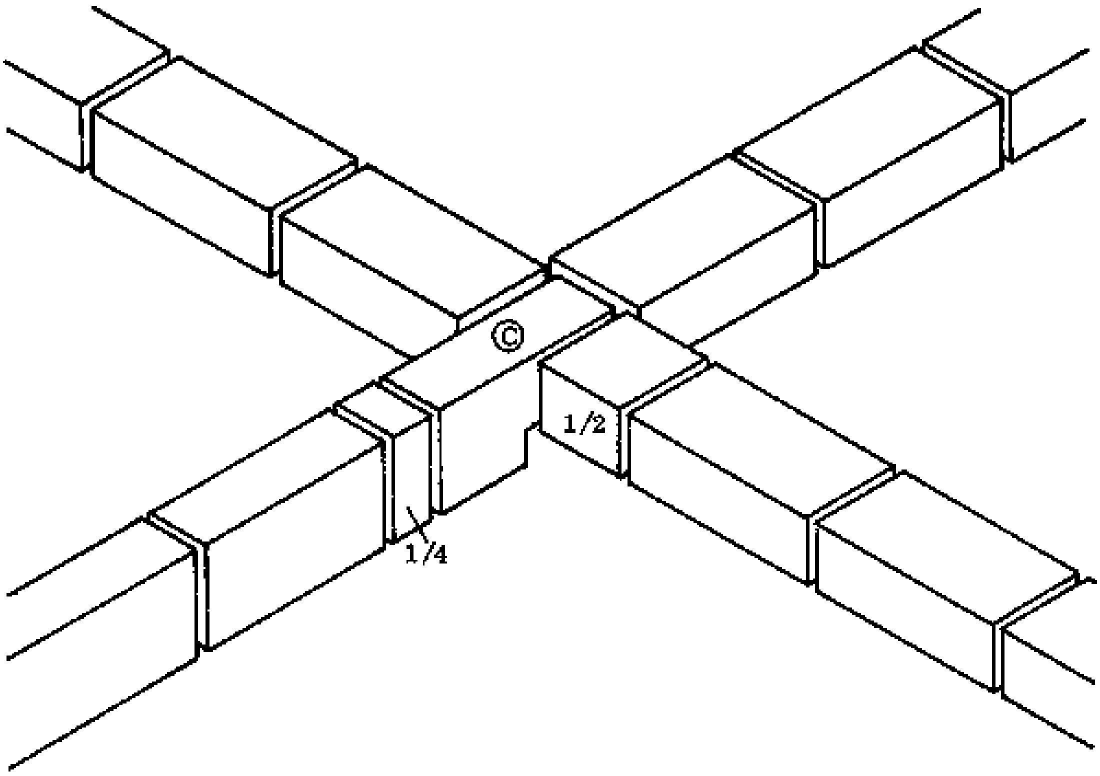

Fig. 1a 1st COURSE

In order to maintain the half-block bond, the second course of the thick wall must contain a block which is 18 cm long, and another 42 cm long; the latter overlaps the 1/2 block below. Don't forget that the first cross joint following the stretcher overlapping the thin wall is 3 cm wide, or else the first two cross joints are made 2,5 cm wide (Fig. 1b).

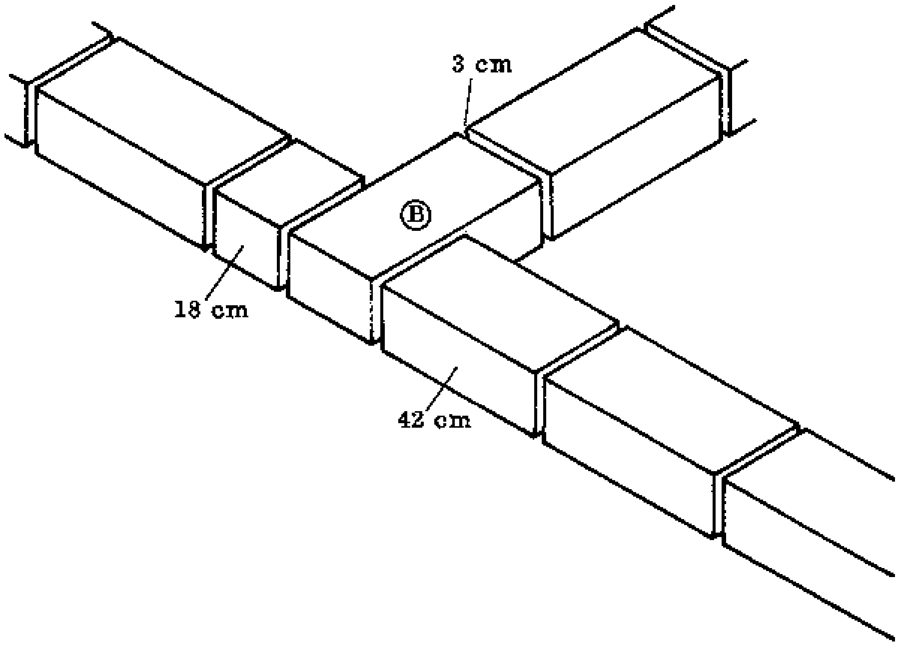

Fig. 1b 2nd COURSE

The third course of the thick walls is a repetition of the first one. The second course of the thin wall starts with a full block (block C) which is the same shape as the 3/4 block below it, so that it can be bonded into the thick wall. It is followed by the 1/4 block which was left over from the first course. Note that the thin wall remains 1 cm lower than the other walls, unless the mortar beds in the thin wall are both made 2,5 cm thick (Fig. 1c).

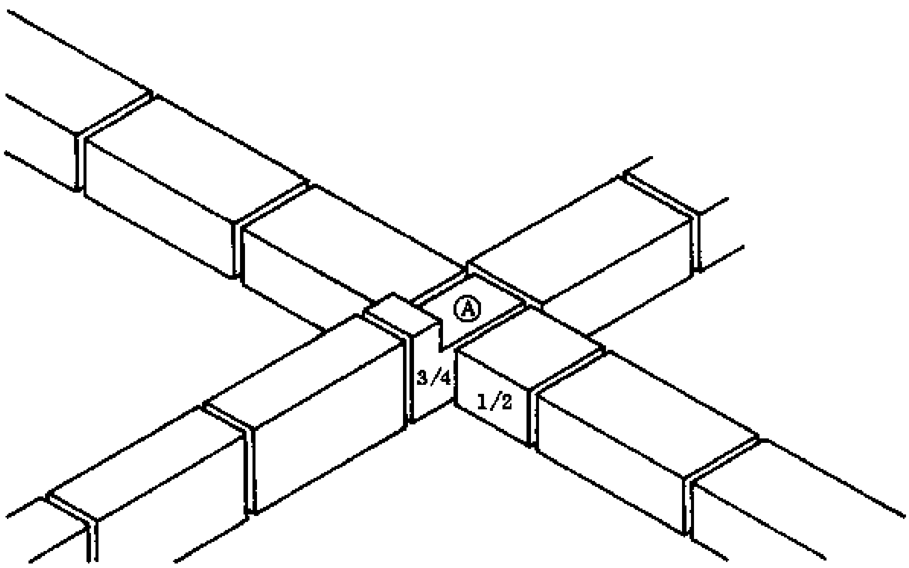

Fig. 1c 3rd COURSE

A disadvantage of this bond is that the overlap across the thin wall is rather short. This problem is not fully solved by using the specially made blocks.

- SPECIALLY MADE BLOCKS: The first course of the thin wall is bonded into the first two courses of the thick one by using a full block (block A). The first cross joint following this block is made 3 cm wide, or else the first two cross joints are made 2,5 cm wide. The first course of the thick walls continues with a 1/2 block (block B) in the direction of the thin wall, and with a 1/2 block (block C) either to the right or left side of the cross. The second course of the thick walls starts with full blocks where there are half-blocks below, and with a half-block which is above the full block of the first course (Fig. 1a).

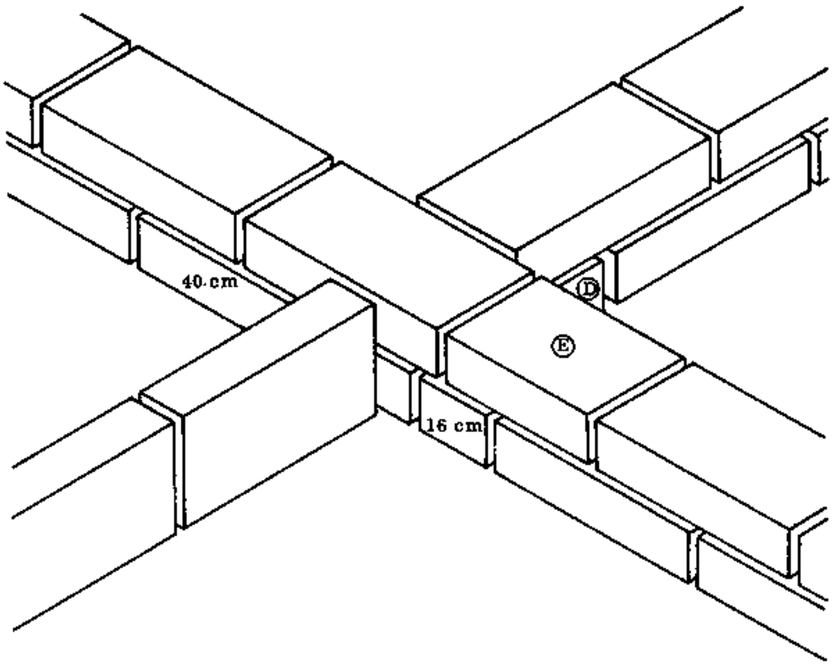

Fig. 1a 1st COURSE

The third course of the thick walls starts with a full block (block D) covering three cross joints. A block of 16 cm in length is placed beside this, above the full block; and a block of 40 cm length is placed on the other side, above the 1/2 block. The second edgewise course and the fourth flatwise course consist of full blocks, with the exception of a 3/4 block (block E) overlapping the 16 cm block below by 10 cm (Fig. 1b).

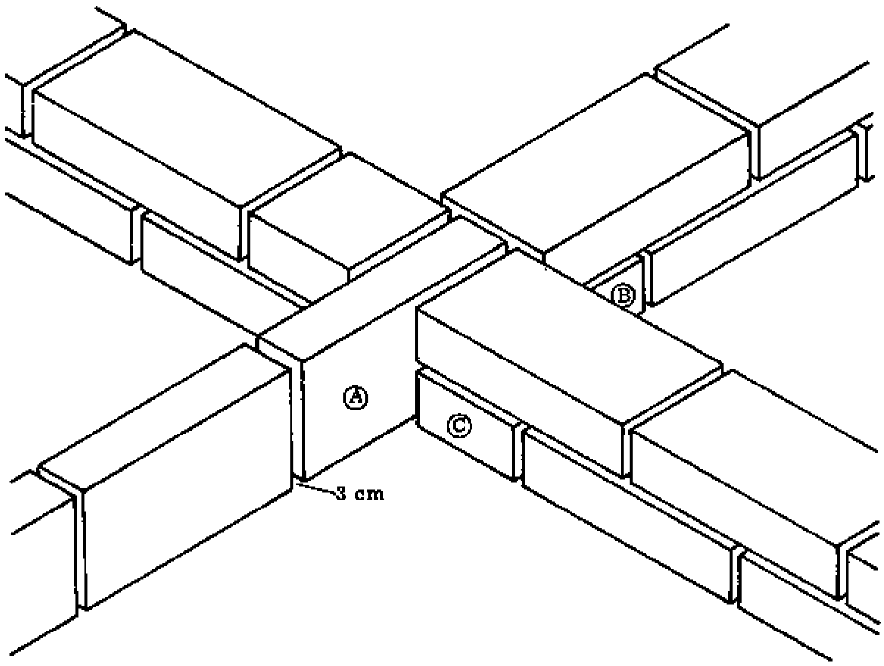

Fig. 1b 2nd COURSE

This cross junction bond, even with the use of the specially made blocks, still does not provide a very good overlap.

NOTES:

- STAGGERED BOND WITH SPECIALLY MADE BLOCKS: A simple but good masonry bond can be achieved by staggering the bond. This means that the thin wall is shifted to either side of the crossing thick wall. The distance between the two centre lines of the walls will be about 19 cm (Fig. 1a).

The first course of the thin wall is bonded into the thick one by using a full block. The two courses on the left side of this almost form a quoin, while the courses on the other side are completed in the normal way. Apart from the 1/2 block in the second course, only full blocks are needed (Fig. 1a).

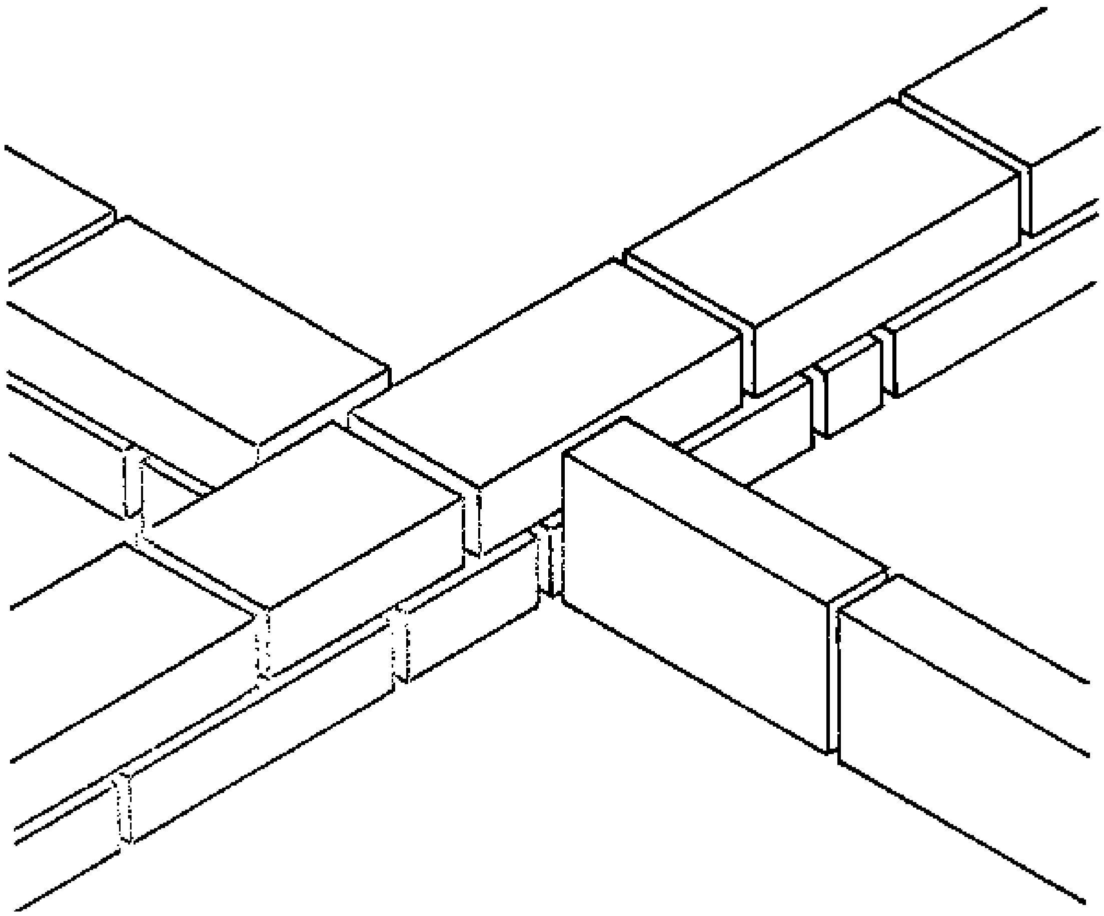

Fig. 1a 1st COURSE

The third and fourth courses of the thick wall are bonded as if in a T-junction, except that the 1/4 block of the third course is placed further away from the junction, to avoid having too many cross joints in the junction area (Fig. 1b).

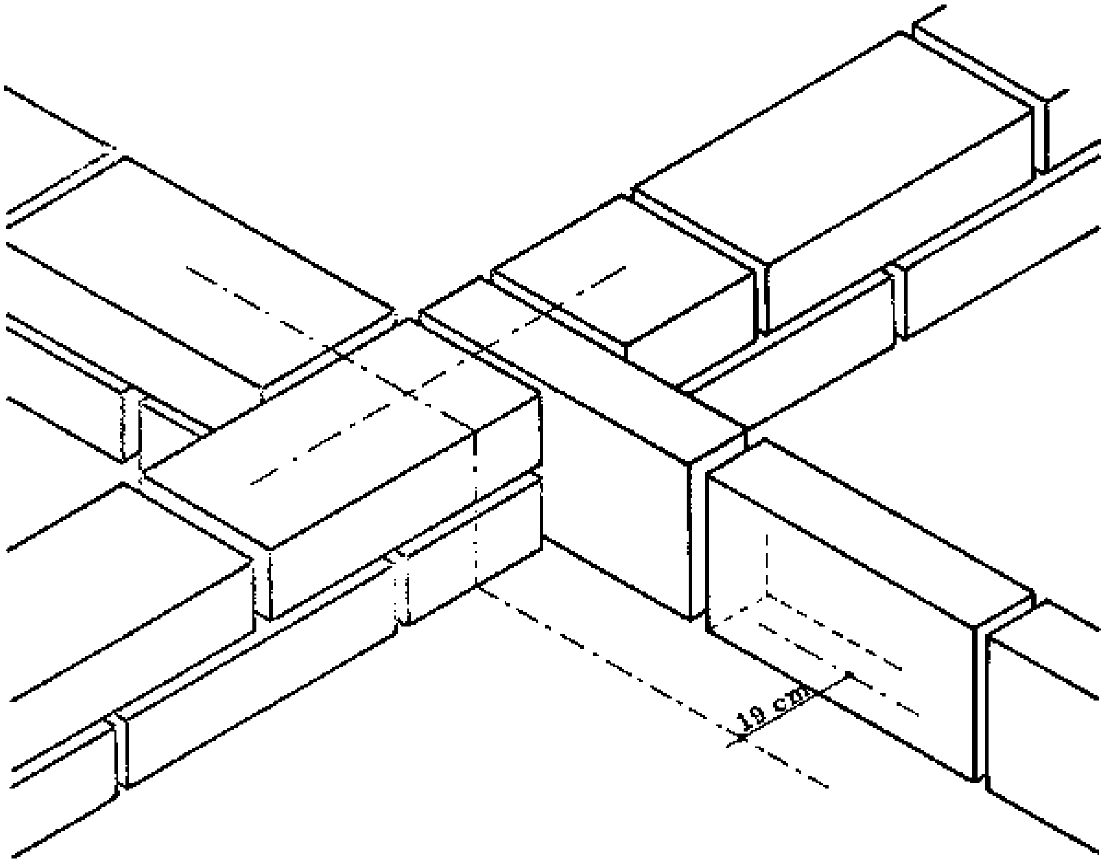

Fig. 1b 2nd COURSE

- NOTE: By planning ahead and doing a little extra work in setting out, you can avoid complicated and costly constructions.

For footings where there will be junctions between flatwise and edgewise blocks, it is always better to use specially made blocks which are 10,5 cm thick. These allow proper bonding, are more economical, and avoid the necessity for constructing junctions between two edgewise courses and three flatwise courses.

Cross junctions between different wall thicknesses should be avoided because the bonding is difficult and the overlap is poor. A staggered bond is preferred in those cases where a simple T-junction cannot be made instead of the cross junction.

NOTES:

HARDCORE FILLING

Functions of the hardcore filling

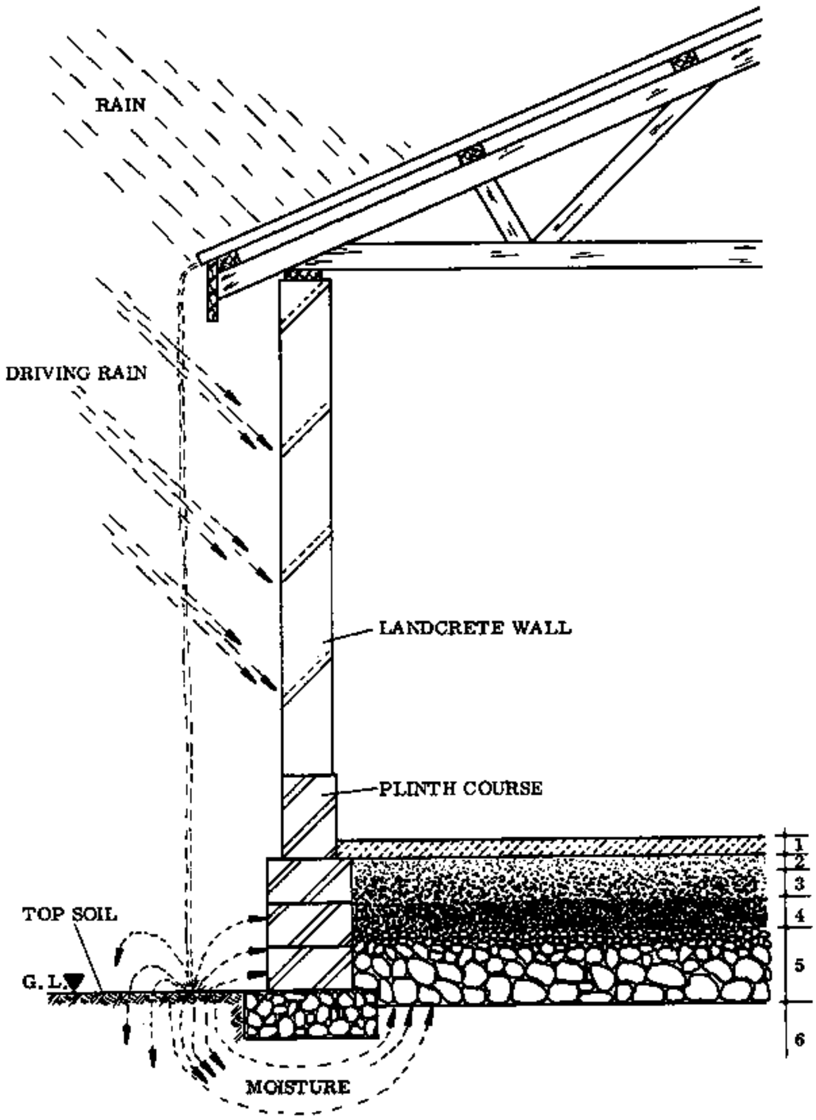
The two main functions of the hardcore filling are:

- To support the concrete floors, including all loads imposed on the floors
- To raise the floors high enough above ground level to prevent dampness from penetrating.

The hardcore has to be made from hard, solid materials which are arranged in such a way that moisture is not able to rise through them to the floor.

Materials and arrangement

All topsoil is removed before the hardcore is applied. Then the filling is applied in layers no more than 15 cm thick. Each layer is compacted thoroughly before the next one is added. The hardcore filling occupies the space between the subsoil and the tops of the footings (Fig. 1).



THE HARDCORE FILLING PREVENTS MOISTURE FROM RISING UP TO THE FLOOR

1 = CONCRETE FLOOR
2 = FINE SAND
3 = FINE GRAVEL
4 = COARSE GRAVEL
5 = ROCKS & STONES
6 = FIRM SOIL

The first layer consists of rocks, stones and broken sandcrete blocks. These are no smaller than fist-size and no bigger than 15 cm in diameter. The stones for this layer are preferably set into place by hand, according to their shape, in order to fit them together.

For the second layer we use broken stones which are about half the size of a fist. The following layers are formed of smaller stones, coarse gravel, or gravelly laterite soil; up to about 6 cm below the tops of the footings.

The last 6 cm to the top of the footings should be filled with sand or laterite soil to seal the surface of the hardcore, in order to keep the cement paste from the floor from leaking downwards.

- BACK-FILLING: If the foundation consists of stone masonry, the extra space left inside the foundation trenches has to be filled in before the hardcore is done. If the space is more than about 30 cm wide, it is best to use hardcore to fill it. If less, rammed soil will be sufficient.

The outside of the trench excavation has to be refilled with gravel, to prevent erosion around the foundations (Foundations, page 19).

Never be tempted to fill up the site with soil underneath the hardcore, even on a sloping site: even if the soil is compacted it will still settle and cause the floor above to settle and crack. The hardcore should rest directly upon the subsoil.

Compaction of the hardcore

All the layers are normally compacted by hand with heavy rammers. This exhausting work can be made easier by using heavy iron or concrete rollers, or by driving a tractor several times over the hardcore to compact it.

Wet down the gravel and sand layers as they are filled in. This not only reduces the dust in the air but also makes compaction easier and ensures a dense layer.

Sometimes the building schedule allows construction to halt during the rainy season. If so, then it is a good idea to plan ahead in order to complete the hardcore filling before the rains come. This is done so the hardcore can be left open during the rainy weather to become very well compacted by the rain. However, it is still necessary to compact the layers of hardcore as they are added. The hardcore can be inspected from time to time during the rainy season, and any sunken areas can be filled up as they develop.

- NOTE: It is sometimes observed that a builder uses soil excavated from the foundation trenches to make the hardcore. This is convenient, but it is a bad procedure. The laterite soil acts as a sponge to draw moisture up from the subsoil into the building. The hardcore is made with a rock base because the rocks do not draw moisture upwards, so the building stays drier.

Gravelly laterite soils can be used for the layers just below the final layer, and fine laterite soil may be used for the final layer which seals the hardcore filling.

PLINTH COURSE

The plinth course forms the first course of the rising wall, immediately above the footings. Its sole function is to raise the landcrete blocks or sun-dried laterite blocks of the following courses high enough to protect them from moisture penetration.

The materials used for the plinth course should therefore be moisture resistant to some extent, such as natural stone or sandcrete blocks (Fig. 1, last page). It is known from experience that one plinth course is sufficient in northern Ghana, but there are situations where it is better to use a more durable material up to window cill level, especially in the rain-forest areas of Ghana.

In northern Ghana the rising landcrete walls are erected flush with the outside of the plinth course. In the south, however, it is advisable to lay the landcrete blocks flush to the inside of the plinth, so that thicker render can be applied on the outside to protect against moisture penetration.

POSITIONS OF DOOR AND WINDOW FRAMES

Before the plinth course is laid, the positions of the doors are marked on the footings.

If the door frames have been already made and painted they may now be set into place according to the marks. If the frames are not yet available, the plinth course and the rising walls can be erected anyway. In this case one must remember that the measurements given in the drawing are the outside measurements of the frame. Therefore the opening left in the wall must be about 1 cm wider on all sides, so that later on the frame can fit in (see Fig. 1).

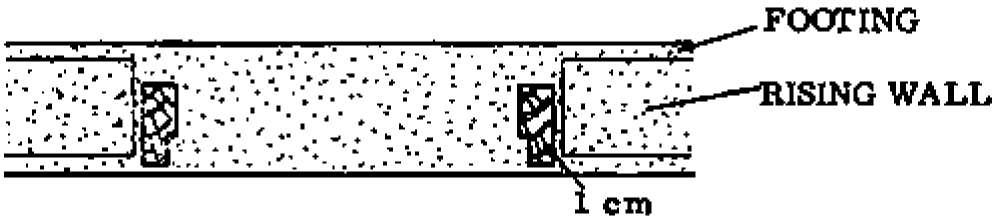


Fig. 1

The way the door and window frames are positioned in the surrounding masonry depends on the type of door or window, which way it opens, and whether mosquito-proofing and/or burglar-proofing will be installed.

Fig. 2 shows the most common position in which the frame is set flush to the outside of the render. The frame may be flush to both the inside and outside surfaces (Fig. 3), although the cill may project past the render on the outside face. Keep in mind the thickness of the plaster or render when you set the frame in the unplastered wall. The frame edge should be in line with the future plaster surface.

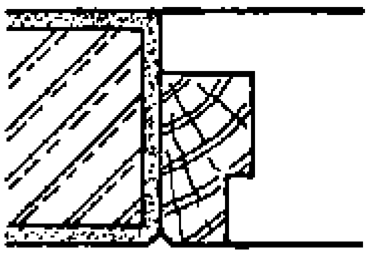

Fig. 2

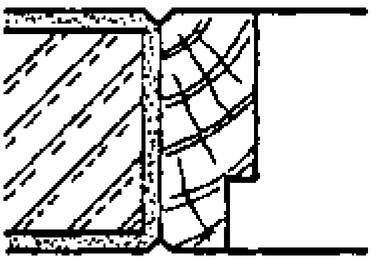

Fig. 3

Vibrations from opening and closing the door or window, as well as the shrinking and swelling of the frame, will cause cracks to appear in the plaster and even cause pieces of plaster to come off. To prevent this and to cover the unavoidable cracks, a V-joint is made wherever plaster or render is flush to the frame. This may be covered with a wooden strip (Fig. 4). It is incorrect to apply plaster or render directly against the frame (Fig. 5, arrow).

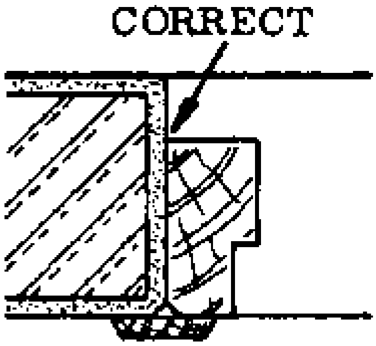

Fig. 4

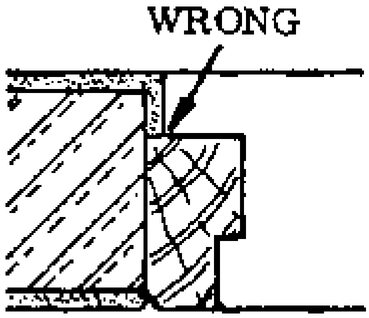

Fig. 5

DOOR FRAMES

Types of door frames

The door frame provides a secure attachment for the door. Depending on the type of door, its function, and its location, different types of door frames can be constructed. The most common door frame consists of three members (Fig. 1):

- Two vertical members called posts (a)
- One horizontal member called a head (b).

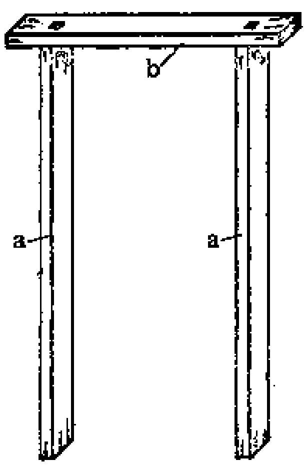

Fig. 1

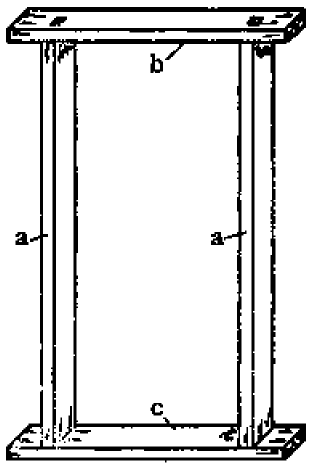

Fig. 2

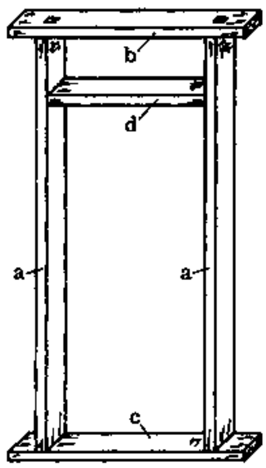

Fig. 3

When it is necessary for the door to fit tightly in the frame, it consists of four members (Fig. 2):

- Two posts (a)
- One head (b)
- One member on the floor, called the threshold (c).

When additional light or ventilation is needed for a room, a fanlight is added to the frame structure by adding one more member between the posts, called a transom (Fig. 3, d).

Note that since the threshold is in direct contact with the floor, or even partly embedded in the floor, it is in special danger from attack by termites or fungus (Reference Book, pages 141 to 144).

- BEAD OR REBATE TYPE DOOR FRAMES: Each of the above door frames can be made either with beads (Fig. 4) or a rebated construction (Fig. 5).

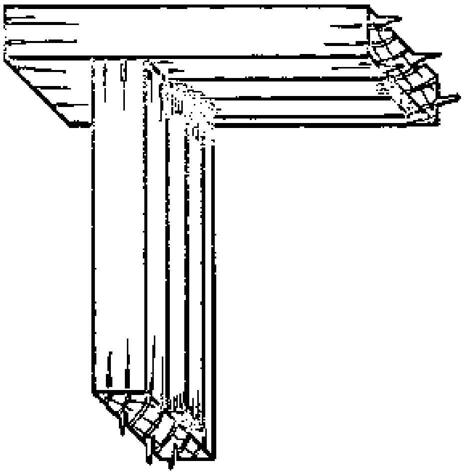

Fig. 4

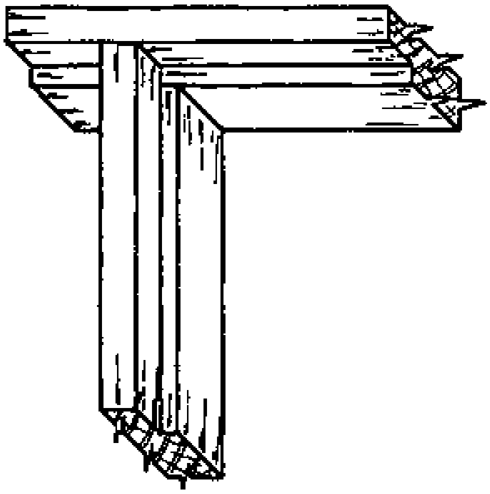

Fig. 5

Beads are preferred over a rebate for two reasons: the construction is easier, and it is possible to adjust the beads after the door is hung. Beads are always fixed into place after the frame is installed and the door is hung.

Rebates, however, do have a better appearance than beads, and no extra wood is required to make a rebated frame.

NOTES:

Joints for door frames

- JOINTS FOR DOOR FRAMES WITH BEADS: The joints for a door frame made with beads can be common mortice and tenon joints for box-like constructions. They may be either pegged, wedged or nailed (Basic Knowledge, pages 104 to 106, and 124; also Drawing Book page 43 and pages 67 to 71).

If a transom is required, it should be installed using a stub tenon joint to prevent water from penetrating the mortice (Basic Knowledge, page 122).

If a threshold is installed, a common mortice and tenon joint is used for it, but wedges should not be used since they might fall out. Pegs cannot be used either, because the threshold is too thin. This joint should be nailed.

- JOINTS FOR DOOR FRAMES WITH REBATES: If the door frame is made with a rebate, take care that the shoulders of the tenons are set out and cut correctly. One shoulder of the tenon is cut longer to fit the rebate (Drawing Book, pages 67 &68).

The thickness of the tenon is affected by the size of the rebate. If the rebate is 1/3rd or less of the width of the member, the tenon will not be reduced in size (Fig. 1). If the rebate is wider than 1/3rd of the member, the thickness of the tenon (and accordingly the mortice width) is reduced by the depth of the rebate (Fig. 2).

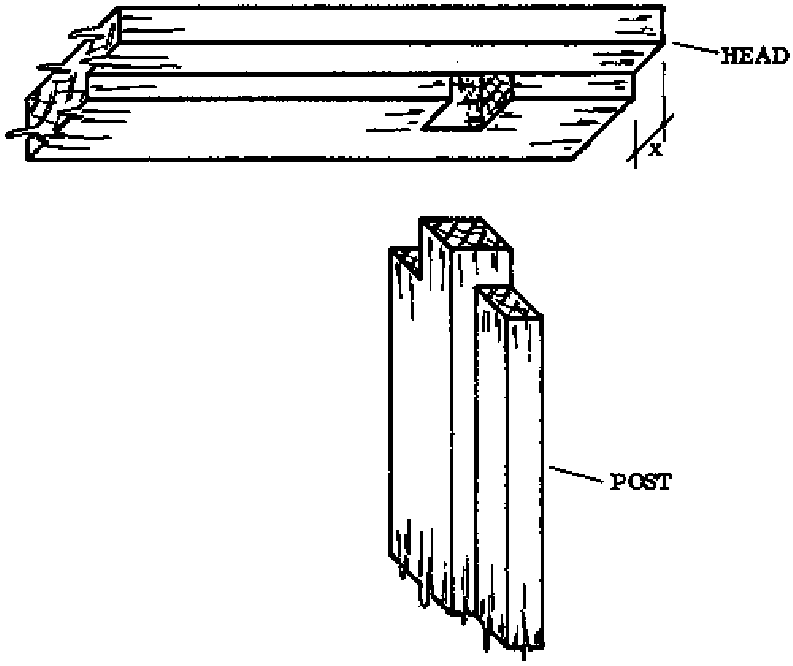

Fig. 1 WIDTH OF REBATE (x) 1/3 OR LESS

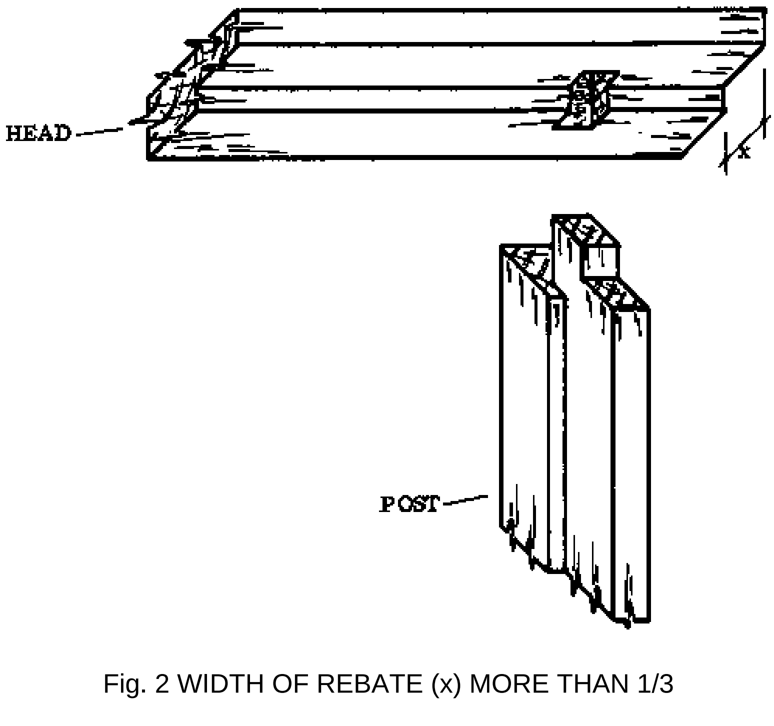

Fig. 2 WIDTH OF REBATE (x) MORE THAN 1/3

Besides these considerations, the construction of these joints will be the same as for any common mortice and tenon joints for box-like constructions.

NOTES:

Heads of door frames

- HORNS: In order to provide an additional attachment to the wall, the ends of the head and the threshold can project beyond the posts into the wall. This is especially necessary in mud walls.

These projecting parts can be shaped like horns (Fig. 1), or else the front corners can be cut off at an angle (Fig. 2). These shapes give a good appearance to the frame head when the frame is built into the wall.

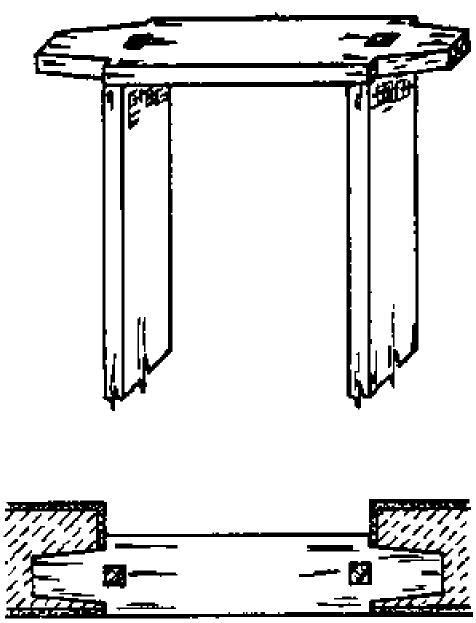

Fig. 1

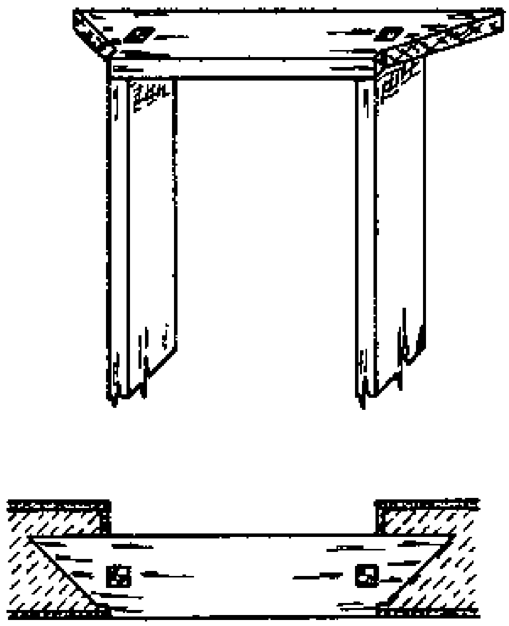

Fig. 2

- WEATHER STRIPS: If a door frame is to be installed in an outside wall, you need to take some extra precautions to prevent water from entering between the lintel and the frame head, and between the door itself and the door frame.

Weather strips (Fig. 3) can be fixed on the door head to keep water out. We will learn more about weather strips later in the book, in the section on window frame heads.

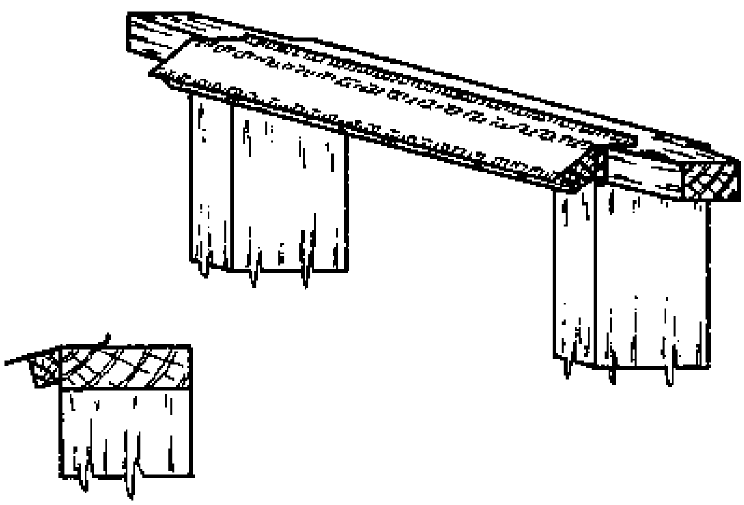

Fig. 3

- STEEL CRAMPS: These are pieces of mild steel rod which are fixed into the door posts (Fig. 1, next page). They are fixed about 60 cm apart; near the head, middle and foot of the frame.

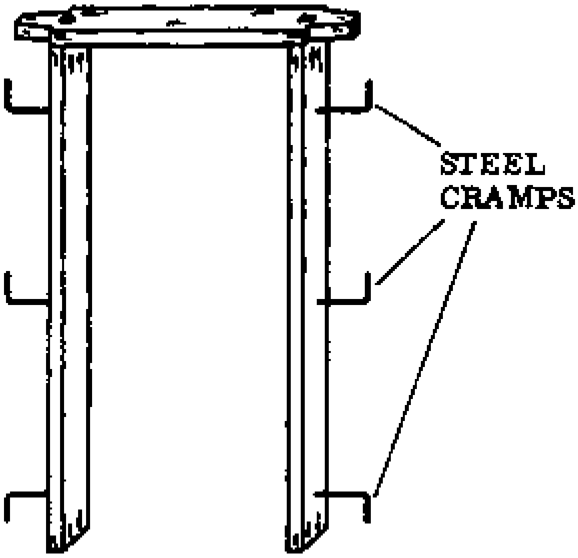

Fig. 1

The function of these cramps is to secure the frame rigidly to the blockwork. They are set in the posts in positions which correspond with the bedjoints of the blocks, so that they can be built into the bedjoints.

To fix the cramps in the door frame, drill holes in the posts. The holes should have a diameter a little smaller than the rods, and should not go all the way through the post. Bend one end of the rod to form a head (Fig. 2, next page) and knock the head into the post. Bend the other end to a right angle so it fits into the cross joint between the blocks (Fig. 2, next page).

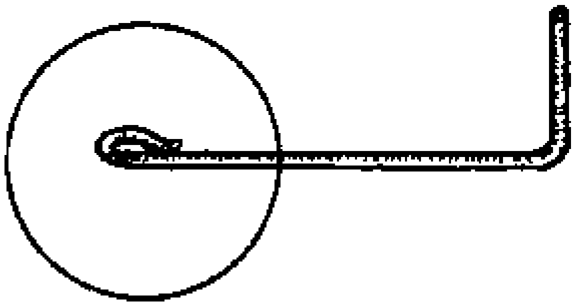

Fig. 2

NOTES:

Measurements for door frames

- MEASUREMENTS OF THE TIMBERS: Usually door frames are made of timbers which are about 10 cm wide and about 5 cm thick. If the posts are held in the wall by steel cramps, it is possible to reduce the size of the timbers to 7,5 by 5 cm. The cramps provide a good grip to the wall so the frame doesn't have a lot of stress on it. This means that the timbers can be made smaller and thus less costly. The cramps are made by cutting iron reinforcement rods.

The frame itself is always measured from inside face to inside face. Unless it is stated otherwise on the estimate, measurements given for door frames are always inside measurements.

- MEASUREMENTS OF THE FRAME WITH RESPECT TO THE MASONRY: To make the work easy, to avoid extra block-cutting, and to reduce waste, the outside measurements of the frames should correspond to the building unit measurement of the blocks used to construct the wall. For example:

- The building unit measurement for landcrete blocks is 31 cm wide by 24 cm high.

The outside height of the door frame will be 8 x 24 = 192 cm.

The outside width of the door frame will be 3 x 31, minus 2 cm for one cross joint = 91 cm (Fig. 3).

The steel cramps are also placed according to the building unit measurement of the blocks, so that they will fit into the bedjoints of the wall (Fig. 3).

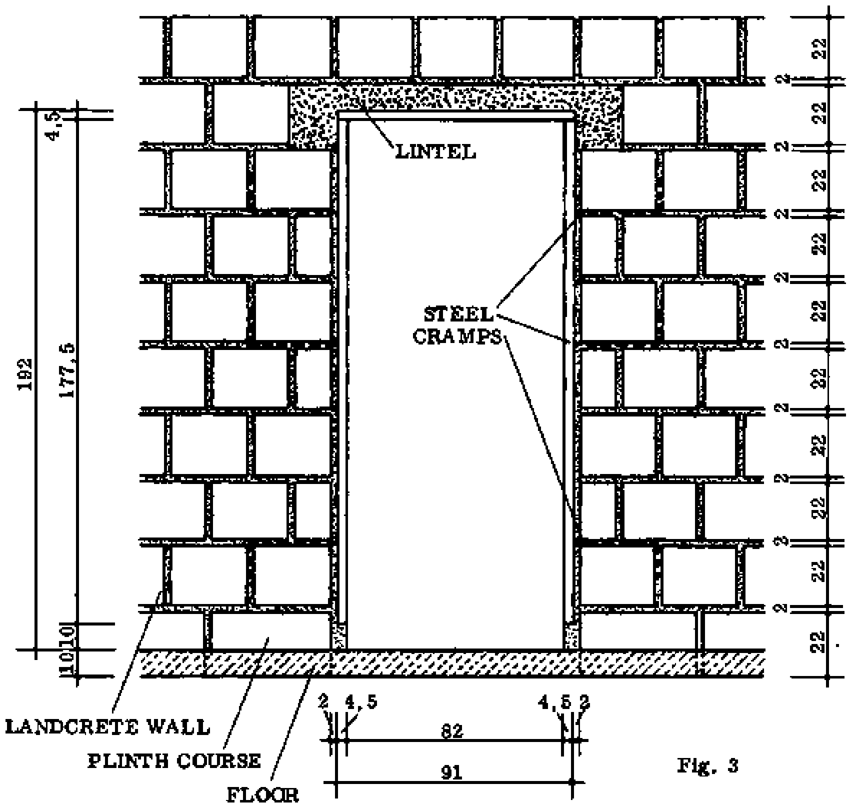

Fig. 3

NOTES:

Concrete shoe

In order to give a firm base to a door frame with no threshold, concrete “shoes” can be fitted on the posts.

To make the shoes, drive steel dowels into the bottom end of each post before setting the frame in the wall (Fig. 1). The projecting ends of the dowels are enclosed later by the finished floor and the shoe (Fig. 2).

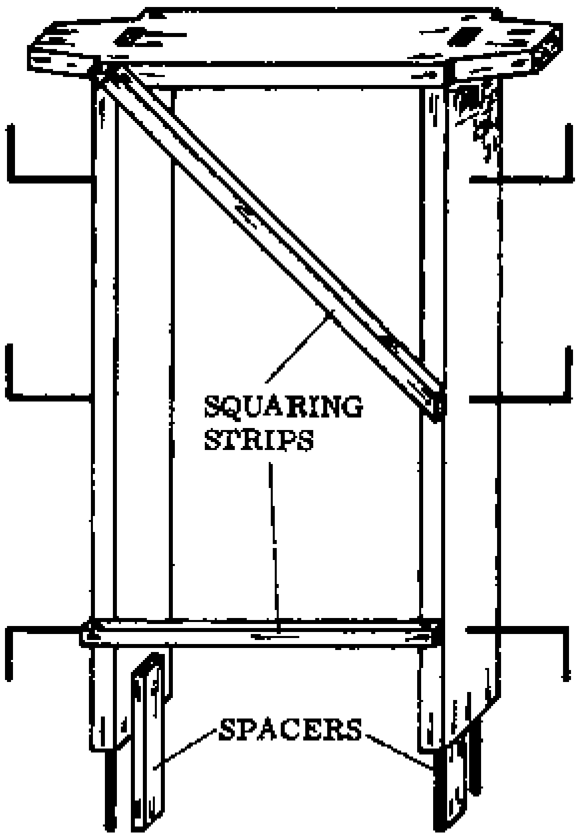

Fig. 1

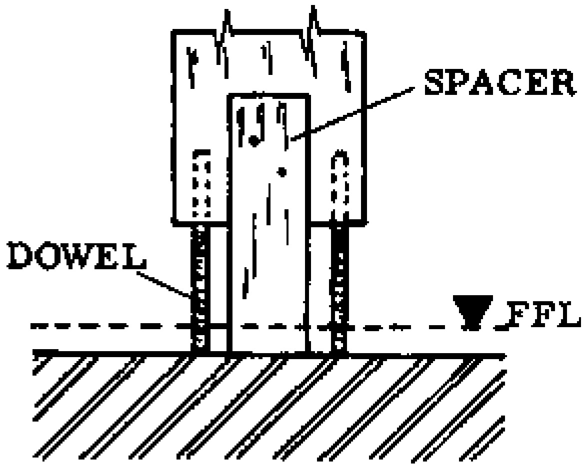

Fig. 2

Spacers are used to keep the frame at the correct height during the building operations (Fig. 1). The steel dowels are short pieces cut from reinforcement rods.

- ADVANTAGES AND DISADVANTAGES OF THE THRESHOLD (Fig. 3):

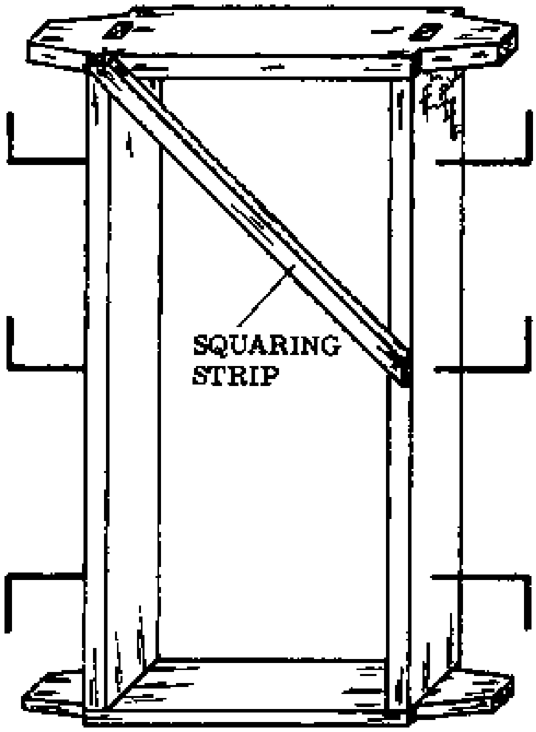

Fig. 3

advantages:
- The door closes tightly into the framework.
- If the threshold is thick enough, it can be made with a rebate.

disadvantages:
- The threshold is easily attacked by wood diseases or termites.
- More materials are needed.
- More joints have to be made, therefore construction is more difficult.
- Water can penetrate between the threshold and the finished floor (Figs. 4a & 4b).

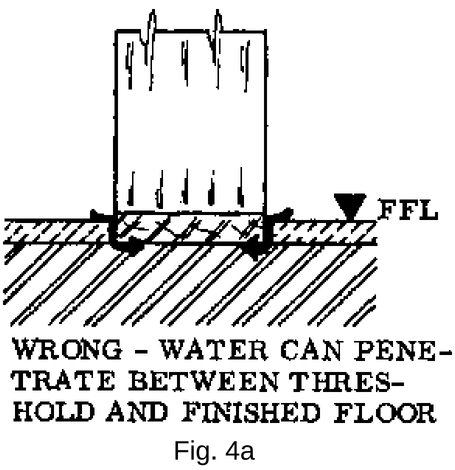

Fig. 4a

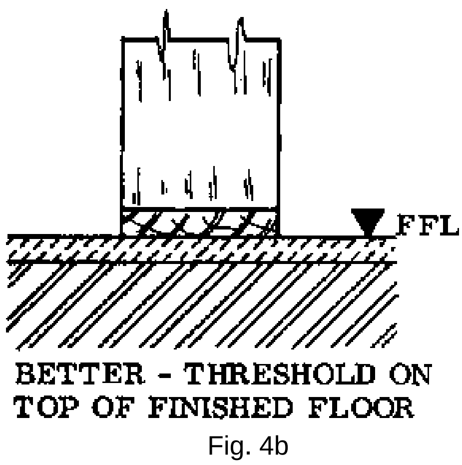

Fig. 4b

- ADVANTAGES AND DISADVANTAGES OF THE CONCRETE SHOE

advantages:
- The wood is not in direct contact with the floor, so there is less danger of attack by termites, etc.
- Less materials are needed.
- The shoe secures the doorframe to the floor.

disadvantages:
- The door might not close as tightly as with a threshold.
- If the frame is not well braced during the building operations, there may be a danger of distorting it while fixing it in place.

- SEQUENCE OF OPERATIONS FOR MAKING A REBATED DOOR FRAME WITH A CONCRETE SHOE: (see Drawing Book, page 67)

a. Study the drawing.

b. Prepare a cutting list.

c. Select the wood.

d. Plane the wood to the required sizes (as indicated on the cutting list).

e. Make the face marks.

f. Mark out the joints (take special care in marking out the shoulders of the tenons on the posts) and mark the length of the posts.

g. Mortice the head and rip the tenons at the posts.

h. Plane the rebate.

i. Cut the shoulders of the tenons.

j. Drill the holes for the steel dowels.

k. Clean up the inside edges.

l. Paint all the members with a primer, especially the joints.

m. Fix the steel dowels and the wooden spacers.

n. Drill the holes and set anchors at the correct places (steel cramps).

o. Assemble the frame with squaring strips.

p. Cut the horns to the required shape and paint them.

Take care when marking the lengths of the posts. They should be the length of the door; plus the upper joint, and minus the height of the concrete shoe.

- ASSEMBLING THE DOOR FRAME: To keep the door frame rigid and square during the various building operations, it needs to be braced. This bracing is done with squaring strips (Fig. 1, last page). These, strips are about 2 x 5 cm, and they are cut into the rebate or nailed to the face of the frame. They hold the frame square and keep the correct distance between the posts.

The proper steps for assembling a door frame are as follows:

a. Knock the frame together.

b. Place the frame, rebate side up, on the workbench.

c. Clamp the posts to the head (use sash clamps or the wedges on the bench).

d. Nail a squaring strip to hold the posts at the correct distance apart.

e. Test for squareness from corner to corner (diagonally).

f. With the clamp still in position, fasten the joints.

g. Cut and nail the other squaring strip diagonally from the head to the post (Fig. 1, last page). This holds the frame square.

h. Cut the posts to the required length.

i. Drill the holes for the steel dowels and fix them. They should be long enough to anchor into the concrete floor.

j. Nail wooden spacers into the inside of the rebate. These keep the frame at the correct height during the building operations (Figs. 1 & 2, page 70).

k. Finish off the frame. The priming coat of paint should be applied to the external woodwork before it is fixed in place.

When timber with a small section, for example 5 x 7 cm or 5 x 10 cm, is used for the posts, an extra squaring strip should be fixed horizontally in the middle of the frame. This prevents the pressure of the blockwork from distorting the frame.

Installing door frames

Frames which are improperly built-in can cause problems later, when the plastering is done or the doors are hung. Therefore we must give special attention to setting the frames properly.

A door frame should be fixed in such a way that the door can open flat to the wall. Otherwise, the door will form a lever to the frame, and the hinges will be forced out when the door swings wide open suddenly.

Door frames can be fixed in position either during the masonry construction or after the walling has been completed.

- SETTING FRAMES DURING MASONRY CONSTRUCTION: The first frames to be set are those of the outside walls. When the masonry work has been built to floor level, the door frame is placed in position according to plan and at the correct height, and held there by means of wedges (Fig. 1, a, next page).

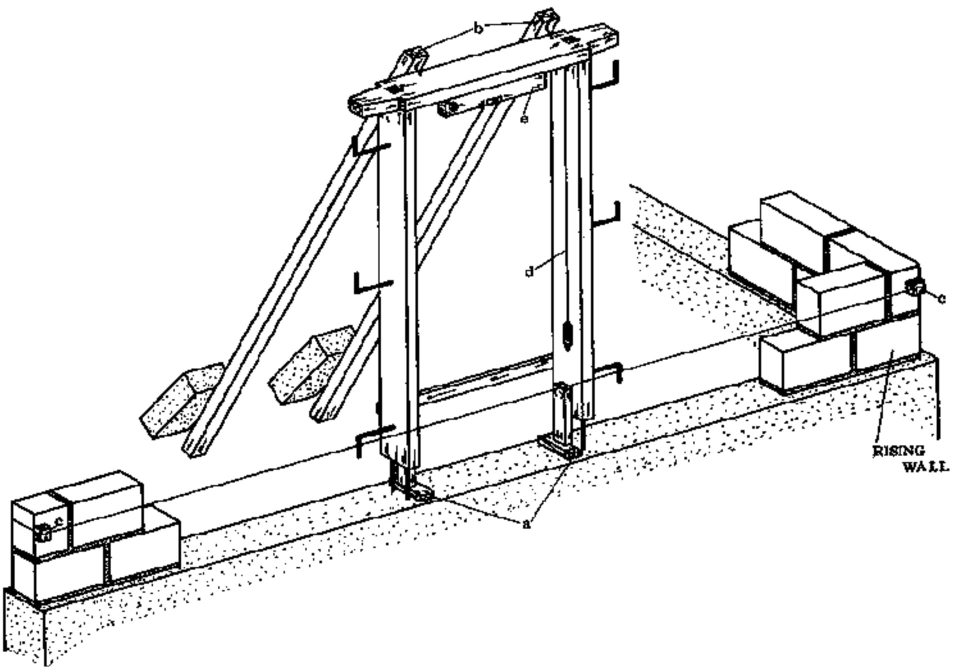

Fig. 1

To hold the frame in position during the following building operations, we use struts. These are braced against blocks on the ground and lean up to the head of the frame, where they are secured with two nails (Fig. 1, b, and Fig. 2, next page).

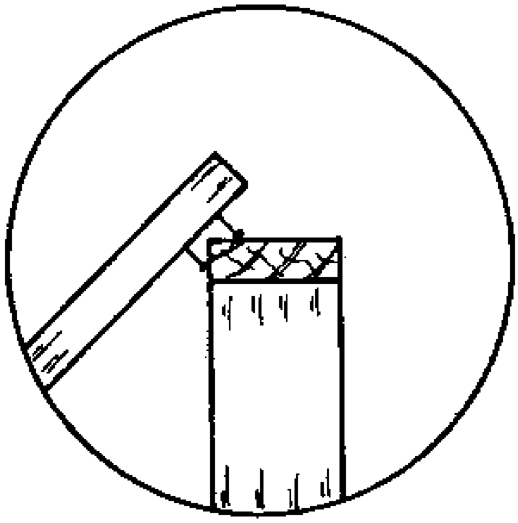

Fig. 2

The masonry line is used to align the frame with the face of the wall. The line is fixed at the two corners of the wall and two small wooden blocks are used to hold the line out from the wall by the same amount as the thickness of the future render layer; so that the line shows the position of the face of the render on the finished building (Fig. 1, c, next page).

The line should be free (not touching any frame or block) from corner to corner of the building. It should be separated from the frame faces by about a trowel's thickness (Fig. 3, next page).

Because the posts are long, the plumb bob is the best tool for making sure that the frames are straight and upright. Hold the bob at the inside top of the frame, so it has room to swing freely (Fig. 1, d). Check both posts (Reference Book, page 5)

To adjust the frame, the wedges are knocked a bit in or out, thus raising or lowering one post at a time until the frame is straight.

The face of the frame can be plumbed at the same time. To do this, step to one side of the frame and sight the edges of the post and plumb line. A helper should stand by the struts and either “give” or “pull” them until the frame is straight. Take care that the space between the face of the frame and the mason line remains correct (Fig. 3).

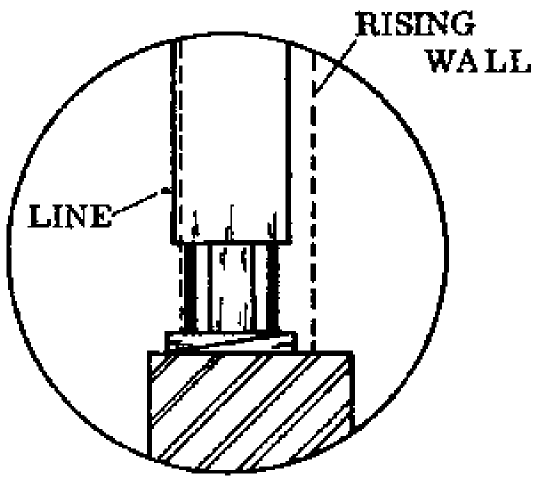

Fig. 3

As a final check, the soffit (underside) of the head can be levelled with a spirit level (Fig. 1, e).

- REMEMBER: Be sure that the face of the frame is in line with the mason line, not flush with the face of the blocks. When the building is finished, the render surface and the face of the frame should be flush.

Make sure that the frame remains at the correct height, so that the steel cramps can fit into the bedjoints and the frame does not get twisted.

After several courses of blocks have been laid, the frame should be rechecked to make sure that it has not become distorted by the blocklaying. Blocks should be laid on both sides of the frame at the same time, so that it does not get pushed out of plumb.

The struts and braces are taken off only when the blockwork has reached the head of the frame.

If more than one frame is erected, walk around the building and look from a distance to compare the frames with each other and make sure that they are all in the correct alignment.

- SETTING FRAMES AFTER THE WALLING HAS BEEN COMPLETED: In this method, the installation of the frames is postponed until the roof construction is complete, in order to reduce the risk of damage to the woodwork from the rain and sun.

Hardwood or plastic plugs (Reference Book, page 215) are driven into the bed-joints to serve as anchors for the frame. The frame is then put into position and nailed or screwed to the plugs.

NOTES:

WINDOW FRAMES

Types of window frames

The function of a window frame is to admit light and air into the building. The most common frame used in Ghana is the solid window type, consisting of an outer frame into which a casement or louvres are fitted.

The most common window frame consists of four parts (Fig. 1):

- Two posts (a)
- One head (b)
- One cill (c)

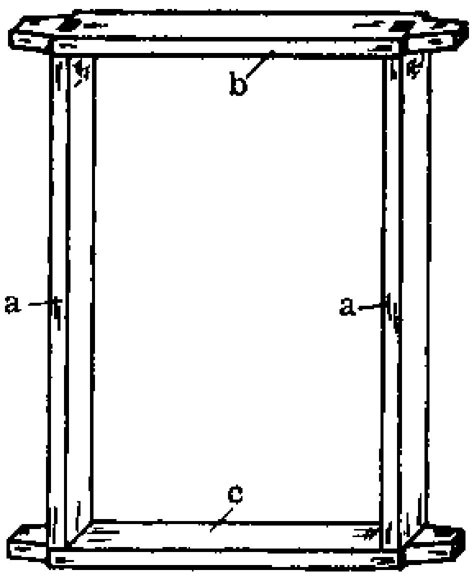

Fig. 1

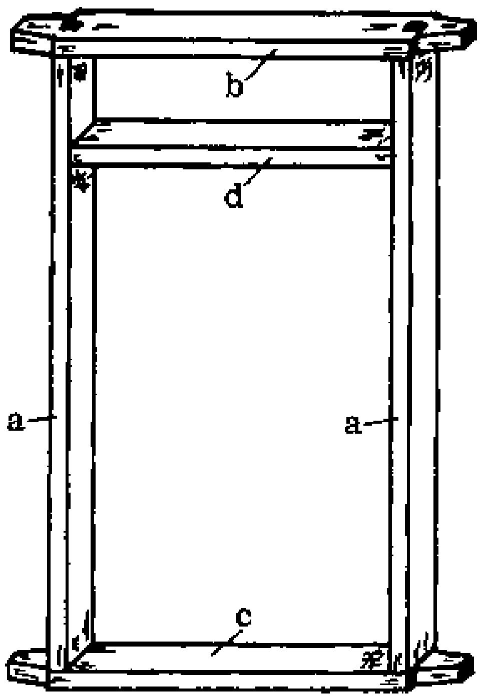

Fig. 2

When additional light and ventilation are needed, a fanlight can be added. The extra piece is called a transom (Fig. 2, d).

If wider windows are required, a mullion (Fig. 3, e) can be added.

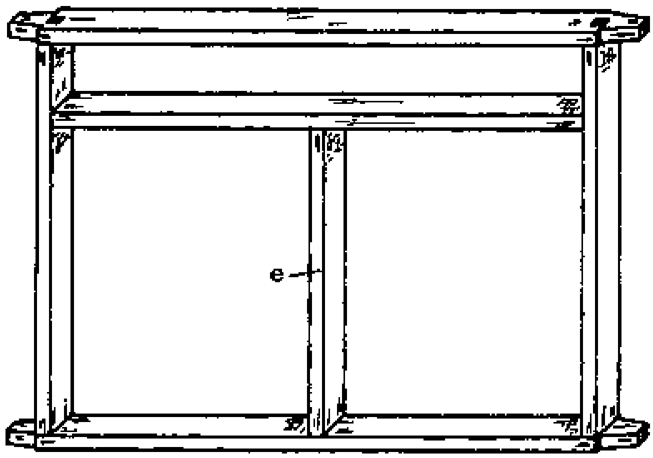

Fig. 3

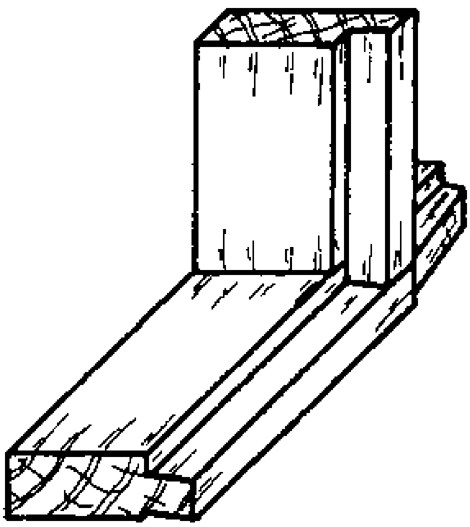
Any of these frames can be made with a rebate or with beads, or with a combination of the two (Figs. 4 & 5).



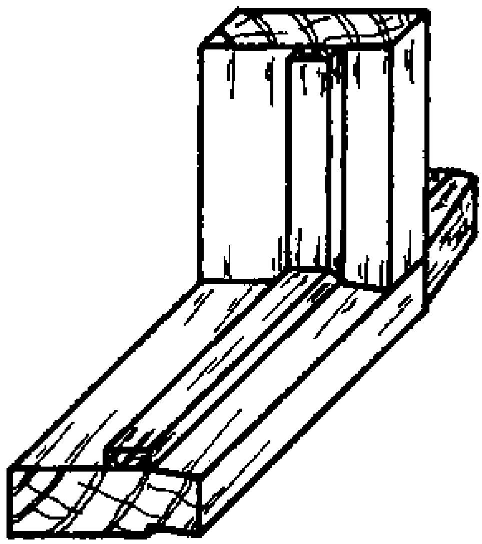


Fig. 4 WITH REBATE

Fig. 5 WITH BEADS

For a list of the advantages and disadvantages of beads or rebates, see the section on door frames. If beads are used, they are fixed after the casement is installed, so they can be adjusted (see Drawing Book, pages 42 & 72).

Measurements of window frames

Before you start constructing a window frame, you have to decide:

- whether the window will have shutters, louvres or any other kind of closing;
- if there will be any burglar proofing, and if so what kind;
- if any mosquito proofing is required;
- and where the window will be installed (does it have to be opened frequently, for example).

All these factors can influence the kind and sizes of timber we use, and the size of the frame itself.

- REMEMBER: Window frame measurements which are given with no further explanation are always inside measurements.

NOTES:

- MEASUREMENTS OF TIMBER SIZES FOR WINDOW FRAMES: A very common size of timber used for window frames is 7,5 to 10 cm wide, by about 5 cm thick. This size of timber is readily available and relatively inexpensive. If large frames are required, the timber size should be about 15 cm by 5 cm.

- MEASUREMENTS WITH RESPECT TO THE CASEMENTS: The height and width of the window frame are partly determined by the kind of casements which will be used. If ready-made casements are used, the frame has to be the right size to fit them. If the casements are to be made, consider the timber sizes which are available and choose the size of the casements according to the size of the boards, to avoid waste.

- MEASUREMENTS WITH RESPECT TO LOUVRES: If glass louvres will be in stalled, their size will determine the height and width of the frame. Find out the size of the louvre first, then start making the frame, not the other way around. Mistakes here can be very expensive!

Also make sure that there is room enough to open and close the louvres and that the mosquito proofing, if present, does not interfere with them.

Louvre windows will be discussed thoroughly in one of the next lessons.

The type of burglar proofing which is chosen will also affect the construction of the window frame, and we will consider this in one of the later lessons.

Steel cramps

If steel cramps are used to hold the frames, they should be positioned to fit into the horizontal joints (bedjoints) of the walls (see Measurements of Door Frames section, page 69).

Joints for window frames

When you are marking out the joints, first decide whether the frame is to have a rebate or beads.

In general, the joints for window frames are the same as those for door frames (see the section on Joints for Door Frames, page 65).

NOTES:

- SEQUENCE OF OPERATIONS FOR MAKING A WINDOW FRAME WITH TRANSOM AND MULLION: The joint for the transom-mullion connection should be a stub tenon, to prevent water from entering the mortice at the top.

Take care when marking out and cutting the shoulder of the tenon where it meets the slope of the cill, so that they fit together exactly (Drawing Book, pages 46, 47, 70, 71 and 72).

a. Study the drawing.

b. Prepare the cutting list.

c. Select the timber.

d. Cut the timber to size.

e. Plane the timber to size and make the face marks.

f. Mark out the joints. Take special care in marking out the shoulders of the joints. The head, transom, and cill must be marked out together, as the two posts and the mullion must also be marked out together.

g. Mortice the head and cill, and make stopped mortices in posts and transom.

h. Rip the tenons for the transom, posts and mullion.

i. Rip the horns on the head and cill.

j. Prepare the rebate and throating if required.

k. Cut the shoulders of the tenons.

l. Smooth and clean up the inside edges.

m. Paint the frame with a primer coat, especially at the joints.

- ASSEMBLING THE WINDOW FRAME:

a. Place the frame on the workbench, with the rebated side up.
b. Fix the transom to the posts.
c. Fix the mullion to the transom.
d. Clamp the head and the cill to the posts and mullion.
e. Test for squareness at the four corners, and check the diagonals.
f. Cut and nail the squaring strips.
g. With the clamps still in position, fasten the joints.
h. Finish off the frame.

Cells of window frames

The cill should have a slope on the outside, to keep rain out of the building. This slope can be constructed by chamfering the cill (Fig. 1) or by a combination of chamfering and rebating (Fig. 2).

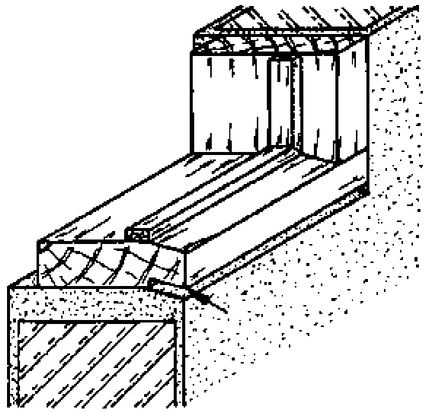

Fig. 1

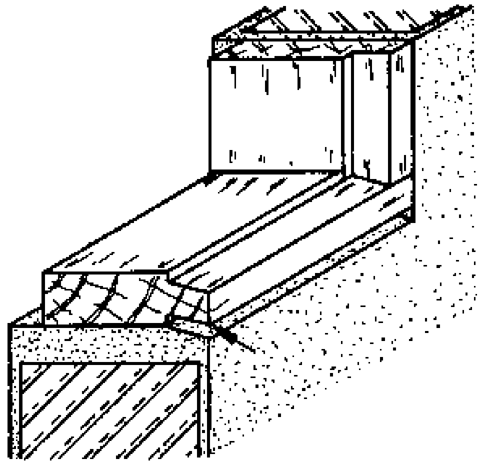

Fig. 2

It is important to prevent rainwater from entering the space between the cill and the wall, where it could cause the cill to rot. A throating at the soffit of the cill (Figs. 1 & 2, arrows) allows water to drip down instead of running back under the cill. The angle of the throating should be parallel to the slope of the cill.

Another way to keep water out is to fix a metal strip, called a drip, under the cill (Figs. 3a & 3b). The drip is fixed in a sawcut in the underside of the cill, so that the water which drips onto the metal will not run inwards. The slope of the metal comes to just inside the face line of the cill (Fig. 3b).

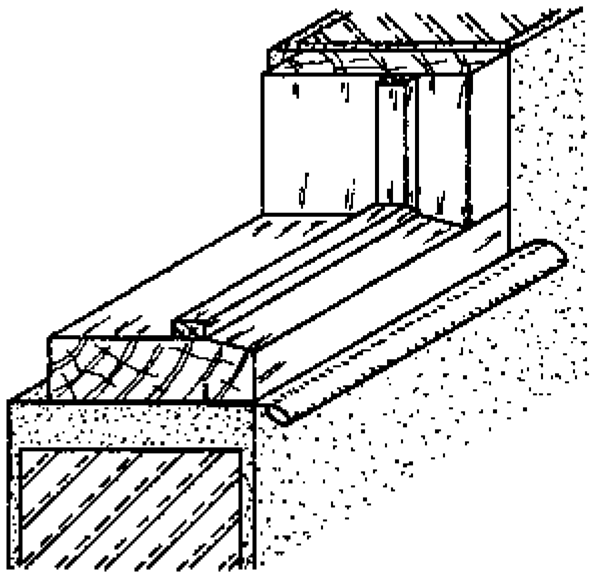

Fig. 3a

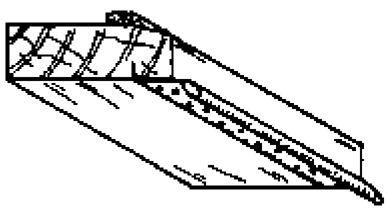

Fig. 3b

The metal strip should extend past the ends of the cill. If it does not, the water which runs down the posts of the frame will damage the render around this part at the corners of the frame.

It is also possible to combine the two solutions, by fixing a metal strip onto the throating.

Every cill should have some kind of protection to keep water from entering between the cill and wall. All cills must come out at least as far as the finish line of the render.

As an alternative to the wooden cill, the window can be constructed with a plaster cill. The posts are fitted with steel dowels and a concrete shoe. The construction is similar to that of a door frame with a concrete shoe (Fig. 4, also see Concrete Shoe, page 71).

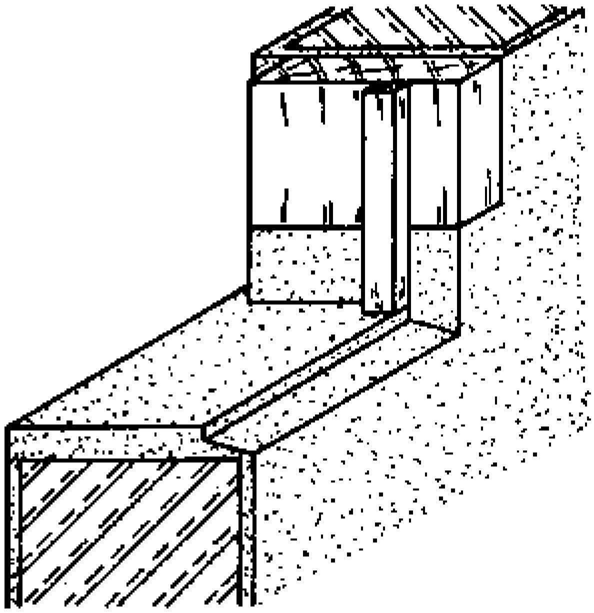

Fig. 4

NOTES:

Heads of window frames

Some protection must also be added at the head of a window frame to prevent any water from entering the space between the head and the lintel and causing damage to the wood. The simplest method is to fix a metal strip similar to the one on the cill. The part of the strip which is plastered over should be bent slightly upwards to prevent water from entering (Fig. 1a, arrow).

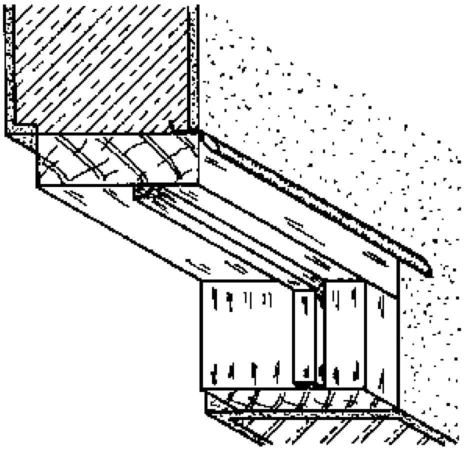

Fig. 1

Note that the line of nails is staggered so that the drip (or weather strip) is firmly secured to the head (Fig. 1a). Otherwise, movement of the strip during heavy rains or storms would probably loosen the render.

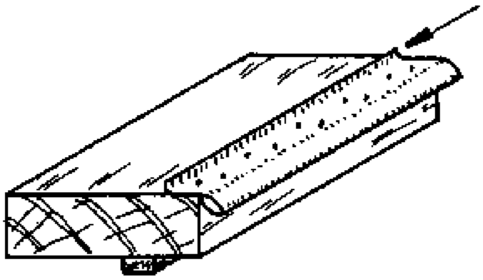

Fig. 1a

These metal drips may be put on when the frame is set up, or left until just before the rendering is done.

An alternative method would be to fix wooden battens, shaped as shown in Fig. 2, on the face of the window head. This method gives a more satisfactory appearance to the window frame.

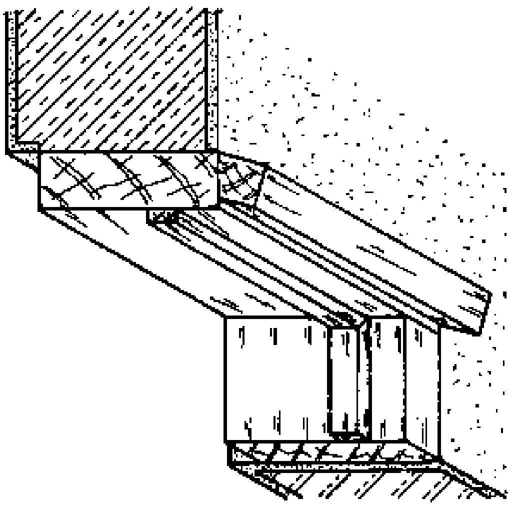

Fig. 2

A combination of both these methods is also possible (Fig. 3).

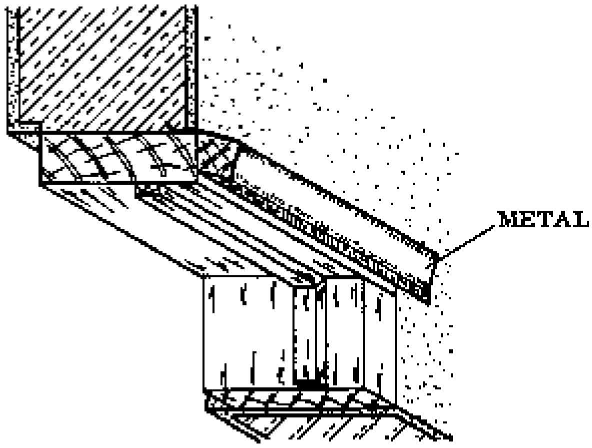

Fig. 3

The importance of fixing weather strips on both the cill and the head of the frame cannot be over-emphasized. They are easily overlooked during the construction of the building and one might be tempted to do a quick job and leave them out. But in the long run the strips will save money by preventing water damages to the wood and expensive repairs.

The same kind of protection can be applied to the heads of door frames.

The heads and cills of window frames can be provided with horns to give an additional secure fixing to the wall (see Heads of Door Frames).

NOTES:

Installing window frames

Installing window frames is similar to installing door frames (see Door Frames section). A window frame should be fixed in such a way that the casement can open flat to the wall, otherwise the casement will form a lever with the edge of the wall. This can cause the hinges to be forced out when the window is blown open by the wind.

Window frames can be installed either during the construction of the walls, or after the walling has been completed.

- INSTALLING THE FRAMES DURING THE WALL CONSTRUCTION: When the blockwork has reached window cill level, the frames can be set and aligned in the same way as a door frame. The chief difference is that in the window frame the horizontal members are usually longer than the vertical members, and for that reason more attention is given to levelling the head and cill of a window frame than to levelling the head of the door frame (Fig. 1).

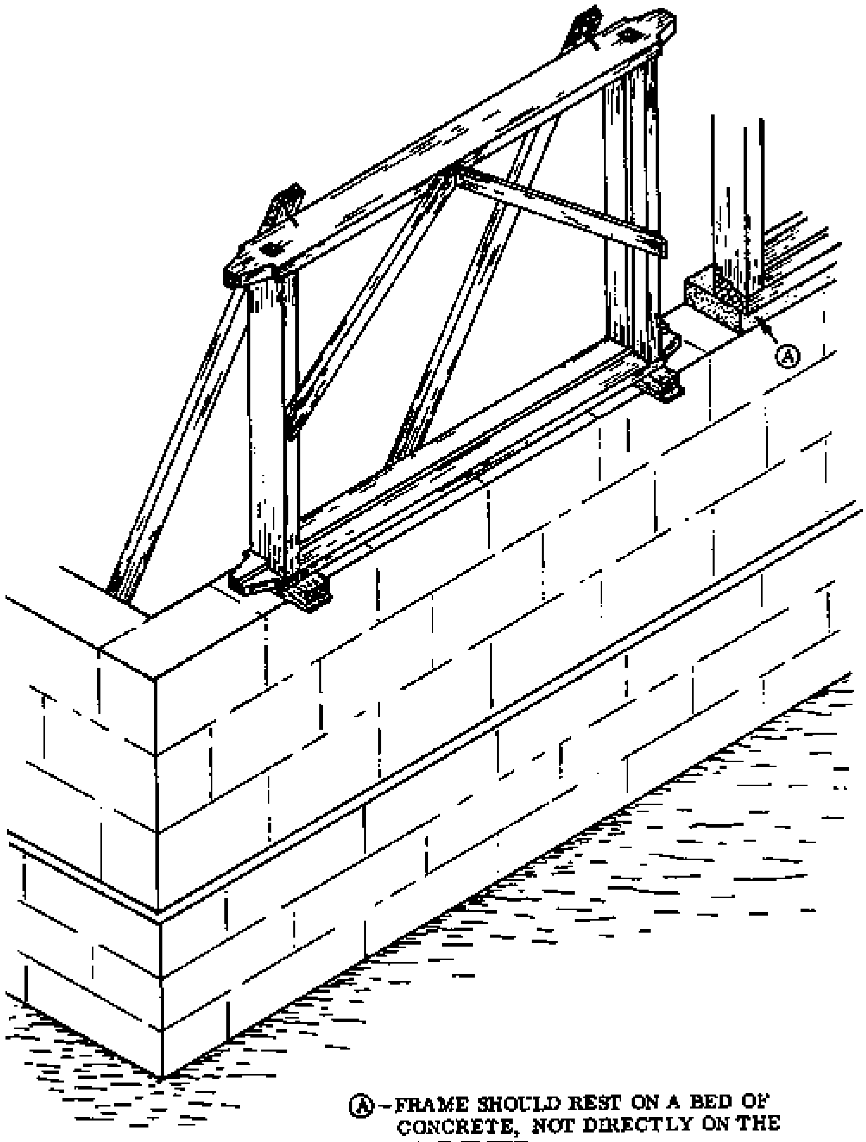

Fig. 1

If more than one frame is installed, check them by comparing from a distance to see if they are aligned, as with door frames.

- INSTALLING THE FRAMES AFTER WALLING HAS BEEN COMPLETED: This second method is not so commonly used, but it also has its advantages. In order to keep the frames clean, square and dry, they are kept in a store until the building is roofed. Openings are left in the blockwork to receive the frames, horns, and steel cramps. The frame is set into this opening and the steel cramps and horns are secured with mortar.

Sometimes hard wood or plastic plugs are used to secure the frame in the wall.

- NOTE: The window frame does not rest directly on the landcrete wall; this would provide a path for moisture to get into the landcrete and weaken or damage it. The window frame is set upon a bed of concrete or cement mortar (Fig. 1, A).

NOTES:

WALLING UP BETWEEN FRAMES

First mark the positions of the blocks on the outsides of the frames. Mark both the height of the blocks (Fig. 1, a) and the face line of the blockwork (Fig. 1, b). The face line of the blockwork will be inside the face line of the frames, because the faces of the frames must be flush with the finish line of the render.

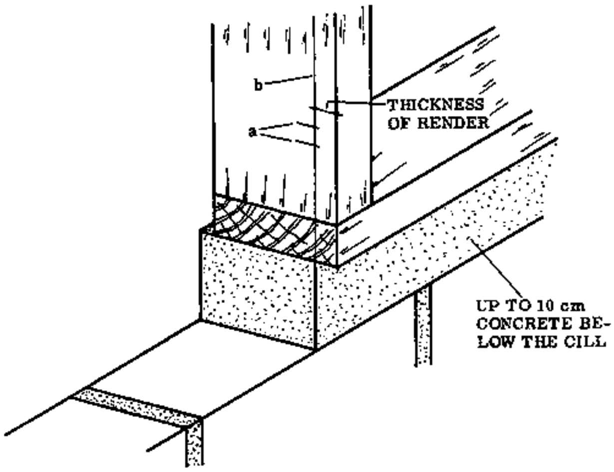

Fig. 1

- NOTE: The window frame does not rest directly on the landcrete blocks. This is because moisture could enter between the cill and the landcrete and get into the blocks, where it would cause them to swell and fall apart. To protect the landcrete blocks, the cill must rest upon a bed of concrete which can be up to 10 cm thick. By adjusting the height of this concrete bed, the anchorage irons and the heads of the frames can be brought into alignment with the bed joints of the blocks.

The first blocks laid are those which touch the frames. The courses in between are completed and aligned with the aid of either a straight edge, spirit level, or mason line, depending on the distance between the frames.

Pay special attention to the anchorage irons of the frames. Make sure that they are not just embedded in the bed joint; instead make grooves in the bed faces of both blocks, which can be filled with mortar to anchor the iron and to protect it from rust (Fig. 2).

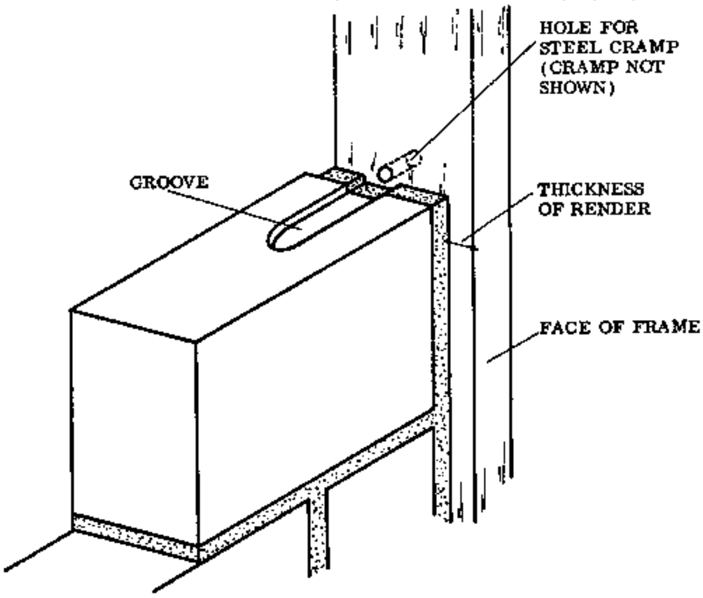

Fig. 2

MOSQUITO PROOFING

It is often necessary to install mosquito wire on doors and windows. The wire screen is normally attached with wooden beads directly onto the window frame. For louvred windows it is fixed on the outside. For casement windows which open outwards, the wire screen has to be attached on the inside or onto a separate framework which is hinged onto the inside of the frame.

A separate framework for the mosquito wire is commonly constructed on doors. Make this framework like a panelled door (this door and its construction are described in one of the following sections, under Doors). Use one or two braces in the framework to keep the door rigid. Often a spring is attached to the wire door to keep it in the closed position.

BURGLAR PROOFING

It is practically impossible to keep burglars out of a house when the occupants are away, but it is at least possible to make the house burglar proof to the extent that burglars cannot enter without making considerable noise and so alerting people in the area.

Types of burglar proofing for windows

- One of the most common methods is to fix mesh wire or expanded metal directly onto the frame, in a way that it cannot be torn off without making consider able noise or using a special cutting tool. Use strong beads to attach the wire to the frame and plenty of screws or nails (Fig. 1).

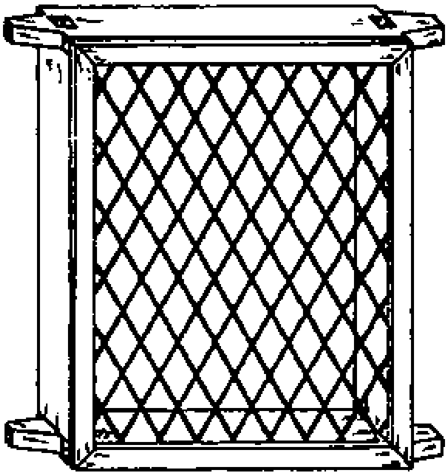

Fig. 1

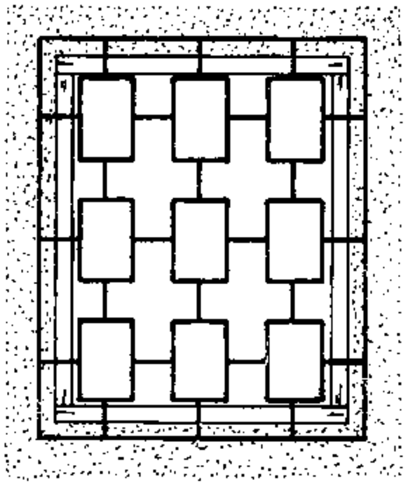

Fig. 2

- Sometimes burglar proofing is made from welded iron rods in different patterns and fixed directly into the wall around the window. It should be anchored well and deeply enough so that it cannot be pulled out (Figs. 2 & 2a).

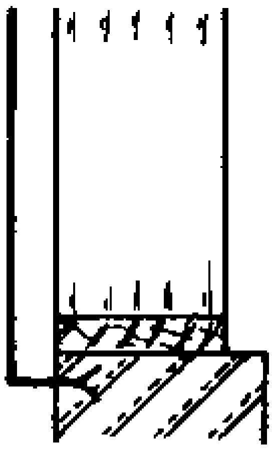

Fig. 2a

- Another way to make a window safer is to fix iron bars horizontally into the frame. This must be done during the assembly of the frame. If some of the bars stick out at the sides of the frame, they can also be used as an additional anchor for the frame in the wall (Fig. 3). If the span between the posts of the window is large, the horizontal bars may need to be reinforced by having vertical bars welded onto them, so that they cannot be bent up or down to allow the burglar to enter.

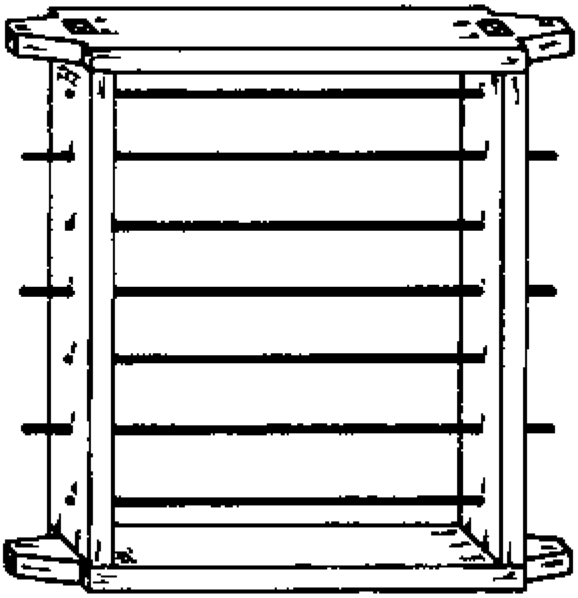

Fig. 3

The bars can also be applied to windows fitted with louvres. In that case, the iron bars are placed between the louvre glasses (Fig. 3a). They must be placed in such a way that they will not obstruct the louvres when they are opened.

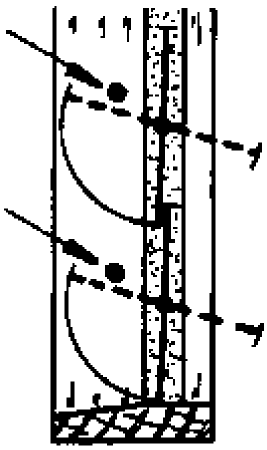

Fig. 3a

- A relatively inexpensive and reliable burglar proofing is the wooden type. During assembly of the frame, this burglar proofing is installed into mortices made in the head, cill and posts of the frame. The separate pieces are fitted together with halving joints in a crosswise pattern (Fig. 4).

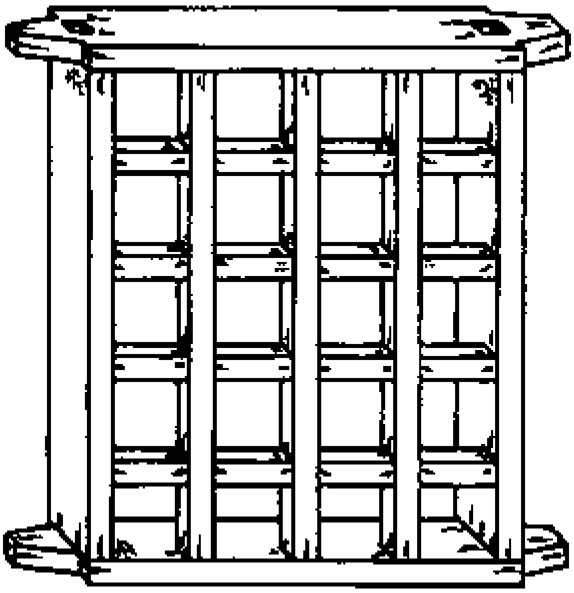

Fig. 4

If outward-opening casements are installed in a frame, install the burglar proofing on the inside face of the frame. Leave a small opening in the burglar proofing for the hand to pass through in order to open and close the window.

For louvred windows the burglar proofing is always installed on the outside.

DOORS

The door is an essential part of the building structure. It must have the right proportions: not so large that it weakens the wall of the building, and not too small either. People, goods, and equipment, according to the uses of the building, have to be able to pass through the door easily.

Types of doors

In Rural Building, doors are classified as follows:

- Ledged and battened doors (Fig. 1)

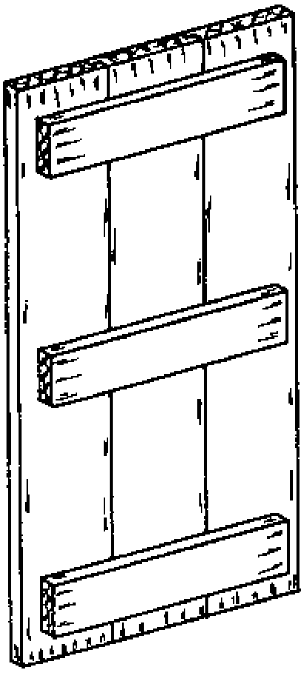

Fig. 1

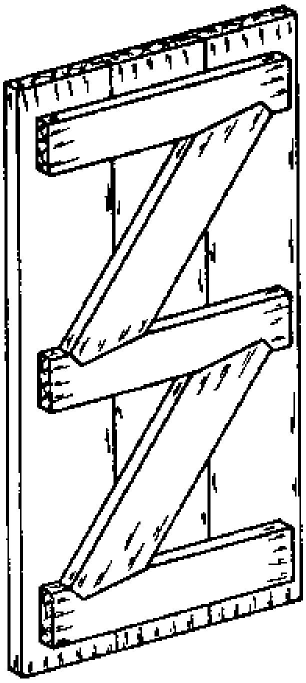

Fig. 2

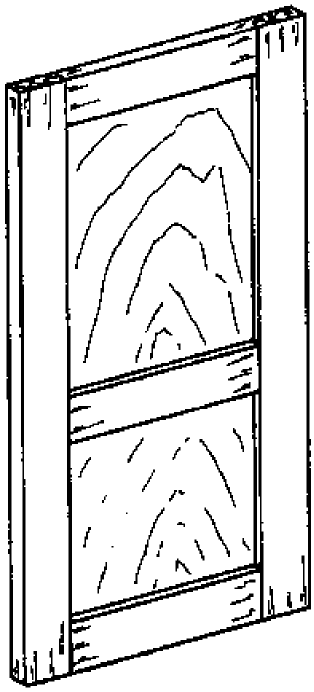

Fig. 3

- Ledged, braced and battened doors (Fig. 2)
- Panelled doors (Fig. 3)
- Flush doors (Fig. 4)

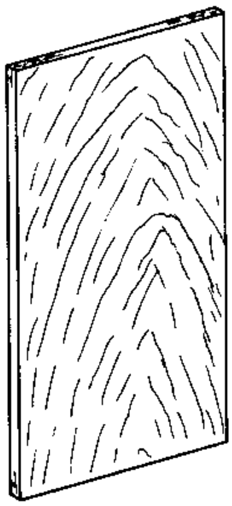

Fig. 4

For an outside door which is exposed to rain and sun, it is best to choose a weather resistant door like a battened or panelled door. If the door is protected inside the building then a flush door made of plywood will be satisfactory.

Sizes of doors

The size of the door depends on:

- Where it will be used (entrance doors will naturally be slightly larger than other doors, and bathroom doors will be a bit smaller)

- The materials which are available (plan the door according to the sizes of wood and plywood which are available).

A common door size is 198 cm by 76 cm. This is wide enough to allow most sizes of furniture to pass through. Nearly all modern furniture has one dimension which is 76 cm or less: a standard table, for example, is 76 cm high.

Living room and bedroom doors are sometimes larger for reasons of ventilation.

Position of the door

Outside doors should always open to the outside. This makes them more weatherproof and easier to open in case of an emergency such as a fire, when you want to get out quickly.

Try to position the door so that you cannot look directly into the room from the outside.

Finishing treatment of the door

All doors should be painted or varnished, or preserved in some way. A good paint job preserves the door from decay and reduces shrinkage and swelling, thereby lengthening the life of the piece (Reference Book, pages 200 & 201).

Paint is especially important for flush doors. They should be well painted and the edges of the door should be soaked in paint.

Ledged and battened doors

These doors consist of vertical boards called battens (Fig. 1, a) which are nailed or screwed to the horizontal members, called ledges (b). Often the battens are a-bout 15 to 18 cm wide and 2 to 3 cm thick. Doors made with narrow battens like these have a better appearance.

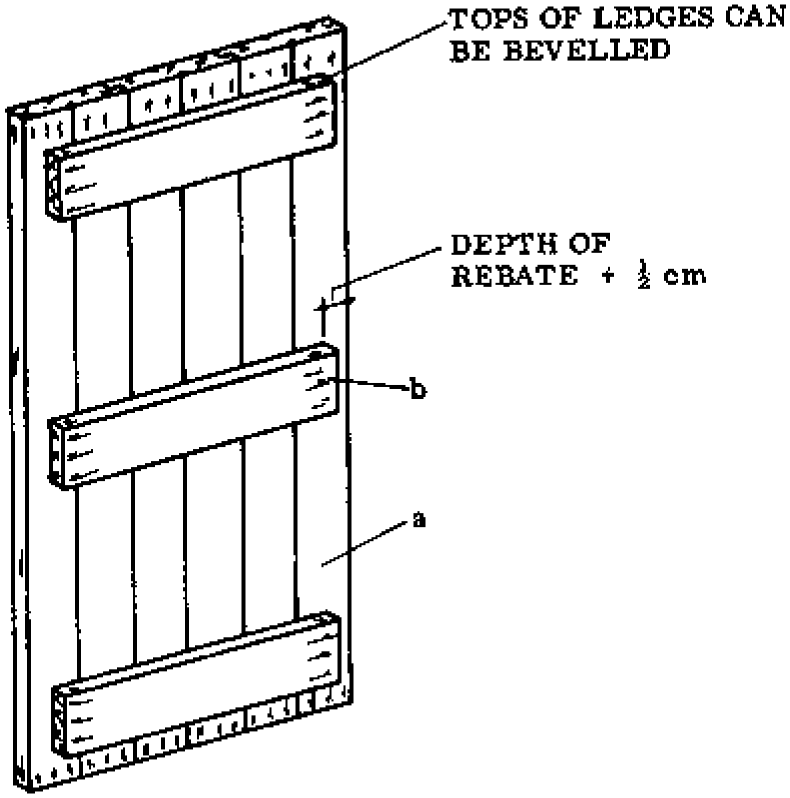

Fig. 1

Because of the climate in the northern part of Ghana, here it is better to use boards which are up to 30 cm wide. These wider boards are less likely too twist and warp at the ends (Fig. 2). The boards should be well seasoned so that they won't crack at the ends.

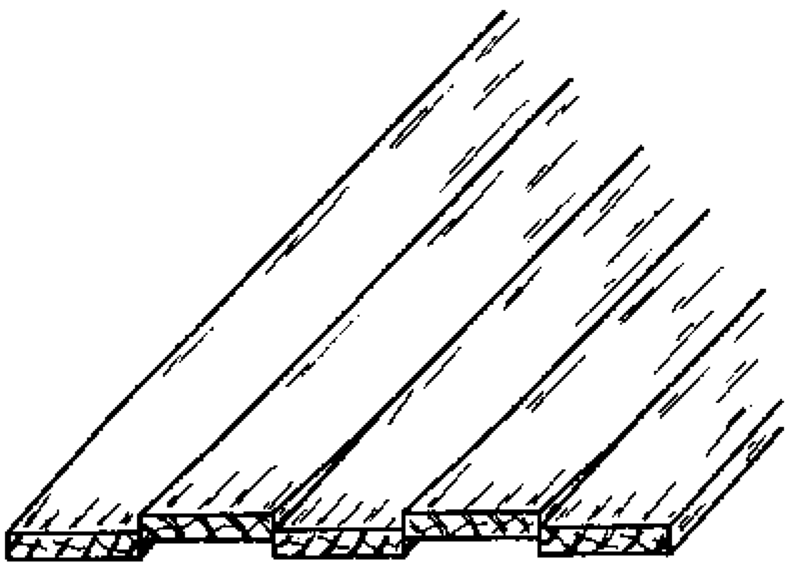

Fig. 2

The width of this door is usually the width of 2 1/2 or 3 boards (Figs. 3 & 4).

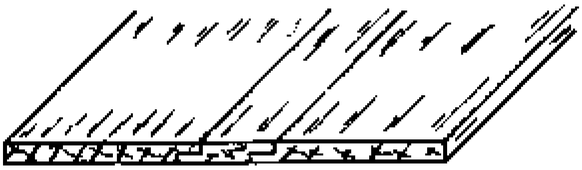

Fig. 3 2 1/2 BOARDS

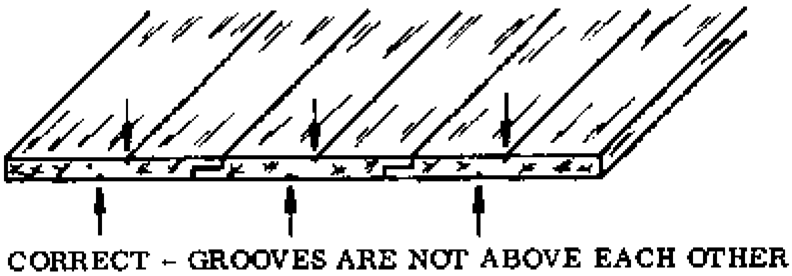

Fig. 4 3 BOARDS

Grooves can be made in the wide battens, to produce a pleasing appearance as if the door were made with narrow battens (Fig. 4). The grooves should not be made from both sides of the door at the same spot, above each other, because this will make the door weak (Fig. 5).

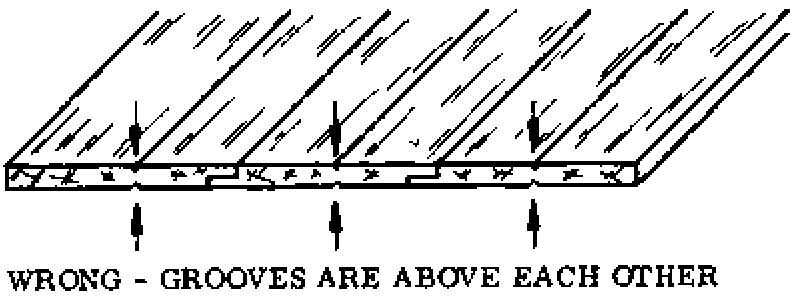

Fig. 5

The ledges should be as long as possible to prevent cupping of the battens, and to provide a solid attachment. The length of the ledges will be the width of the door minus the depth of the two rebates or beads in the door frame, and minus a 1/2 cm allowance on each side (Fig. 1). The ledges are usually 2 to 3 cm thick. When this construction is used for an external door, the tops of the ledges should be bevelled (Fig. 1).

The ledged and battened door is the simplest type of door. It is often used for narrow openings. It is relatively cheap to construct, but unfortunately it tends to sag because of its weight.

NOTES:

- JOINTS FOR LEDGED AND BATTENED DOORS: We use special types of joints to connect the battens of this door. These joints are known as matchboarding joints.

A matchboarded door will have a good appearance even when the boards have shrunken and the joints are opening. Matchboarding joints are not glued like ordinary widening joints (Basic Knowledge, pages 130 to 136). They are left loose so that shrinkage can take place, and the battens are held together by the ledges.

In Rural Building we use two different matchboarding joints: the loose tongued joint (Fig. 1), and the rebated joint (Fig. 2).

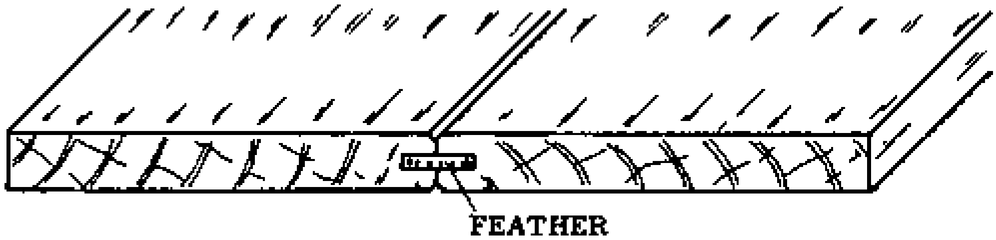

Fig. 1

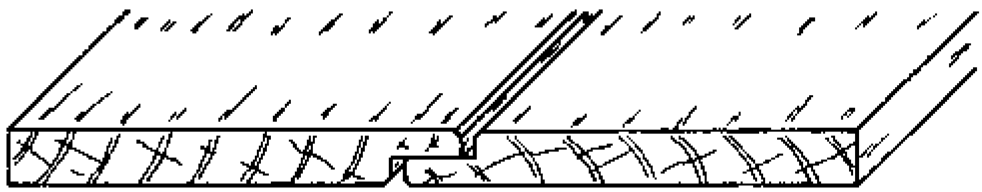

Fig. 2

The loose tongued joint has a tongue made of plywood. It is glued into only one side of the groove so that shrinkage can take place (Basic Knowledge, page 134).

There are several possible ways to make the rebated joints used in battened doors (Fig. 2).

When you assemble this joint, put a strip of wood in between the battens with the same thickness as the gap you want. This keeps the gap between the battens open as the door is assembled.

Any batten-type door made during the rainy season should be assembled with the matchboarding joints closed. If the door is assembled during the dry season, then the joints should be kept open (Fig. 2, also see Reference Book, pages 129 to 130). There should be enough allowance between the battens to allow them to swell up to 5% of the width of the board (for a 30 cm board size the gap will be up to 1 1/2 cm). If this is not done the door will start to warp when it swells in the rainy season.

- SEQUENCE OF OPERATIONS FOR MAKING A (NAILED) LEDGED AND BATTENED DOOR:

a. Study the drawing.

b. Prepare the cutting list.

c. Select the wood.

d. Cut the timber to the right size, leaving a 1 cm allowance in the length of the battens for finishing off.

e. Plane the timbers to size. Mark the boards (Basic Knowledge, page 88).

f. Plane the matchboarding joints.

g. Paint or varnish the edges of the battens.

h. Fit the battens together. Use a wooden or metal sash clamp to hold them.

i. Mark the positions of the ledges.

j. If the door is to be an external one, bevel the tops of the ledges.

k. Paint or varnish the inside faces of the ledges and battens.

l. Nail the ledges lightly to the battens (Fig. 3, previous page).

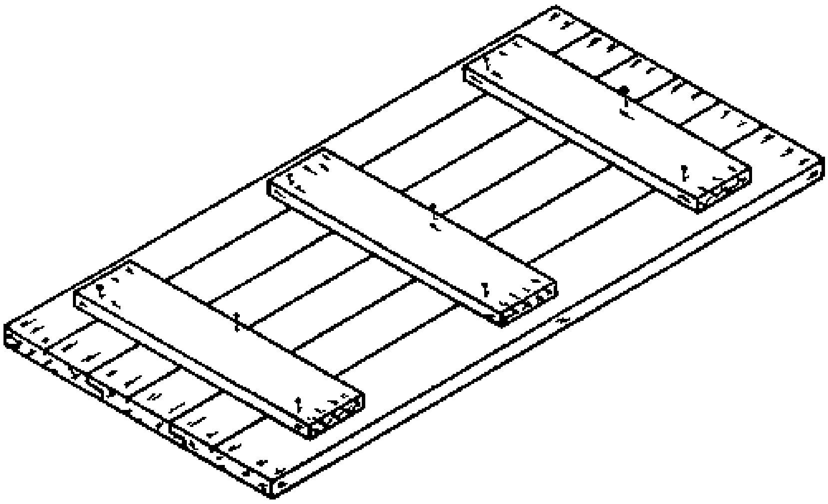

Fig. 3

m. Turn the door over put three pieces of wood under the ledges for support during nailing (Fig. 4, previous page).

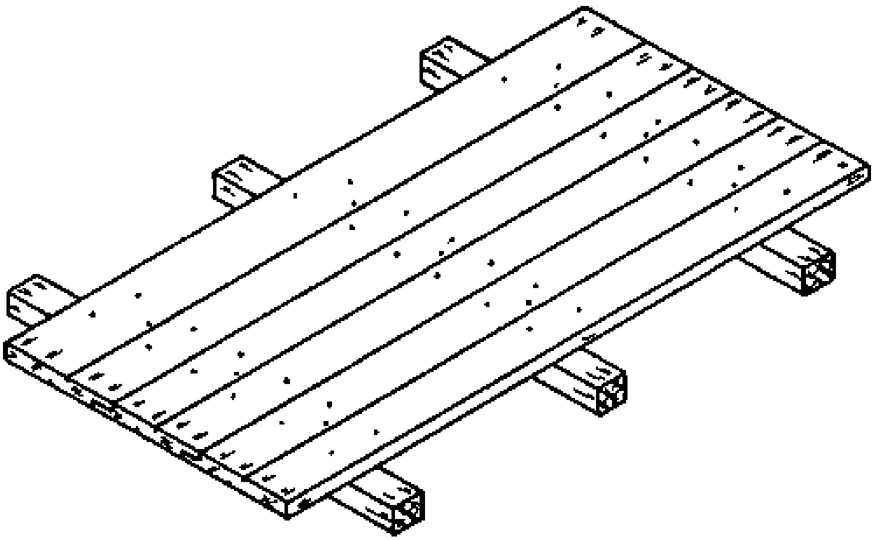

Fig. 4

n. Drive the nails through the battens and ledges and punch the heads under the surface of the wood.

o. Turn the door over and clench the nails. Remove the nails used in step “1” to nail the ledges lightly to the battens.

p. Cut off and level the battens at the top and bottom.

- REMEMBER: To avoid splitting the wood, always blunt the nails and drive them in a staggered pattern (Fig. 4, previous page). Clench all the nails to prevent them from being pulled out if the wood warps or swells. For clenching, the nails have to be long enough to go through the wood and out the other side by about 5 mm (Basic Knowledge, pages 92 to 94).

Ledged, braced and battened doors

This is a ledged and battened door to which braces have been added to prevent sagging (Figs. 1 & 2). These braces must slope upwards from the hinge edge of the door, and they are housed with a skew notch into the ledges (Drawing Book, page 73).

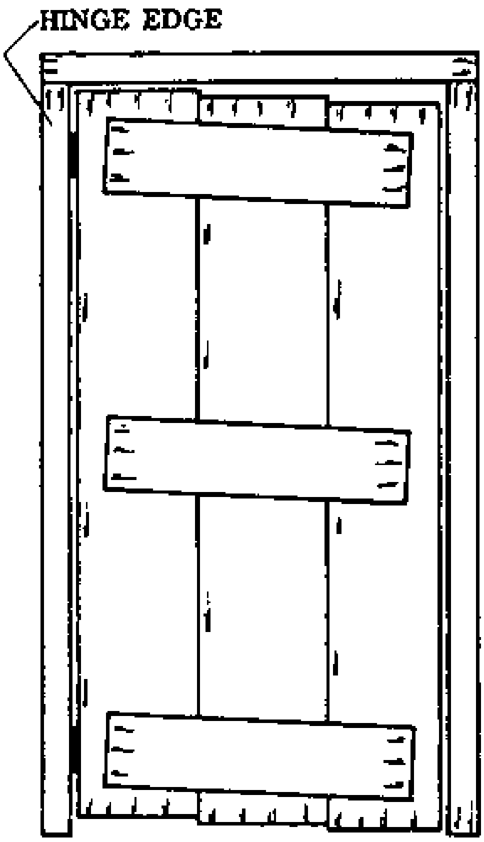

Fig. 1 NO BRACES - DOOR MAY SAG

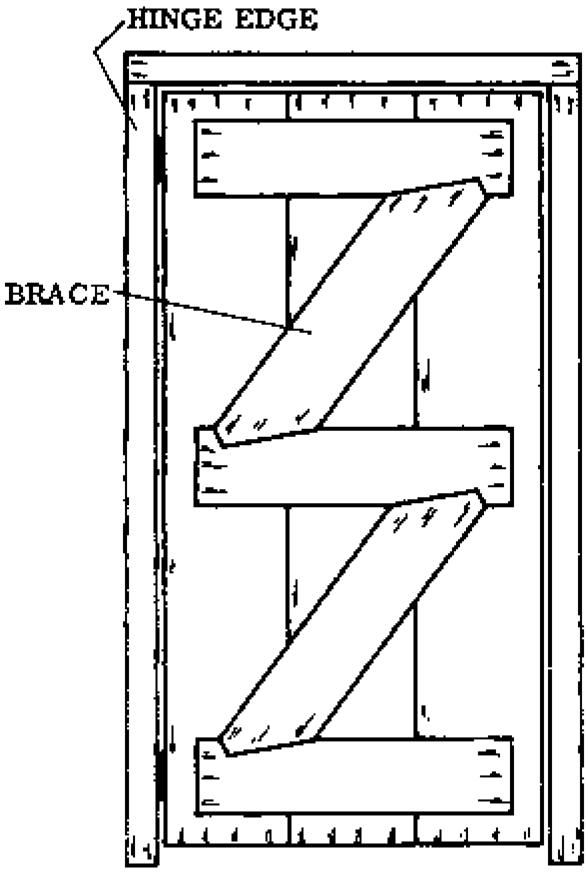

Fig. 2 BRACES PREVENT SAGGING

The skew notch helps to distribute the force from the weight of the door, so that the ledges have an even pressure on them. To achieve an equal distribution of the force, the angle of the short shoulder of the skew notch has to bisect (divide in two) the angle between the ledge and the brace (see Fig. 3, angle “x” = angle “y”).

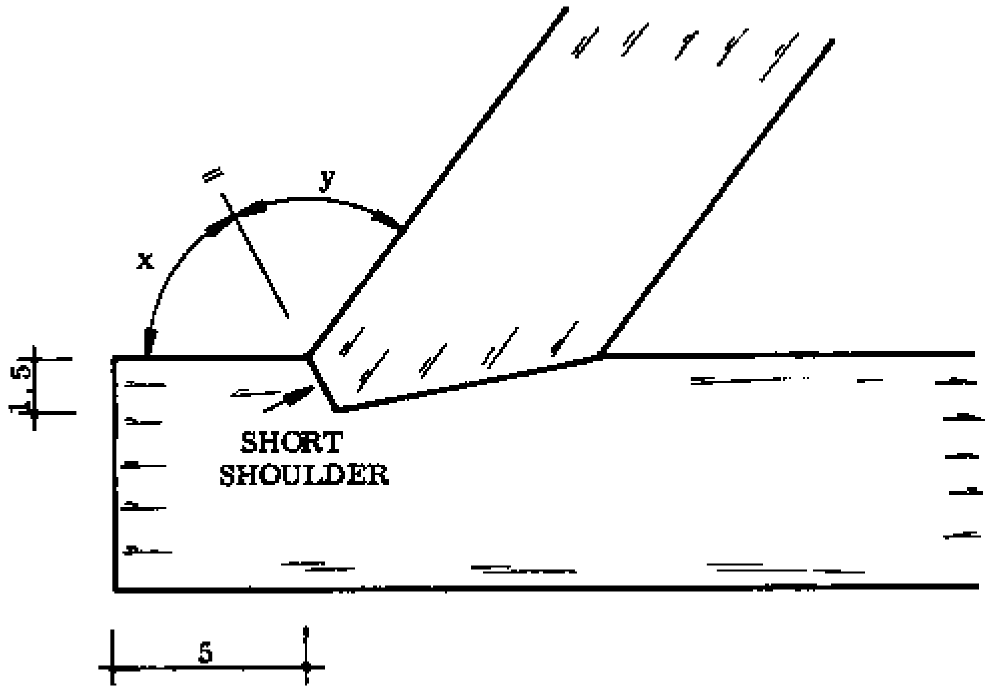

Fig. 3

The skew notch should start from a point 5 cm from the end of the ledge, to prevent shearing off. The depth of the skew notch will be 1,5 cm (Fig. 3).

This type of door construction may be used for large openings because of its greater strength.

The sequence of operations to make this door is the same as for the ledged and battened door. The braces are fitted to the door after the ledges are nailed lightly to the battens (step "1" in the construction).

- SEQUENCE OF OPERATIONS FOR MAKING A (NAILED) LEDGED, BRACED AND BATTENED DOOR: Proceed in the same manner as for the ledged and battened door,' until you reach step "1". Continue as follows:

m. Place the braces on top of the ledges (Fig. 1).

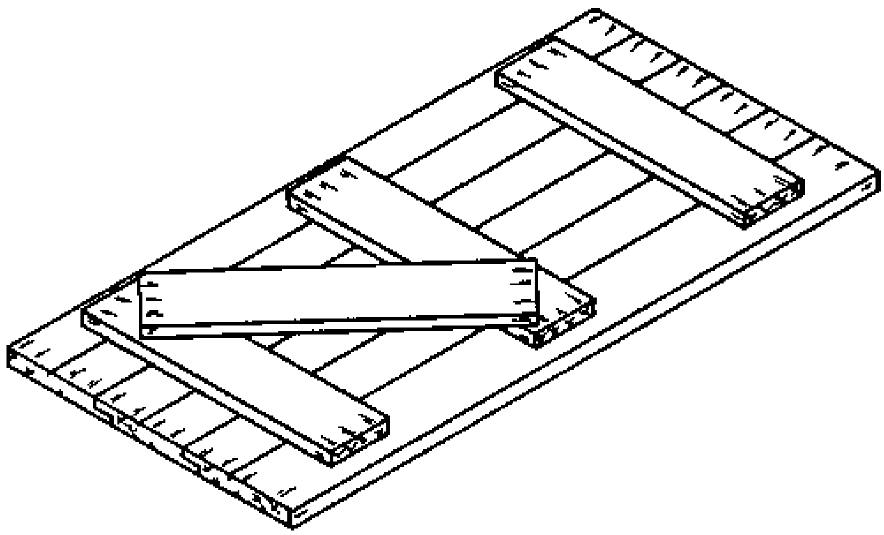

Fig. 1 (m)

n. Mark out the skew notches on each end of the braces.

o. Cut the braces according to the marks.

p. Place each brace in position and mark out the positions on the ledges (Fig, 2).

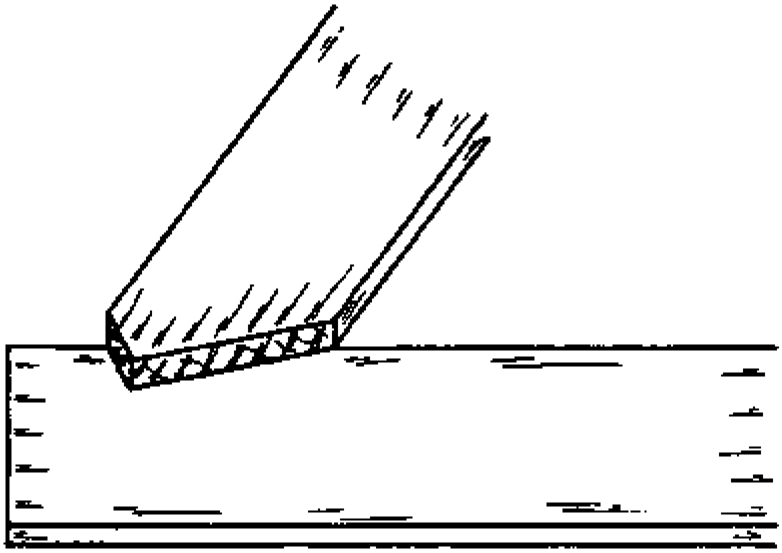

Fig. 2 (p)

q. Chisel the notches in the ledges (Fig. 3).

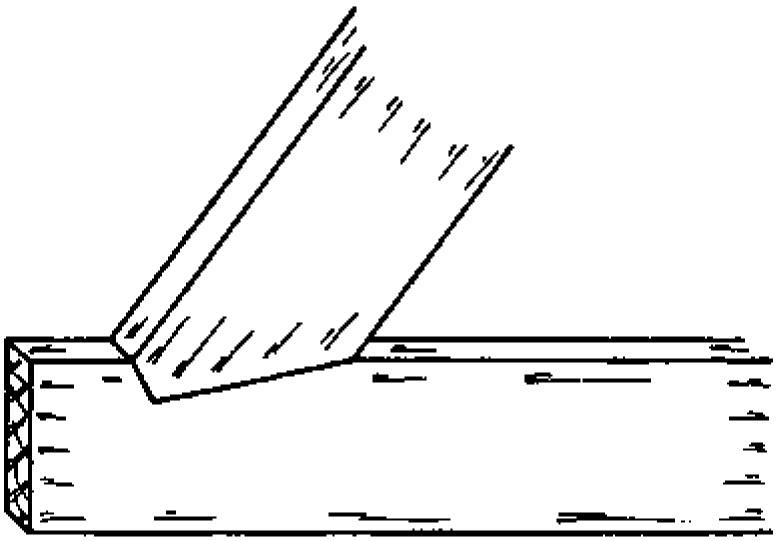

Fig. 3 (q)

r. Paint the skew notches.

s. Nail the braces lightly to the battens.

t. Turn the door over and place three pieces of wood under the ledges for support during nailing.

u. Drive nails through the battens, ledges and braces, and punch the nail heads under the surface.

v. Turn the door over and clench the nails. Remove the nails which were used to hold the braces and ledges lightly to the battens in step “s”.

w. Cut off and level the battens at the top and bottom.

NOTES:

Panelled doors

These doors (Fig. 1) consist of a frame made up of stiles (a), a top rail (b), a bottom rail (c) and sometimes an intermediate rail (d). Into this framework a plywood panel (e) is fitted. This panel may fit into a groove or a rebate (Drawing Book, pages 75 to 78).

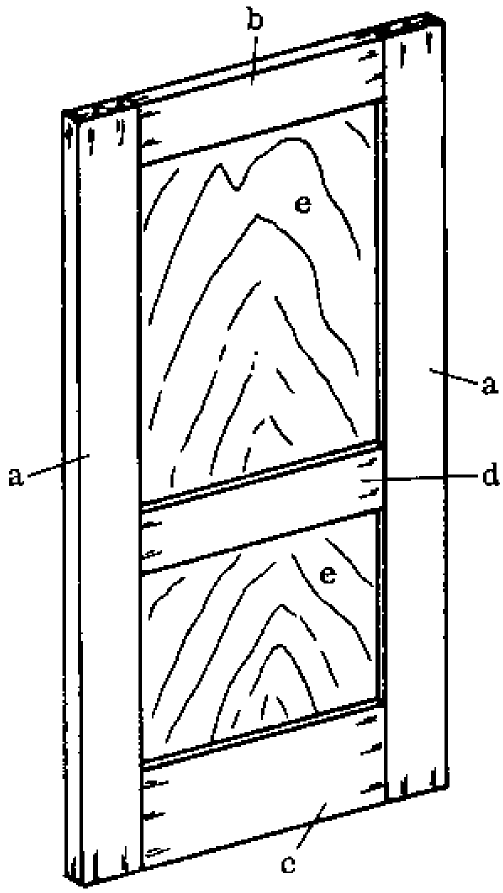

Fig. 1

- GROOVED-IN PANEL: This construction can be used only on doors which will be protected from the rain. If water enters the groove, it will not be able to dry out and can cause the plywood to rot (Fig. 2).

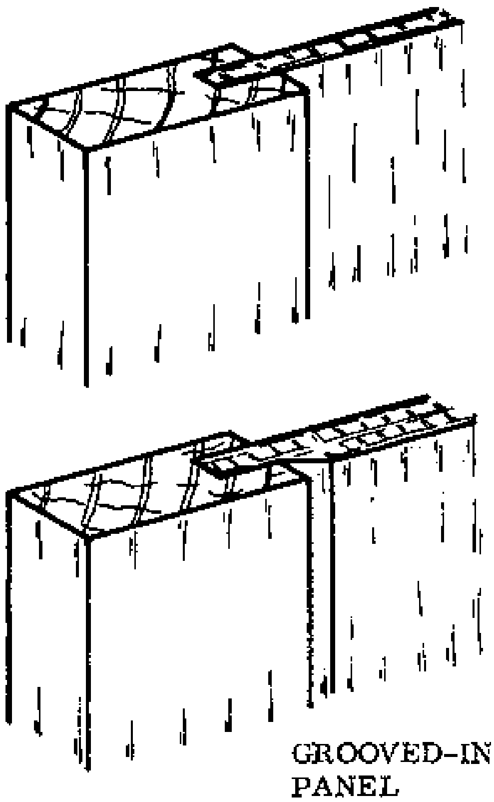

Fig. 2

If the door will be painted or varnished, the edges of the plywood panel and the inside of the grooves should be treated before the door is assembled.

The depth of the grooves is usually 1/3rd of the thickness of the members. The grooves are made as explained in the Basic Knowledge book, page 136.

The joints for this kind of door will be a haunched stub tenon for the top and bottom rails (Fig. 4), and a stub tenon for the intermediate rail (Basic Knowledge, pages 118 to 122). Note that the width of the tenon has to be reduced by the depth of the groove (Fig. 4, arrow) and the mortice is reduced accordingly.

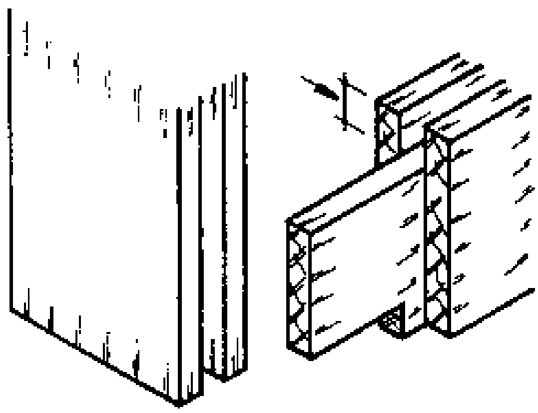

Fig. 4

- REBATED FRAMEWORK: When the panel will be fixed after the frame is assembled, a rebated framework is used. A rebate is made in the frame and the panel is secured with beads (Fig. 3).

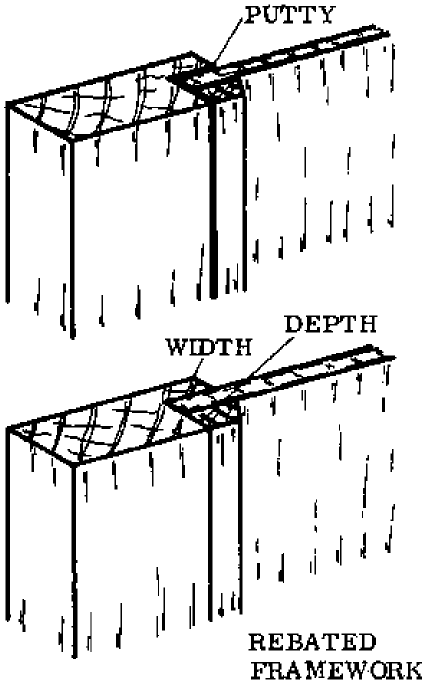

Fig. 3

Unlike the grooved-in panel door, this door can be used in places where it is exposed to rain. In that case, the plywood is set in putty so that water cannot penetrate inside, and the tops of the intermediate and bottom rails should be bevelled. The beads are also set in a thin layer of putty, then secured with nails.

If the door will be painted or varnished, the joints, edges of the plywood, rebates and beads all have to be painted before assembly.

The width of the rebate is usually 1/3rd of the thickness of the frame member, and the depth is usually 2/3rds of the thickness of the member (Fig. 3).

The joints for this kind of door will be haunched stub tenons for the top and bottom rails and stub tenons for the intermediate rail. Note that one shoulder of the tenon has to be longer to fill the rebate (Fig. 5, a). The widths of the tenon and mortice have to be reduced by the size of the rebate (Fig. 5, b; also Drawing Book, page 78, and Basic Knowledge, pages 118 to 120).

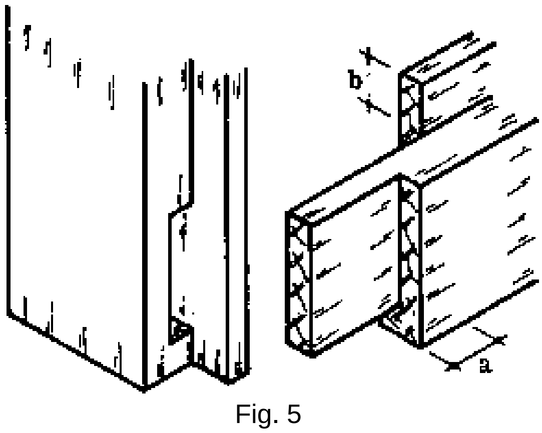

Fig. 5

NOTES:

- TIMBER MEASUREMENTS FOR PANELLED DOORS:

Stiles and top rail - 3 to 4 cm thick, 10 cm wide
Intermediate rail - 3 to 4 cm thick, 10 cm wide
Bottom rail 3 to 4 cm thick, 15 to 20 cm wide

- HOW TO PREVENT A PANELLED DOOR FROM SAGGING: Very often panelled doors will sag after a certain length of time. This is due to the joints drying out and loosening, and to the weight of the door.

The key to the door's ability to resist sagging is the plywood panel. For this reason the panel must be properly secured and fit tightly into the frame.

The tenons must also be well secured. If we can prevent the joints from opening we prevent the door from sagging. A good method of securing the joints is to nail through the joint and pinch off the heads of the nails. They should only be long enough so that they can be punched under the surface but do not come through the other side of the frame (Fig. 1b).

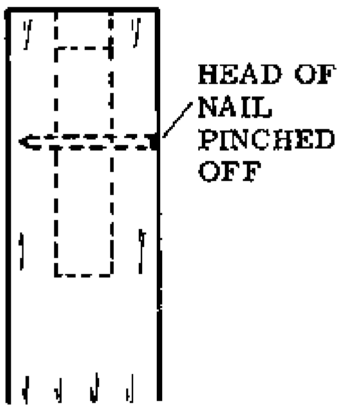

Fig. 1b

Note the staggered positions of the nails in Fig. 1a on the left. This prevents the nails from splitting the wood.

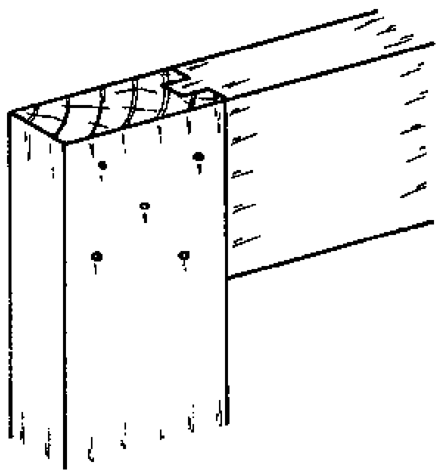

Fig. 1a

On the hinge stile of the door, the joints tend to pull apart at the lower edge. To prevent this, fix strips of sheet metal at the top hinge corner and at the lower corner opposite from the hinge stile. Use small nails to fix the metal (Fig. 2).

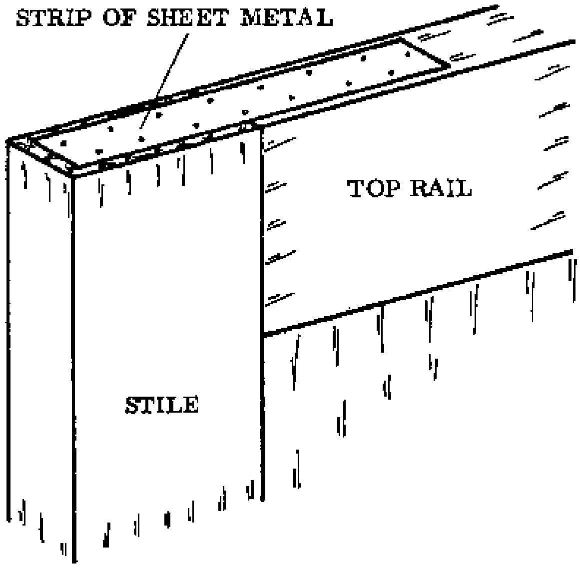

Fig. 2

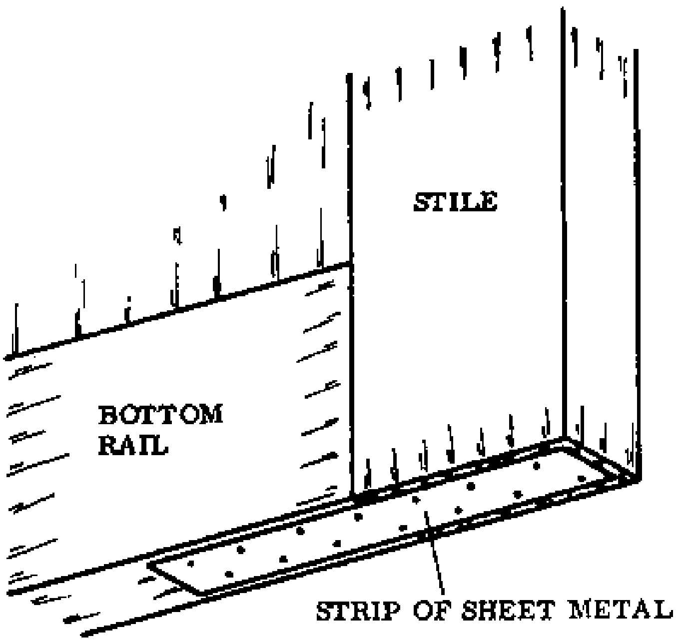

Fig. 2

NOTES:

Flush doors

The flush door with a framed core (Fig. 1) is a type of door that we frequently make in Rural Building. This door consists of a frame which has stiles (a), top and bottom rails (b & c), and narrow intermediate rails (d). It is covered on each side by a sheet of plywood (e). Sometimes flush doors for the outside of the building are covered on one or both sides by sheets of thin metal, usually aluminium or galvanized iron. Plywood-covered flush doors cannot be used where they will be exposed to rain and sun.

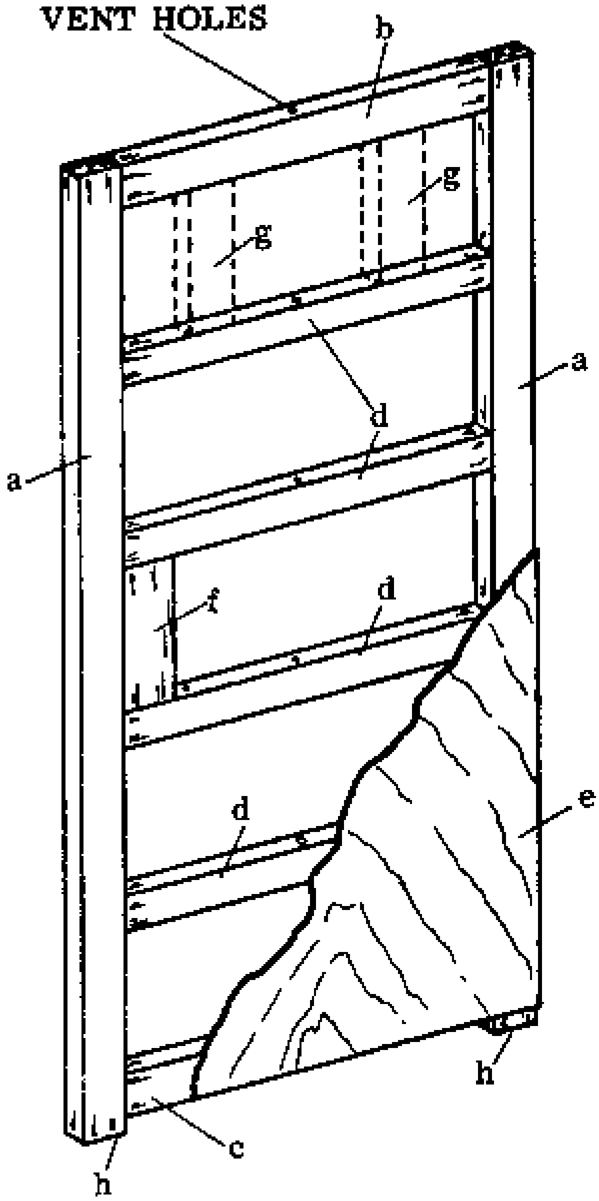

Fig. 1

Well seasoned Wawa is used for the frame. If the stiles are not wide enough to provide room for the mortice lock (Reference Book, page 223), then a lock block (f) is added. This block should be long enough so that does not restrict the lock position to only one spot. The location of the lock block should be indicated on the outside edge of the frame so it can be found later after the plywood or metal sheets are fixed.

When two additional members are placed between the rails (g), a pane of glass can be set in them to provide additional light for the room (Figs. 1 & 2).

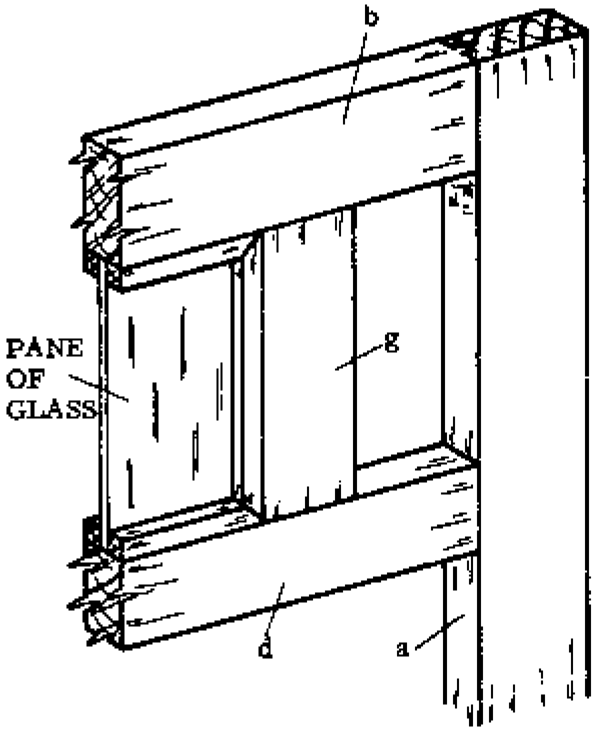

Fig. 2

To prevent damage to the top and bottom rails when the door is stored and moved around, the stiles can be left projecting past the rails (h), thus forming a rest for the door.

Ventholes can be drilled through each of the rails to ensure good air circulation within the frame. Take care that the ventholes in the top and bottom rails are not blocked by paint.

The joints for the flush door can be haunched stub tenons for the top and bottom rails (Fig. 3) and stub tenons for the intermediate rails.

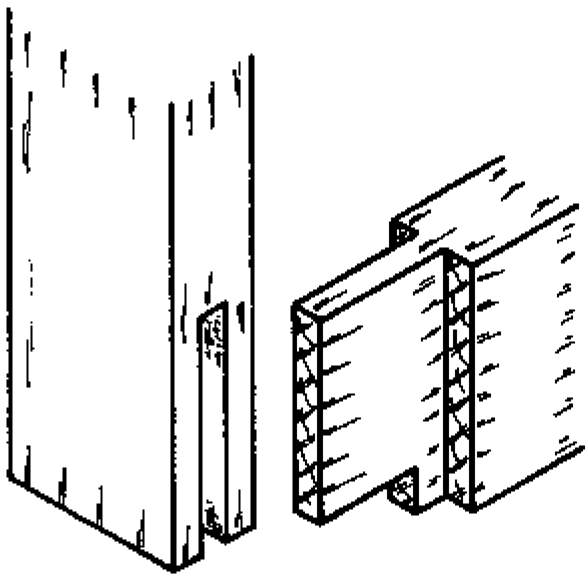

Fig. 3

- LIPPING: A strip of hard wood (Fig. 4) can be fixed to the striking stile to prevent damage to the plywood edges. Lipping is always done after the plywood has been fixed. A thoroughly painted lipping can be added to the top of the door if necessary to keep water out. The lipping joint should be a mitre joint.

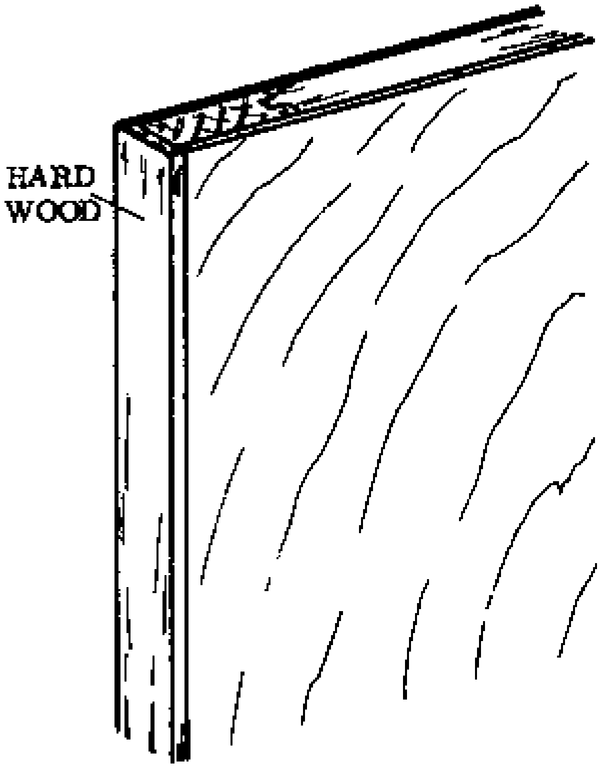

Fig. 4

NOTES:

- SEQUENCE OF OPERATIONS FOR MAKING A FLUSH DOOR: (also see Drawing Book, page 74)

a. Study the drawing.

b. Prepare a cutting list.

c. Select the wood.

d. Cut the wood to the right size. The plywood should be cut slightly larger than the door, so it can be planed to size later.

e. Plane the wood to size, and make the face marks.

f. Mark out the joints.

g. Prepare the joints.

h. Drill the ventholes.

i. Glue and clamp the frame together.

j. Fix the lock block. Indicate the position of the block on the outside edge of the door.

k. Plane the frame so the surfaces are flush.

l. Glue the plywood on both sides of the door and secure it with wire nails to the rails and stiles. If more than one door is being made, the doors can be set on top of one another and weighted down until the glue hardens.

m. Fix the lipping and finish off the door.

- TIMBER MEASUREMENTS FOR FLUSH DOORS:

Top and bottom rails	-	3 to 4 cm thick, 7 cm wide
Stiles	-	3 to 4 cm thick, 7 cm wide
Intermediate rails	-	3 to 4 cm thick, 5 cm wide
Plywood	-	6 mm thick
Distance between rails	-	30 cm

NOTES:

Large doors

Sometimes a large door is needed for a store or a similar building.

Large doors can be constructed like panelled doors. In addition to this framework, braces are used. The braces slope up from the bottom of the hinge side to the top of the opposite side.

The frame can be covered with plywood on the inside, and with either sheet metal (Fig. 1) or horizontally fixed overlapping boards (Fig. 2) on the outside. If corrugated sheet metal is used, the top edge has to be covered to prevent water from entering between the sheet metal and the door frame (Fig. 1, arrow).

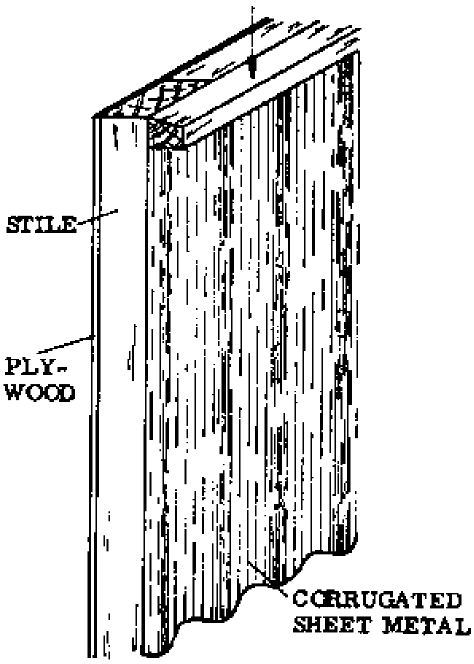

Fig. 1

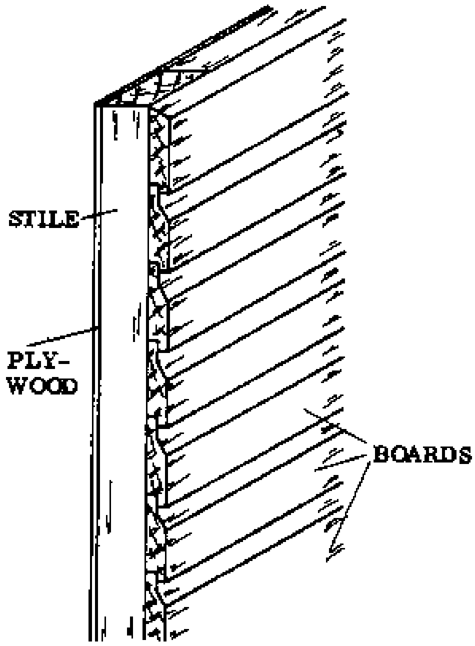

Fig. 2

The frame used for this kind of door should be heavier than the one used for an ordinary panelled door. The timber for the frame should be no less than 5 cm thick.

Each large door should have 3 band-and-hook hinges. If T-hinges are used, the strap has to be long enough to overlap a part of the rails. If the hinges are fixed to the stile only, the door will tend to sag.

In the Reference Book, page 229, there is a description of a simple locking device which can be made for this type of door.

WINDOWS

The function of a window is to let light and air into the building. When closed, the window should be draught-proof, weather-proof and burglar-proof. The size of the window should be appropriate for the room.

In Rural Building, windows consist of a window frame into which louvres or casements are fitted.

Casements are hinged to open to the outside. This makes them easier to waterproof than if they opened to the inside. The hinges should be fixed so that the casement opens flat to the wall. The frame of the window is set flush to the outside surface of the wall (see Installing Window Frames section, page 85).

Sometimes the hinges are fixed at the head of the window frame. This allows the casement to open upwards, thus providing shade for the opening and the wall. Refer to the Drawing Book, page 50, for ways to show the positions of hinges in the drawing.

Types of casements

In Rural Building, we deal with 5 different kinds of casements:

- Ledged and battened casements (Fig. 1)

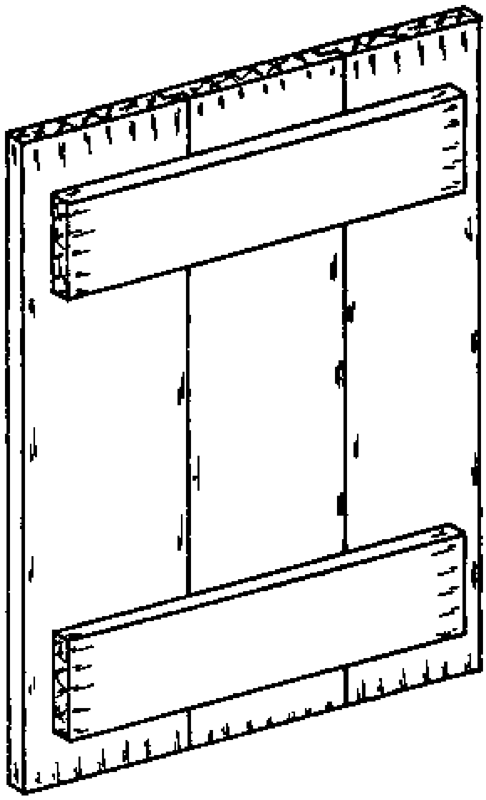

Fig. 1

- Ledged, braced and battened casements (Fig. 2)

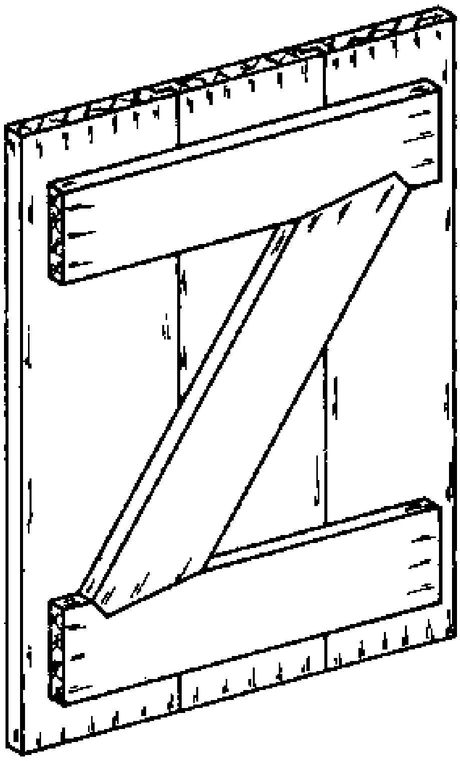

Fig. 2

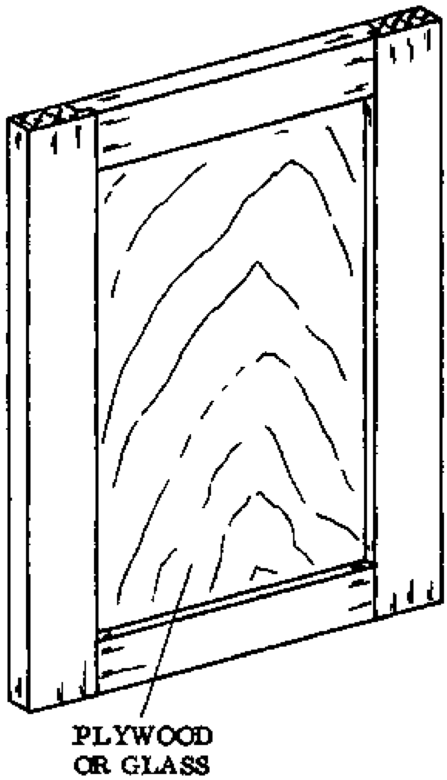

Fig. 3

- Panelled casements (Fig. 3)
- Glazed casements (Fig. 3)
- Flush casements (Fig. 4)

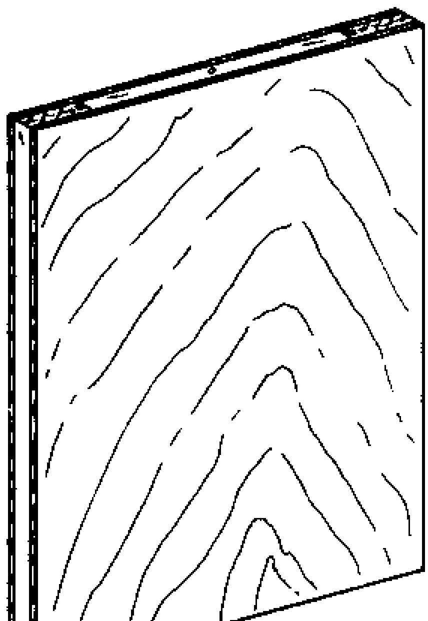

Fig. 4

It is necessary to leave at least 3 mm of play on all sides between the casement and frame (more if the casement is made during the dry season) so that the casement can open freely. This allows for expansion and shrinkage in the frame and casement.

Battened casements

Both types of battened casements are constructed in the same way as the corresponding type of door.

Matchboarding is also done in the same manner as for a door. Depending on the size of the casement, usually only two ledges are needed (Drawing Book, page 73).

Panelled casements

These can be made with grooved-in or rebated frameworks, in the same way as panelled doors (see Doors, page 101).

Usually the panels are made from plywood. Be sure to cut the bottom rail of the casement according to the slope of the cill.

The measurements of the members can be 5 to 7 cm wide and 3 to 4 cm thick.

The overall size of a panelled casement equals the inside measurement of the window frame, minus the allowance of at least 3 mm all around (Drawing Book, page 75).

Glazed casements

These are made with a rebated framework. The construction is the same as for a panelled door or casement (see Panelled Doors, page 101). Instead of a plywood panel, a pane of glass is installed in the framework (Fig. 1).

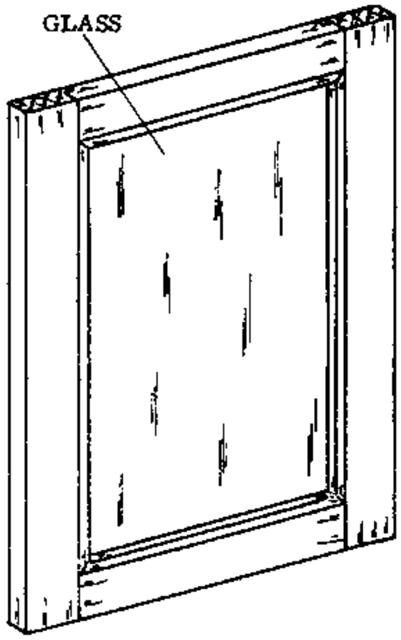

Fig. 1

Select the wood for this casement very carefully. It should be well seasoned and straight grained, so that the frame will not twist and cause the glass to break.

The joints are usually haunched stub tenons. Paint the joints and rebates before assembling the frame. The glass pane is always fitted after the frame has been assembled. The rebated framework is used because it permits the replacement of broken glass.

There are different ways of securing the glass in the rebated framework:

- By using beads, where the casement does not have to be waterproof (Fig. 1a)

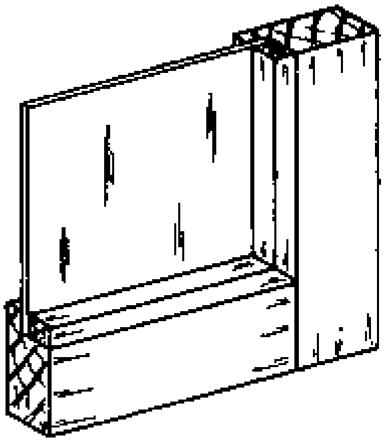

Fig. 1a BEADS

- By using putty, to make a waterproof seal (Fig. 1b)

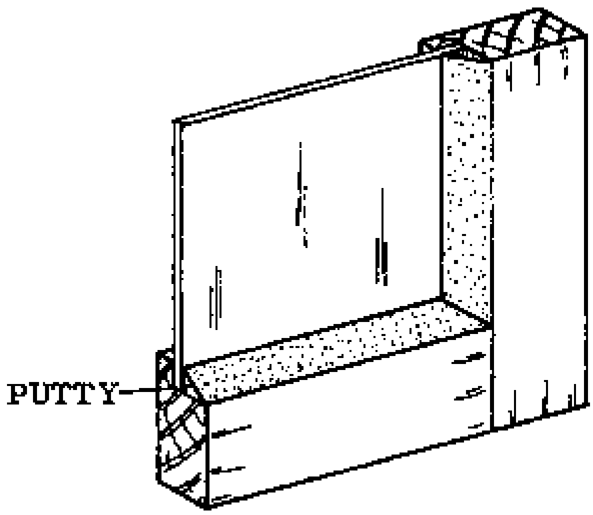

Fig. 1b

- By a combination of a thin layer of putty and beads.

The glass should always be cut 2 mm shorter in the length and the width, to make it easier to fit in the frame.

The sections of the frame members will be: 5 to 7 cm wide and 3 to 4 cm thick.

Flush casements

These are constructed in the same way as flush doors. Flush casements can be covered on one or two sides with plywood or sheet metal (aluminium or galvanized iron).

Flush casements should only be used where they will be protected from the rain and sun, for instance on a verandah.

Plywood should be glued and nailed to both sides of the casement, not one side only, to keep the casement rigid, straight and strong. For outside work, use waterproof glue.

- TIMBER MEASUREMENTS:

Top and bottom rails	-	3 to 4 cm thick, 5 to 6 cm wide
Stiles	-	3 to 4 cm thick, 5 to 6 cm wide
Intermediate rails	-	3 to 4 cm thick, 4 to 5 cm wide
Plywood	-	6 mm thick

The lower part of the bottom rail must be planed to fit the slope of the cill. The distance between the rails is approximately 30 cm (Drawing Book, page 74).

Joints

Note that in the construction of window frames and casements, different methods of framing are used.

For window frames, the horizontal members (heads and cills) have mortices, and the vertical members (posts and mullions) have tenons (Fig. 2, a; previous page).

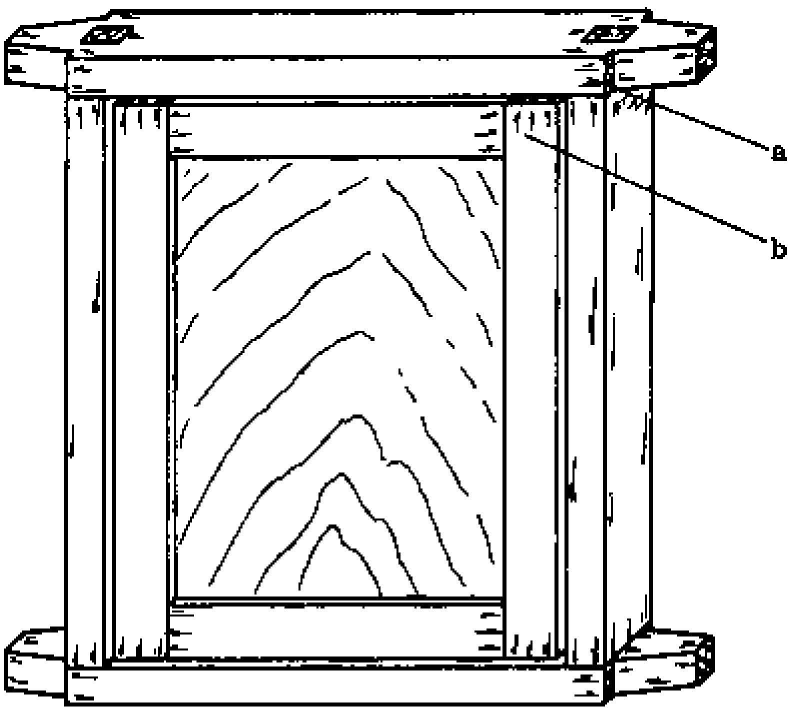

Fig. 2

For the casements, the vertical members (stiles) have mortices and the horizontal members (rails) have tenons (Fig. 2, b; previous page).

The same system applies for door frames and doors.

NOTES:

Louvre windows

- SEQUENCE OF OPERATIONS FOR INSTALLING LOUVRE WINDOWS: (see Reference Book, page 217)

a. If there will be mosquito wire on the window, you will have to be careful to set the louvre channels so that the louvres will be able to open without touching the wire.

b. Mark the position of the channel on the wooden frame, at the side where the operative channel (the one with the handle) will be fixed.

c. Grease the moving parts on the inside of the channel (use grease, not oil).

d. Fix the operative channel with one screw near the top.

e. Plumb this side. Secure the channel firmly with screws (the screw size will be 3 x 30, round head screws).

f. Install the non-operative channel, parallel to the first channel.

g. Secure this side loosely near the top, leaving the bottom free so it can be adjusted later.

h. Put in the louvre glasses, starting from the top and working down. Close the clip ends to secure the glasses in place.

i. When all the glasses are installed, close the louvres.

j. Move the bottom of the non-operative channel until the louvres fit tightly together and are parallel.

k. Now secure this side firmly with screws.

l. Check the installation (screws, clip ends, etc.) and operate the handle several times to make sure that the louvres move freely.

m. Fix the waterbar (either a wooden bead or a ready-made aluminium bar) at the head (outside the glass) and the cill (inside the glass), so that it is just touching the glass when the louvres are locked.

NOTES:

- SEQUENCE OF OPERATIONS FOR INSTALLING A SELF-MULLIONING LOUVRE WINDOW: If two or more louvres are to be set across the window frame, the metal channels can be fixed together with screws, to form a metal mullion. The metal mullion is installed before the other channels.

a. Mark the centres of the head and cill. The width of the window frame has to correspond to twice the length of a louvre glass, plus 3,8 cm for each set of channels, making 7,6 cm for both sets.

b. Mark out the position of the metal mullion on the head and cill. Keep in mind the position of the mosquito wire (Fig. 1).

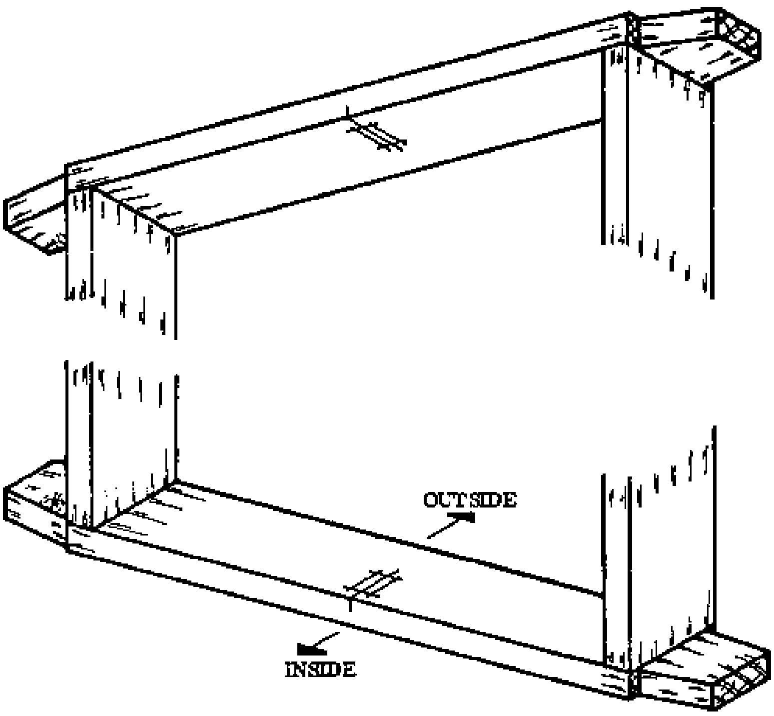

Fig. 1

c. Fix the bottom spacer on the cill (Fig. 2) at right angles to the face of the frame. The frame must be painted before the spacers are fitted.

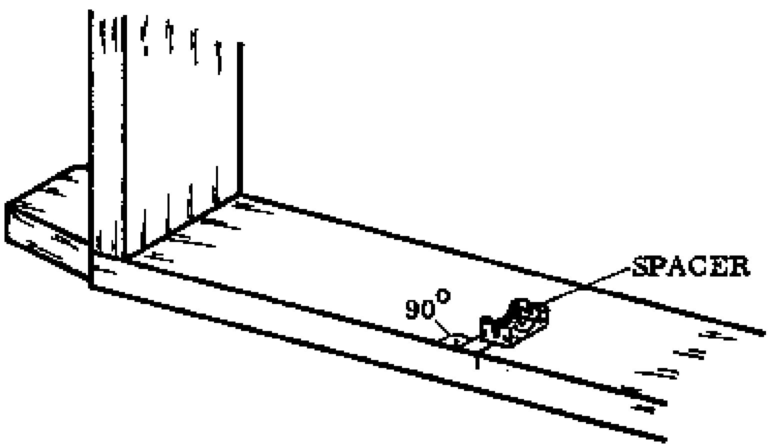

Fig. 2

d. If the cill is sloping, bend the lugs of the spacer so that they are upright. The bottom end of the louvre channel should be cut to fit the slope of the cill, so that it fits tightly (Fig. 3).

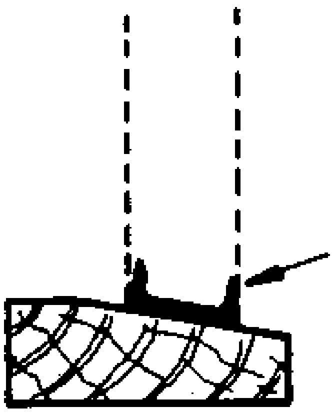

Fig. 3

e. To position the top spacer, place a louvre channel against the bottom spacer and plumb it with a spirit level. When it is straight, fix the top spacer exactly above the bottom spacer.

f. Take the non-operative channel and fit spacers into it at the places indicated by holes; these serve to stiffen the mullion.

g. Attach the non-operative channel to the spacers at the head and cill of the frame (Fig. 4).

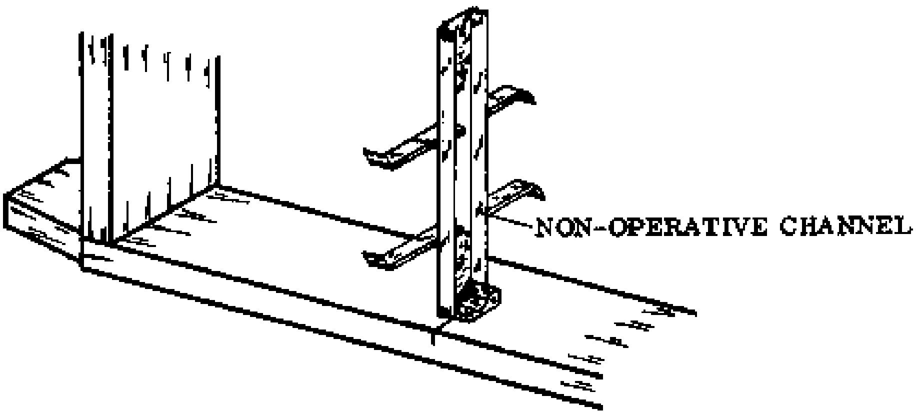

Fig. 4

h. Attach the operative channel to the non-operative channel with the special bolts and nuts.

i. Check the installation and operate the handle several times.

j. Install the other louvre channels to the window frame as in the previous page on installing louvre windows.

k. Make sure that all the channels are the same distance from the inside face of the window.

NOTES:

WORKING SCAFFOLDS

These are scaffolds which the workers stand upon to reach the higher parts of the construction. The tools and a supply of materials are also on the platform with the worker.

Jack scaffold

Although it can be no more than 2 m high, the jack scaffold is a satisfactory working scaffold for most jobs in Rural Building (Fig. 1). The block and trestle scaffolds which may be used for low level work are described in Basic Knowledge, page 158.

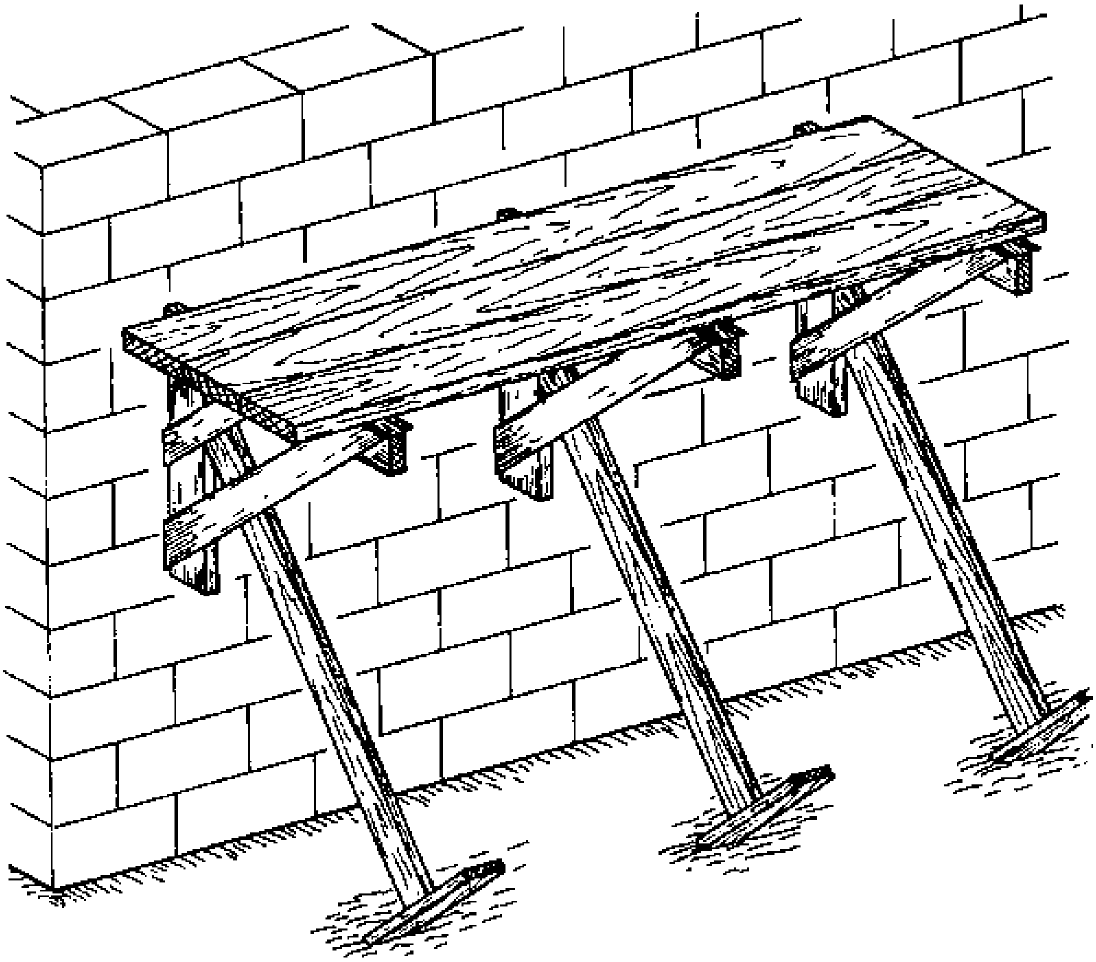

Fig. 1

The jack scaffold is a dependent scaffold, which means it is propped against the wall for support instead of standing independently like other scaffolds. The feet of the props have to be properly set in place so that they will not move and settle when the scaffold is in use. Never try to put any support under the wall leg of the jack, as this would actually make the scaffold unstable.

Each jack scaffold consists of three jacks, three props and three (approximately 4,5 m long) planks. If the scaffold is to be only 2 m long or less, two jacks are enough.

- CONSTRUCTING THE SCAFFOLD PIECES: The jacks consist of a wall leg and a ledge which is nailed edgewise to the top of the wall leg. Both boards must be at least 5 cm thick by

10 cm wide, and about 100 cm long. The right angle is braced with two ties on each side, in a way similar to the construction of a large square (Fig. 2, also see Reference Book, page 13).

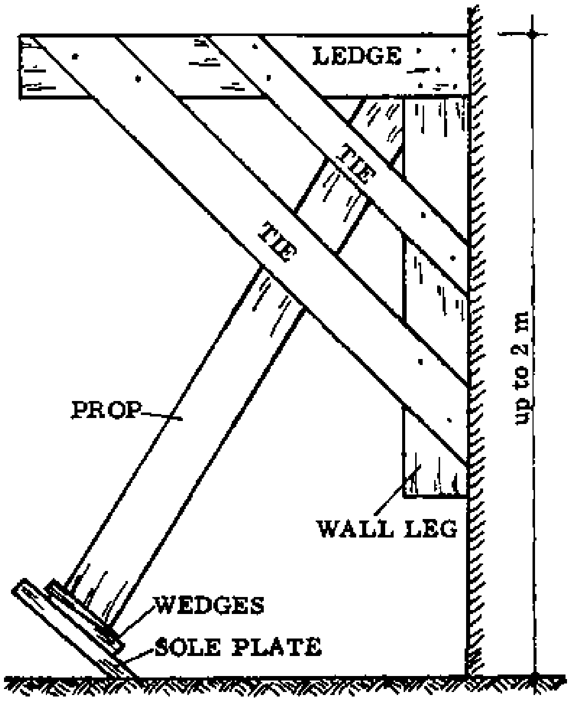

Fig. 2

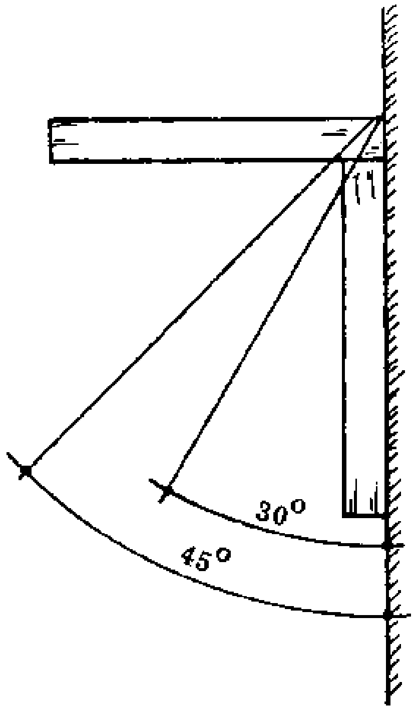

Fig. 3

The shorter tie should be set so that it doss not cover the corner of the jack, where the prop meets the angle. An opening is left, through which the position of the prop can be checked. The prop has to fit securely into the corner of the jack, without any "play" in the connection. The ties should be at least 2,5 cm thick, and the prop will be 5 by 10 cm by whatever length is required (remember that this scaffold should not be more than 2 m in height).

- ERECTING THE SCAFFOLD: Hold the jack with its wall leg against the wall, and fit the prop into the corner of the jack. Set the foot of the prop securely in the ground. The other jacks are set up in the same way. Check that all three are at the same height and the distance between them is not more than 2 m. The angle between the prop and the wall should be no less than 30 degrees and no more than 45 degrees (Fig. 3). In soft soil, sole plates must be set under the feet of the props.

- SAFETY PRECAUTIONS:

- Check that all the members of the scaffold are sound and without cracks.

- Check whether the upper ends of the props fit well and without play into the corners of the jacks

- Make sure that the feet of the props will not slip. In soft soil, they should be supported by sole plates set in the ground, at right angles to the props (Fig. 1).

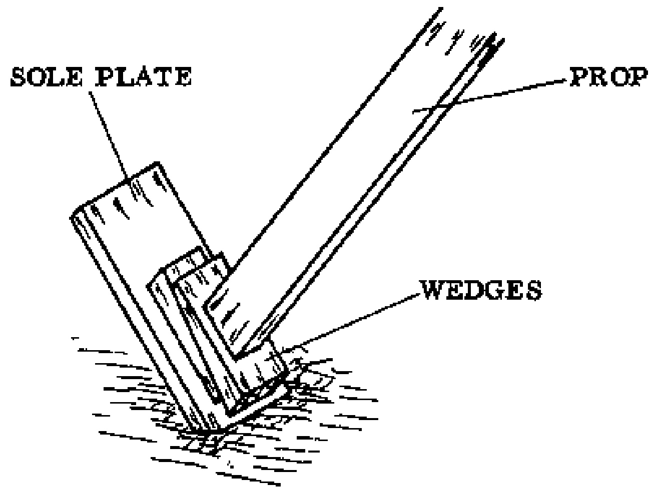

Fig. 1

- Pay attention when you lay the platform boards, so you don't create a scaffold trap. This is a place which looks safe but is not (Figs. 2 & 3). The free ends of the platform must not project by more than 25 cm past the ledge, and they should be blocked off by a foot-stop (Fig. 4).

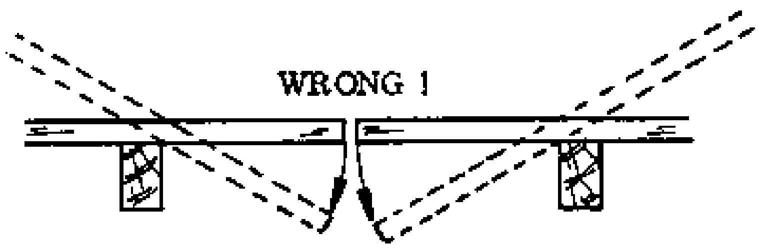

Fig. 2

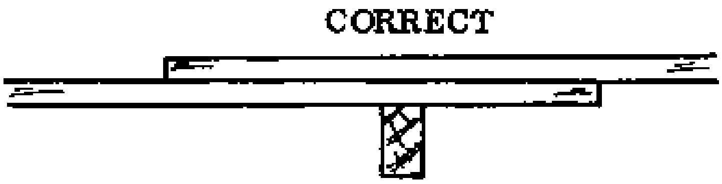

Fig. 3

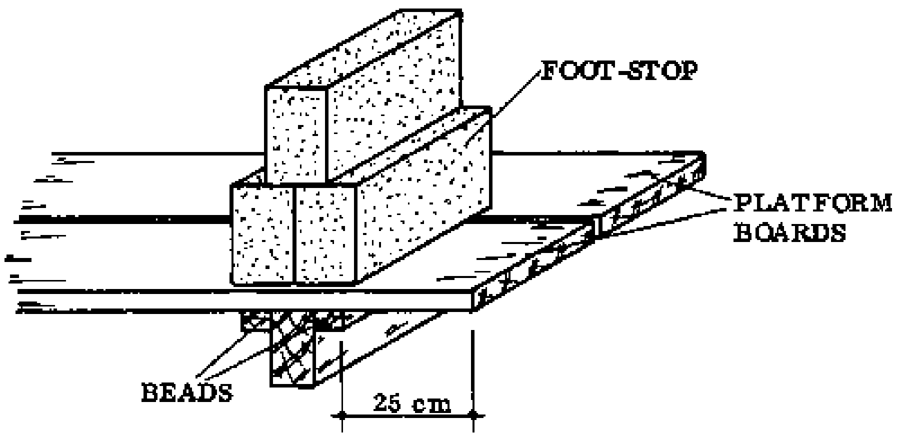

Fig. 4

- Wedges are used between the foot of the prop and the sole plate. By adjusting these, the prop can be tightened against the angle.

- Beads can be attached to the bottom of the platform boards to prevent them from shifting along the ledges (Fig. 4), or the platform boards can be nailed directly to the ledges.

- NOTE: Always pay attention to the safety of the scaffold. A carelessly erected scaffold is a danger to the lives of workers and passers-by.

NOTES:

Blocklayers scaffold

Like the jack scaffold, this scaffold is dependent on the wall for support. The construction is fixed with “putlogs” into the wall, and secured on both sides of the wall with cleats which are nailed to the putlog (Fig. 1).

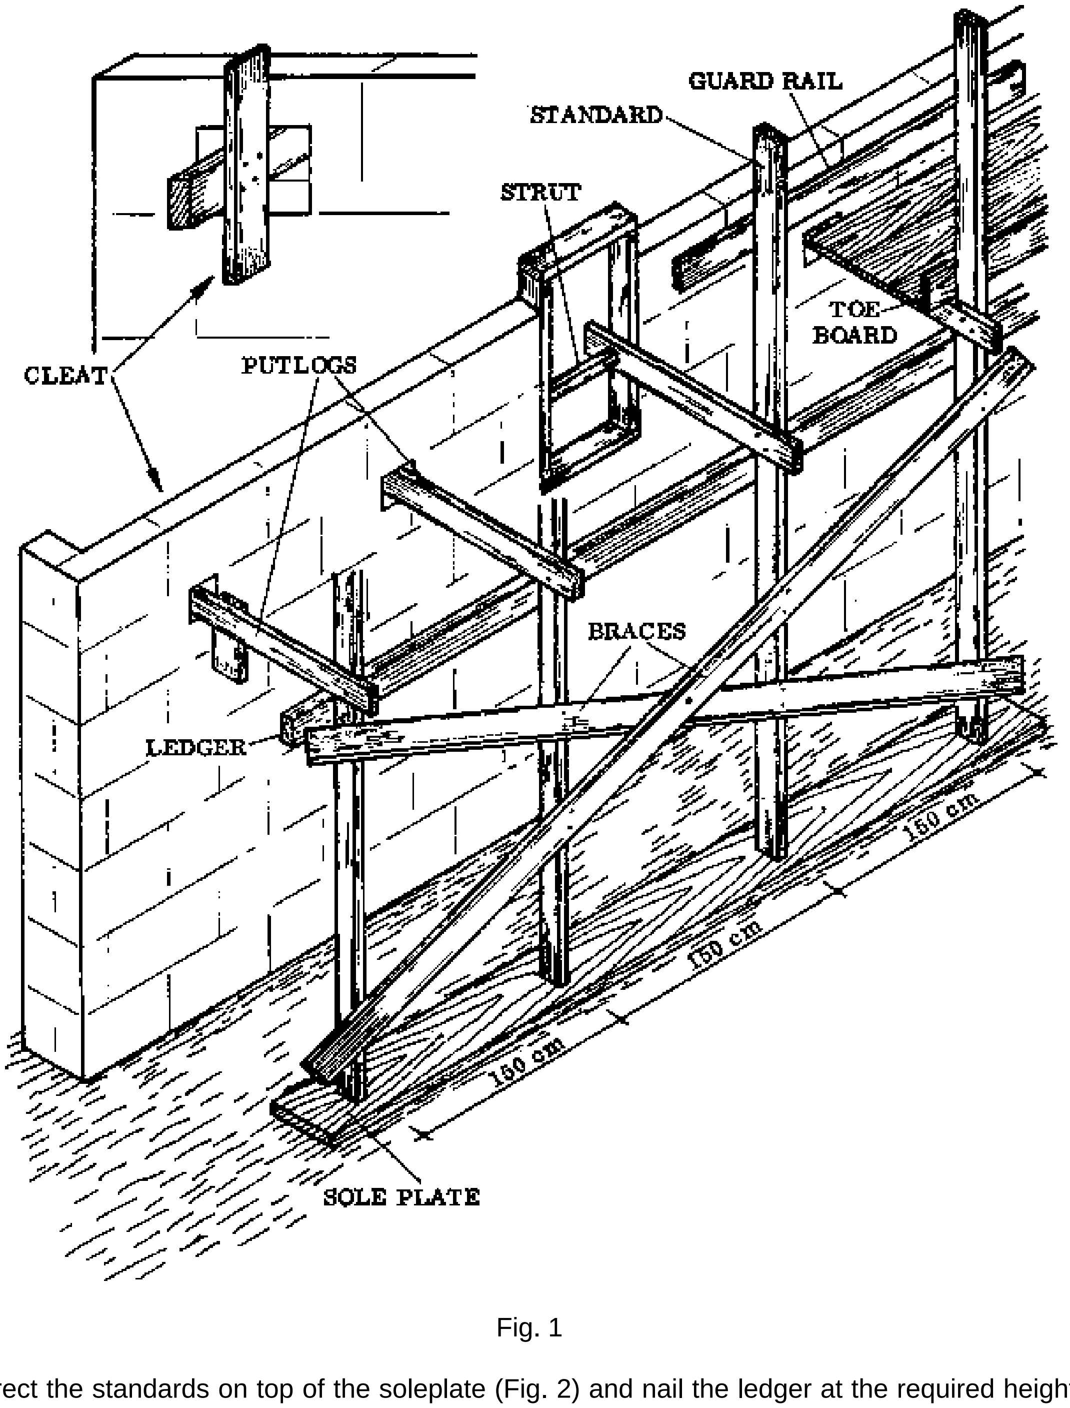

Fig. 1

Erect the standards on top of the soleplate (Fig. 2) and nail the ledger at the required height. Each putlog will have one end in a wall opening which was left during the blocklaying; and the other end is supported by the ledger and nailed to the standard. Secure the putlogs into the wall with two cleats, one on either side of the wall. Make sure that the cleat on the outside of the wall does not project above the putlog, where it will interfere with the platform boards.

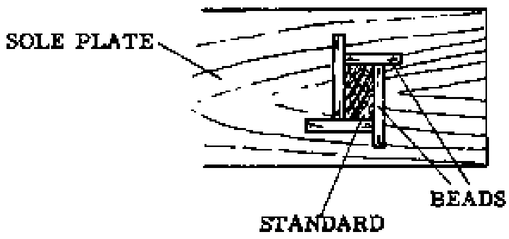

Fig. 2

Once all the putlogs have been secured, nail braces across all the standards to make the whole construction rigid.

Check the construction, then lay the platform boards. Fix the toe board, and nail the guard rail at a height of 90 cm above the platform.

If a putlog is secured inside of a window frame, add an additional strut inside the frame (Fig. 1).

The advantage of this type of scaffold is that it requires less wood to make the frame. The holes left in the wall are easily filled with small blocks before the plastering is done.

- MEMBERS OF THE SCAFFOLD: (see Fig. 1)

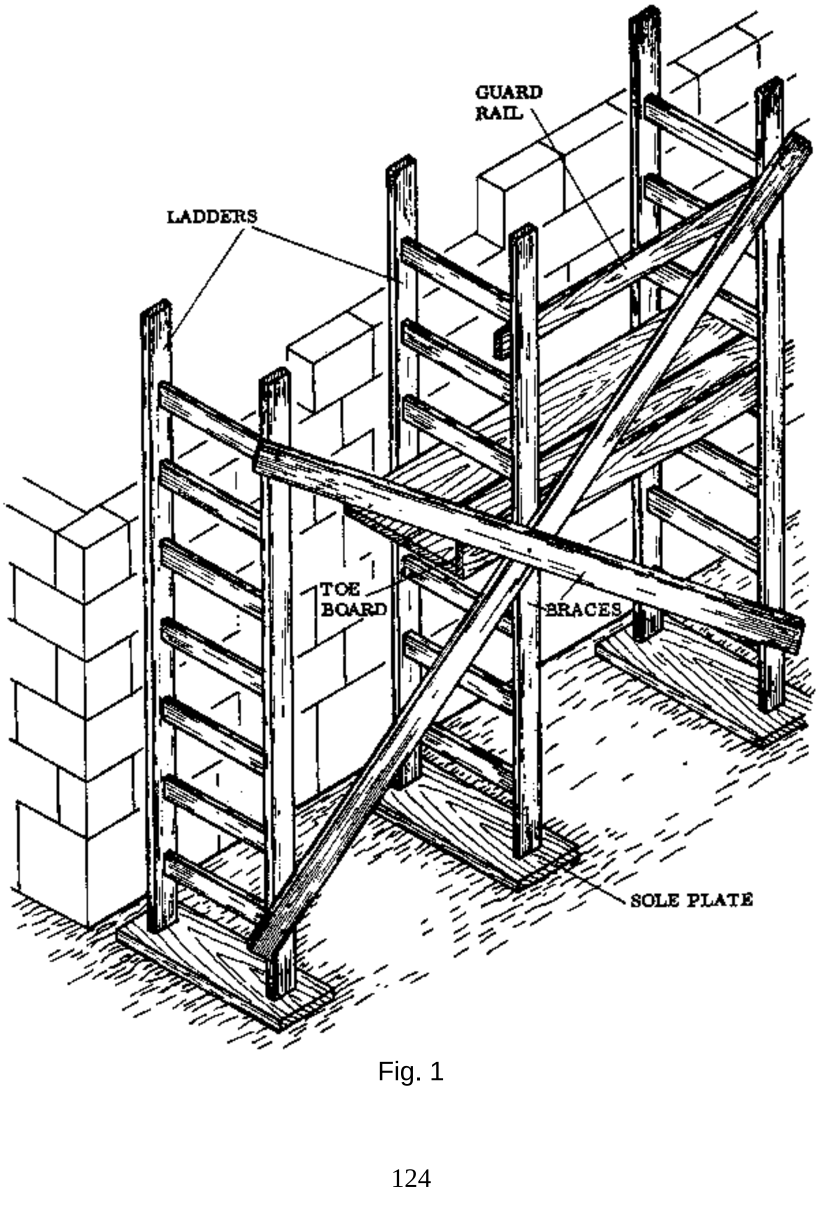

Fig. 1

- Sole plate
- Standards
- Putlogs
- Cleats
- Ledger
- Braces
- Platform boards
- Toe board
- Guard rail
- Struts (if needed)
- Pieces to secure the standards to the sole plate (Beads)

NOTES:

Ladder scaffold

This is an independent working scaffold, that is, it is not supported on the building but stands free. A ladder scaffold can be used where the height of the building is no more than 3,5 m.

Three or four ladders are usually used. Erect the ladders on top of the sole plates so that they do not sink into the ground under use. Keep the ladders plumb and straight, and nail two braces diagonally across the side.

If necessary use some wedges under the ladders to keep the structure steady.

Lay the platform boards and fix the toe board and the guard rail. The guard rail is fixed 90 cm above the platform.

Before any workers use the newly erected scaffold, make sure that all the parts are well secured and fixed according to the safest manner. Be aware that the scaffold has to carry not only the workmen but also a load of building materials.

NOTES:

Independent scaffold

This is similar to a ladder scaffold with the difference that no ladders are used. Timbers are used instead; these should be 5 x 10 cm by approximately 4,5 m long.

Sort out the timber, keeping the straight pieces for standards and the bent pieces for shorter members like putlogs.

Mark the height of the working platform on the standards, and nail the putlogs to the standards. Erect the standards on top of the sole plates, and nail the necessary braces to the outside of the structure.

Nail two additional boards (ledgers) under the putlogs. These give support to the putlogs.

Lay the platform boards and secure them with nails or battens. Fix the toe board. Nail the guard rail 90 cm above the platform.

If necessary, place some wedges under the standards to make sure that the whole structure is steady. Extra braces can be added to the outside of the structure; secure them to the ground with pegs (Fig. 1, broken lines).

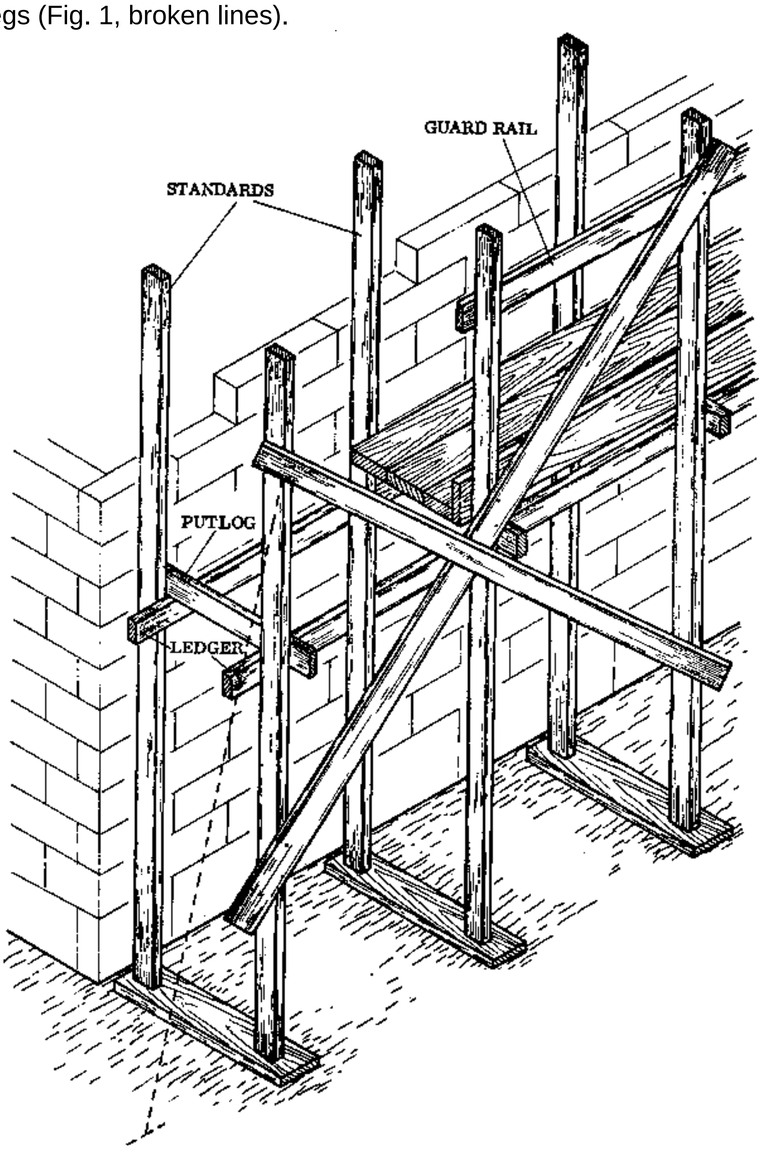

Fig. 1

Fig. 2 shows an alternative way to support the putlogs, with a wedge-shaped piece of wood nailed to the standard underneath the putlog.

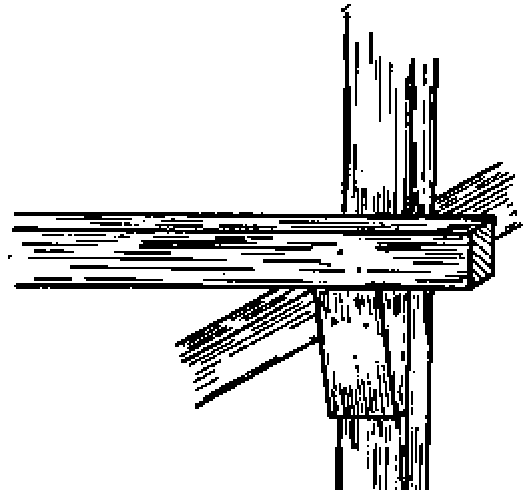

Fig. 2

SUPPORTING SCAFFOLD

As the term indicates, a supporting scaffold is used to support members of the structure until the mortar or concrete has hardened or cured; or until the parts are assembled, when the member will be able to support itself and the scaffold can be taken away.

The supporting scaffold is seldom used in Rural Building because in most cases a lighter and simpler strutting will serve for the purpose of supporting the usual reinforced concrete members as they are cast-in-situ. See page 167 of the Basic Knowledge book for an illustration of a typical strutting for a reinforced concrete lintel.

The heavier supporting scaffold is used only in cases where the member to be supported is very large and heavy. The supporting scaffold arrangement is shown in the illustration on the next page.

When you construct a supporting scaffold, pay particular attention to the stability of the structure, since it usually has to support very large and heavy members. The distance between the standards (also called struts) must be no more than 1 m (Figs. 1 & 2). All the shorter braces, which reinforce the connections between the putlogs and the standards and between the standards themselves, are fixed at 45 degree angles. The long braces, which go from the top of the structure down to pegs in the ground, are fixed at an angle of no less than 30 degrees. These help to keep the scaffold from tilting or overturning.

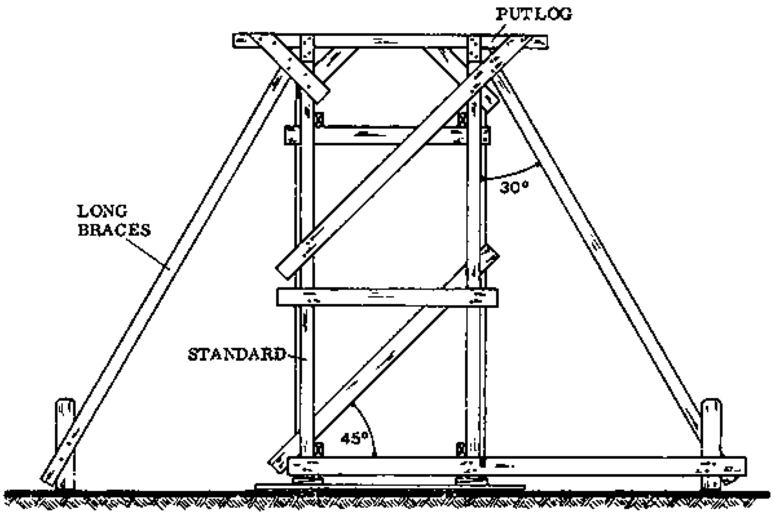

Fig. 1 SIDE VIEW

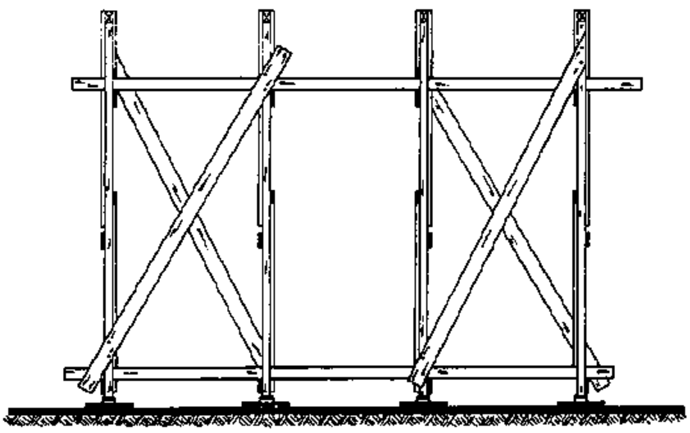

Fig. 2 FRONT VIEW

PROTECTIVE SCAFFOLDING

On most Rural Building construction sites, protective scaffolding is not necessary. This is because the structures are relatively low in height. However, when a higher structure such as a water tower is constructed, protective scaffolding becomes necessary to protect the people underneath from falling objects. On jobs where walls are being broken down, or where large and heavy objects are handled, it is advisable to erect a protective scaffold of some sort.

A second platform is made below the working platform, and a side projection is fixed at an angle to this (Fig. 3).

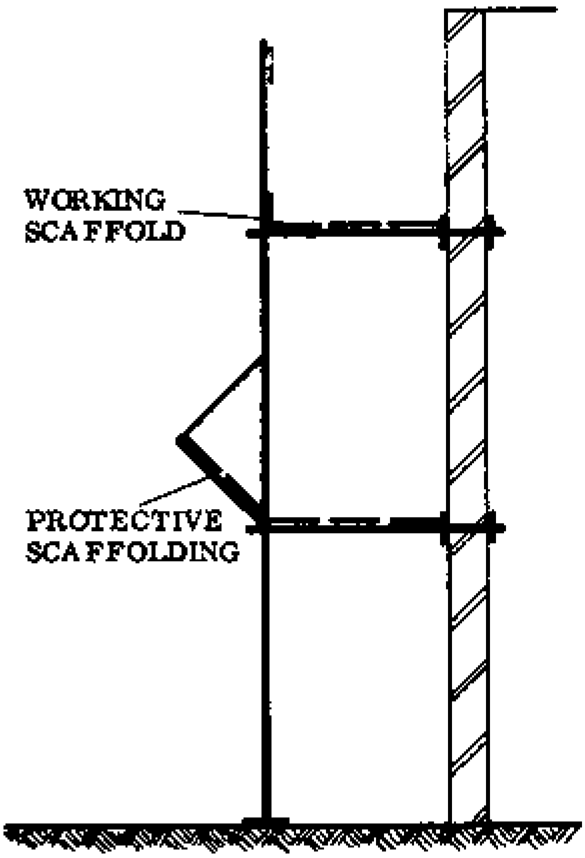

Fig. 3

The projecting piece is attached to the standards by wooden braces.

Any tools or materials which fall from the working platform will hit the projecting piece and roll onto the second platform, instead of falling to the ground.

NOTES:

ARCHES

Openings in walls such as doors and windows have to be closed at the top in such a way that the structure above them is supported. Before the use of reinforced concrete became common, smaller openings were bridged with wooden lintels, solid stone lintels and arches (see Basic Knowledge book, pages 162 to 164).

Wider openings were generally spanned by arches, or by a series of arches carried on piers or columns: the so-called arcade. In this book we discuss only one type of arch, the "segmental arch" where the arch is formed like a segment of a circle. Many other forms are possible with arches, but they are not important for Rural Building.

Before we continue with this chapter, it is essential to understand the technical terms that are used in connection with arches. The terms below are indicated in Fig. 1.

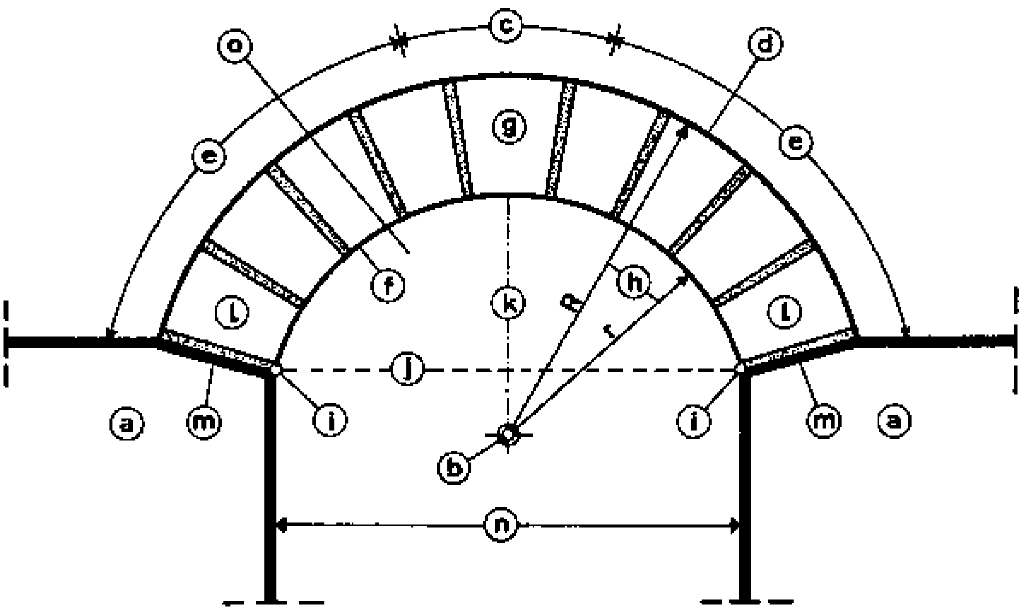

Fig. 1

Technical terms

- ABUTMENT: The word "abut" means to meet at one end or to border on something. An abutment (Fig. 1, a) is that portion of solid masonry that carries the weight of the structure of an arch. In Rural Building, the minimum width of an abutment at the end of a wall should be 3/4 of the span of the arch. This means that the distance from the arch to the end of the wall should be at least 3/4 of the span of the arch.

- CENTRE: This is the midpoint of the circle which describes the curve of the arch (b).

- CROWN: This is the portion of the arch which forms the top of the curve (c).

- EXTRADOS: The outer curved line of an arch, or the upper surface of the archstones (d).

- HAUNCH: The flanks of an arch, the sides of the curve (e).

- INTRADOS: The under surface or soffit of an arch (f).

- KEYSTONE: The central wedge-shaped archstone at the crown of an arch (g), which is the last stone to be put in place.

- RADIUS: The straight line (h) from the centre of an arch to any point on its intrados (the shorter radius, r); or to any point on its extrados (the longer radius, R).

- SPRINGING POINT: The point of intersection (i) between the intrados and the faces of the wall or pier blocks below. From there the arch “springs”.

- SPRINGING LINE: The line across the arch which would connect the springing points (j).

- RISE: The height of an arch measured perpendicularly from the springing line to the highest point of the intrados (k).

- SPRINGER: The first stone laid in an arch on either side (1).

- SKEWBACK: That portion of the abutment which directly supports the springers (m). It is so called because the surface slopes towards the opening.

- SPAN: The horizontal distance between the springing points (n); the length of the springing line.

- CAMBER: This is the space between the springing line and the intrados (o).

- ARCHSTONES: These are any of the stones or blocks which form the arch itself.

NOTES:

Stability of arches

All arches, regardless of their shape or dimensions, function as wedges. An arch distributes the load imposed on it to the abutments on both sides; these have to be strong enough to withstand the pressures (Fig. 1, a). This is the reason why the abutment which is at the corner or end of a wall must be at least as wide as 3/4 of the span of the arch (Fig. 1, b). Between two arches, thinner supports such as columns or piers can be used (Fig. 1, c).

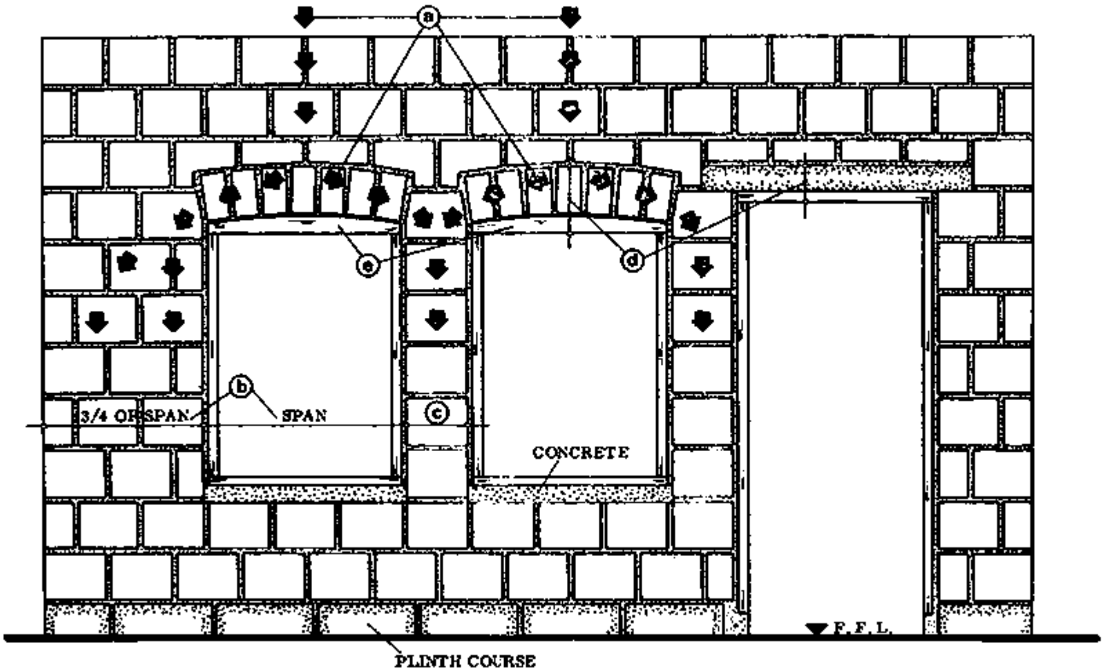

Fig. 1

It is always better to build two or three courses of blocks above an arch because this weight will improve its stability. The preferred material for constructing an arch is sandcrete blocks, because they can be cast to any shape required and can withstand high pressures. Of course landcrete or mud blocks can also be used, but these must be well protected against moisture penetration.

- DISADVANTAGES OF ARCHES:

  - All arches, especially those which have unusual shapes, require more space than a lintel (Fig. 1, d).

  - Frames must be shaped on their top according to the curve of the intrados (Fig. 1, e); or if a square frame is to be fitted, the remaining space above it must be closed with plywood etc.

  - A temporary wooden support, the centring or turning piece, is needed during the construction; this piece has to be exactly the correct shape.

  - Masonry arches cannot be prefabricated.

  - Specially made archstones are often required.

- ADVANTAGES:

  - Arches are more economical because scarce and expensive building materials like reinforcement iron are not needed.

  - Locally available building materials such as mud blocks can be used to build arches.

  - In contrast to cast-in-situ lintels, the walling above an arch can continue immediately after it is completed, because the arch does not have to set.

  - Traditional building styles can be maintained and developed in a simple and cheap way.

- Arches, if well constructed, give the building a more attractive appearance and demonstrate the skill of the builder.

The segmental arch

The segmental arch is the most important one in Rural Building. This is mainly because:

- The construction depth measured from the springing line to the crown is comparatively small; with the result that the building costs are low.

- The construction is not too difficult and specially made tapered blocks are not necessarily required.

- The time spent on the construction of this kind of arch can be shorter than the time spent for constructing a reinforced concrete lintel.

Types of centring

“Centring” is the term generally applied for the curved wooden piece which temporarily supports arches or domes during their construction. It is comparable to the strutting (not the shuttering) for concrete members.

The actual shaping part of the centring is called the “turning piece”. There are three main types of centring:

- A solid wooden board, about 5 cm by 7,5 cm, placed edgewise. Its upper surface is carefully and evenly shaped according to the curve of the intrados (Fig. 1). Its use is restricted to short-span openings; not exceeding about 100 cm wide. The disadvantage of this type is that the archstones rest on only a small area, which might lead to the blocks tilting during the laying.

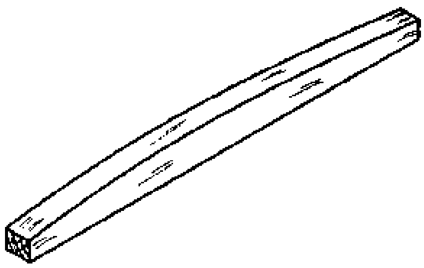

Fig. 1

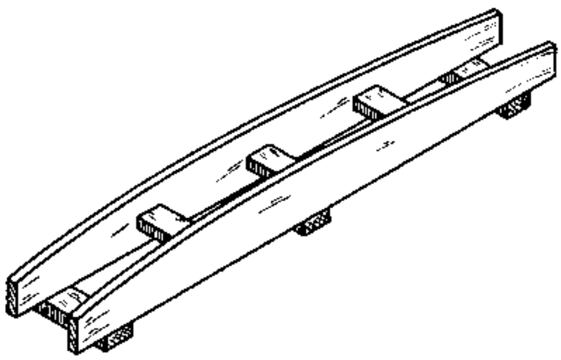

Fig. 2

- Two wooden planks or sheets of plywood are connected by spacers, so that the archstones are supported on their outer edges (Fig. 2). Both turning pieces must be precisely cut and planed to the same shape, and must match with the curve of the intrados.

- Arches spanning wider openings and those which have a rise of more than about 1/10th of the span need to be supported by a stronger centring, with either open or closed lagging (Fig. 3).

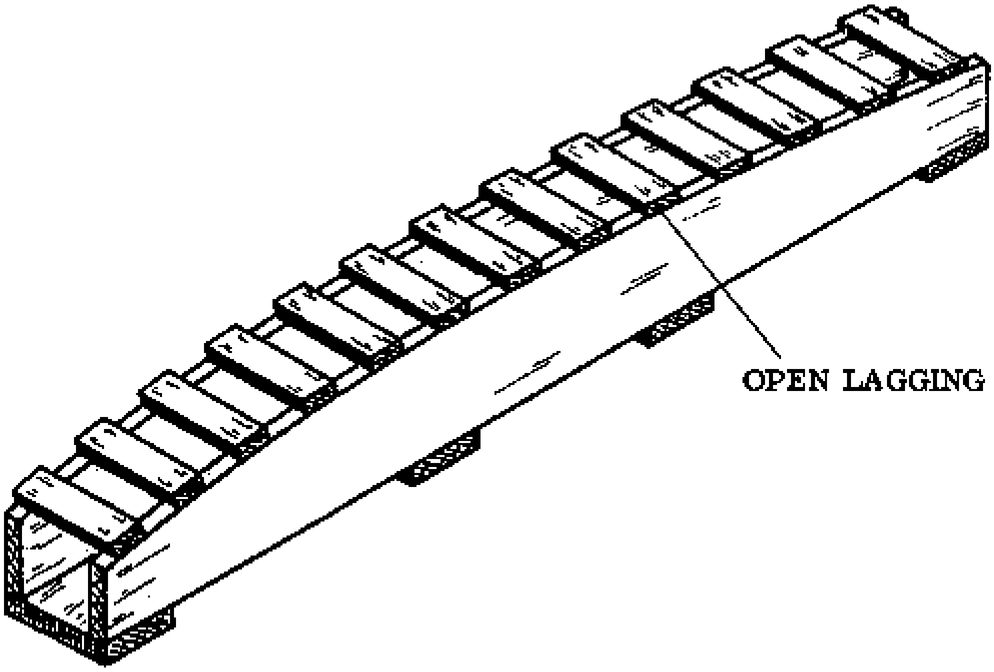

Fig. 3

The three types of centring may be combined with the frame or may form part of the frame; the head. In this case no strutting is needed, and the centring piece simultaneously acts as a permanent seal of the space between the springing line and the intrados (Fig. 4). The lagging must then be fixed in between the turning pieces so it is flush with the upper curved edge and is not seen (Fig. 4).

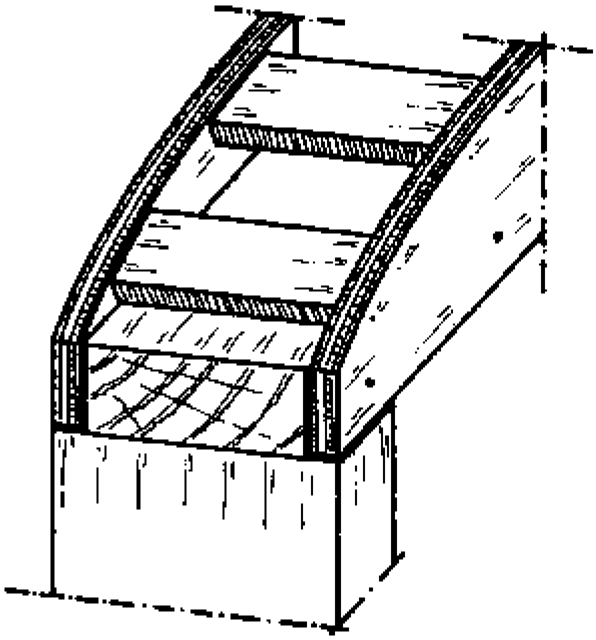

Fig. 4

Setting out the turning piece

To set out the turning piece means to mark the curve of the intrados on a suitable piece of board or plywood, so that after it is cut and planed it can serve as a temporary support and guide for the arch construction. The positions of the archstones are also marked on the turning piece so that no mistakes can be made during laying.

As far as Rural Building is concerned, the radius of the circle which describes the curve of the intrados will always be three times the span of the opening. For example: if the span of the opening is 80 cm (the clear width), the radius must be 3 x 80 cm = 240 cm; if the span is 180 cm, the radius is 540 cm, etc.

The curve obtained from this rule will result in an arch which is flat enough so that not much space is wasted, but also curved enough to ensure stability.

- SEQUENCE OF OPERATIONS:

- You need a large, flat and level space for the setting out.

- Mark the span of the opening on a suitable board (Fig. 1, a).

- Determine the springing points (at least 2 cm from the edge of the board) and drive in short nails to mark these points. Leave the nails projecting, and make sure that they are both the same distance from the edge of the board (Fig. 1, A & B).

- Place the board on the ground and secure it with nails or pegs as shown, so that it cannot shift to any side.

- Fix your mason line on nail A, and measure off from there three times the span of the opening along the line. Use this length to describe a short section of a circle on the ground (Fig. 1, b).

- Repeat this procedure with the line fixed on nail B (Fig. 1, c). Both circle sections will intersect at point C, which is the centre of the arch. Secure the centre point with a nail or peg.

- Fasten the mason line on peg C and tie a pencil at the distance of three times the span of the opening.

- Keep the line taut and describe a circle section, while marking the section on the board. This curved line should intersect with the springing points, A and B, and the curve resembles the curve of the intrados.

- To check the accuracy of the setting out, measure the rise of the arch perpendicularly from the springing line to the highest point of the curve. This distance must be 4,2% of the span (0,042 x span (in cm) equals the rise (in cm).

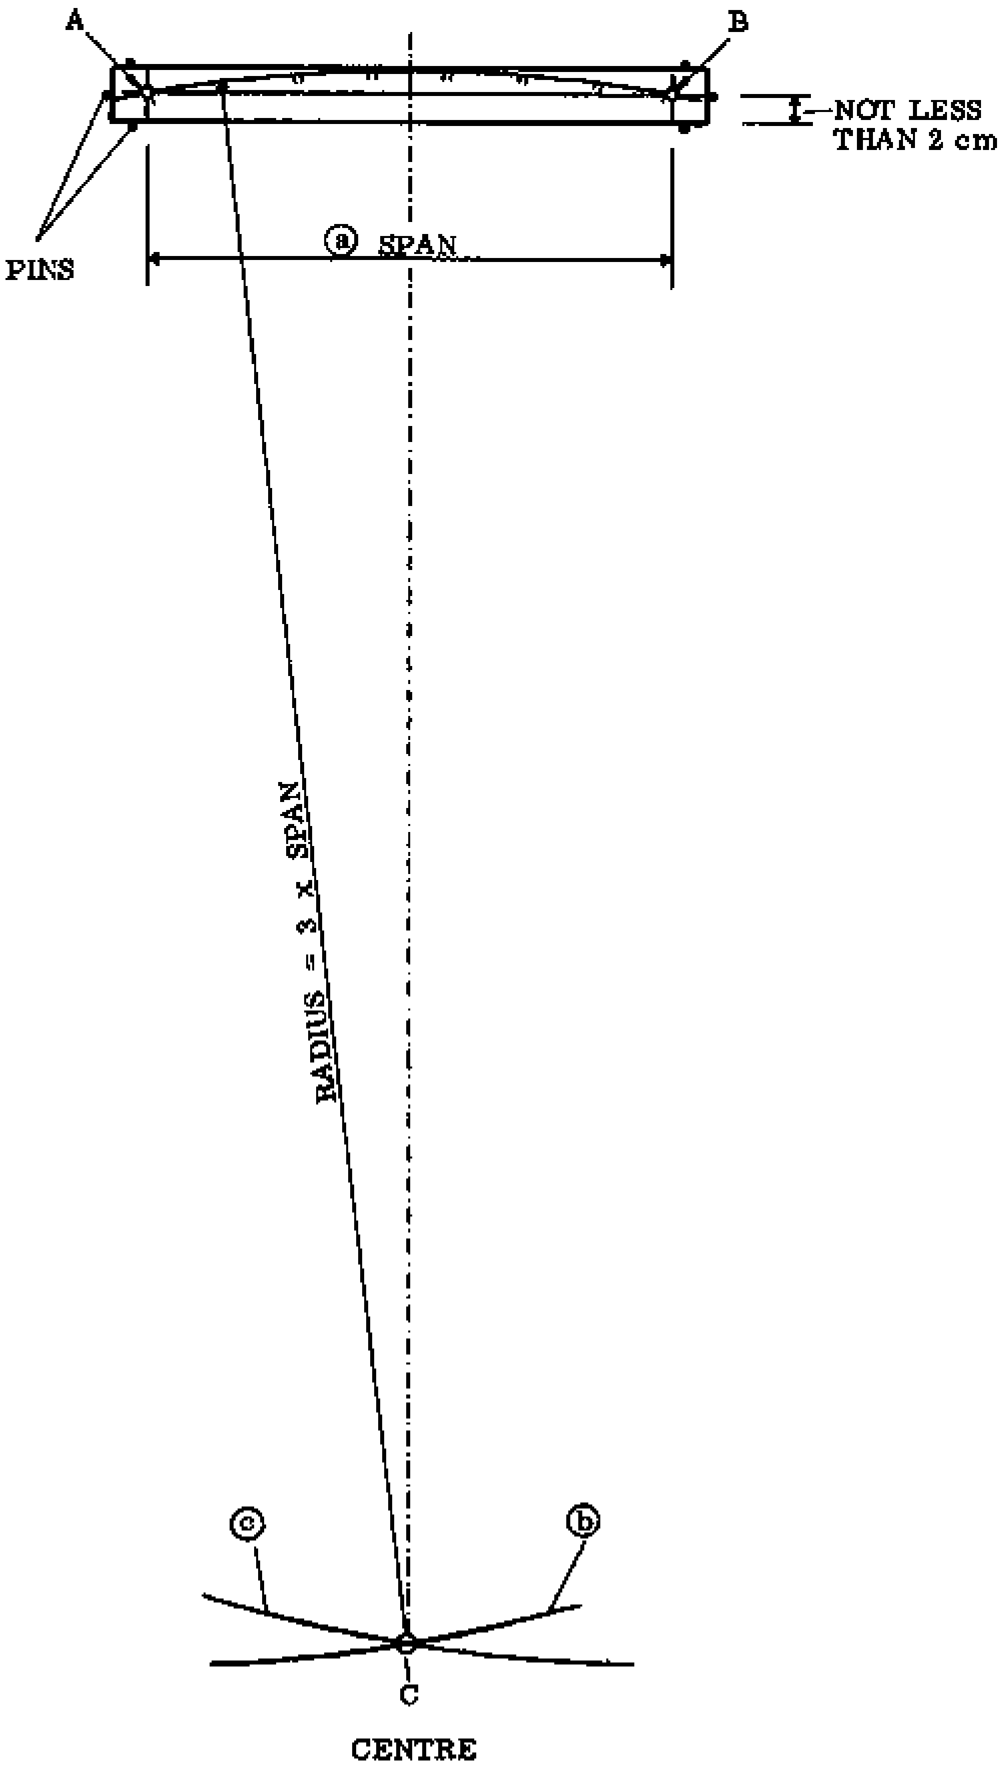

Fig. 1

Positions of the archstones

Regardless of which type of arch is constructed and what kind of archstones are used, the total number of blocks or bricks must add up to an odd number: the keystone in the middle is flanked by an even number of archstones (Fig. 1).

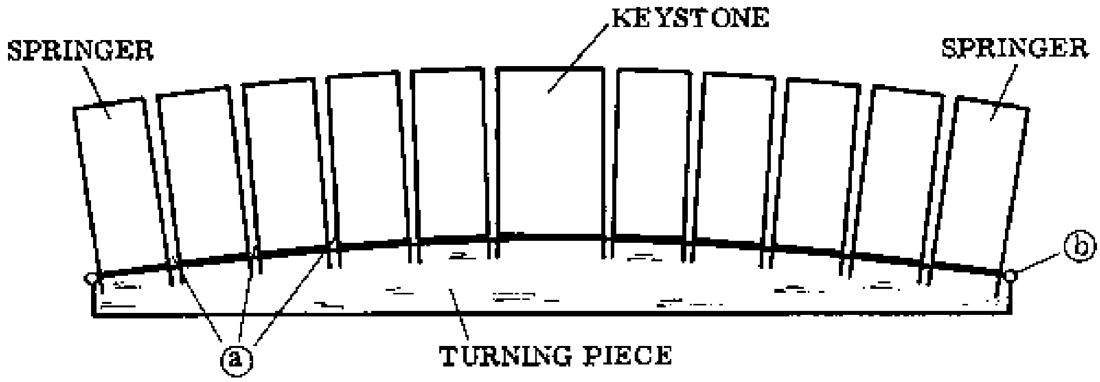

Fig. 1

Therefore the position of the keystone is usually marked first, followed by the archstones to the left and right. Cross joints are 1 cm wide at the intrados (Fig. 1, a), and wider at the extrados, because common blocks are used which results in wedge-shaped joints.

The marking continues until the springing points are either just reached or a little overlapped (Fig. 1, b). If it happens that there is a distance of more than 1 cm between the lower outside corner of the springers and the springing points, then one more block must be added to each side (Fig. 2). These two blocks will then become the springers, although they overlap by far the springing points.

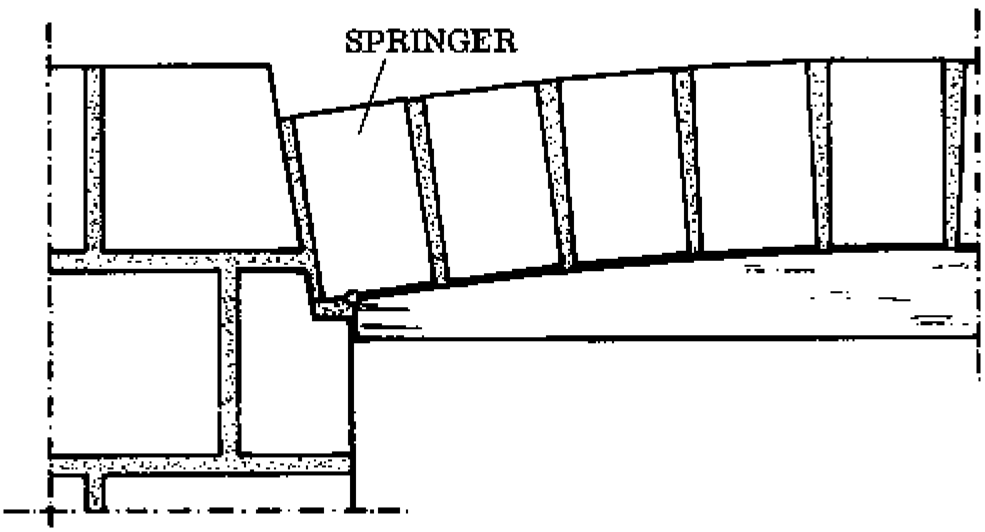

Fig. 2

There are two ways to avoid this:

- One can reverse the marking by starting from the springing points and marking by turns from the left and right up towards the crown. The remaining opening is then filled with either a specially made keystone, or with concrete (Fig. 3). This is preferred if the springers would overlap the springing points by too much.

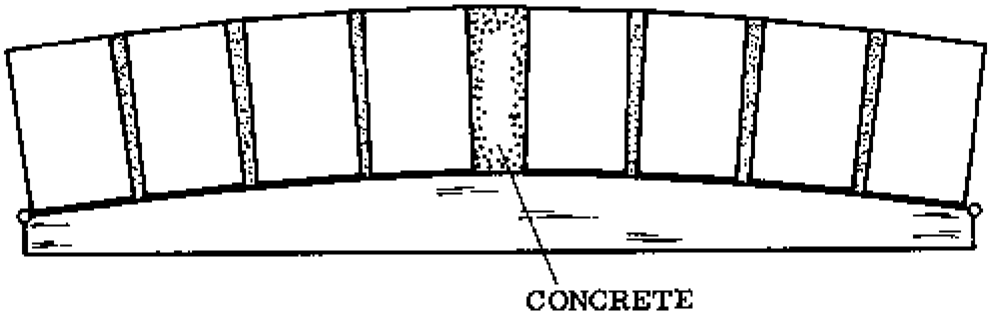

Fig. 3

- The most perfect solution would be to use specially made archstones which are wedge-shaped and fit exactly in the arch (Fig. 4). This requires some detailed and accurate planning, and more time and materials.

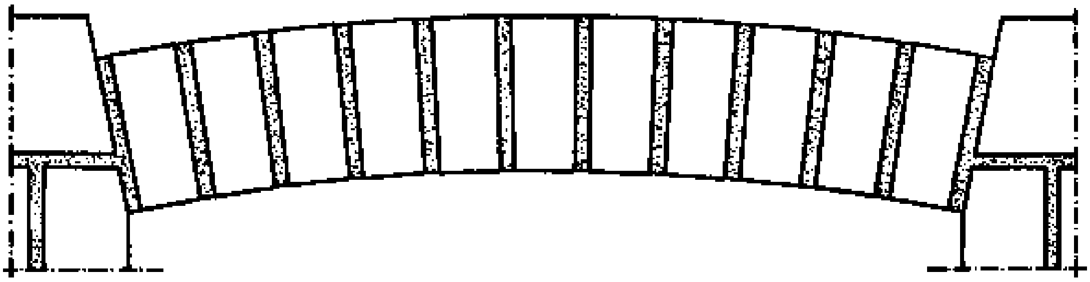

Fig. 4

NOTES:

Setting up the centring

The board on which we marked the curve of the intrados and the positions of the archstones is now prepared for assembly and erection.

The first step is to cut off both ends of the board squarely at the marks which indicate the span. These cuts must pass through the springing points. Then the intrados is roughly shaped with the saw and then exactly planed to the mark, to make a smooth and evenly curved edge.

If the centring will be a part of the frame, it is now fitted to the frame head as in Figs. 1 and 2, and set into its place together with the frame. In this case it is best to make two identical turning pieces to seal the camber on both sides of the wall. They are fixed outside and inside flush with the frame. The hollow part in between the pieces is filled with a mixture of sand and ash; both to keep insects out and - if there is no lagging - to give more support to the archstones which otherwise would have to rest on the turning pieces only.

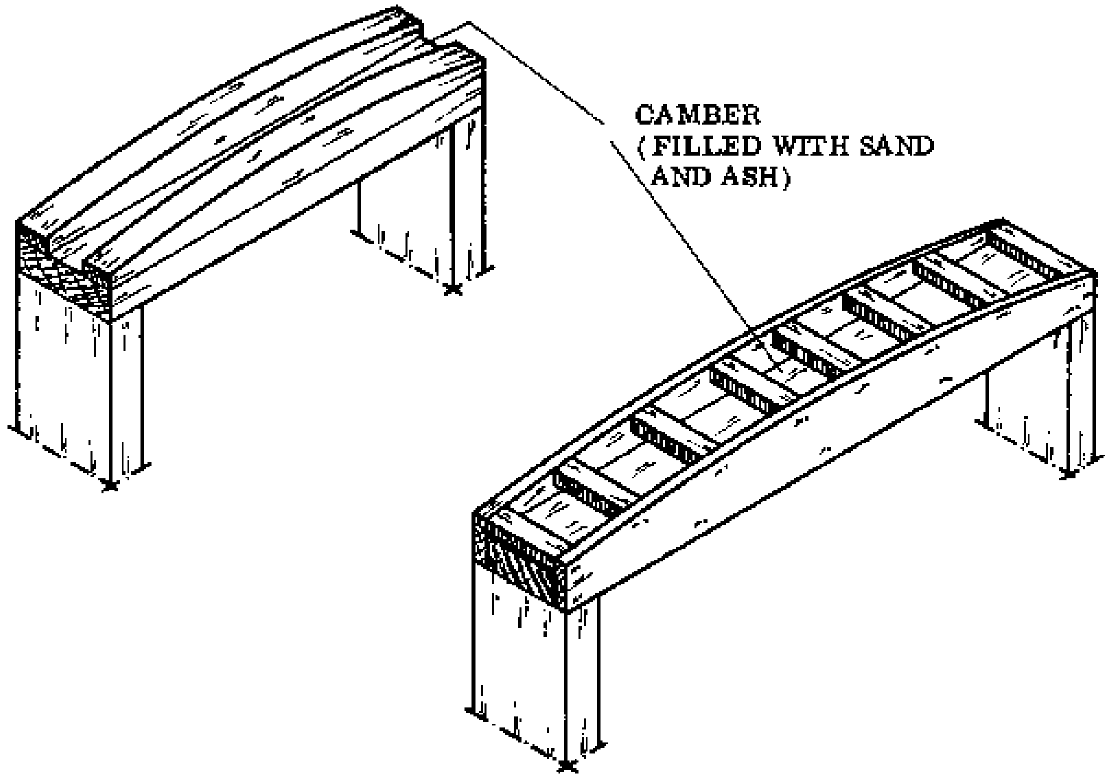

Fig. 1

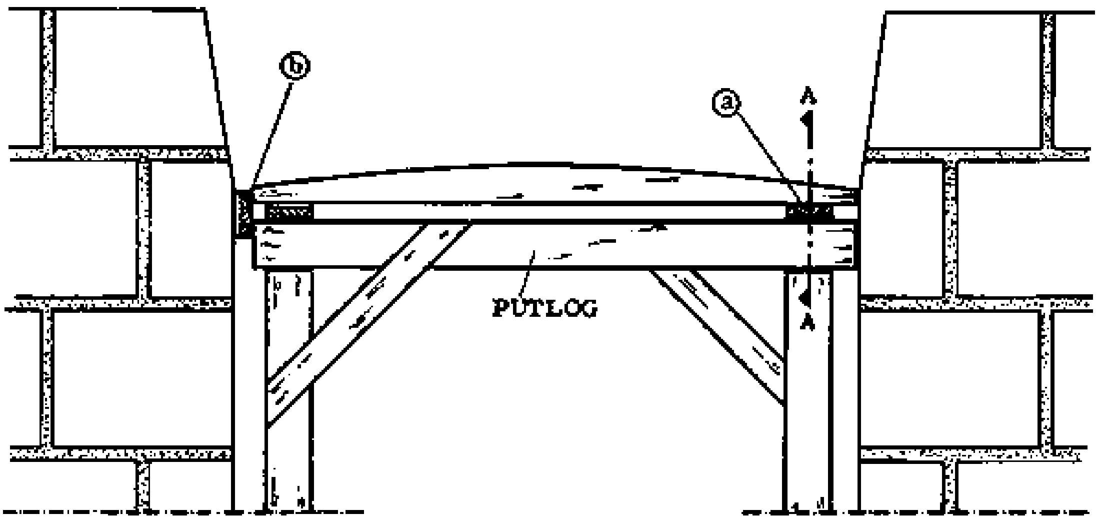

Fig. 2

Note that the marks of the springing points are cut off when the turning piece is combined with the frame. This is because it is cut flush with the outside of the frame. This means that the thickness of the joint between the frame and the wall has to be taken into account when marking the slope of the skewback.

If the centring piece is to be removed after the arch is finished, it must be set in a way so that it can easily be taken out. This is done by placing it on wedges as in Fig. 3, (a). It might be necessary to cut the turning pieces slightly shorter on one end so that the centring fits easily into the opening. In that case the end which has not been cut rests against the wall while the gap on the other side is closed tight with wedges to prevent shifting (Fig. 3, b).

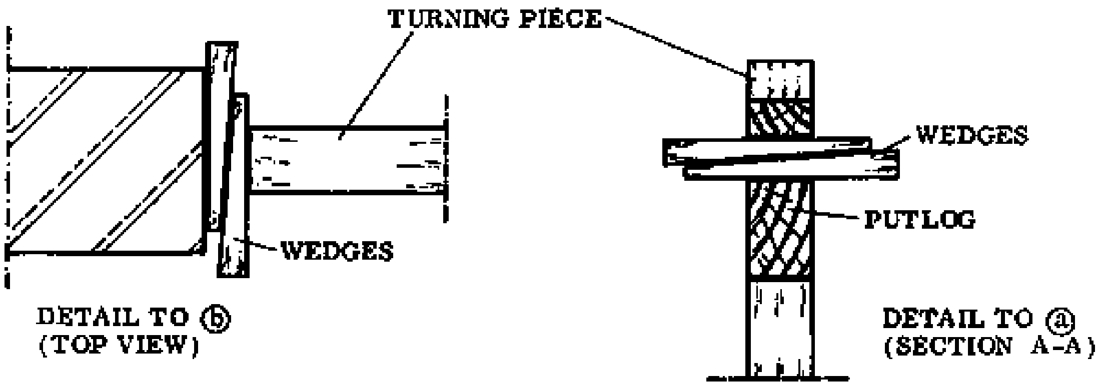

Fig. 3

Try to avoid making the springing points in line with a bed joint. The sideways force from the arch can possibly cause cracks along the bed joint. The best solution will be to distribute the pressure over two courses (Fig. 3).

When you set the centring piece in position, do not forget to level the soffit, which must be exactly horizontal and parallel to the springing line.

NOTES:

Skewback template

Before you can start laying the archstones, the abutments with their skewbacks must be prepared so that the springers can be laid at the correct angle. To be sure that the angle of the skewback is correct, the Rural Builder can use the template described below (Fig. 1).

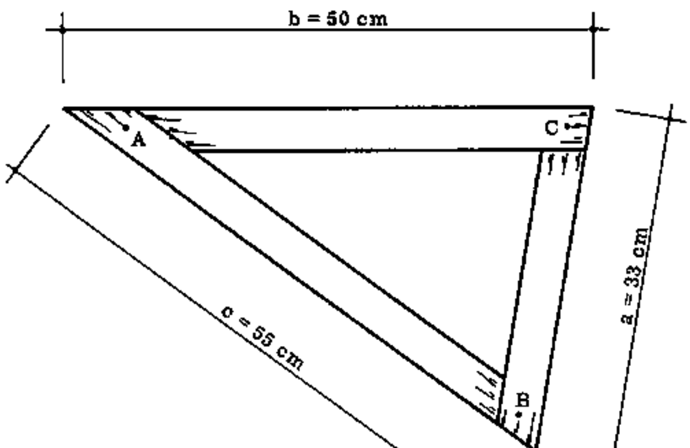

Fig. 1

This skewback template can only be used for a segmental arch where the radius of the arch is 3 times the span of the opening. Provided the rule of “r = 3 x span” is observed strictly, the same template can be used for any segmental arch, regardless of the length of the span. In other words the width of the opening and the size of the arch make no difference in the angle of the skewback for arches made according to this rule; the angle will always be the same.

- MAKING THE TEMPLATE: The template is made from wooden battens. It is simply a triangle with the outside dimensions as follows: side “a” = 33 cm, side “b” = 50 cm, and side “c” = 55 cm (Fig. 1). The angle at C is the angle we need to mark the skewback.

Use three battens that are a few centimetres longer than the measurements required. This allowance can be cut off when the template is assembled. Plane one edge of each until it is exactly straight and mark the length on this edge. Nail the battens together as in Fig. 1; or make accurate halving joints and join the pieces together with wing nuts instead of nails, so that they can be taken apart and put back together when they are needed in the future. The corners should be marked on both sides with the letters A, B and C, so that the ends are not accidentally mixed up when it is reassembled.

- USE OF THE TEMPLATE: The outside edge measuring 50 cm (side b) is held along the springing line, while the tip of the corner C is at the springing point (Fig. 2). The direction of the shortest side (side a) extended upwards with a straight edge gives the slope of the skewback. To mark the skewback on the other side, the template is simply turned around and the procedure is repeated.

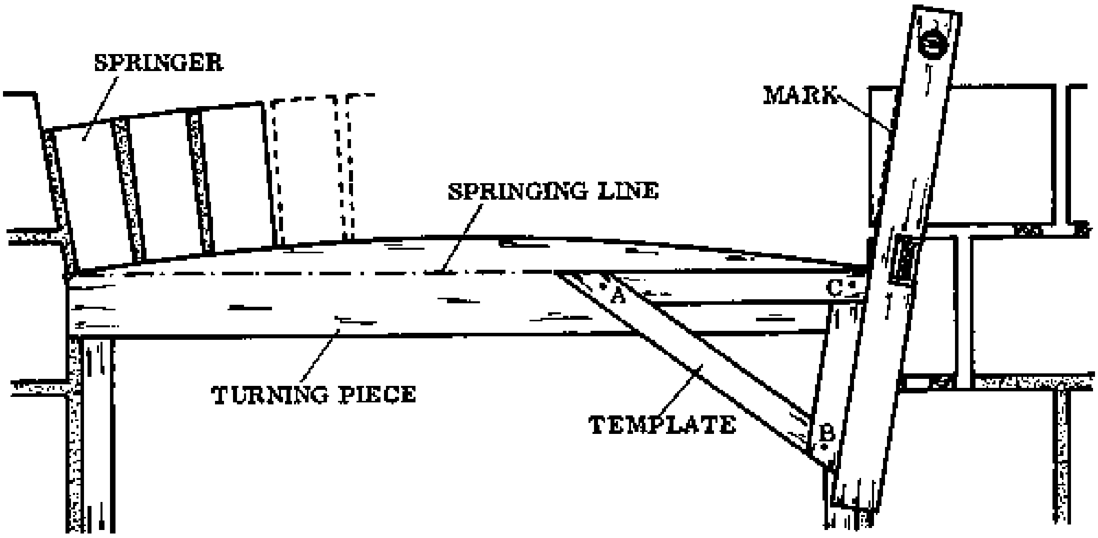

Fig. 2

- Note that corner B must always point downwards during the marking.

NOTES:

Laying the archblocks

The four blocks which have the skewbacks are marked and cut before they are laid in mortar. They are set temporarily in place on wooden battens which have the same thickness as the bed joint (Figs. 1 & 2, right sides). Mark the slope of the skewback with the template, and remove the blocks to cut them to shape. Then they can be laid in mortar and the arch can be continued.

Fig. 1 shows a segmental arch built with landcrete blocks. For this purpose, 1/2 blocks have to be cut, or preferably made specially in the Tek block press. This is easily done by putting a 1 cm thick board (for the 1 cm joint) edgewise in the middle of the mould box. The arch is built up by laying the blocks by turns on alternate sides, as indicated in Fig. 1 by the numbers.

The axis of each block should point towards the centre of the arch, with the result that ideally only the middle part of each block should rest on the turning piece, and the lower corners of the blocks do not contact the turning piece; there should be small wedge-shaped gaps. This is because the block faces are straight but the top edge of the turning piece is rounded.

The wedge-shaped joints between the archblocks need special attention. They must be properly filled with a rather wet mortar. If there is a gap left in the centre of the arch it is closed with concrete, which functions as a keystone (Fig. 1).

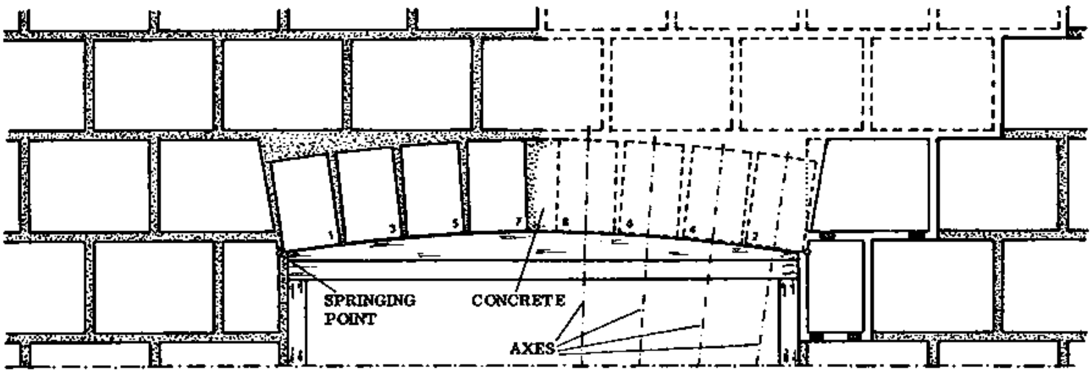

Fig. 1

Segmental arches over a span exceeding approximately 120 cm should be constructed with sandcrete blocks. The skewback blocks which abut the springers should also be sandcrete, so as to better distribute the pressure (Fig. 2).

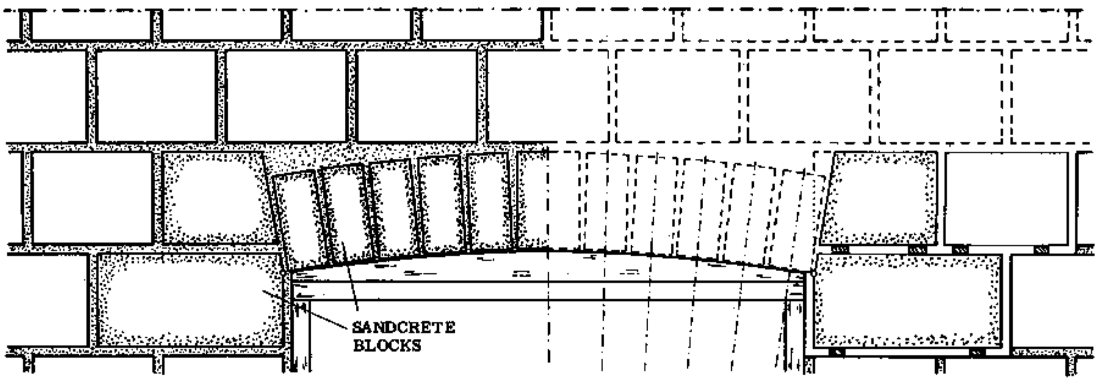

Fig. 2

To meet this requirement specially made blocks are needed. The skewback blocks must be 1 cm smaller in height than normal sandcrete blocks, so that they fit in with the landcrete courses. This is achieved by inserting a 1 cm thick piece of wood into the sandcrete block machine.

The archstones consist of 1/4 blocks which can also be made in the machine by inserting three 2 cm thick boards at a distance of 10 cm apart. The keystone is formed with a normal block of 15 cm thickness, cut to match the thickness of the wall.

If the centring is not combined with the frame, it is slightly lowered on completion of the arch, and removed after four days.

- NOTE: Try to set the centring so that the crown of the arch will be level with the top of the upper abutment course (Figs. 1 & 2) and not somewhere in the middle. The distance between the springing line and crown can be calculated as follows: 0,042 x span, plus height of archblocks.

REINFORCED CONCRETE LINTELS

Formwork

The formwork for cast-in-situ lintels consists of two main parts: the shuttering and the strutting. Precast lintels need only shuttering because they are cast on the ground.

- CONSTRUCTION: The construction of the formwork is shown in Fig. 1, page 167 of the Basic Knowledge book. This illustrates a situation where the frame will be set later or where there is an opening without a frame.

Since in most cases the frames are set already, the formwork does not require special strutting (Fig. 1). The head of the frame then acts as part of the soffit of the shuttering. The side boards must be fixed so that the vertical sides of the concrete lintel will be flush to the surface of the blockwork (Fig. 2).

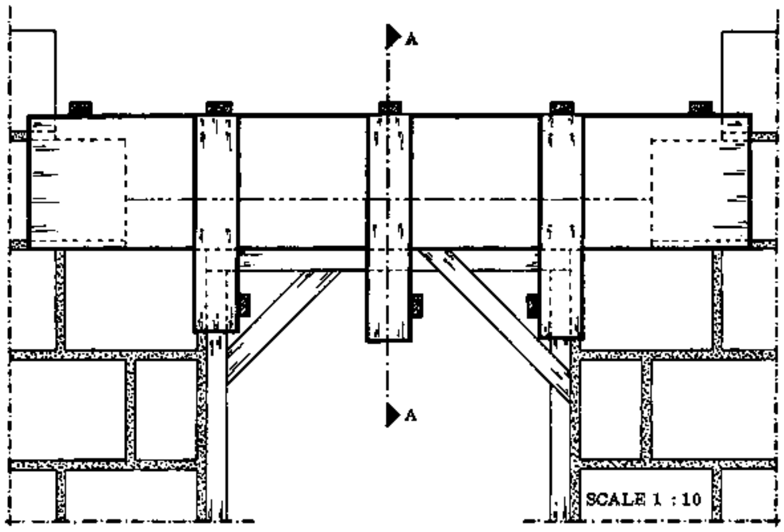

Fig. 1

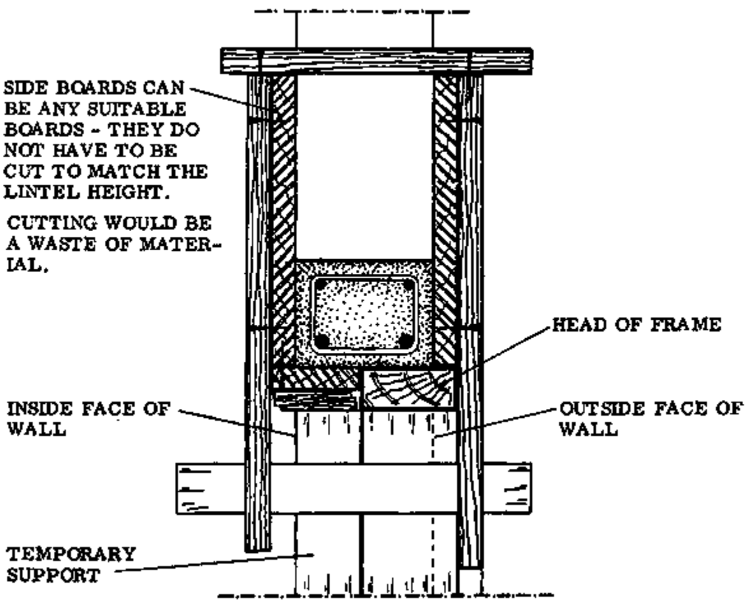

Fig. 2 CROSS SECTION A-A SCALE 1:5

- PREPARATION: If the lintel will not be plastered over later, the inside of the shuttering boards which are in contact with the concrete should be planed until they are smooth. This makes the stripping easier and also gives the concrete surface a nicer appearance. The inside of the shuttering may be treated with a special formwork lubricant, if this is available. Old engine oil can serve the same purpose; it should be applied lightly.

In case the lintel will be plastered later, it is better to leave the contact faces of the shuttering rough-sawn. Instead of oiling, wet the shuttering boards thoroughly with water, so that they don't absorb too much moisture from the freshly cast concrete.

Before casting the concrete make sure that the inside of the shuttering is clean; all joints, slits and gaps closed; and that the clear cover (the thickness of the concrete covering the reinforcement iron) is the correct thickness everywhere.

NOTES:

Reinforcement

The reinforcement for a lintel consists of a combination of different iron rods assembled to form a so-called “reinforcement cage” (see Basic Knowledge book, page 166).

In Rural Building the most commonly used reinforcement iron is round and has a smooth surface. It is available in rods with diameters ranging from 6 mm to 28 mm; but the most common sizes the Rural Builder uses are 6 mm (1/4”) rods and 12 mm (1/2”) rods.

If ribbed bars or tentor bars are available, these are preferred because the concrete grips better to a rough surface. Figs. 1a, b, c, and d show how the surfaces of some reinforcement bars look. Also see page 171 of the Reference Book.

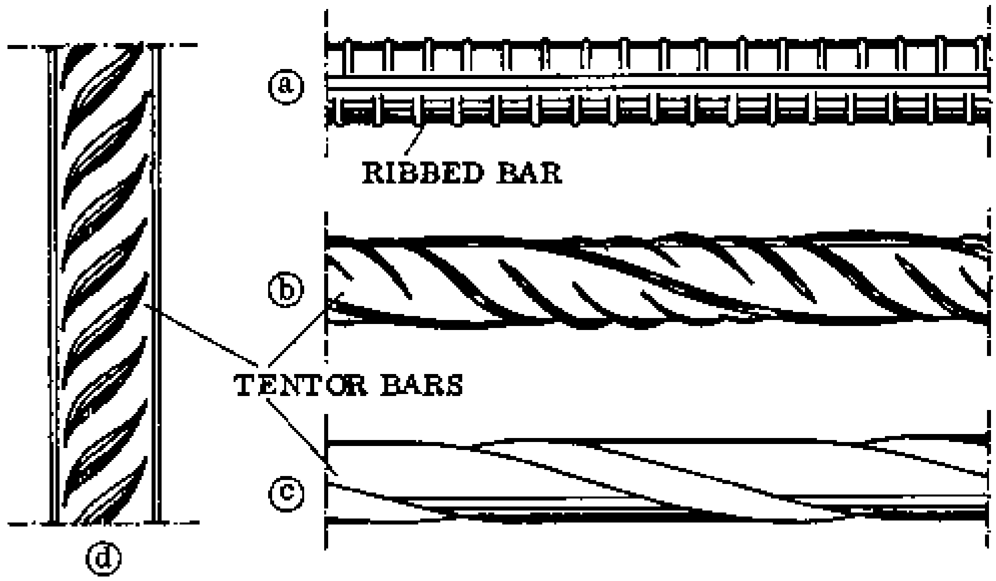

Fig. 1

- BENDING REINFORCEMENT BARS: According to how they will be used, sometimes iron rods must be bent or shaped to a hook form at the ends so that they can be well anchored. This must be done according to the following rules:

- All circular bars with smooth surfaces must have U-shaped end hooks (see Figs. 2a & 3a). For ribbed bars and tentor bars L-shaped hooks are sufficient (Figs. 2b & 3b).

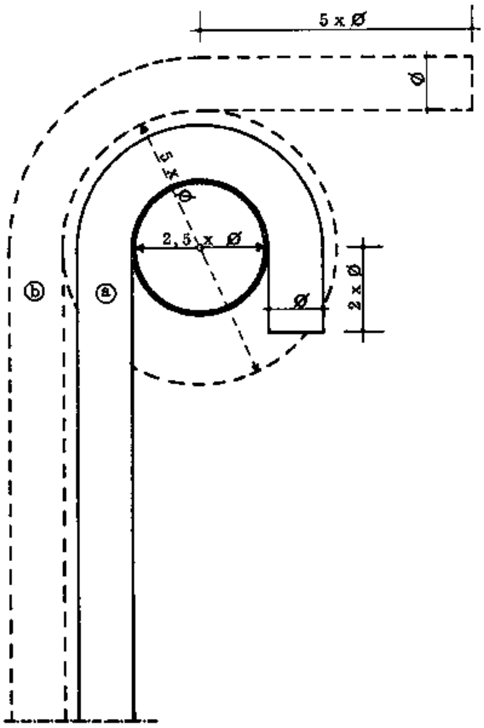

Fig. 2

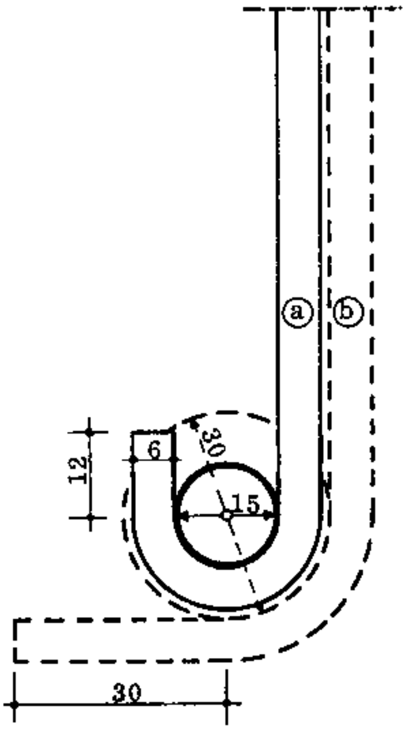

Fig. 3

- The minimum length for the straight end part of the hooks is: 2 times the rod diameter for circular bars; and 5 times the rod diameter for ribbed bars and tentor bars (Figs. 2 & 3).

- The smallest permissible bending diameter can be calculated according to the figures in the table below.

DIAMETER OF ROD	CIRCULAR BARS	RIBBED BARS & TENTOR BARS
6 mm up to 20 mm	2,5 x rod diameter	5 x rod diameter
22 mm up to 28 mm	5 x rod diameter	7 x rod diameter
more than 28 mm	-------------	10 x rod diameter

The smallest permissible bending diameter for the 6 mm circular bar in Fig. 3a will be 15 mm; or 2,5 x 6 mm. For the 6 mm ribbed bar in Fig. 3b, the bending diameter will be at least 30 mm, or 5 x 6 mm.

- NOTE: As a rule, main bars should never be extended. If this is necessary, the shortest overlap for bars under tension is 75 cm, and the ends of the bars must have U-shaped hooks (Fig. 4).

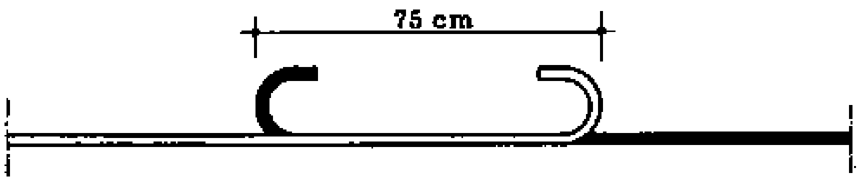

Fig. 4

Reinforcement systems

The construction of large reinforced concrete members usually requires complicated calculations to determine the diameters, number, shape and arrangement of the rods. This job should be left to a qualified design engineer.

However small and simple members of the structure such as lintels, columns, short span beams, etc. can be constructed by the Rural Builder according to the sketches, particulars and hints given here.

To place the reinforcement rods correctly, it is essential to understand and be able to predict in which part of the concrete member tensile stress (tension) is likely to occur. This is where the member has to be reinforced by the main bars. Fig. 1a shows the bold outline of a lintel; the dotted line shows how it would tend to bend under pressure. The arrows show how the whole upper part is under pressure, while the lower surface is under tension.

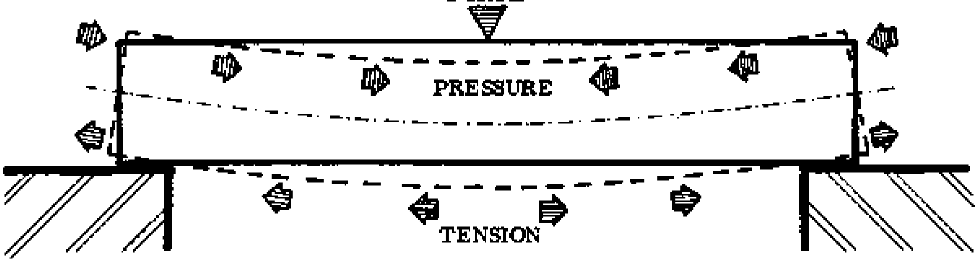

Fig. 1a

Fig. 1b illustrates how the lintel can be reinforced against this tension. Note that the main bars are on the bottom, in the zone which is under tension; and that the ends of the main bars are anchored on top, within the zone that is under pressure.

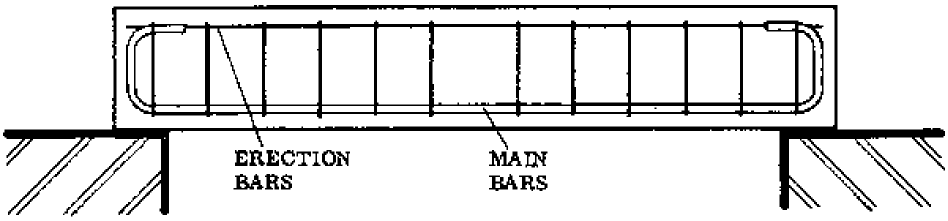

Fig. 1b

Fig. 2 shows another situation, where a beam is supported from one side only. This is called a cantilever beam. The unsupported end will tend to bend as shown. Here the main bars are on top to counteract the tension in the top surface (Fig. 2b).

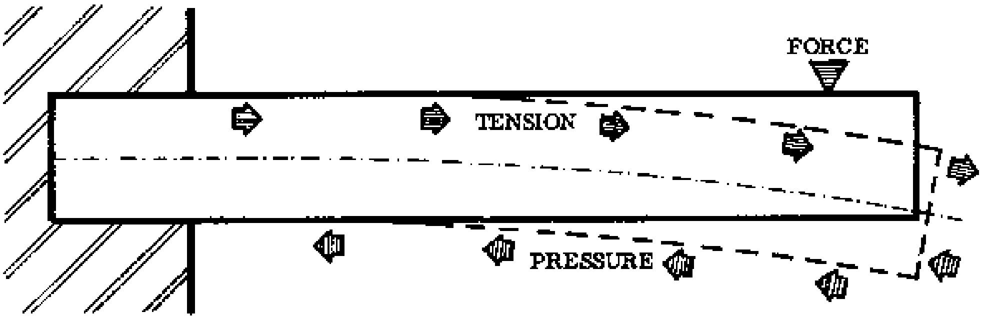

Fig. 2a

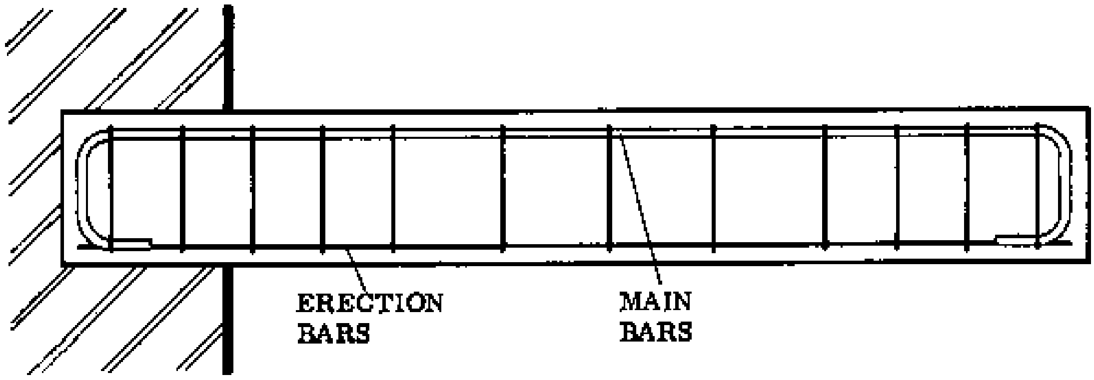

Fig, 2b

NOTES:

The longer reinforced beam or lintel shown here in Figs. 1a and 1b is reinforced with main bars on the top and bottom.

The cross section in Fig. 2 shows how the clear cover is measured from the outside of the stirrups to the outside face of the concrete. In other words, the clear cover or concrete cover is the distance between the concrete surface and the nearest reinforcement bar, regardless of the function of the bar.

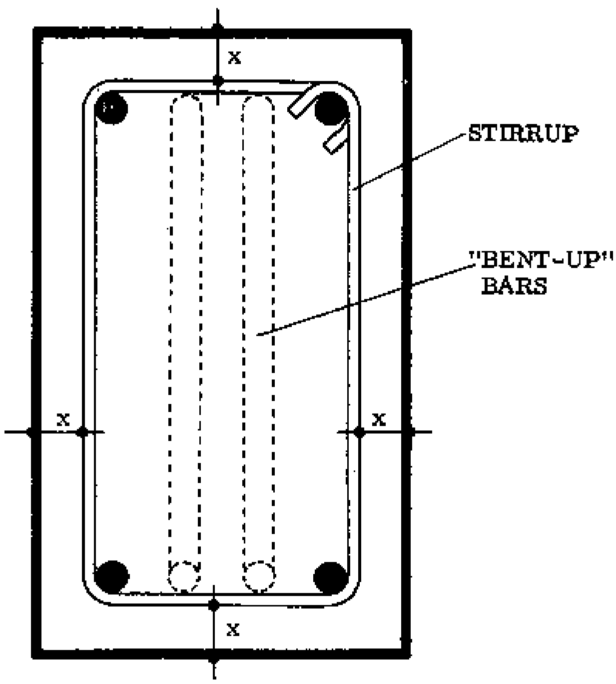

Fig. 2 CROSS SECTION A-A

x = CLEAR COVER

The distance between the stirrups is never more than 20 cm. For safety, the Rural Builder is advised to put the stirrups no more than 15 cm apart. The stirrups closer to the supporting walls (50 cm away and closer) should be no more than 10 cm apart (see the illustrations here and on the next page).

So-called “bent up” bars are sometimes used as part of the reinforcement system (Figs. 1 & 2) but these are not used in Rural Building because of the difficult calculations required to place them correctly; also they are not necessary for the small structural members which are required in Rural Building.

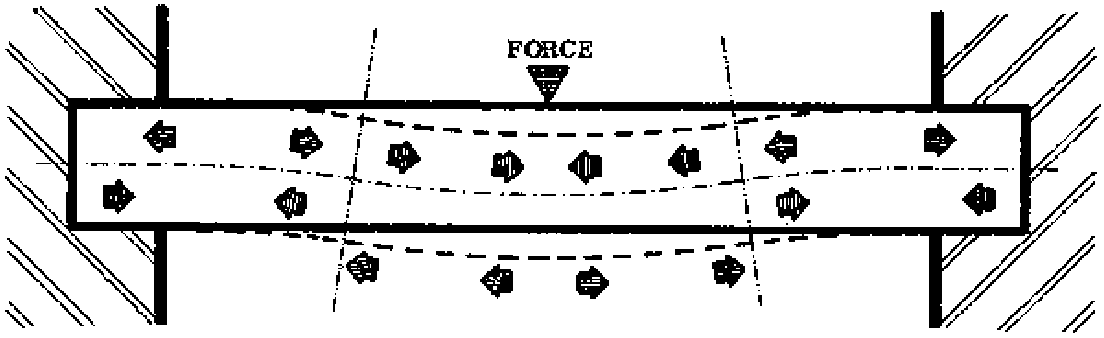

Fig. 1a

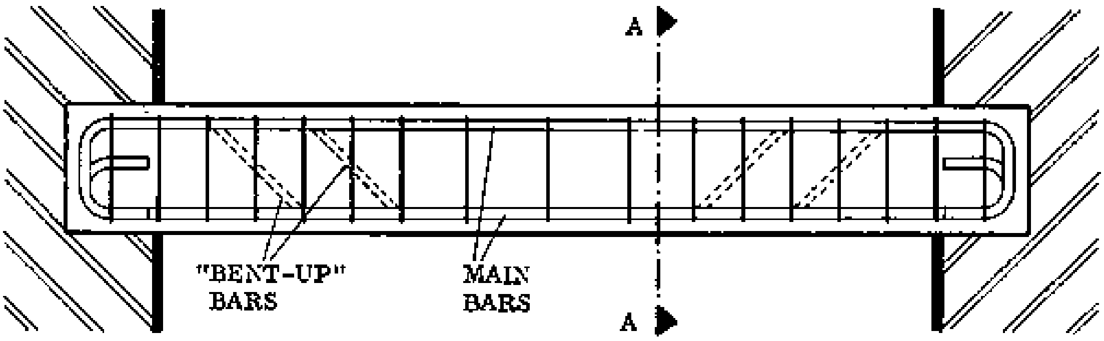

Fig. 1b

NOTES:

On the left is a drawing of a reinforcement system for a continuous beam; this might occur for example in an eave beam supported by a reinforced pillar (Fig. 1).

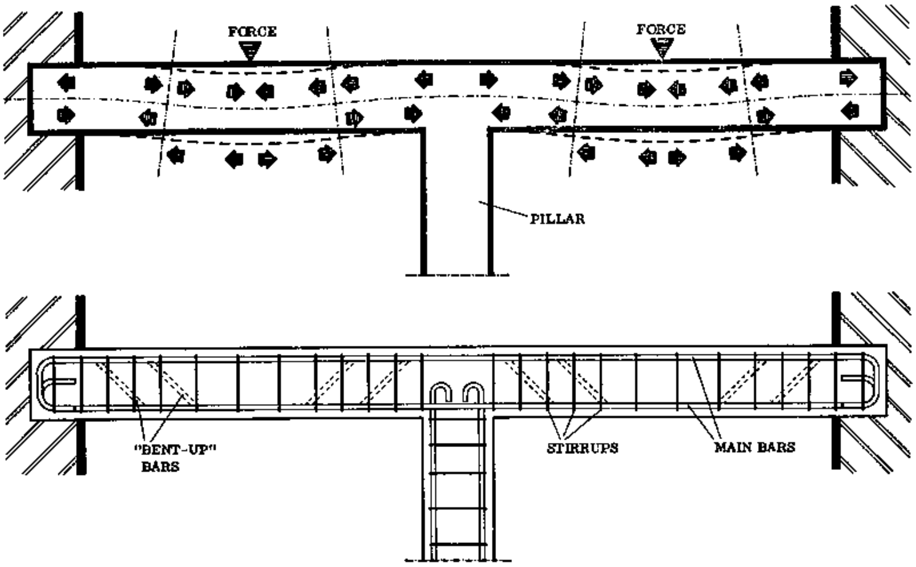

Fig. 1

Corrosion in reinforced concrete

It may seem strange, but the weakest part of a reinforced concrete structure is the hard iron, because it is easily broken down if it is not protected well. The structure remains stable only as long as the iron is protected against corrosion.

The main problem with reinforced concrete is the development of very small cracks in the concrete, which means that the iron is exposed to air and becomes rusty. On the concrete surface below the cracks, reddish brown rust stains appear. Once these are visible it is usually too late to save the member.

Unless immediate protective measures are taken, the rust develops more and pressure builds up between the iron and concrete, causing the concrete cover to break open; this speeds up the rusting process and eventually the reinforcement bars become too weak to carry loads or to withstand other forces. The system then collapses.

- PREVENTION OF CORROSION: Here we must include a strong warning against over-reliance on concrete strength. Not only laymen, but also many construction experts believe “the more cement, the harder and the better the concrete”, and they tend to improve the mix proportions by using greater amounts of cement. This is wrong, because very hard concrete is not only expensive but it is also not necessarily the best protection against rust. Therefore, the Rural Builder is advised to follow the correct mix proportions.

If possible use high quality steer for the reinforcement as this does not rust as easily as common circular bars.

The surface of the concrete should be protected against the weather by the application of a waterproof cement paint (see Reference Book, page 201). However, such a paint coat is wasted if rust stains are already present. The paint does not seal the cracks and only makes the stains disappear for a short time, if at all.

- NOTE: Never apply paint on concrete surfaces that have not set hard yet. Possible shrinkage of the concrete during the hardening process would cause tiny cracks in the paint coat, making the paint useless as protection against the penetration of water and air.

WALLING ABOVE FRAMES

The last part of the walls above the frames should consist of at least three courses of blocks, so that the roof construction can be well anchored. Experience has shown that anchoring the trusses in the ring beam alone is not sufficient for them to withstand strong wind forces. Therefore, the anchorage irons are placed in the first bed joint just above the frames (see Anchorage, page 197).

If the exact positions of the trusses are not known yet, the irons can be set later, in the finished wall. This is done by passing the iron through a hole chiselled in the bed joint (Fig. 2 a). It is generally better and easier though to plan ahead and place the irons during the wall construction. The irons are set in grooves so that they will be flush to the wall surface and will be covered and protected later by the plaster or render.

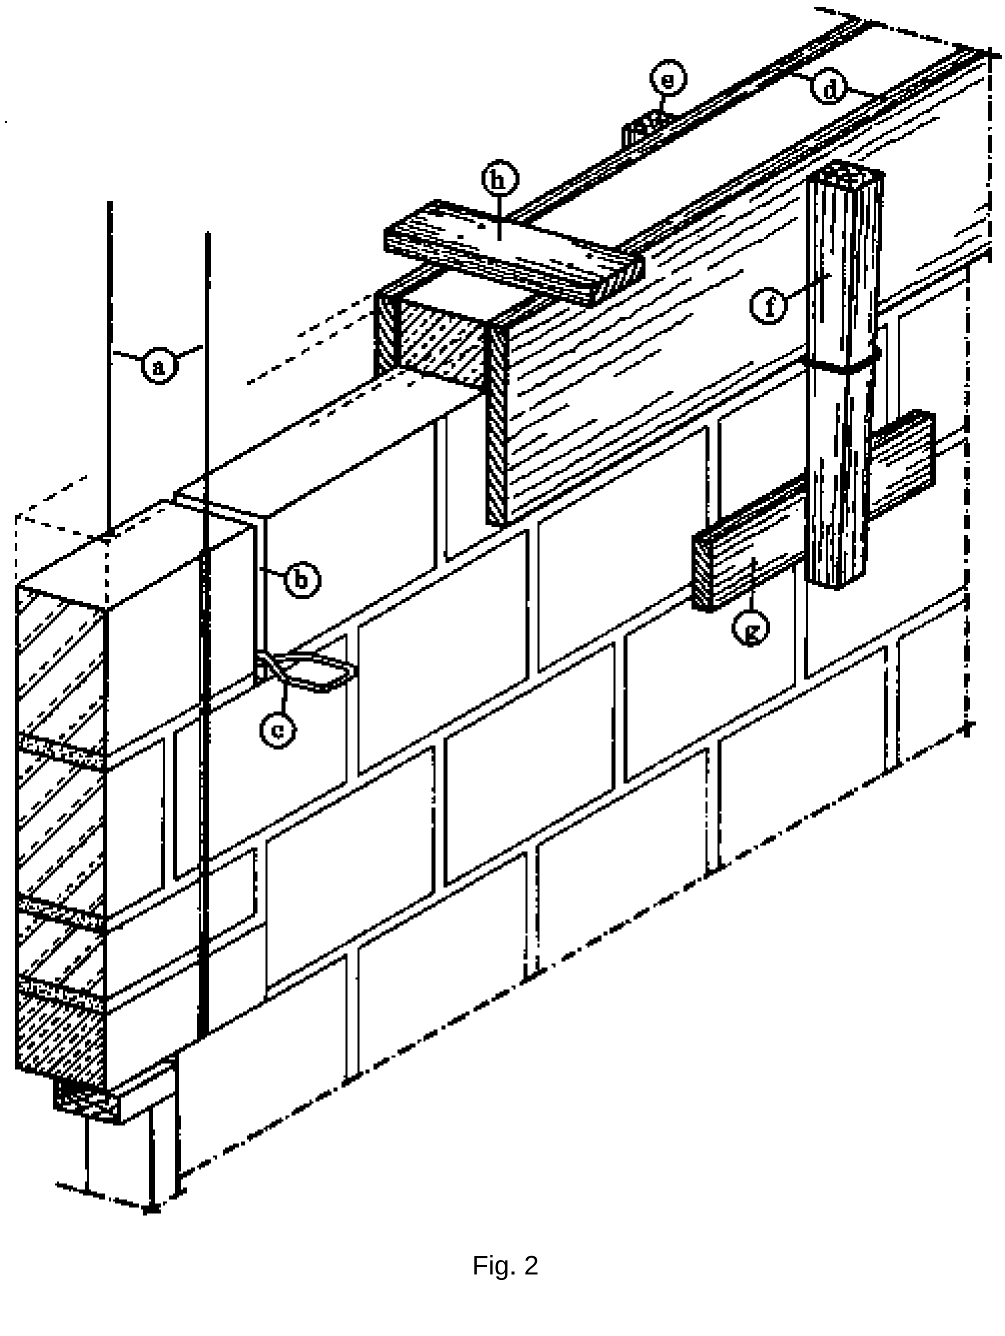

Fig. 2

FORMWORK SYSTEM FOR RING BEAM

If a reinforced concrete ring beam will be made, every third cross joint in the last course is left open (Fig. 2, b) so that formwork clasps can be inserted.

These special clasps have been developed and manufactured at NPVC in order to save strutting materials and to ease the construction of the formwork for a ring beam. Formerly long standards and braces in great number were needed to construct the formwork. With the clasp however, only a few short boards are necessary for the bracing. The formwork clasps are easy to handle and have passed all tests at NPVC. They are made from a piece of iron rod bent as shown in Fig. 1, and welded to hold the loop ends closed.

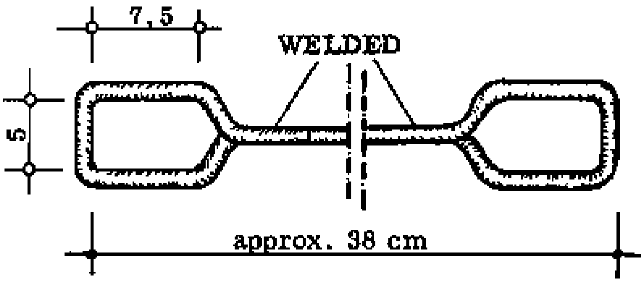

Fig. 1

Fig. 2 shows the formwork system, and Fig. 3 shows the cross section. When the clasp is inserted in the open cross joint (Fig. 2, c) the remaining open space must be closed with paper (empty cement bags) to make it possible to remove the clasp later. The side boards (d) rest on the clasps and are pressed against the wall by straight boards (e) on one side, and wedge-shaped boards (f) on the other side. Short pieces of board below the side boards (g) act as distance pieces to keep the shuttering boards plumb. Cleats or spreaders (h) may also be used to maintain the correct width of the beam. There are no nails used, except for fixing the cleats, which reduces the damage to the boards.

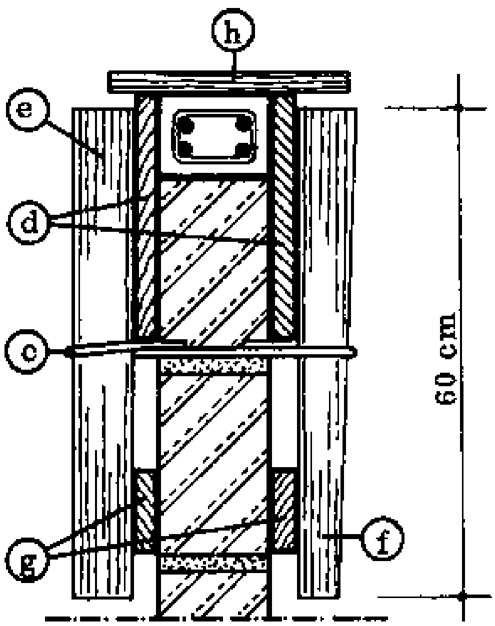

Fig. 3

The Rural Builder is advised to supply himself with at least four clasps and to carry them along with his set of tools.

ROOFS IN GENERAL

The roof is a very important part of the building structure. It performs several essential functions:

- It gives shelter to people.
- It provides shade.
- It isolates the building from cold and heat.
- It keeps out dust and dirt.
- It protects the interior of the building.
- It sheds rainwater.

Roof types

There are many different types of roofs. In Rural Building we deal only with the following four types:

- The lean-to roof (Fig. 1)

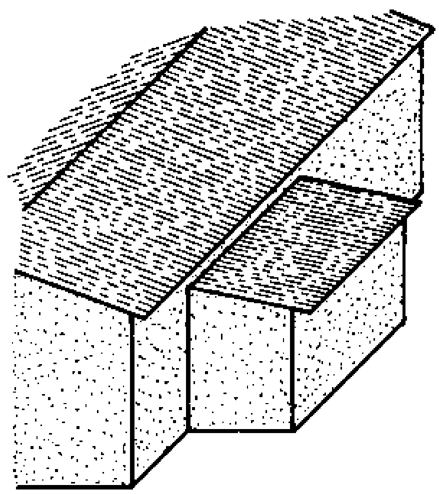

Fig. 1

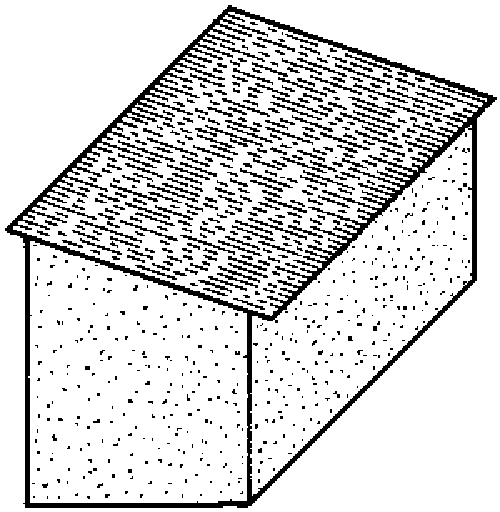

Fig. 2

- The pent roof (Fig. 2)

- The gable roof (Fig. 3)

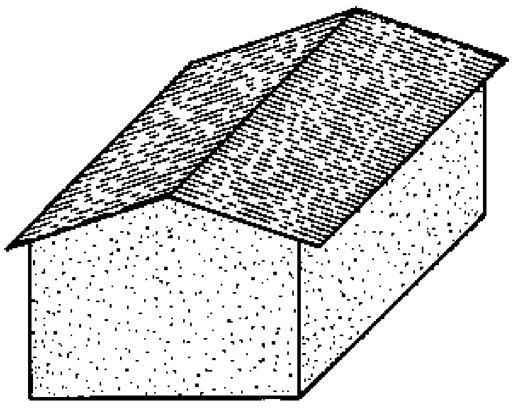

Fig. 3

- The hipped roof (Fig. 4).

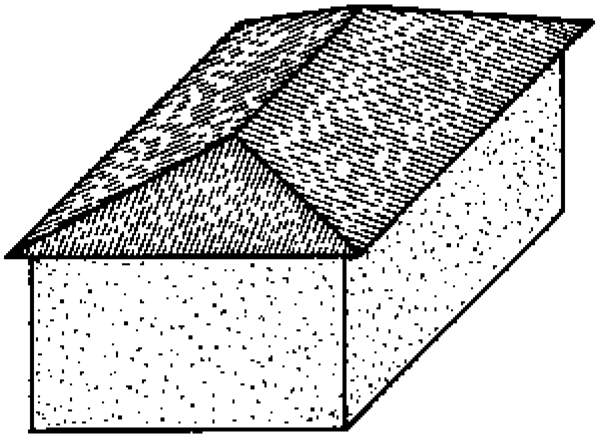

Fig. 4

These roofs will be described in detail in the following sections of the book. In the next few sections we will describe some factors which are important in the construction of all roofs. These must be understood well before we can go on to describe the construction details of the particular roof types.

NOTES:

Size of the roof

The cost of roofing sheets will be a significant part of the cost of the whole building. Therefore it is the size of the roofing sheets which will determine the size, and especially the width, of the whole building.

For this reason, we make an outline design of the roof before we determine the other measurements of the building. We cannot design the building first and later fit a roof on it. The outline design tells us the width that our building should have so that we can fit a roof on it without unnecessary and wasteful cutting and trimming of the sheets (Reference Book, pages 239 & 240).

To make the outline design of the roof, we need to know:

- the pitch of the roof
- the effective length of the sheets
- the distance the roof will project past the outside walls of the building.

Roof pitch

The angle of the slope of the roof is called the pitch. Most roof types have a standard pitch. If corrugated sheet materials (Reference Book, pages 230 and 231) are used, the pitch angle should be between 15 and 20 degrees (Fig. 1).

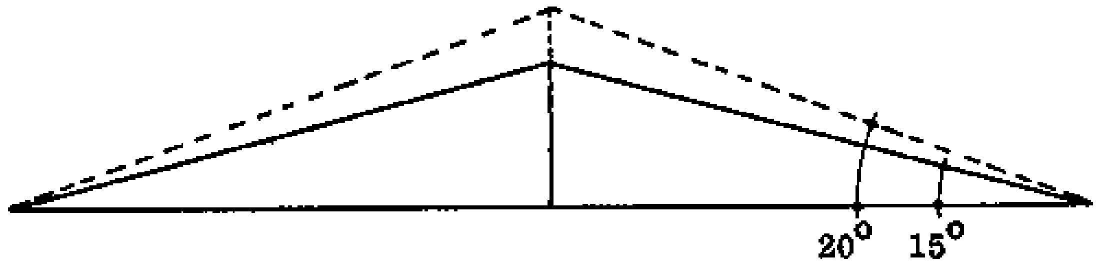

Fig. 1

NOTES:

Effective length of the sheets

The effective length of roofing sheets is the length of the sheet (x) minus the overlap (y) between the sheets (Fig. 2).

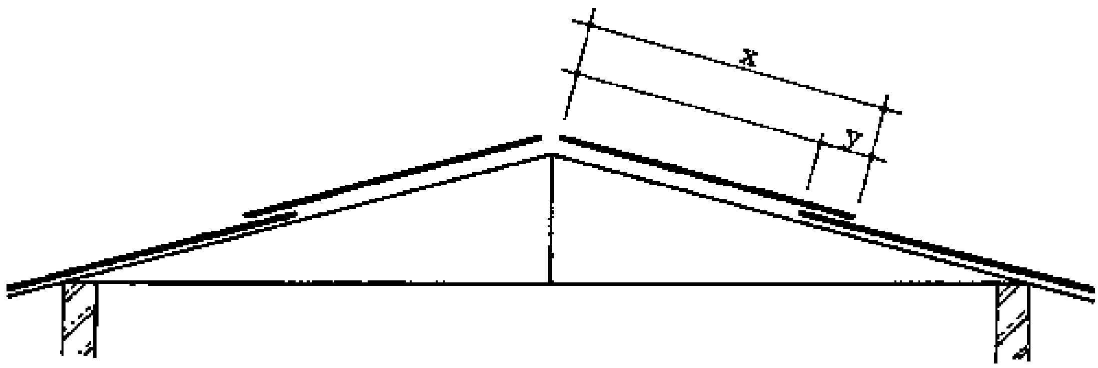

Fig. 2

The minimum overlap in the length for corrugated sheeting materials is 15 cm. The most common length for roofing sheets in Ghana is 244 cm.

In order to use the sheet materials as economically as possible, we use either 1, 1 ½, 2, 2 ½ or 3 (and so on) sheets to cover the distance from the highest point of the roof to the lower edge. Thus the effective length will be:

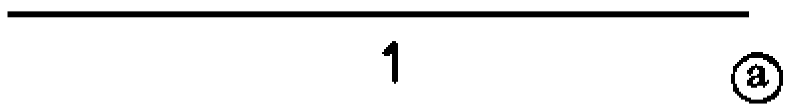
-	for 1 sheet	-	244 cm
-	for 1 ½ sheets	-	244 cm + 122 cm - 15 cm = 351 cm
-	for 2 sheets	-	244 cm + 244 cm - 15 cm = 473 cm
-	for 3 sheets	-	(244 cm x 3) - (15 cm x 2) = 702 cm
-	and so on.	-	

NOTES:

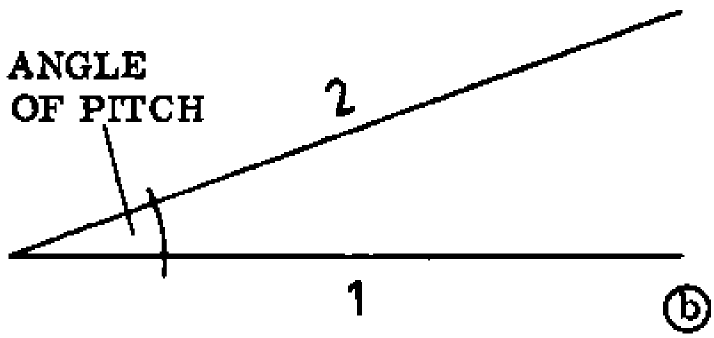
Outline design

The outline design should be made in as large a scale as possible, since it is used to find some measurements for the future building design.

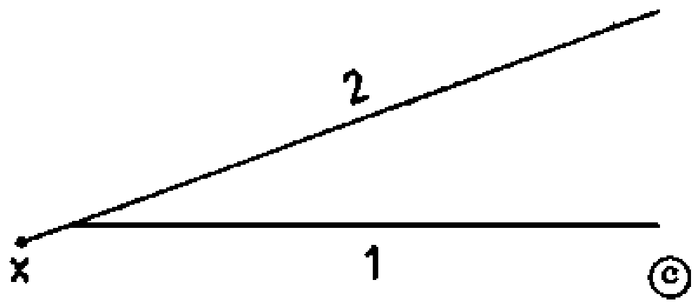
a. Draw a horizontal line (line 1).



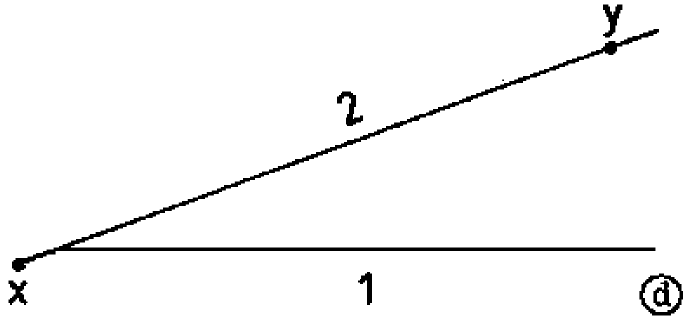
b. Draw line 2. The angle between line 1 and line 2 should be the angle of the pitch of the roof.



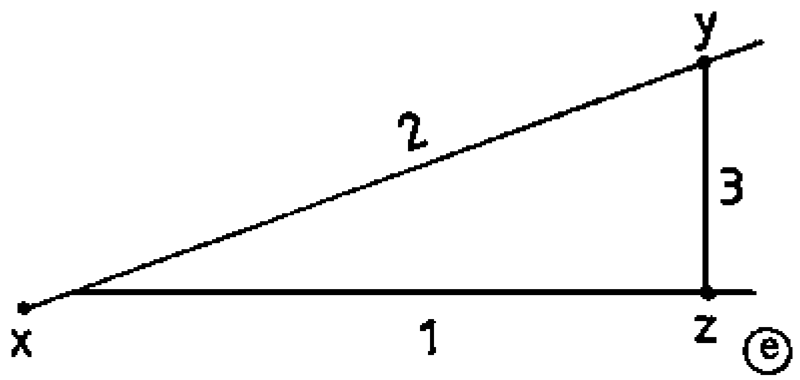
c. Extend line 2 to show the projection of the roof beyond the wall of the building. Mark point x at the end of line 2.



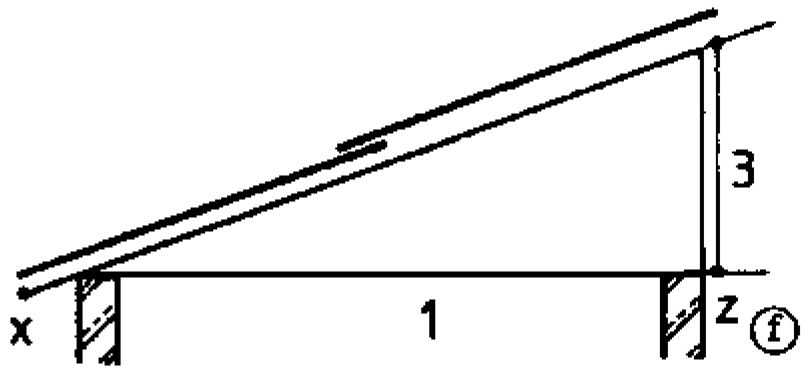
d. Measure the effective length of the sheets from point x, remembering to sub tract the overlap. Mark point y on line 2.



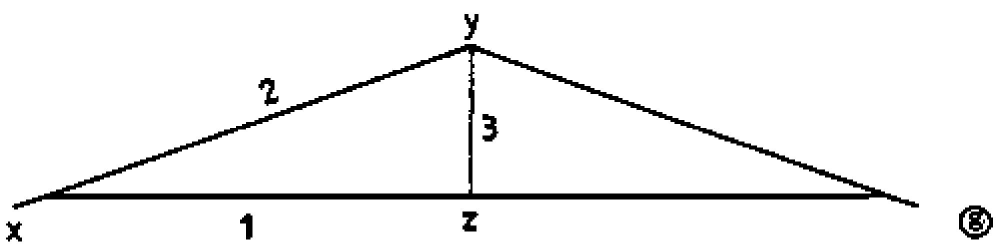
e. Make a line perpendicular to line 1 and passing through point y. This is line 3. Mark point z on line 1.



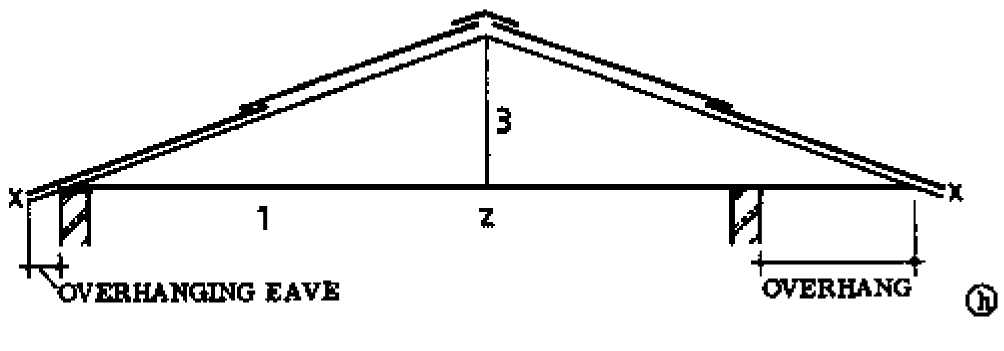
f. If a lean-to or pent roof is planned, the length of line 1 up to point z gives the width of the building. Now indicate the supporting walls and the sheets with the overlap. In a lean-to roof, remember that the end of the sheet at the top is en closed in the wall; and for the pent roof, the sheets project past the wall on the top side.



g. If a gable roof is planned, draw the other half of the roof in the same manner. The extended line 1 will give the width of the building.



h. Indicate the supporting walls, sheets and the overlap.



- TERMS: The point where the sloping lines meet, point y, is called the “ridge”. Line 3 is the “rise” of the roof.

If the horizontal line (line 1) projects beyond the supporting walls, the projecting part is called an “overhang”.

If the sloping part projects beyond the wall, the projecting part is called an “overhanging eave”.

The lowest part of a sloping roof is called the “eave” (point x).

NOTES:

Loads

In order to build a good strong roof, it is necessary to take into account certain forces that will affect it. We call these forces “loads”.

Some of the loads come from the weight of the roof itself and the ceiling. These are called “dead loads”. They consist of: (see Fig. 1)

- the weight of the roof covering
- the weight of the roof construction
- the weight of the ceiling
- the weight of anything attached to the ceiling such as ceiling fans or light fixtures.

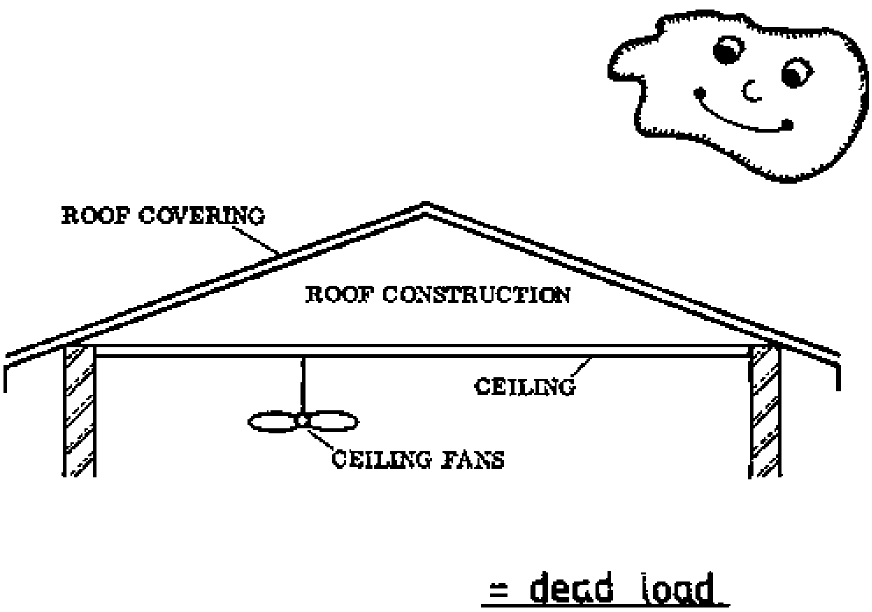


Fig. 1

Other loads are caused by external (outside) forces such as rain or wind. These are called "external loads". External loads are: (see Fig. 2)

- windloads
- rainloads

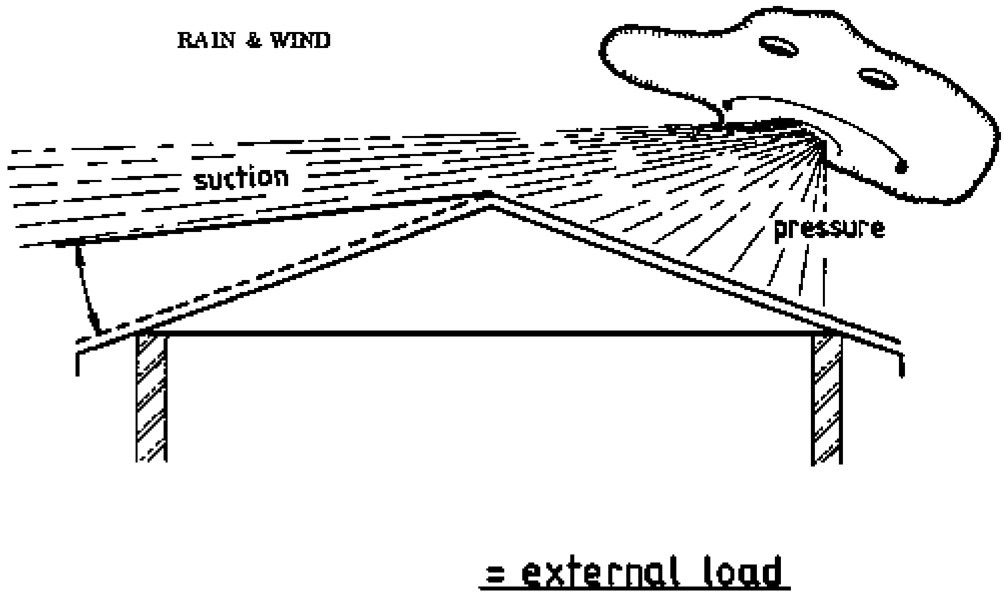

Fig. 2

All loads, external and dead loads, must be taken into account in the planning and construction of a roof.

The most dangerous load in Ghana is the windload. Strong winds or storms can cause a lot of damage to a roof if it is not well made and securely fixed to the building.

One particular danger is the suction on one side of the roof caused by the wind, which creates pressure on one side and suction on the other side of the roof (Fig. 2). This suction on roofs can be demonstrated by an experiment. Fold a sheet of paper in half and blow over the top edge. The other half of the paper will be lifted up by suction.

- SHAPE OF THE ROOF WITH RESPECT TO WINDLOAD: Roof constructions can be severely damaged by storms. Apart from the precaution of anchoring the roof well, which will be discussed later, there are some ways to shape a roof so that it is less vulnerable to the force of the wind:

- Consider carefully the pitch of the roof. Roofs with a pitch of less than 10 degrees are much more prone to high suction forces.

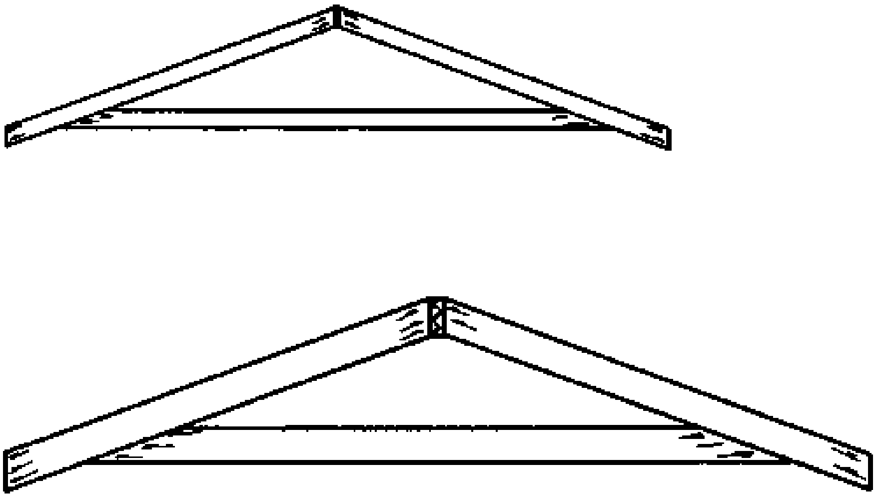
- 15 to 20 degrees is a better roof pitch, because it causes less suction.

- Consider making a hip roof instead of a gable roof. This will decrease the suction even more.

- See the Drawing. Book, pages 105 and 106, for more suggestions.

LIGHT-WEIGHT STRUCTURES

As the span (width) of the building increases, the strength of the roof construction must also be increased. Formerly this was done by using thicker and wider timbers (Fig. 1).



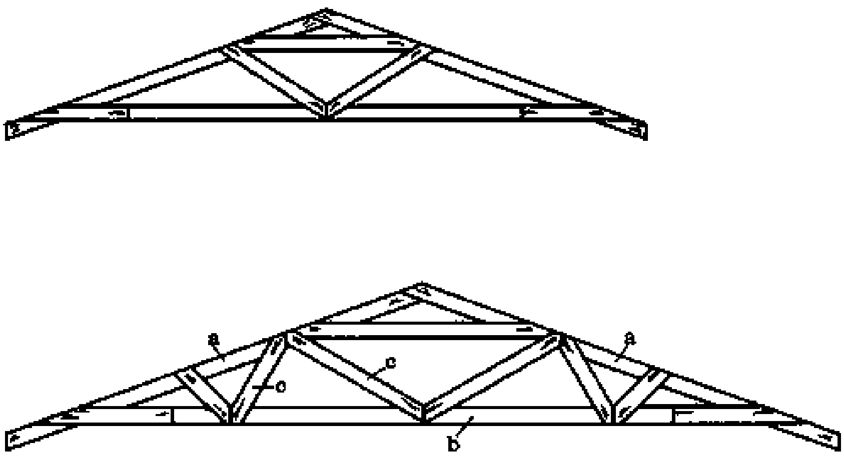
FOR INCREASED SPAN LARGER TIMBERS ARE USED

Fig. 1 TRADITIONAL ROOF CONSTRUCTION

This method resulted in very heavy and expensive roof constructions. Large timbers are normally much more expensive than smaller timbers (compare the cost of 5 x 7,5 cm Odum and 5 x 15 cm Odum).

This kind of roof construction is now uneconomical, as well as difficult because of the complicated joints needed for large timbers.

In modern light-weight structures, the strength of the roof is increased for larger spans by building up brace structures in the shape of triangles (Fig. 2), instead of using larger timbers. This construction uses small timbers, which are cheaper and lighter in weight; therefore we get a light-weight structure.



FOR INCREASED SPAN MORE BRACES ARE USED

Fig. 2 MODERN LIGHT-WEIGHT STRUCTURES

Light-weight structures are less costly, and result in a smaller dead load on the roof. Another advantage is that we can use simple joints instead of complicated roofing joints.

Since the construction is built up from small members, it is sometimes called a “built-up structure”. This is the only type of roof construction we will learn in Rural Building.

- TERMS: The sloping members are called “rafters” (Fig. 2, a).

The horizontal member is called the “tie beam” (b).

The members strengthening the construction are called “braces” (c).

NOTES:

Basic shape of the roof construction

It is essential that the roof construction remains rigid. To ensure this, we need to find a shape for it which cannot be distorted.

- NOTE: The only construction shape that cannot be distorted is a triangle.

The strength and efficiency of the triangular construction can be proven by experiment:

For example, a square shaped construction (Fig. 1) can easily be distorted. The only resistance to the distortion is in the corner joints. This construction is called a “non-perfect” or imperfect structure.

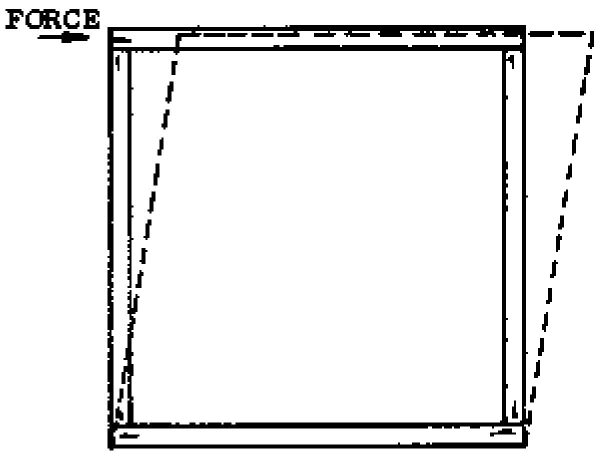


Fig. 1

A triangle shaped structure cannot be distorted (Fig. 2). When force is applied to any part of it, the frame remains rigid. This construction is called a “perfect” structure.

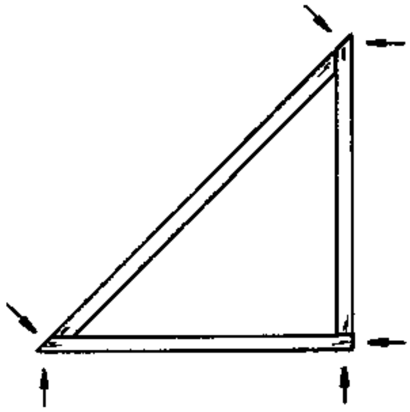

Fig. 2

As soon as a diagonal brace is introduced to a square shaped frame (Fig. 3), it becomes rigid. The brace changes the square shape into two triangles, making it a perfect structure.

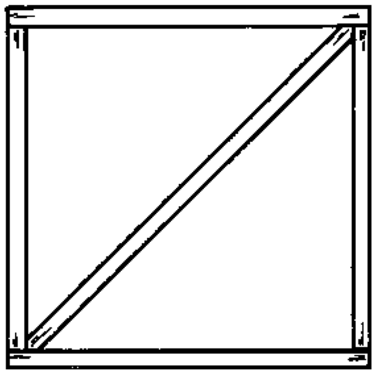

Fig. 3

If the brace were to be installed vertically or horizontally instead of across the diagonal, the structure could still be distorted because it would still be non-triangular, and thus an imperfect structure.

There are many examples of triangular constructions in our surroundings. Look at a bicycle frame, scaffold braces or braces for a door frame, for example.

In Fig. 4 are shown some perfect structures.

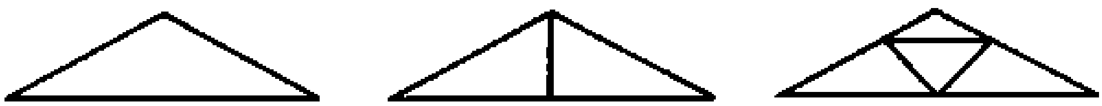

Fig. 4 PERFECT STRUCTURES

In Fig. 5 are shown some imperfect structures.

Fig. 5 IMPERFECT STRUCTURES

In roof construction, it is essential to make only perfect structures.

Technical terms

- TIE BEAM: This is the horizontal member of the roof structure which ties together the feet of the rafters (Fig. 1, next page).

- RAFTERS: These are the sloping members which give support to the purlins (Fig. 1, next page).

- BRACES: These are the members which strengthen the construction.

- ROOF TRUSS: This is the structure made up of the rafters, tie beam and braces, which forms the main load carrying unit in some kinds of roofs.

- PURLINS: These members lie across the rafters and support the roofing sheets.

- RIDGE: This is the highest point of a roof construction.

- RISE OF THE TRUSS: This is the vertical height of the truss (Fig. 1, a), measured between the highest point of the truss and the soffit of the tie beam.

- SPAN OF THE TRUSS: This is the clear horizontal distance between the internal faces of the rafters (b) at the point where they meet the soffit of the tie beam.

- SPAN OF THE BUILDING: The building span is the clear horizontal distance between the inside faces of the walls which support the roof (c).

- OVERHANG: When the tie beam projects beyond the supporting wall, the projecting part is called the overhang (d). The overhang is measured square to the wall.

- OVERHANGING EAVE: When the rafters project beyond the supporting wall, the projecting part is called an overhanging eave (e). The width of the overhanging eave is measured square to the wall.

- EAVE: This is the lowest part of the overhang or overhanging eave (point x).

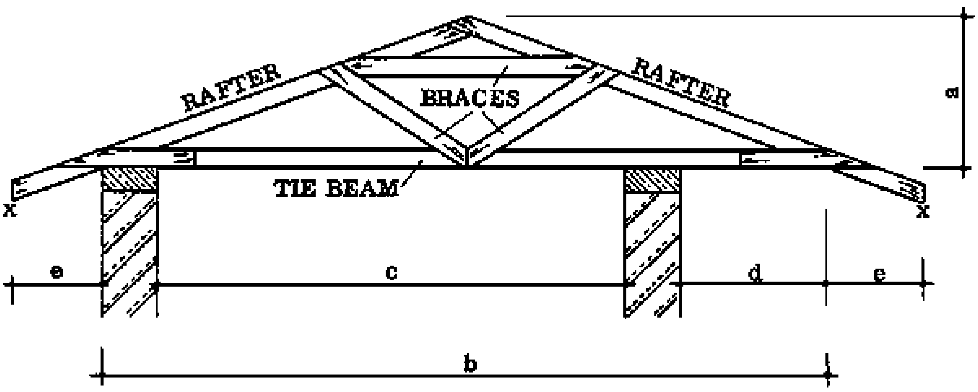

Fig. 1

NOTES:

LENGTHENING JOINTS FOR LIGHT-WEIGHT STRUCTURES

Always select the timbers before starting work on the roof construction. Keep the long straight pieces for the rafters, tie beams, and purlins; and the short pieces for braces.

Sometimes pieces of the right length may not be available. Then it may be necessary to join the members in order to make them longer.

All joints used for lengthening the members of the roof construction will be fish joints with one or two fish plates. These will be discussed in detail in the next section.

Keep in mind that each lengthening joint in the roof construction will weaken the roof. Therefore, try to select the timbers so that you don't need to use many lengthening joints.

Where to place a lengthening joint

It is often difficult to judge where to place a lengthening joint. In general, one can say that it should be as close as possible to a support such as a wall or pillar, but we must also keep in mind that the joint is weak, so it cannot be in a place where it is under strain.

For example: A 6 m long tie beam is needed. The only long piece of wood you have is 5,70 m long. If you join that to a 30 cm piece to make 6 m, then the joint will indeed be near a load-carrying wall - but in relation to the entire structure the joint will be in the wrong place, because most of the weight of the truss is concentrated in that area, where we now have a weak joint.

In this case, a better solution is to join two shorter pieces to get the required length.

Lengthening joints should also not be placed where the braces meet the member.

NOTES:

Fish joints

We have said that a fish joint will be sufficiently strong for most parts of the roof construction. However, when we assemble a fish joint, we have to follow certain guidelines to end up with a strong joint.

A fish joint will usually be assembled with nails. The strength of the nailed fish joint depends first on the number of nails used; and second on whether one or two fish plates are used. The length of the fish plates should be at least 5 times the width of the joined members.

ONE NAILED FISH PLATE

- SHEAR STRESS IN A JOINT WITH ONE FISH PLATE: If one nailed fish plate (Fig. 1) is used, the nails tend to shear off (break) at the joint line between the members and the fish plate because of the force exerted as the members try to move apart (Fig. 3). The joint is said to be in single shear (Fig. 2).

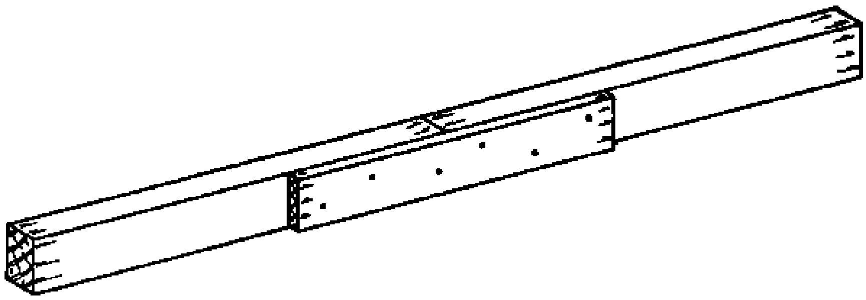

Fig. 1

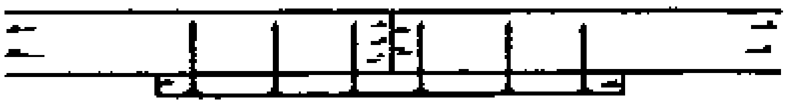

Fig. 2

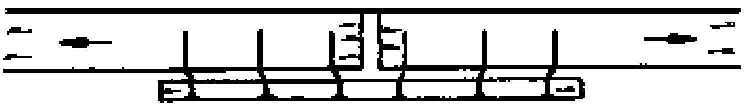

Fig. 3

In order to prevent the members from moving apart and shearing the nails, it is necessary to clinch the nails, so that they are anchored firmly (Fig. 4).

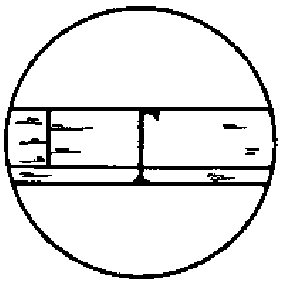

Fig. 4

TWO NAILED FISH PLATES

- SHEAR STRESS IN A JOINT WITH TWO FISH PLATES: When two nailed fish plates are used (Fig. 5) to join the members together, the nails tend to shear at two points. The joint is said to be in double shear (Fig. 6).

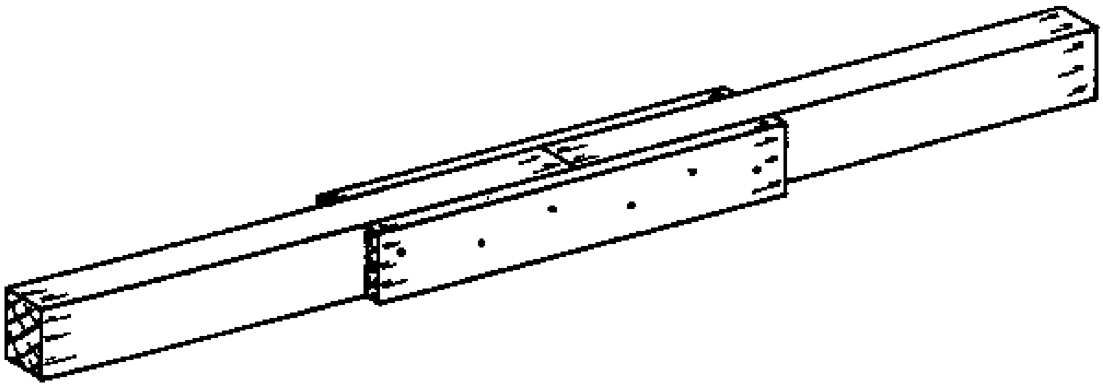

Fig. 5

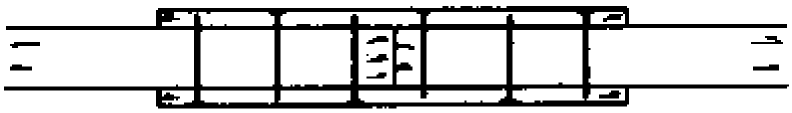

Fig. 6

In this joint there is less tendency for the members to pull apart, since there are two fish plates (Fig. 7). The nails must go through both fish plates.

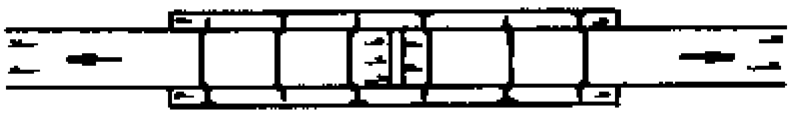

Fig. 7

- NOTE: The strength of a joint in double shear (with two fish plates) is approximately twice that of a similar joint in single shear (with one fish plate).

- NAILING THE FISH JOINT: We have seen that the strength of a nailed fish joint depends on the number of nails used in it and on the number of fish plates. It is important that the nails are fixed correctly, or the joint will be weakened.

- The nails should be evenly distributed over the entire fish plate.

- Nails should always be staggered.

- Nails should always be blunted.

- If thick nails are used, they have a tendency to split the wood. Often staggering and blunting cannot prevent this splitting. In this case it is necessary to drill holes for the nails. The holes should have a slightly smaller diameter than the nails.

There are certain rules for spacing the nails on the fish plate. These are:

- In the direction of the grain, the distance between the nails should be 10 times the thickness of the nail (Fig. 1, next page).

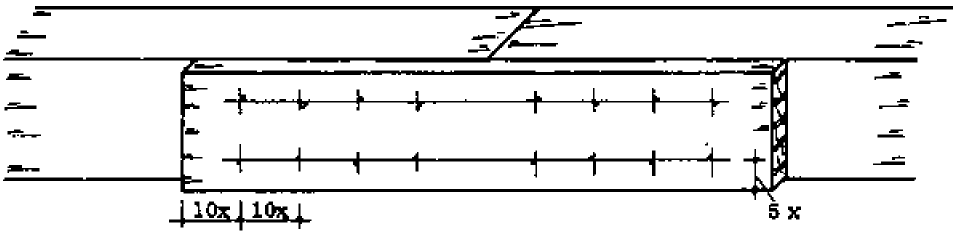

Fig. 1

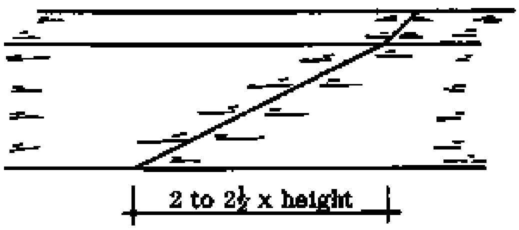
- The distance to the margin of the fish plate should be: in the direction of the grain, 10 times the thickness of the nail; and across the grain it should be 5 times the thickness of the nail (Fig. 1).

- See the Reference Book, page 207, and Basic Knowledge, pages 92 to 94, for more details about nails and nailing.

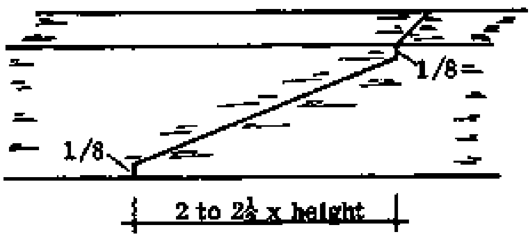
Other lengthening joints

Other joints besides the butt joint with fish plates are sometimes used to lengthen the members of a roof construction. These joints require more work to make and they are not necessarily better than the ordinary fish joint. They are used only if extra strength is required.

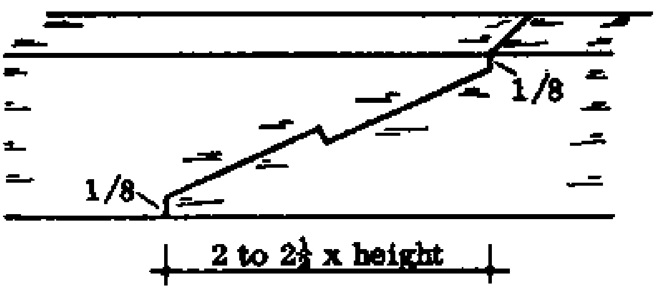
These joints are:



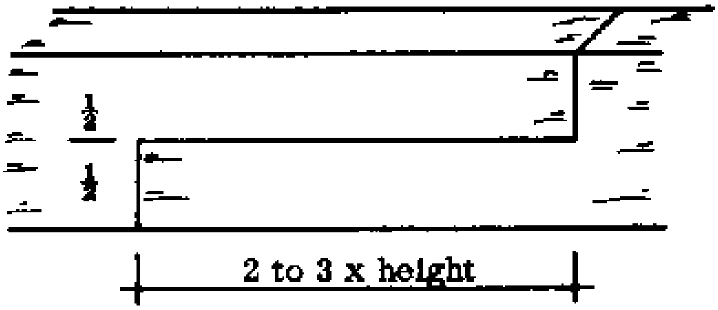
1. COMMON SCARF



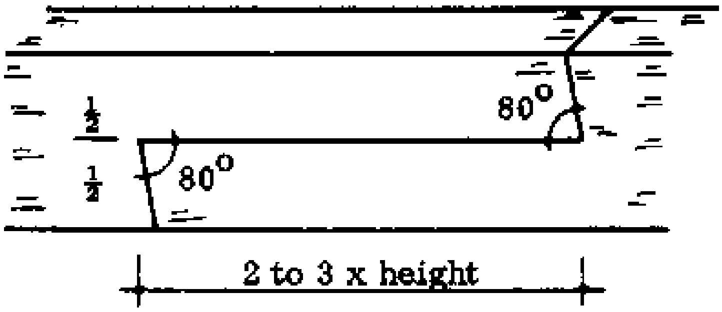
2. STOPPED SCARF



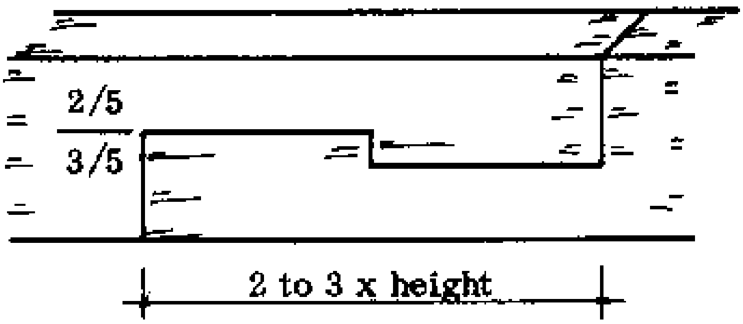
3. STOPPED HOCK SCARF



4. HALVING JOINT (if fish plates are used it is a "splice")

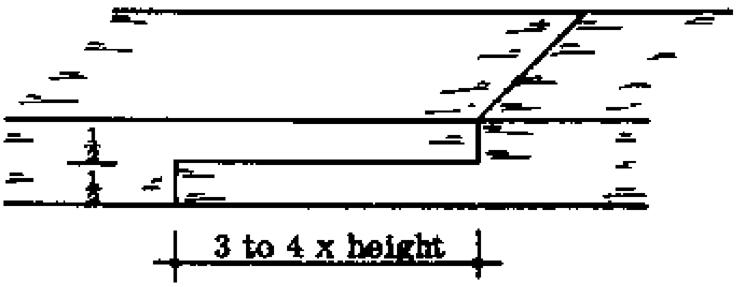


5. HALVING JOINT

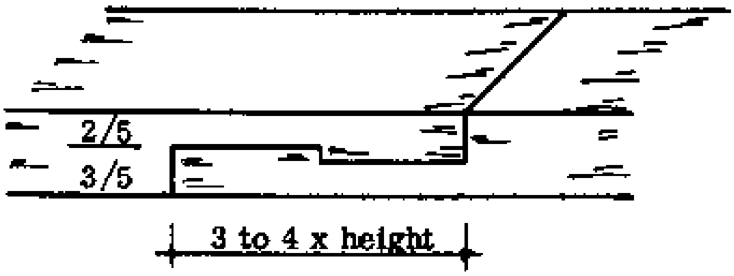


6. HOOK HALVING JOINT

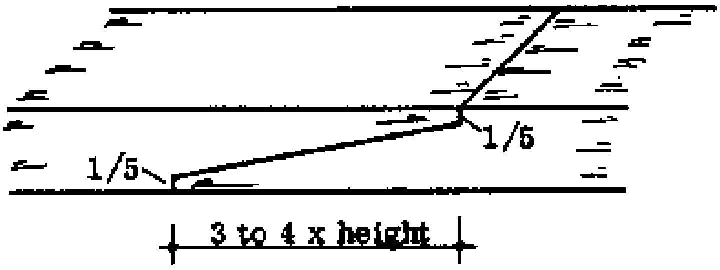
Joints 1-6 are normally used for joining rafters, tie beams or purlins in the length. They can be used with one or two fish plates.



7. HALVING JOINT



8. HOOK HALVING JOINT



9. STOPPED SCARF

Joints 7-9 are used mostly for Joining wall plates in the length. The corner joint for a wall plate can also be a halving joint.

CONSTRUCTION DETAILS

Lean-to roof

A lean-to roof is a sloping roof attached to the wall of another building. It is "leaning" against the building. It is usually used for a small store or similar building which is attached to an existing building. The main members are: (Fig. 1)

- the wall plate (a)	5 x 10 to 15 cm
- the rafters (b)	5 x 7,5 to 10 cm
- the purlins (c)	5 x 7,5 cm
- the fascia board (d)	2,5 x 20 to 30 cm
- the sheet material (e)	

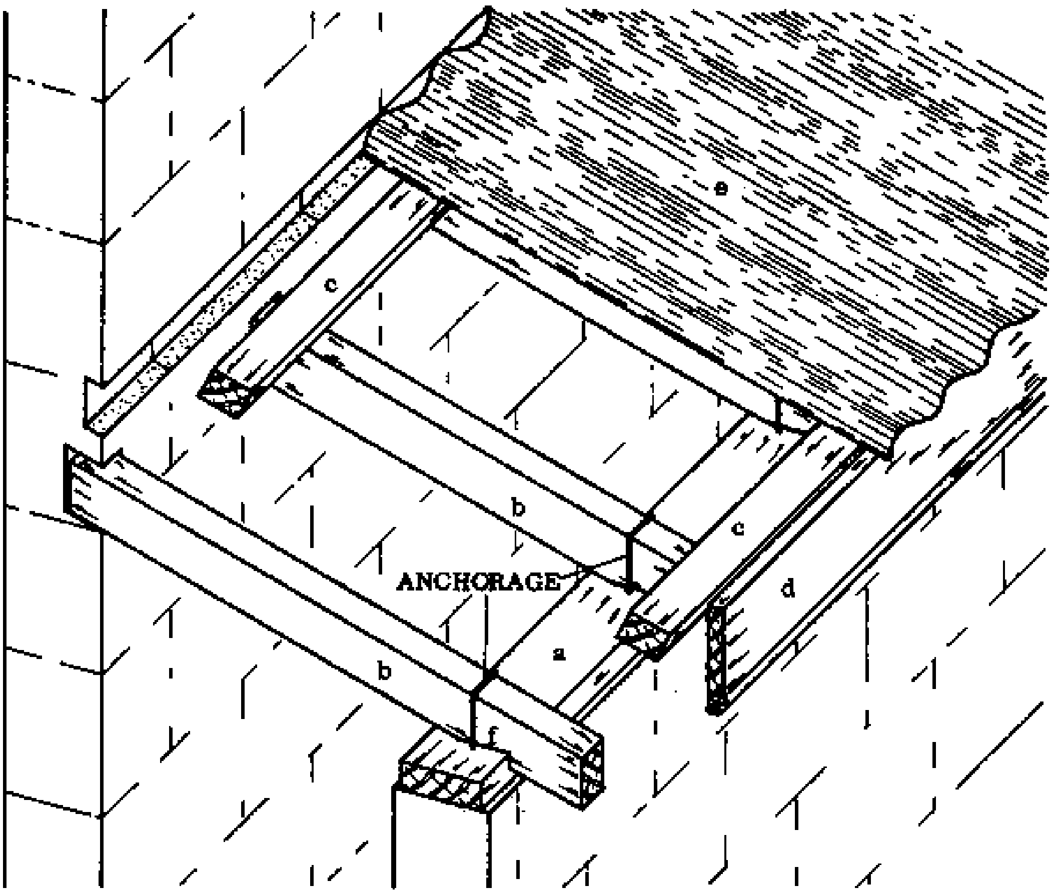


Fig. 1

The above measurements can be used as a guide in selecting timbers for this kind of roof.

Below are some rules for the construction.

- A good method for fixing rafters onto the main wall is to chisel holes in the wall into which the rafters can be fitted. The holes should be deep enough to ensure a safe rest for the rafters (Fig. 1).

- The lower part of the rafter should rest on a wall plate (a) or a concrete belt. The rafter and wall plate should be firmly anchored through at least 3 courses of blocks.

- The rafters should each be fitted with a “bird's mouth” near the end (f). The depth of the bird's mouth should be 1/5th of the width of the rafter. This is so that the rafters rest securely on the horizontal support.

- The purlins (c) should be well secured to the rafters.

- To prevent water from entering between the wall and the sheeting material, the part of the sheet which attaches to the main wall should fit into a recess in this wall, so that the ends of the sheets can be plastered over later (Fig. 1).

- In an open fronted structure, the roof is supported by pillars on the open side, instead of by a wall. The plate which rests on the pillars and supports the rafters is called the “eave plate” (Fig. 2, g). The size of the eave plate should be about 5 x 7,5 to 10 cm.

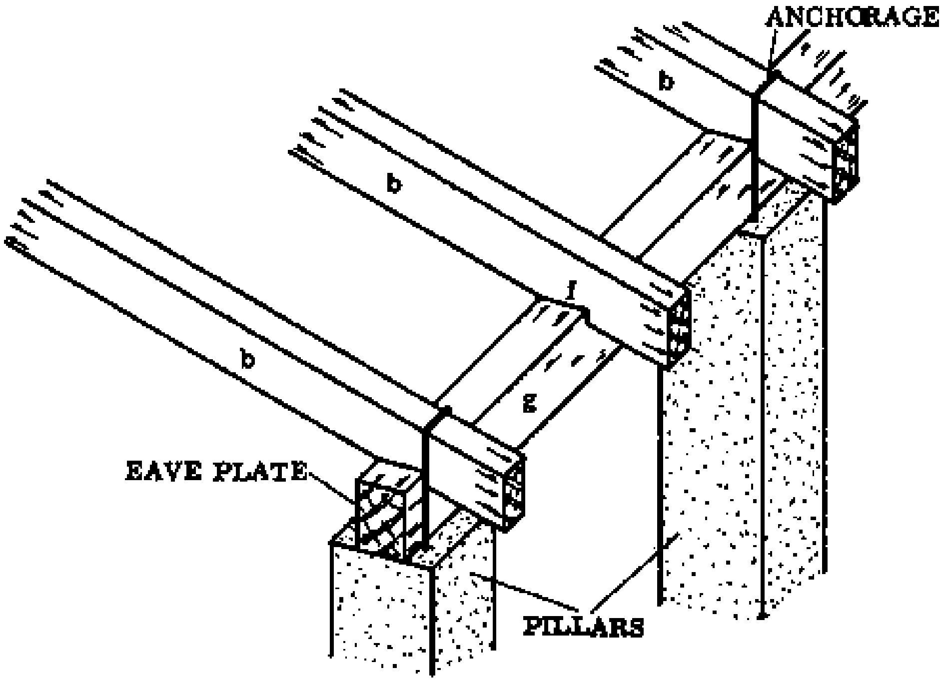

Fig. 2

- Remember that in an open construction the pillars must not only support the dead load of the roof construction, but also must be strongly anchored in the ground so they cannot be pulled out by a strong wind catching the roof from underneath.

- Note that in an open-fronted construction side walls are to be avoided. If they are required, there must be openings in them to permit wind to escape. A building with an open front should never face in the direction of the prevailing wind (the direction from which the wind usually comes).

NOTES:

Pent roof

A pent roof is a roof which slopes to one side. It differs from a lean-to roof in that it is not attached to the wall of another building, but is supported by its own walls.

In Rural Building, we deal with two types of pent roof: the ordinary pent roof and the enclosed or parapetted pent roof.

- ORDINARY PENT ROOF: In this roof, the rafters and purlins project beyond the outside walls and a fascia board is fixed all around the building. The pitch of this roof will usually be about 15 degrees. The main members are: (Fig. 1)

- the wall plate (a)	5 x 10 to 15 cm
- the rafters (b)	5 x 15 cm
- the purlins (c)	5 x 7,5 cm
- the fascia (d)	2,5 x 20 to 30 cm
- the sheet materials (e)	

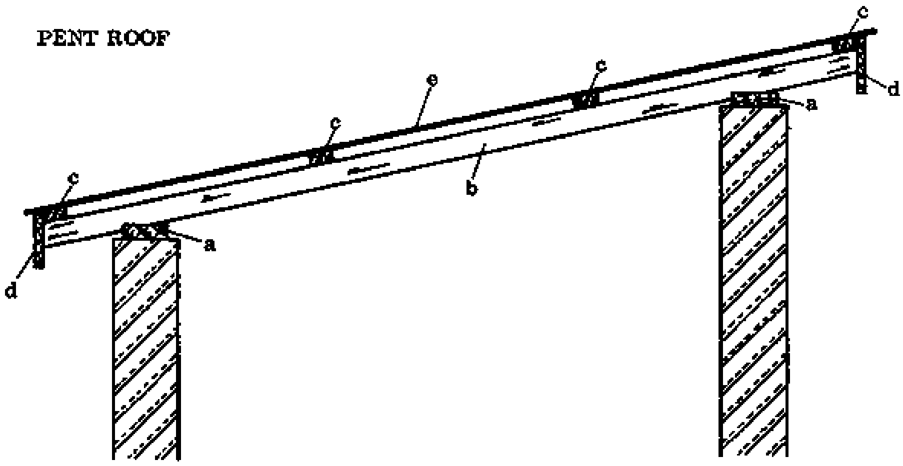

Fig. 1

The above timber measurements can be used as a guide in selecting the timbers for an ordinary pent roof; that is, a pent roof with a span of less than 3,5 m. The distance between rafters should be 1 to 2 m, and the distance between the purlins depends on the size of the sheet material.

There are certain rules for constructing this type of roof:

- The rafters should always be fitted with a bird's mouth so that they rest securely on the wall plate (Fig. 2).

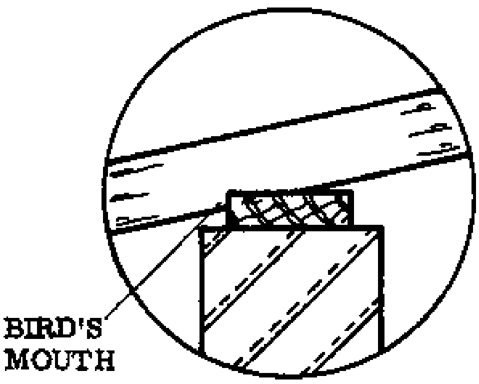

Fig. 2

- Wall plates, rafters, and purlins should be well anchored (see the section on anchorage which comes later in this book).

The pent roof is often used because it is cheaper to construct than other roofs, since only rafters and purlins are used, and no tie beam, braces, etc. are needed.

NOTES:

- ENCLOSED OR PARAPETTED PENT ROOF: In this roof, the higher wall and the two sloping walls enclose and protect three sides of the roof. The parts of the walls which project above roof level are called parapets. Parapets help to reduce suction on the roof and to keep the sheets in place. The pitch of this roof will be about 15 degrees (Fig. 1). The parts of the roof are:

- the wall plate or concrete belt (a)	
- the rafters (b)	5 x 7,5 cm
- the tie beam (c)	5 x 7,5 cm
- the braces (d)	2,5 x 7,5 cm
- the purlins (e)	5 x 7,5 cm
- the fascia (f)	2,5 x 20 to 30 cm
- the sheet material (g)	
- the parapet (h)	

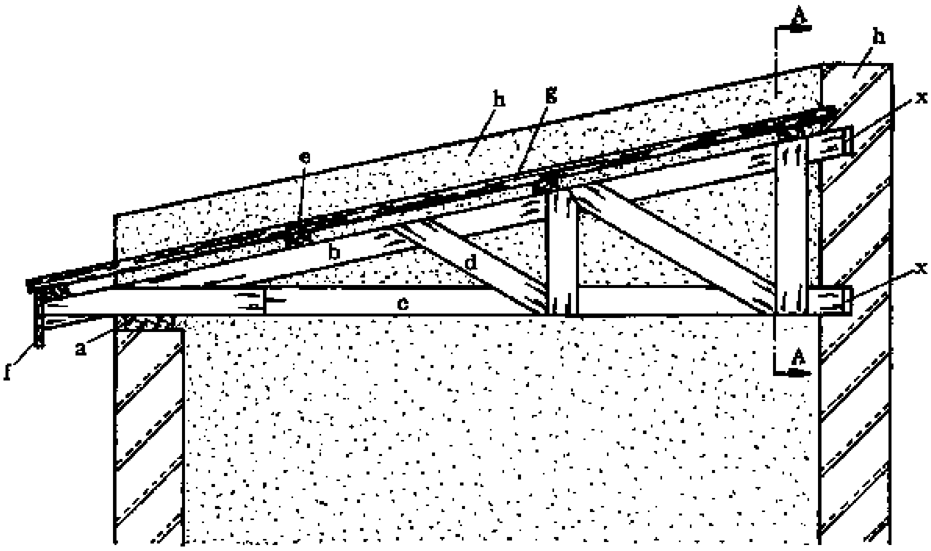

Fig. 1

The measurements above can be used as a guide for constructing this kind of roof. The distance between the rafters should be 1 to 2 m, and the distance between the purlins will depend on the size of the sheet material.

Keep in mind the following construction pointers:

- A built-up structure is used for this roof (a half truss). We will learn about how to make the truss in a later lesson.

- Before the half truss is erected, all the walls should be built to the level of the tie beam. The truss is then erected and the walling continued.

- There should be an expansion gap at the end of each rafter and tie beam (Fig. 1, x) where they fit into the wall; and at the ends of the purlins (Fig. 2, x). The gap prevents the wall from being cracked when the wooden member expands.

- The sheet material should be fixed so that about 1/3rd of a corrugation on each side of the roof is enclosed in the wall (Fig. 2). To keep water out, this edge should be pointing upwards (Fig. 2a).

- Leave about 10 cm space between the last truss and the wall so that there is enough space for plastering (Fig. 2, y).

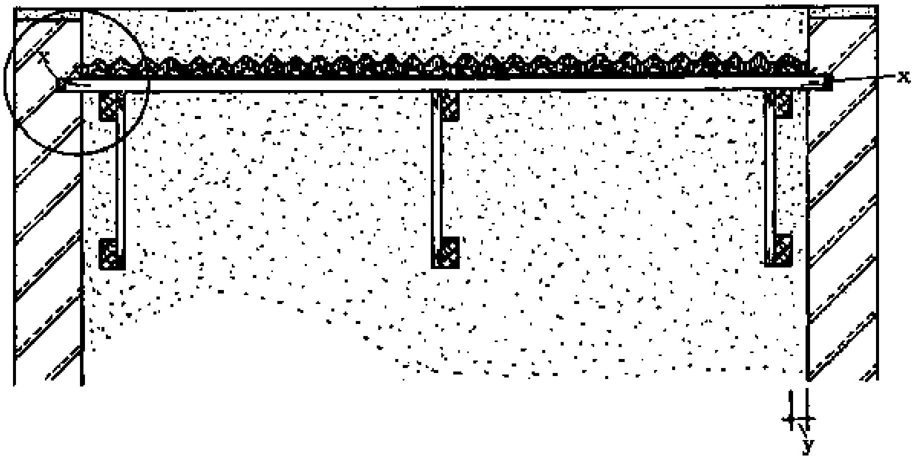

Fig. 2 CROSS SECTION A-A

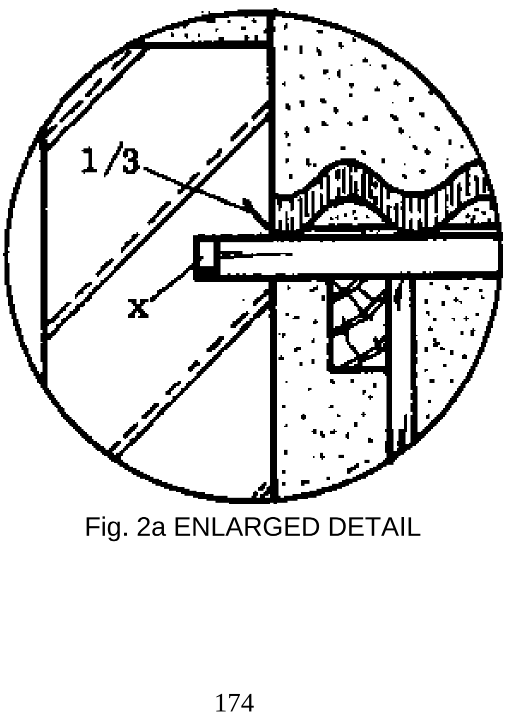

Fig. 2a ENLARGED DETAIL

NOTES:

Gable roof

This is a roof which slopes down on the two sides of the ridge and has a gable on one or two end walls. The gable is the triangular shaped part of the end wall where it comes up to the sloping edges of the roof.

The advantage of the gable roof over the pent roof is that it can be constructed to permit cross ventilation. It can be used for large or small spans.

In Rural Building, the kind of gable roof we make is constructed with built-up trusses. The main parts and members of the gable roof are (Fig. 1):

- the wall plate or concrete belt (a)
- the rafters (b) 5 x 7,5 cm
- the tie beam (c) 5 x 7,5 cm
- the braces (d) 2,5 x 7,5 cm
- the purlins (e) 5 x 7,5 cm
- the fascia (f) 2,5 x 20 to 30 cm
- the sheet materials (g)

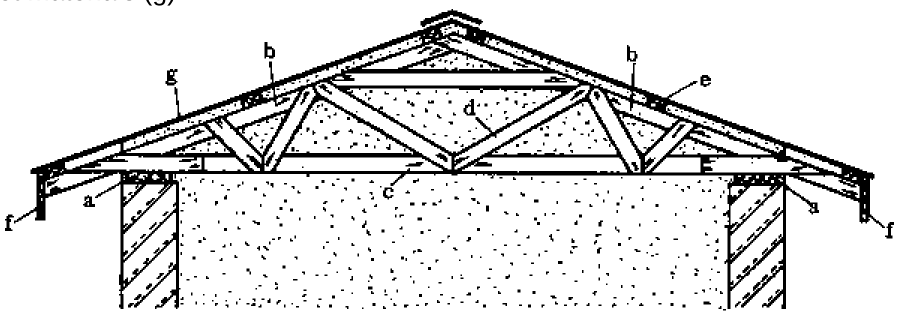

Fig. 1

The above measurements should be used as a guide when you make this type of roof. The distance between the trusses will be about 200 cm. The last truss should be close to the wall, except if parapets are used. In that case leave about 10 cm space for mortaring.

The gable ends can be constructed so that the purlins project beyond the gable and the fascia boards are nailed onto them. The end sheets should be nailed so that the last corrugation folds down over the top of the fascia.

Another way of constructing the gable is to put a parapet on top of the gable in the same way as for a parapetted pent roof. Again, the sheets should be enclosed in the parapet wall by about 1/3rd of a corrugation, with the edge pointed up.

The parapet can be on top of the gable wall only (Fig. 2), or the wall can project with the parapet beyond the ends of the sheets (Fig. 3).

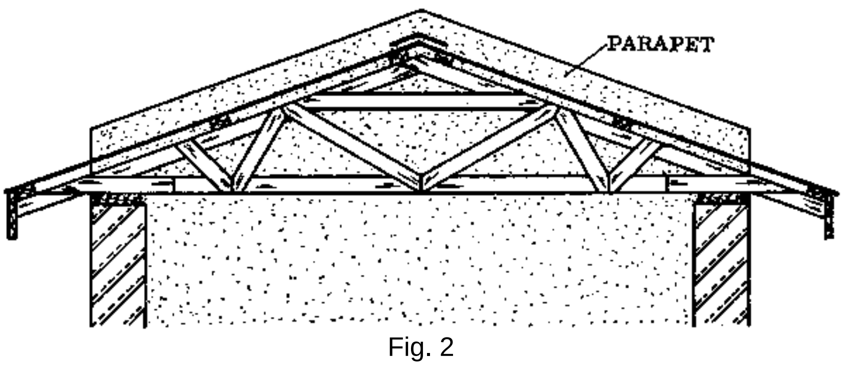

Fig. 2

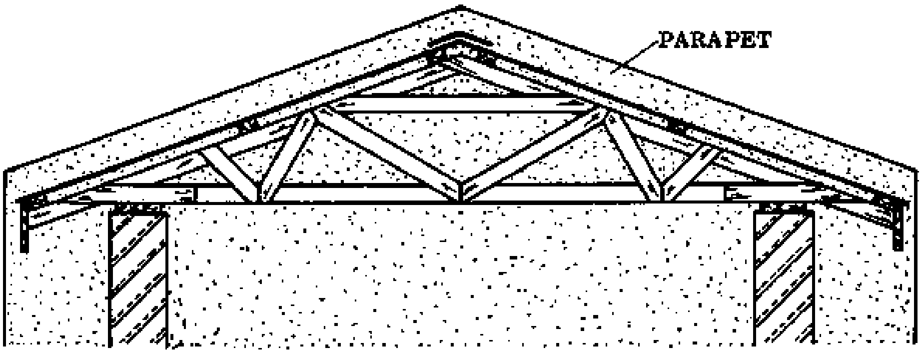

Fig. 3

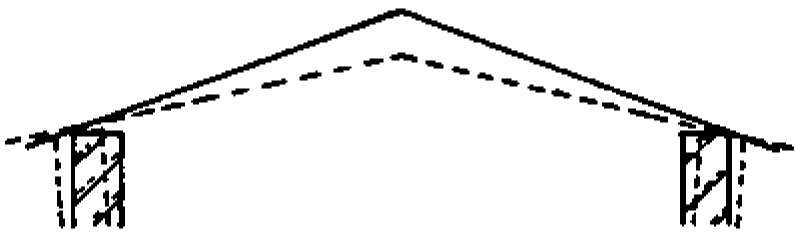
NOTES:

Designing built-up trusses

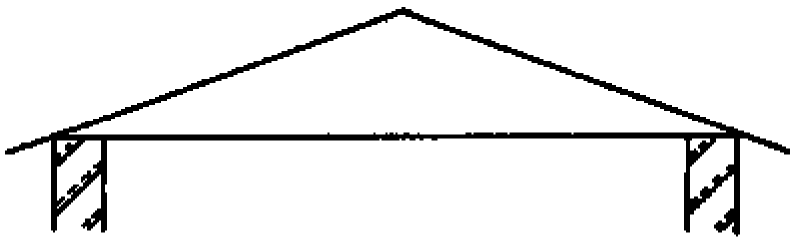
Built-up trusses are used in gable roofs to support the purlins and the roof covering.

In constructing these trusses, we must remember the principle of “perfect structures” (see Light-Weight Structures), otherwise the roof construction may get distorted.

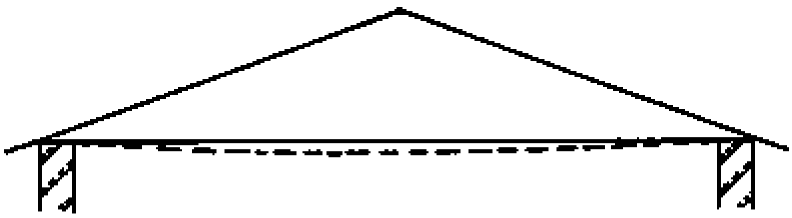
The following points will show why roof trusses are built up in the way they are.



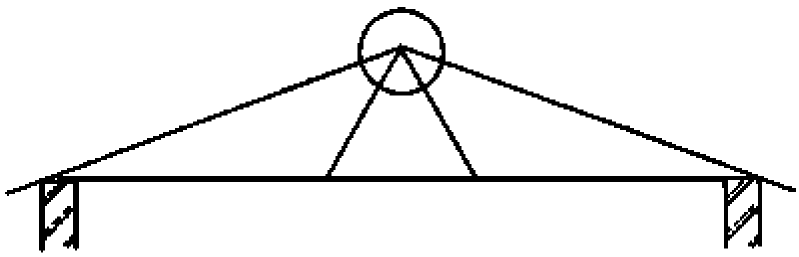
1. Figure 1 shows that a roof construction of only rafters tends to spread the walls. This is because the roof doesn't have a triangular shape, so it is not a perfect structure. This construction could cause damage to the walls, the roof, and the whole building.



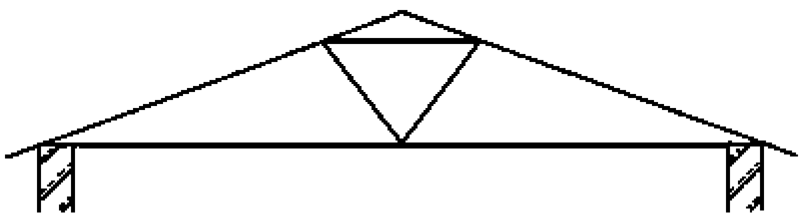
2. As we see in Fig. 2, as soon as a tie beam is introduced we get a triangular shaped, perfect roof structure.



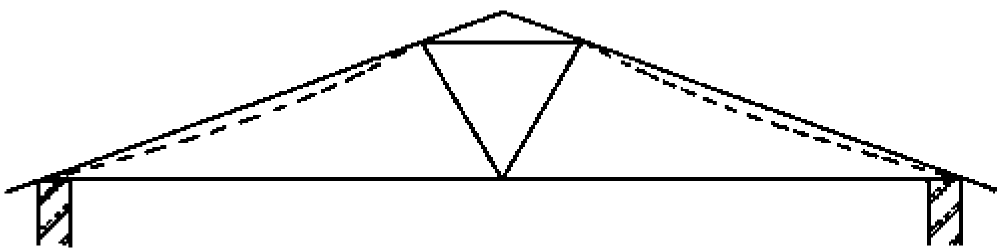
3. As the span of the roof increases the tie beam tends to sag.



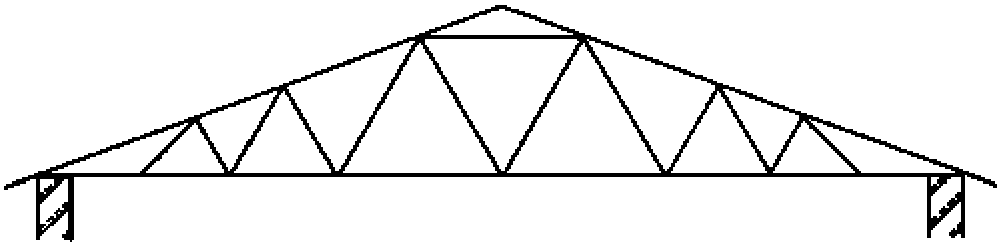
4. To prevent the sagging of the tie beam, braces are introduced. Because there are 4 members (2 rafters and 2 braces) that meet at the ridge, there is a danger of over-nailing the joint, which would weaken the truss. Therefore we need to find another way of fixing the braces while keeping a perfect structure.



5. This is a possible solution to prevent overnailing.



6. As the span increases still further the rafters will also be longer and they will tend to bend.



7. To prevent the rafters from bending, more braces are introduced.

Joints for the truss

At the ridge, two rafters must be joined together. This is done with a halving joint (Fig. 1).

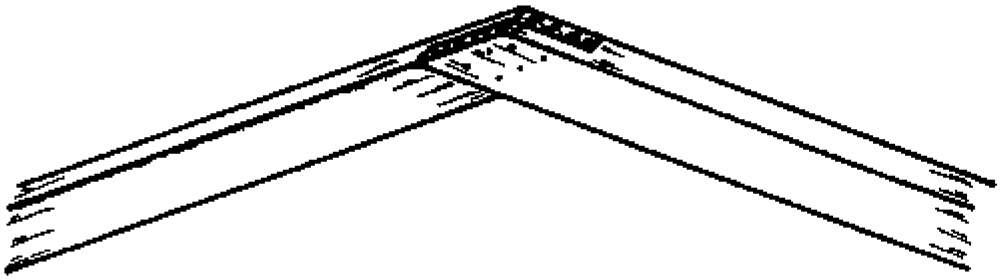


Fig. 1

The halving joint is assembled with a few long nails. They should be long enough that they can be clenched on the opposite side. Take care not to overnail the joint.

The rafter - tie beam joint can be a fish joint with two nailed fish plates (Fig. 2). After the fish plates are fixed, they must be cut so that they don't project past the edge of the rafter.

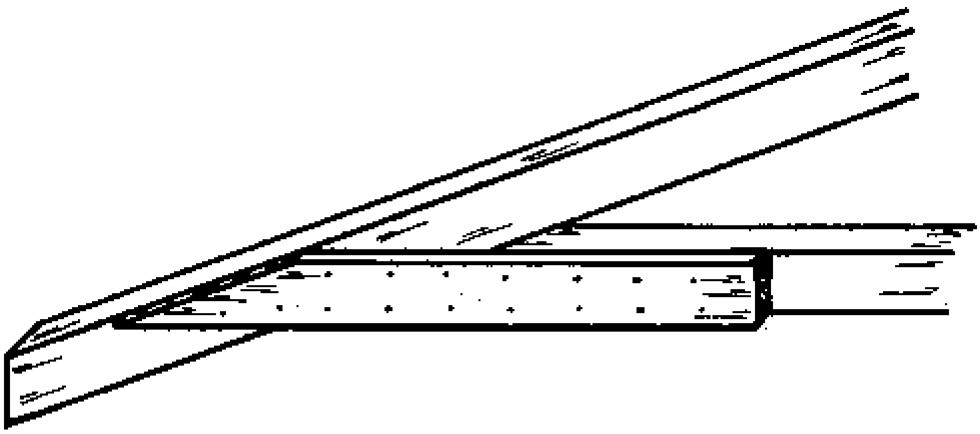

Fig. 2

If large trusses are made, short braces can be used to strengthen the joint instead of fish plates (Fig. 3).

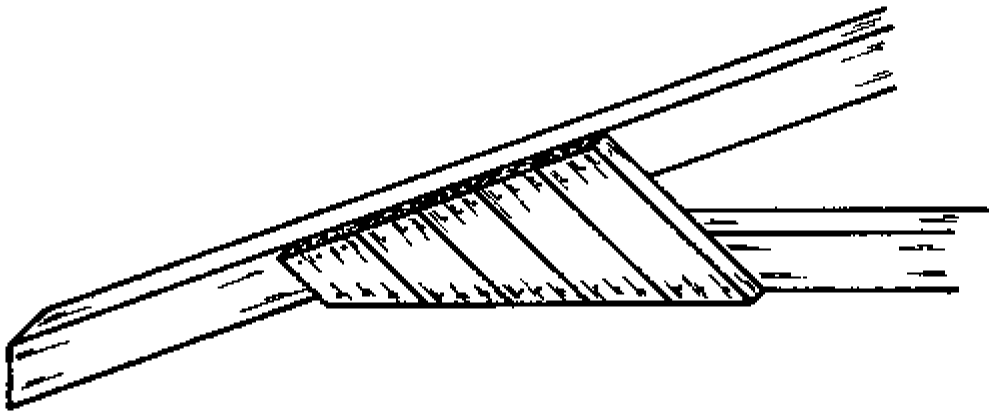

Fig. 3

The braces are added according to the required pattern of the truss. At the place where the two braces meet, they should be cut so that the areas where they are nailed to the truss (areas a and b) are as large as possible and of equal size on both braces (Fig. 4).

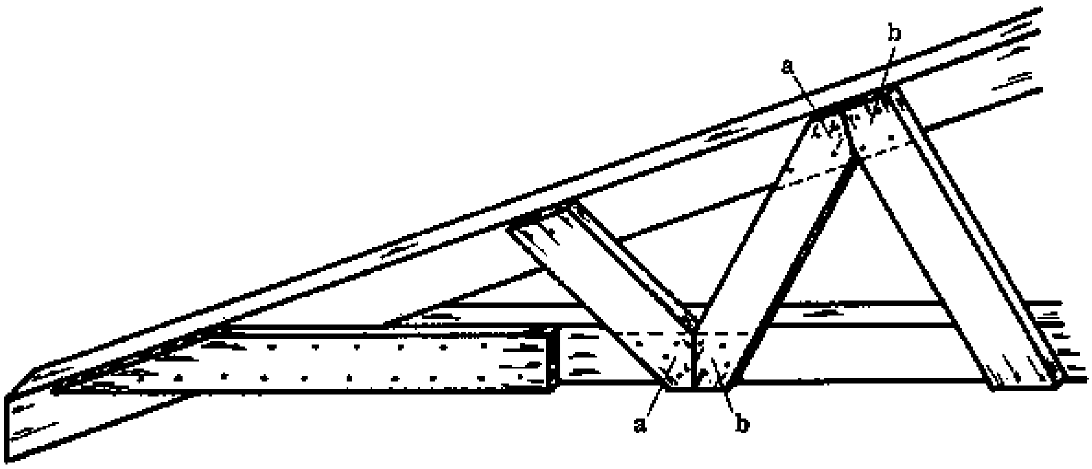

Fig. 4

This is done by placing them on top of each other, marking and cutting during the assembly of the truss.

All of these reinforcements can be added on either one or both sides of the truss, depending on the strength that is needed for the construction.

NOTES:

Marking out built-up trusses

Before you start to mark out the trusses, measure the span of the building at several points and find out the span of the truss. Make sure that the truss is long enough to cross even the widest span of the building.

Do not forget the difference between the span of the building and the span of the truss. You must take into account any verandahs or overhangs in the span of the truss. The outline design will help you to find out the different spans for the building and the truss.

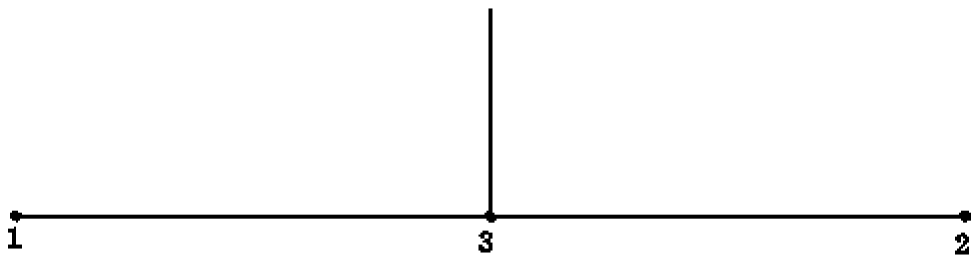
The marking out is done in a cleared, flat area of the building site. After the area is cleared, the shape of the trusses is laid out with iron pins knocked in the ground and with the mason line.

- SEQUENCE OF OPERATIONS:

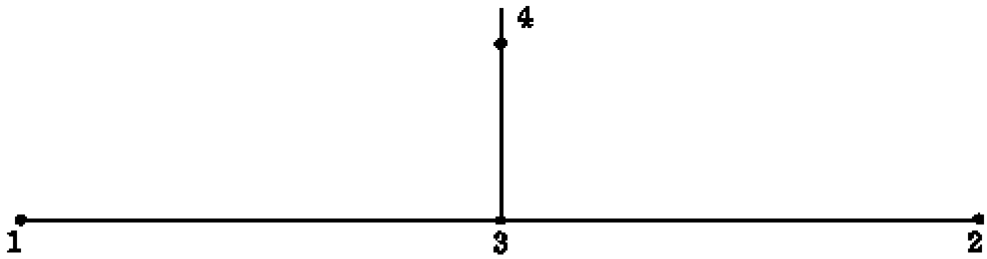
a. Place pegs 1 and 2 at a distance equal to the span of the truss, and stretch a line between them.

b. Divide the distance from point 1 to point 2 in half, and mark point 3.

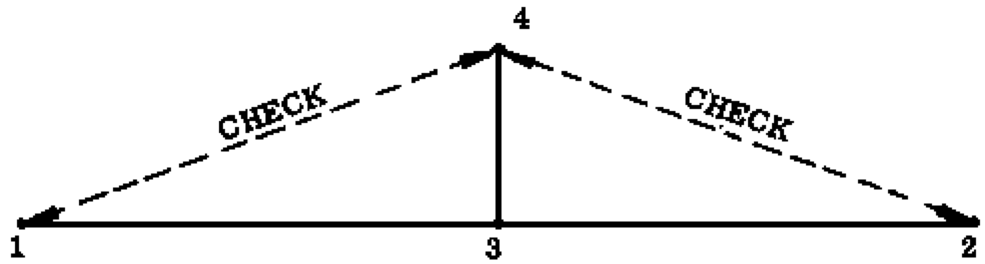
c. From point 3, erect a line perpendicular to line 1-2 (use a large square or the 3-4-5 method).



d. Place peg 4 along the line from point 3, at the distance of the required rise of the truss.



e. Check that the distances 1-4 and 2-4 are equal.



f. Check that the roofing sheets will fit as planned, including a sufficient over lap. Check this by measuring from peg 1 to peg 4, then add the overhang and the projection of the fascia board.

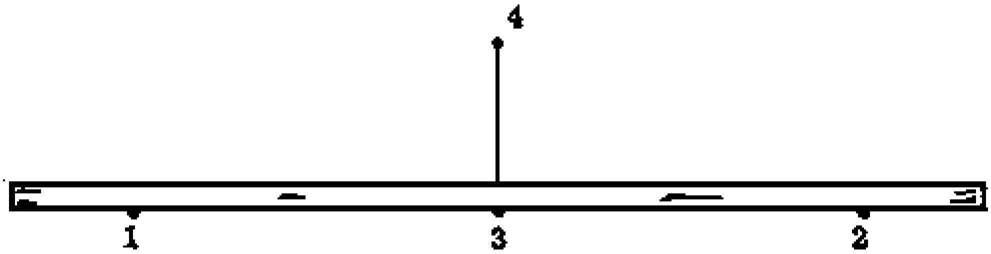
NOTES:

Assembly of built-up trusses

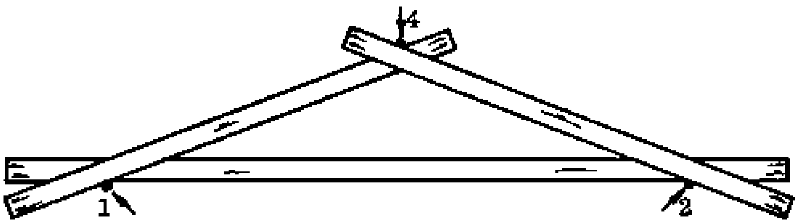
Before you assemble the truss select the timbers, measure them against the setting out, and if necessary join pieces to get members with the required lengths (see Lengthening Joints, pages 169 to 173).

- SEQUENCE OF OPERATIONS:

a. Lay the tie beam along the line from peg 1 to peg 2.

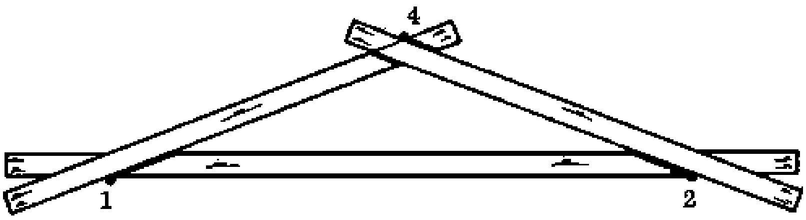


b. Place the two rafters between pegs 1 and 4; and between pegs 2 and 4. Note the positions of pegs 1, 2 and 4 with respect to the boards. This is very important. Rafters should be slightly longer than needed. This allowance is cut off after the trusses are erected.

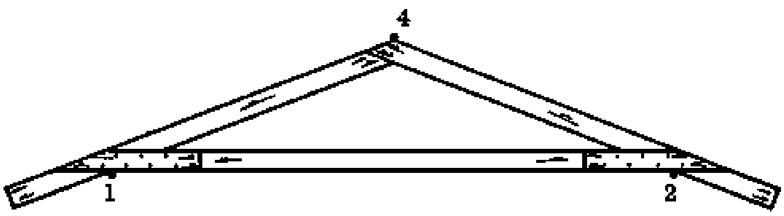


c. Mark the halving joint on the rafters at the ridge and cut it.

d. Mark the cutting lines on the tie beam and cut the ends.

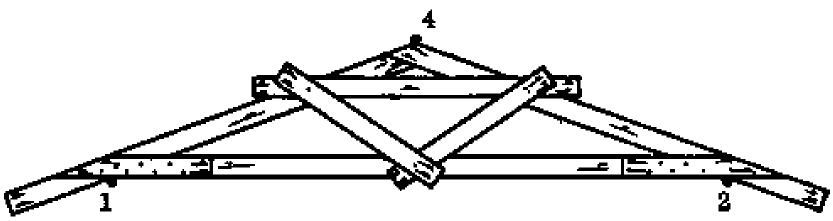


e. Assemble the ridge joint with a few nails; and the rafter to tie beam joint with fish plates.



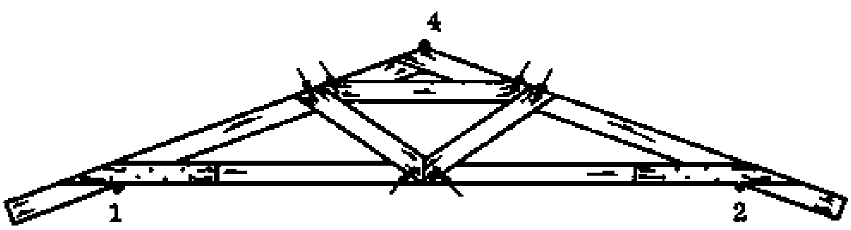
f. Mark the positions of the braces according to the plan, on the rafters and tie beam.

g. Lay the braces one over another on top of the tie beam and rafters. Use a single nail to fix them temporarily.



h. Cut the braces to the correct shape, keeping in mind that the size of the area where each is nailed to the truss must be the same for all of them (arrows).

i. Fix the braces with nails.



j. After the braces are fixed, if necessary a second fish plate can be fixed on the other side of the rafter-tie beam joint. Turn the truss over and fix this plate. Sometimes it is also necessary to fix braces on both sides.

k. Mark the positions of the purlins on the rafters. This will make work easier later on.

l. The other trusses can be assembled on top of the finished first truss.

- NOTE: Always use dovetail nailing, throughout the truss.

NOTES:

Erecting a roof structure for a gable roof

As soon as the trusses are finished, the roof can be erected. If wood preservatives are used they should be applied before the truss is erected. Creosote is often used as a preservative for trusses. If the roof will not be erected immediately, keep the trusses dry and in a shady place.

- SEQUENCE OF OPERATIONS:

a. Hang a truss upside-down across the span of the building, at each gable end (Fig. 1).

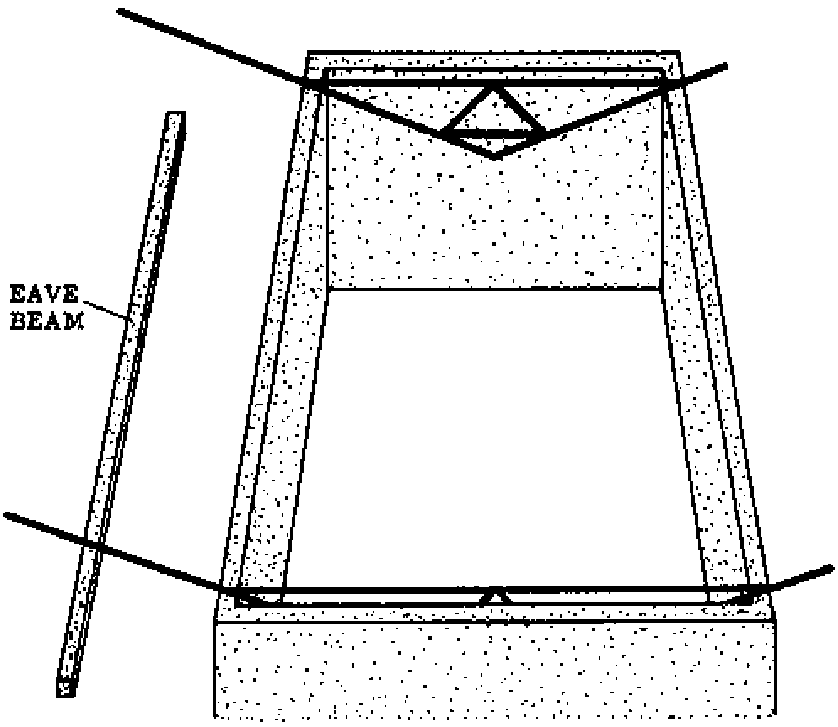


Fig. 1

b. Turn the trusses over and plumb them (Fig. 2).

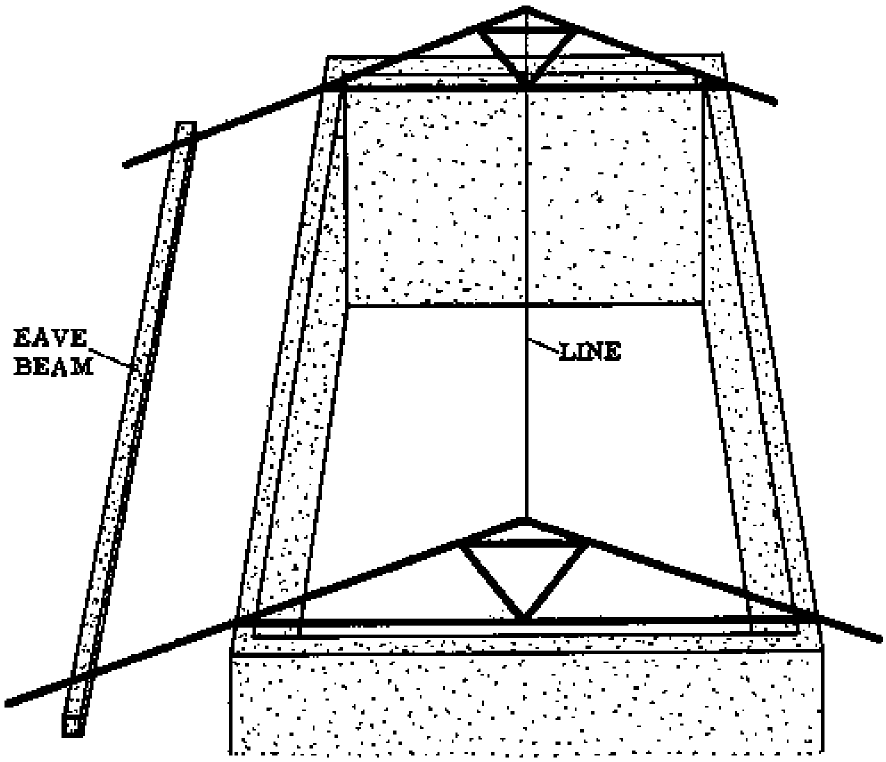

Fig. 2

c. Secure the trusses at the bottom with anchor rods and brace them temporarily from the rafter to the wall plate.

d. Fix a line from one ridge to the other (Fig. 2).

e. Hang the other trusses, one after the other, upside-down between the walls. Turn each one over and plumb it according to the line before hanging the next one. Brace them temporarily.

f. Nail the purlins according to the measurements of the roof covering (the sheets) and secure them (a section on Anchorage is included later in this book). If the rafters overhang to cover a verandah, make sure that the eave plate is also well secured.

g. Fix a line at the bottom end of the rafters, on the gable ends of the roof, at the level of the required overhang. Cut off the ends of the rafters according to the line.

h. Cut off the purlins to the correct length.

i. Build up the gables.

j. Nail the fascia boards on the purlins and rafter ends.

Once the roof structure is erected, cover it as soon as possible to keep out the sun and rain; otherwise the wood may start to twist and the joints will loosen. If the trusses rest on a concrete belt, put roofing felt between the concrete belt and the tie beam to help prevent dampness.

NOTES:

Purlins

The function of the purlins is to support the roofing sheets and to stiffen the whole roof structure. They are supported by the trusses and sometimes the gable ends. The lengthening joints for purlins can be fish joints.

The size of the purlins should be 5 by 7,5 cm.

The lowest purlin of the construction is called the eave purlin (Fig. 1). The highest one is called the ridge purlin.

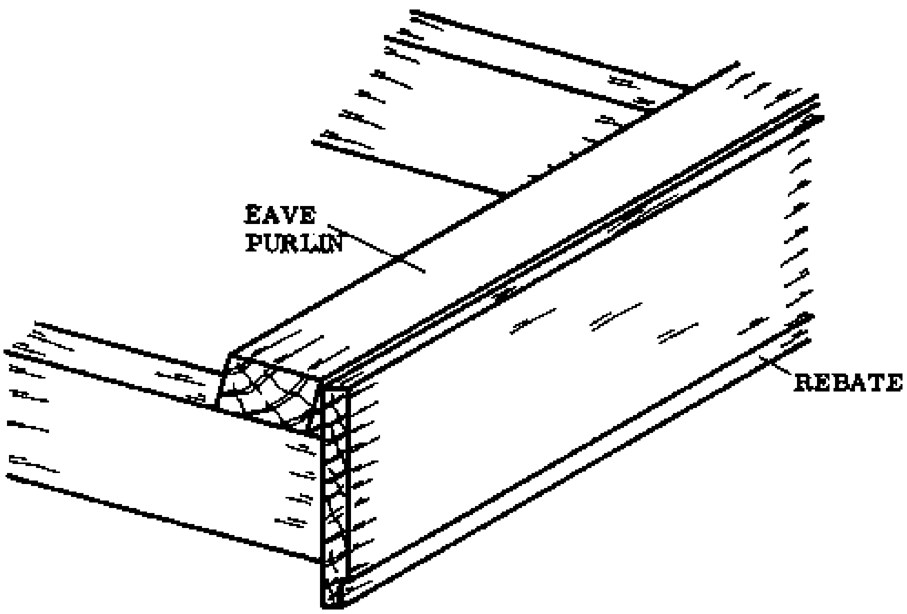

Fig. 1

To make a wider area for nailing the sheets, lay the purlins flat on the rafters. If larger distances must be bridged, lay the purlins on edge. This reduces the nailing area, but it prevents the purlins from sagging.

The distance between the purlins depends on the size and type of sheets which are used for the roof covering. If thick sheets with the normal 244 cm length are used, then one purlin at each end of the sheet plus one in the middle will be sufficient. For very thin sheets one extra purlin should be added for each sheet.

If the building will require more than 2 sheets to cover the length of the rafter, be careful that the purlins are set at the correct distance apart.

It makes work much easier if you mark the positions of the purlins on the rafters as you assemble the trusses.

Fascia boards

Fascia boards are often added to the roof construction. They are wide boards which are fixed on the rafter ends and the purlin ends at the gables of the roof construction.

Fascia boards are about 20 to 30 cm wide and 2,5 cm thick. A small rebate can be made into the lower edge of the board to give it a better appearance (Fig. 1).

If the rafter projects below the fascia it can be cut off as shown in Fig. 2.

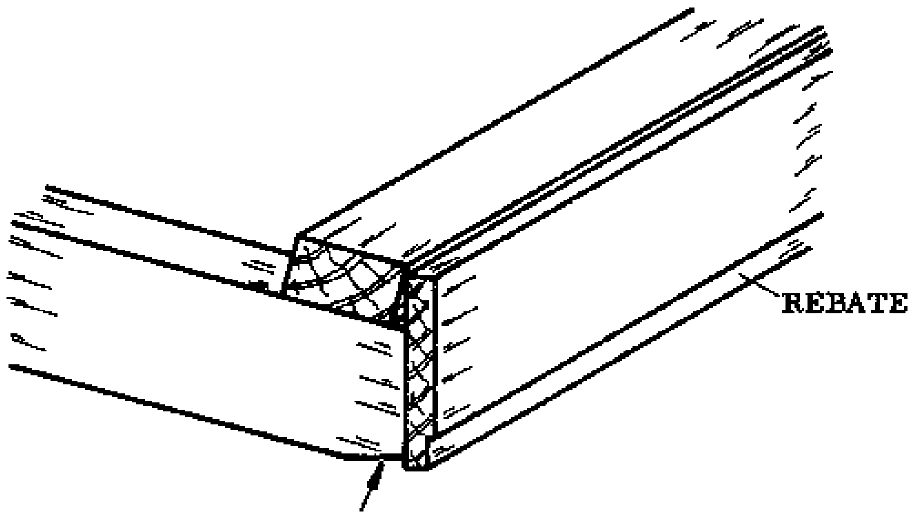

Fig. 2

The eave purlin should be at the correct height so that it does not interfere with the fascia. The fascia boards are fixed before the sheets are laid.

A butt joint is sufficiently strong to use for lengthening the fascia boards, if a fish plate is nailed behind it for strength (Fig. 3). The corner joints should all be mitre joints so that the end grain of the boards is not exposed (Fig. 4).

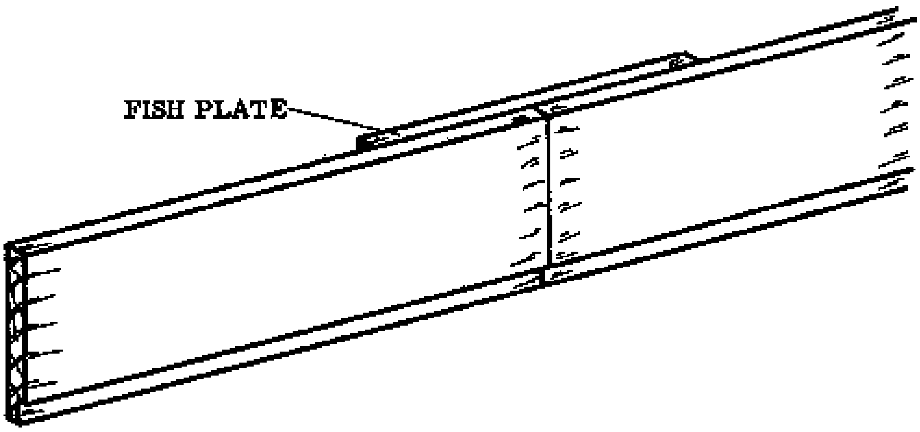

Fig. 3

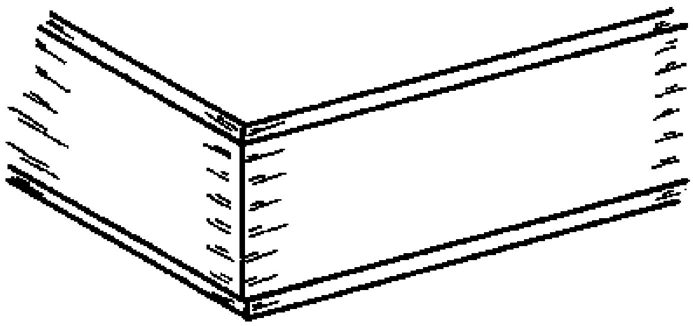

Fig. 4

Before the boards are fixed they should be painted, since it will be difficult to reach some parts later, especially the top edge. Pay special attention to the places where they are joined together. The end grain should be soaked with paint to prevent water from entering there.

Verandahs

When a building with a gable or pent roof has a verandah, there are two possible methods for constructing a roof to cover it:

- By extending the tie beams to cover the verandah (Fig. 1)

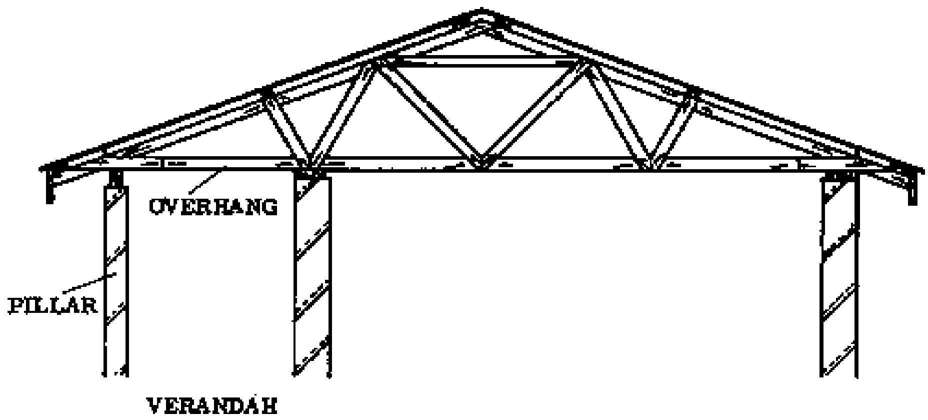

Fig. 1 EXTENDING THE TIE BEAMS

- By extending the rafters to cover the verandah (Fig. 2).

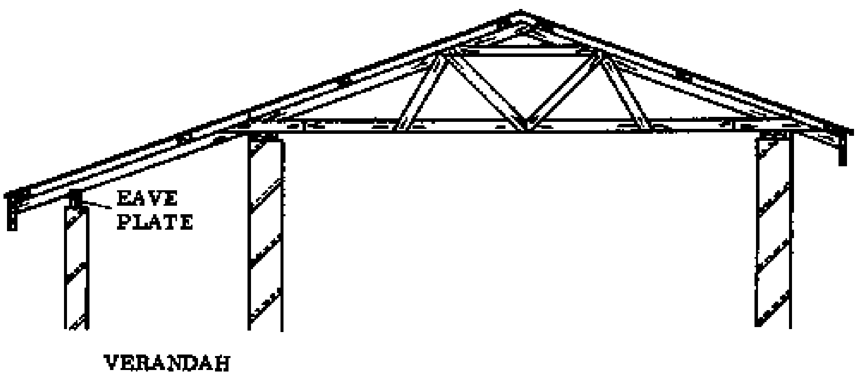

Fig. 2 EXTENDING THE RAFTERS

- REMEMBER: Open verandahs should not face the direction of the strongest winds.

- EXTENDING THE TIE BEAMS: The part of the tie beam that covers the verandah is called the overhang (Fig. 1). For a small overhang, supporting pillars are not necessary, but it should be braced very well. If the overhang is wide, then pillars are needed to support it (Fig. 1).

If the building has a gable roof, an ordinary truss construction can be used, with the span of the truss including the width of the verandah.

Since the parapetted pent roof has a half truss construction with a tie beam, this construction may also be used with it.

- EXTENDING THE RAFTERS: The overhanging rafters cover the verandah. Note that the building must be high enough so that the lower edge of the verandah is not inconveniently low (Fig. 2). This construction can be used with either an ordinary pent roof or a parapetted pent roof as well as with a gable roof.

The feet of the rafters are supported by an eave plate or a concrete eave beam which rests on pillars. The joint between the rafters and the eave plate should be a bird's mouth to ensure proper support for the rafters. The depth of the bird's mouth should be about 1/5th of the width of the rafter.

The eave plate is normally set edgewise on the pillars. In most cases 5 x 10 Odum is large enough for the eave plate. Take care that it is well anchored on the pillars.

There are certain lengthening joints which are often used for joining eave plates. These are described in the chapter on “Lengthening Joints”.

The pillars themselves have to be well anchored in the ground, since they not only have to carry the weight of the structure but also have to hold the roof down in heavy storms (see Lean-to Roofs).

At times the builder may choose to construct the verandah roof using a combination of projecting rafters and projecting tie beams.

Anchorage

Whatever the form of the roof construction, it must be tied securely to its supporting walls or pillars. If this is neglected, the roof can easily be damaged or even torn off in strong winds.

The following are some points which are important in anchoring a roof.

- ANCHORAGE RODS: The roof is secured to the walls by these iron rods. They can be fixed in the wall during the wall construction if the positions of the trusses have been decided, or else they can be fixed in the finished wall.

- In the first method, the rod is inserted in the bed joint as the third course be low the top of the wall is laid. The rod is bent at a right angle so it can fit into the cross joint (Fig. 1); and it is positioned just inside the face of the wall.

When the next course is laid, the block above is chiselled out to make a shallow groove (approximately 1 cm deep) for the rod (Fig. 1).

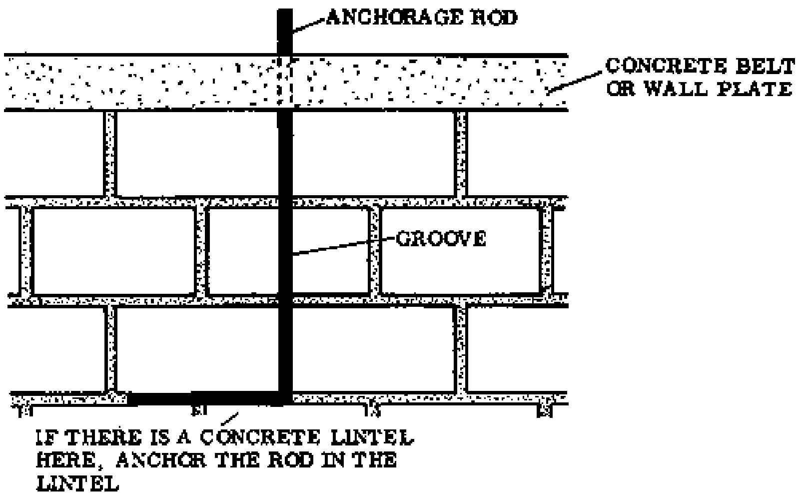

Fig. 1

The rod fits into the next cross joint and is bent gradually inwards toward the top centre of the wall, coming out where it can pass later through the wallplate or concrete belt (Figs. 1 & 2).

When the truss is erected, the rod is bent around the rafter and tie beam both, and secured with nails (Fig. 2).

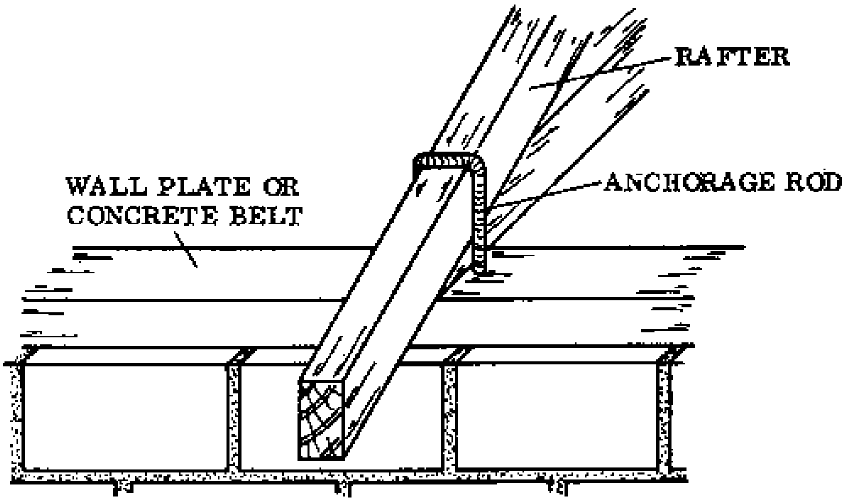

Fig. 2

- With the second method, the rod is inserted through a hole chiselled in the bed joint of the third course from the top, after the wall is complete. The ends of the rod are bent up and over the tie beam and rafter, overlap each other, and are secured on both sides with nails (Fig. 3).

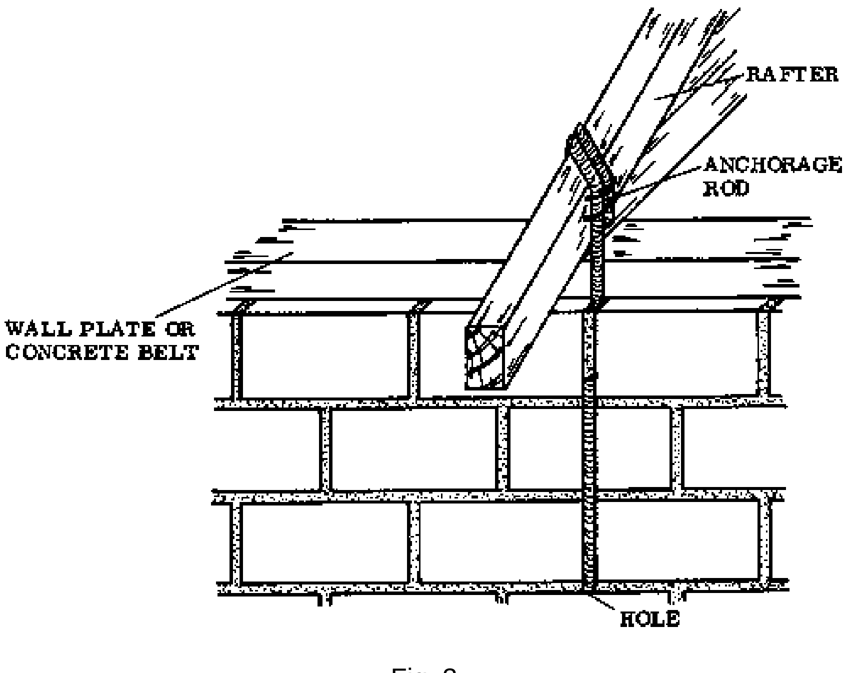

Fig. 3

The second method is chiefly used when the roof of an existing building has to be secured. If you are constructing a whole new building, it is best to plan ahead a bit and use the first method, which is both easier and stronger.

- ANCHOR BEAM: Once the wall is completed, the top of the wall may be covered with a strip of reinforced concrete all around the outside walls of the building. This is the anchor beam, also known as the ring beam or concrete belt. The roof anchorage passes through this belt. The anchor beam performs three functions:

- It keeps the outside walls of the house together, thus strengthening them.

- It provides a firm base for the trusses and distributes their weight over the softer landcrete blocks below.

- It anchors the trusses and adds weight to help keep the roof construction from being lifted up in heavy winds.

- WALL PLATE: For smaller spans the Rural Builder can install a wooden wall plate instead of an anchor beam. The roof anchorage passes through the wall plate and through at least three courses of blocks.

There are several joints that may be used to connect pieces lengthwise to make the wall plate (see Lengthening Joints, page 173). The wall plate should be about 5 cm thick by 15 cm wide.

- TRUSSES: The trusses should be evenly spaced across the roof, with one at each gable end and the rest about 2 m apart from each other. Every truss should be anchored to both the walls that it rests upon. The anchorage rod is bent around both the tie beam and the rafter, and secured with nails (Fig. 2, previous page).

- PURLINS: Tie all the purlins to every rafter, preferably with iron rods. These are shaped as shown in Fig. 1, by hammering the rod flat on both ends and drilling holes in the ends, then bending the rod to a U-shape.

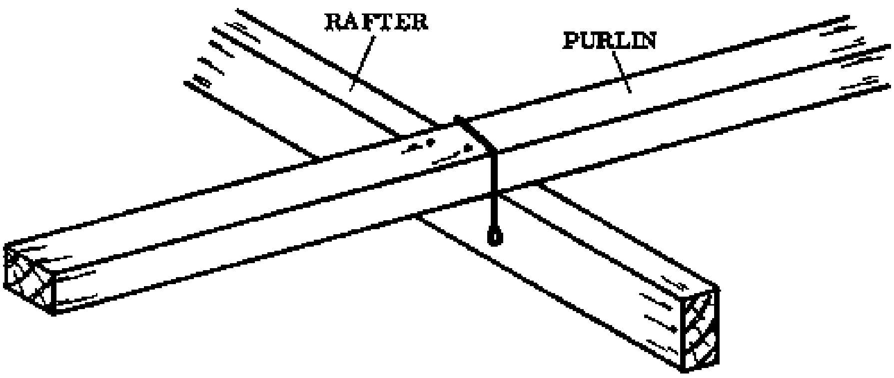

Fig. 1

If these fixings can't be made, it is possible to make wooden fixings (Fig. 2). Two wooden pieces are used, one on either side of the purlin.

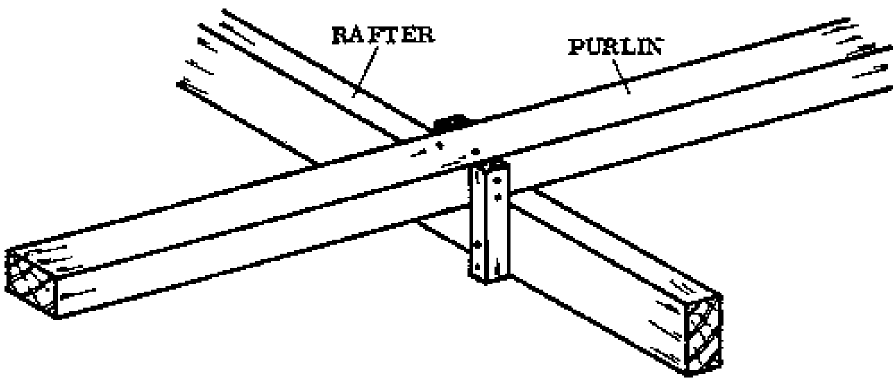

Fig. 2

Barbed wire can also be used as an alternative to the iron rods. Wrap it firmly around and nail it securely.

Whatever fixing you use, take care to fix the nails so they are not pulled out by the force of the wind on the roof. Fig. 3 shows two badly nailed fixings.

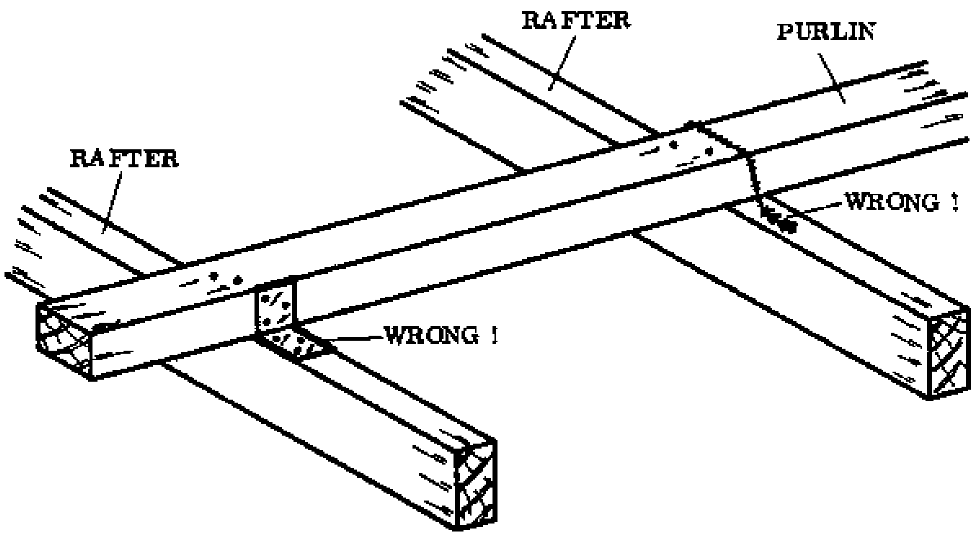

Fig. 3

NOTES:

ROOF COVERING

See the Reference Book, pages 207, 230 and 231 for descriptions of the sheet materials and roofing accessories; also see pages 239 and 240, Tables of Figures.

Alignment of the sheets

If possible, always start laying the sheets from one end of the roof so that the free ends of the sheets face away from the direction of the wind. This reduces the danger of the sheets being blown away as they are being installed.

Start laying from one end of the building to the other. As each new sheet is laid, lift the edge of the previous one so that it overlaps the new sheet by 2 corrugations. Each sheet is thus held in position by the one previously fixed, so they are more easily aligned in the correct position.

Exact sidelaps (2 corrugations) and endlaps (15 cm) are essential to make the roof waterproof.

- NAILING: When you nail corrugated roofing sheets to purlins, always nail through the top of the corrugation. This is so that rain will tend to run away from the nail (Fig. 1).

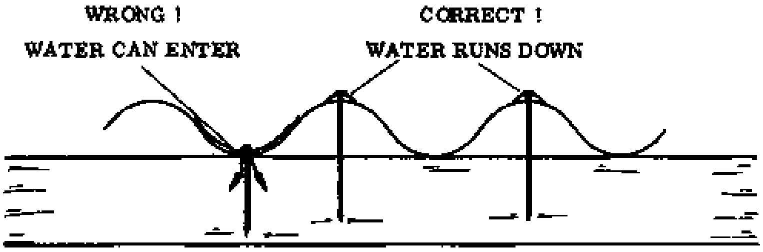

Fig. 1

Each nail should be driven in until the roofing felt just touches the sheet. If it is driven further, the nail will flatten the corrugation and distort the sheet. This can cause the roof to leak.

The sheets should be nailed to all the purlins. Nail every second corrugation in the sheets along the eave purlin and along the ridge purlin; and also on the end sheets at the gables. Over the rest of the roof, nail at every third corrugation over the purlins (Fig. 2).

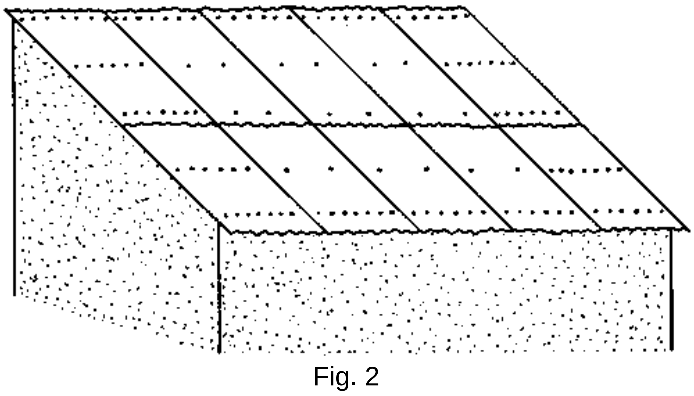

Fig. 2

- HOW TO LAY THE SHEETS: Before the sheets can be laid, the gables must be built up to the correct height. Make sure that all the nail heads of the wooden construction are punched well below the surface.

Fix a line on the eave to indicate the desired projection of the sheets. Note that the sheets should project about 2 cm over the fascia board in order to provide a drip overhang.

It helps to station a helper at eave level to observe if the general line of the sheets is straight and that they project uniformly. Another helper can check that the sheets are straight along the corrugations from the eave to the ridge.

The helpers can also check from both sides of the roof to see if the corrugations match at the ridge line (Fig. 1).

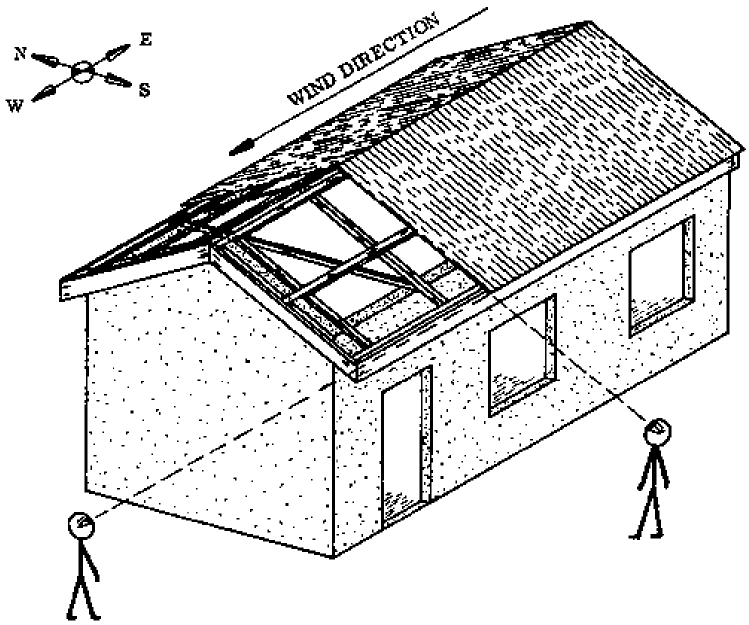

Fig. 1

For nailing the sheets it is best to have one man at each purlin.

- SEQUENCE OF OPERATIONS: In order to join the overlaps correctly, follow this sequence, starting from the end of the roof which is in the direction where the strongest winds are coming from (here it is the east) (Fig. 1).

  a. Place sheets 1 and 2 loosely along the gable end, with sheet 2 overlapping sheet 1 by 15 cm in the length (Fig. 2).

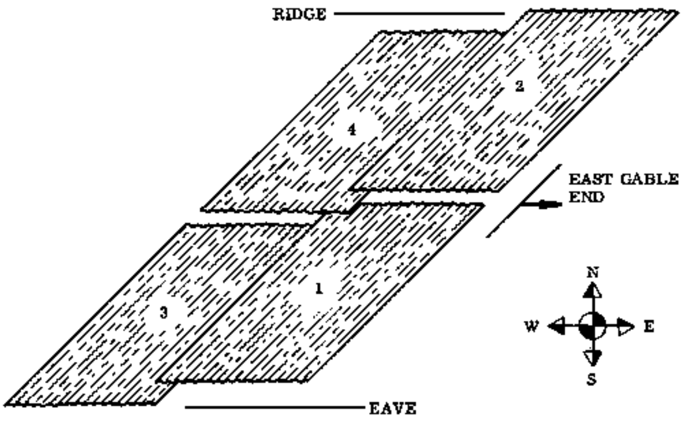

Fig. 2

b. Align them with the help of the two observers on the ground.

c. Secure the sheets with one nail in the middle. One man should do the securing, or the sheets might shift because of the shocks of the hammer blows.

d. Have the observers check that the sheets are still straight in both directions.

e. Nail the sheets home with all of the required nails except the nails at the edges where the next sheet will be fixed under.

f. Place sheet 3, lifting up the edge of sheet 1 until it overlaps sheet 3 by two corrugations (Fig. 2).

g. Place sheet 4, lifting sheet 2 until it overlaps sheet 4 by two corrugations. Sheet 4 should overlap sheet 3 in the length by 15 cm (Fig. 2).

h. Align sheets 3 and 4 with the help of the two observers on the ground.

i. Secure the sheets with one nail each at the centre.

j. Recheck the straightness in two directions.

k. Nail the sheets home with all the required nails except the ones at the edge where the next sheet fits.

l. Continue with this sequence until the whole roof is covered.

m. Proceed to build the parapets if they are required.

If no parapets are made, the last corrugation at the gable ends can be lapped over the fascia board, turned down and nailed onto the face of the fascia. Place the nails at intervals of about 10 cm.

- NOTE: In northern Ghana, the strongest winds are from the east, so you should start laying the sheets from the east end of the building. In areas where the wind comes from another direction lay the sheets accordingly.

Sidelaps

Since corrugations often get distorted or flattened, it can sometimes be difficult to get an exact and watertight sidelap between the sheets.

To straighten the sheet and get a good sidelap, fix all the required nails in the middle corrugation after first securing the sheet with one nail and checking the straightness. Then press the sheet to the correct position and nail the rest of the sheet (Fig. 1).

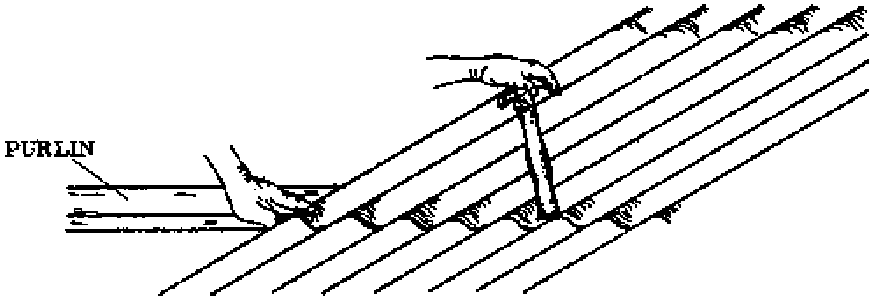

Fig. 1

Do not try to get a sheet in the correct position by nailing the corners where the 4 sheets meet. This will distort the sheet even more.

Ridge caps

If no ready-made ridge caps are available, they can be made on the site with aluminium or galvanized iron sheets. With the help of two straight-edged boards, the sheets are bent to the required angle on the work bench (Fig. 2).

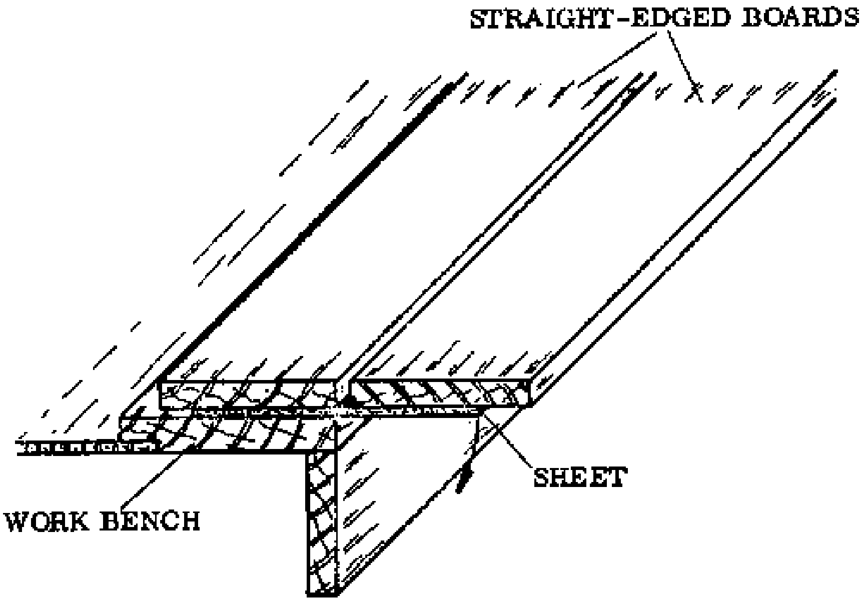

Fig. 2

It is better to make the ridge cap so that the bend goes across the corrugations, rather than along them. This ensures a tighter fit, but the corrugations on both sides of the roof have to match exactly (see Reference Book, pages 231 & 239).

Helpful hints for roof covering

- Put all nails into the washers with the roofing felt before you start laying sheets, to prevent delays.

- The roofing felt can be cut with an iron pipe that has been filed to a cutting edge at one end (Fig. 3).

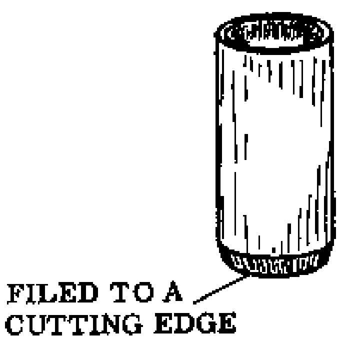

Fig. 3

- Use soap to make driving nails easier in hard wood.

- There should be people on the ground ready to hand up the sheets.

- Before you put a sheet in place, make a mark on the previous sheet to show where the purlin is for nailing.

- Always use a line at the eave, with supports if necessary to keep it straight.

- Have a long, slim and pointed punch ready. It can be made locally from an iron rod. This punch is used to pierce holes through in places where the nail must pass through 4 sheets. Without piercing the hole for the nail first, there is a danger of flattening the corrugation and distorting the overlap while nailing it.

- If a nail begins to bend and should be pulled out, use a round piece of timber or metal as shown in Fig. 4.

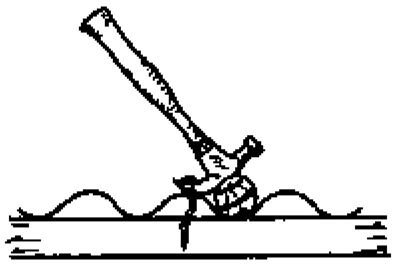

Fig. 4

- Be careful in handling the sheets. They have sharp edges which can cut you deep-

- If a corrugation has been badly damaged through pulling out a nail, try to restore the area around the nail hole to as near as possible the original shape. A round piece of metal can be put under the corrugation to help in this.

- If the sheets have to be cut, do not leave the cut-off pieces lying around. They can still be used for other work.

- Do not leave sheets lying where people might step on them and flatten the corrugations.

- Be sure, especially in seasons where there is a danger of storms, that no sheets are left loosely nailed to the roof, or left on the ground without being weighted down or otherwise secured. A sheet blown around by the wind can easily kill someone.

NOTES:

HEAT PENETRATION - INSULATION

One of the main goals of building in the tropics is to reduce heat penetration into the building. There are a number of building constructions which help to make the building cooler.

- Build in an east-west orientation, so the sun hits directly on only the end walls of the building.

- Construct a verandah to shade the wall.

- Construct overhanging eaves or overhangs to shade the walls.

- Use an open roof construction (no ceilings) on the verandahs, overhangs and overhanging eaves; to permit cross ventilation between the roof and ceilings in the rooms.

- Make ceilings in the rooms so that the sun cannot heat the room directly through the roofing sheets and so that there is cross ventilation between the sheets and the ceiling.

- When possible, use a combination of any or all of the above constructions.

LIGHTENING

To prevent lightening from striking a building, you can install a lightening conductor. This is a pointed copper rod, which is fixed above the highest point of the roof and connected to a copper rod driven into the ground. Long buildings need more than one lightening rod. Follow the manufacturer's instructions to install the conductor.

NOTES:

HIP ROOFS

A hip roof is often chosen as an alternative to a gable roof. It has a nicer appearance, and it is less vulnerable to suction from heavy winds. However it takes more work to construct it, and requires more timber than a gable roof. Also there is a certain amount of waste involved in cutting the sheets at the corners. The hip roof is more apt to leak unless it is constructed exactly right.

The main part of the construction is the same as for the gable roof. In addition, a half truss and two hip trusses are needed for each hip (Fig. 2).

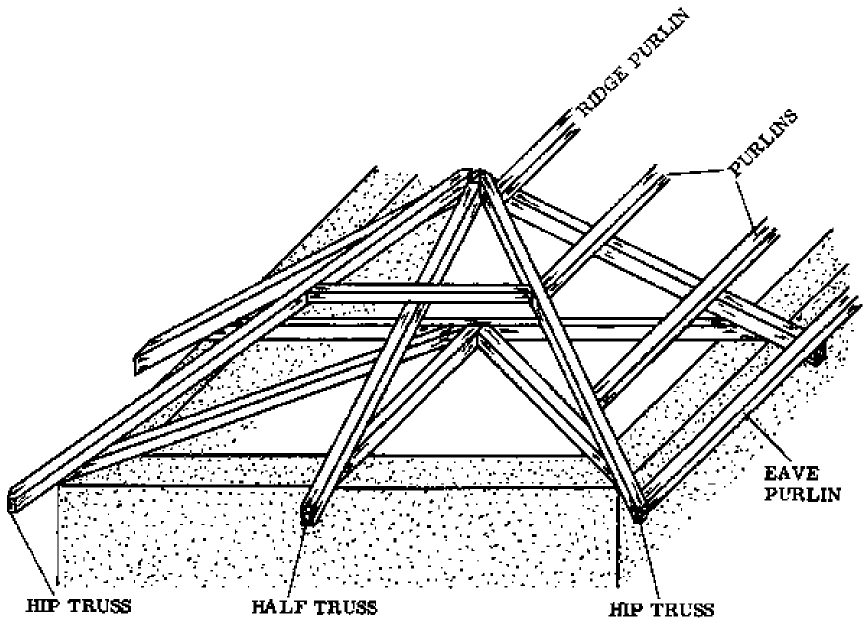

Fig. 2

- NOTE: TO MAKE THE ABOVE DRAWING SIMPLER, BRACES ARE NOT SHOWN.

The two hip trusses run diagonally from the ridge of the last full truss to the corners of the building. The hip rafter has to sit higher than the other rafters, so that the purlins butt into it at the side instead of lying on top of it. This is so that the sheets will be able to fit smoothly around the hip (Fig. 1).

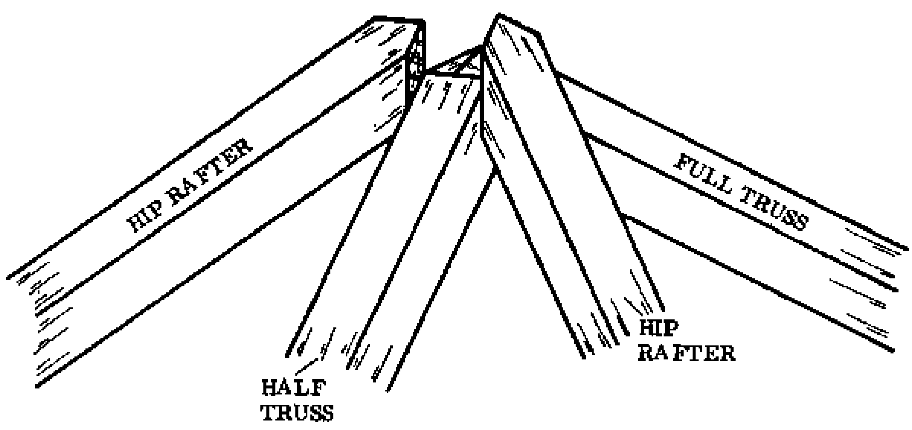

Fig. 1

The half truss is set out in the same way as the full truss, with only half the span. If the tie beams of the other trusses will project beyond the walls, the half truss tie beam has to project by the same amount (Fig. 3).

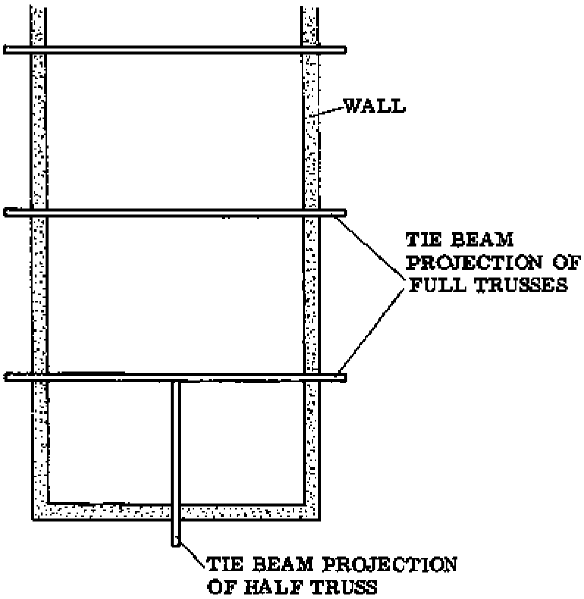

Fig. 3

Setting out and constructing the half truss

Before the half truss is fixed, all the other trusses have to be in place.

To assemble the half truss, use the same setting out which was made for the full trusses. Simply construct half of a full truss. The last brace near the ridge should be set back about 10 cm from the end, to leave space for fixing the trusses together (Fig. 1, arrow).

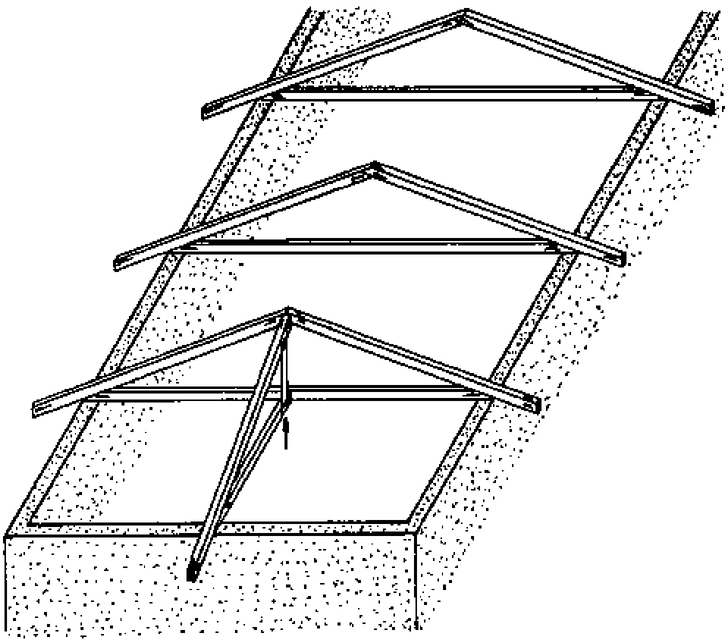

Fig. 1

- NOTE: TO MAKE THE DRAWINGS SIMPLER, BRACES ARE NOT SHOWN.

When the half truss is ready, fix it temporarily into place against the full truss. Remember that if the other tie beams project past the walls, the half truss tie beam must also project, by the same distance.

Position and measurements of the hip truss

Follow the sequence below to find the measurements for the hip truss, as well as its correct position.

a. Lay two purlins flatwise near the eave and ridge, across the last 3 full trusses of the roof. Make sure that they are aligned parallel to the wall, and nail them temporarily (Fig. 2).

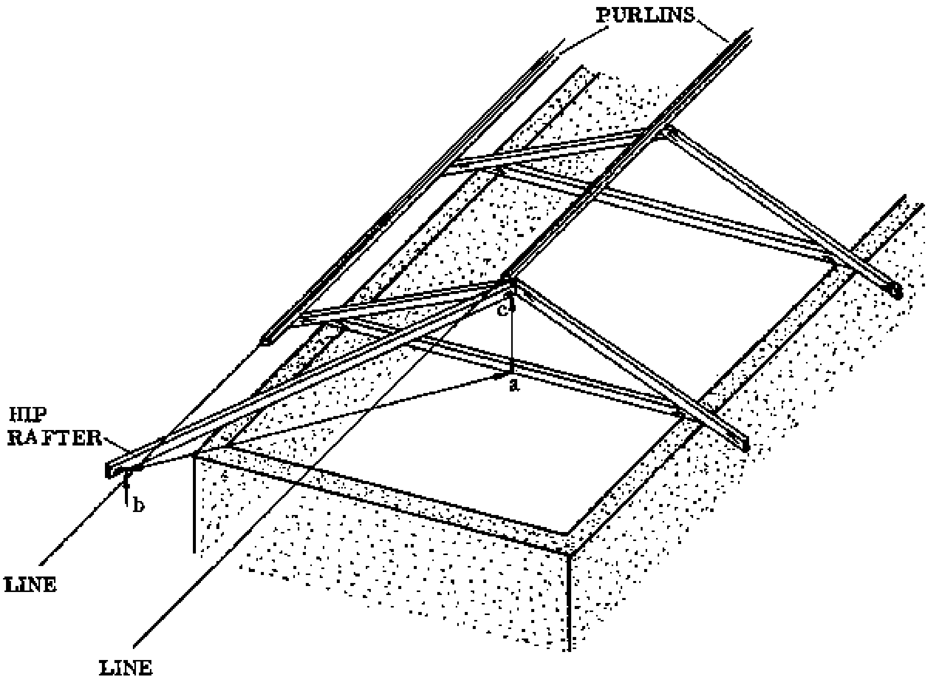

Fig. 2

b. Fix a line along the top surface of each purlin. The lines should extend past the ends of the purlins to the end wall of the building, where they can be held taut by a temporarily fixed pole. The lines must be taut and parallel to the side wall. Each line should touch the whole length of the top surface of the purlin (Fig. 2)

c. Have two men put the hip rafter in position, holding it so that one end is at the ridge and the other end is above the corner of the building. The top surface of the hip rafter should just touch both lines. Thus, the top of the hip rafter is on the same level as the top of the purlins.

d. Now another man can measure the length of the hip truss tie beam, which will be the horizontal distance from the centre of the full truss tie beam (Fig. 2, point a) to the soffit of the hip rafter outside the wall (point b). This distance is the span of the tie beam for the hip truss (see Fig. 3).

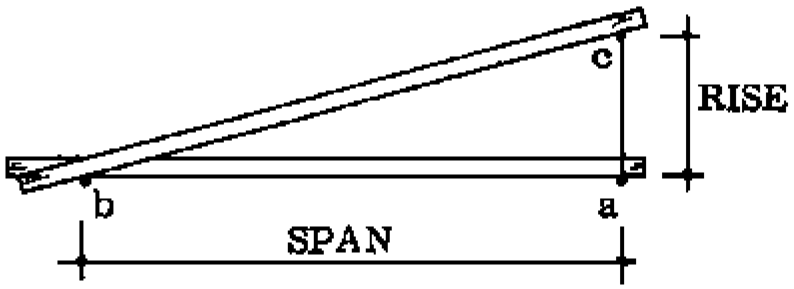

Fig. 3

e. To obtain the rise of the hip truss, measure the distance from the soffit of the full truss tie beam to the soffit of the hip truss rafter (Figs. 2 & 3, point a to point c).

Now that you have the measurements for the hip truss, you can go ahead to construct it. Measure the other hip truss for the opposite side of the roof in the same manner.

Constructing the hip truss

Look at the hip roof design in the Drawing Book, page 108.

- SETTING OUT:

a. Drive pegs 1 and 2 in the ground at a distance equal to the span of the hip truss (the span is measured as described on the previous page). Fix a line between the pegs (Fig. 1).

Fig. 1

b. Fix a line perpendicular to line 1-2, starting from peg 1 (Fig. 1).

c. Drive peg 3 at a distance equal to the rise of the hip truss (Fig. 1).

- ASSEMBLING THE HIP TRUSS:

d. Lay the hip tie beam against pegs 1 and 2 (Fig. 2)

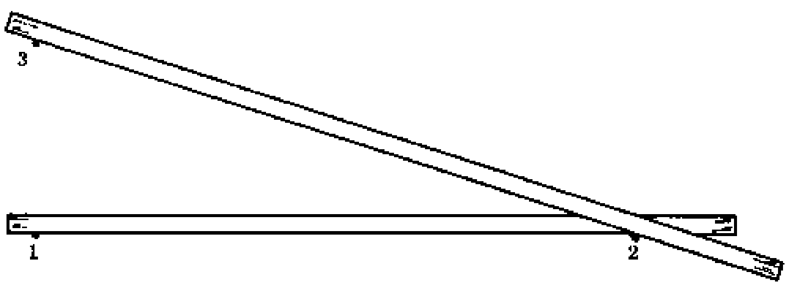

Fig. 2

e. Lay the hip rafter against pegs 2 and 3 (Fig. 2). Make sure that the tie beam and rafter are correctly positioned with respect to the pegs.

f. Cut the rafter-to-tie beam joint. Mark the inside end of the tie beam (a) and the inside end of the rafter (b). Make sure that the rafter has a long project ion on the eave end (Fig. 3). This projection is trimmed only just before the fascia board is fixed (c).

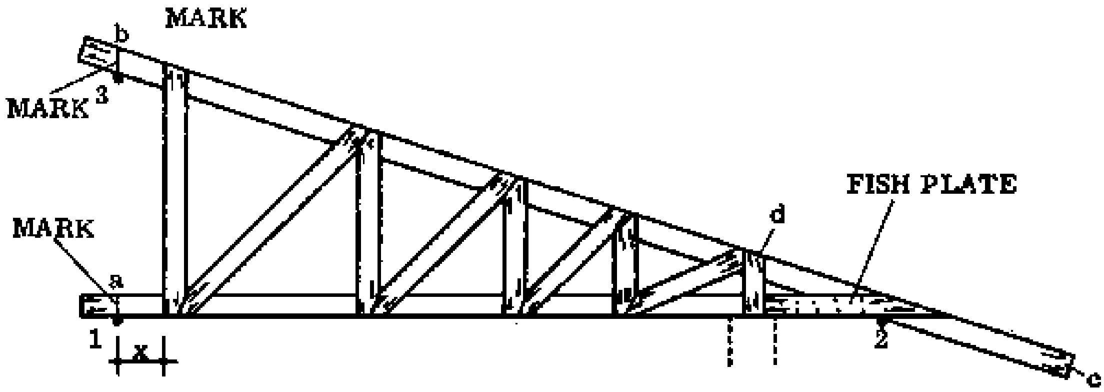

Fig. 3

g. Nail the braces and the fish plates. The last vertical brace on the ridge end is set back (Fig. 3, x) so that there is space to fit the trusses together later. Nail a short vertical brace (Fig. 3, d) where the tie beam meets the supporting wall.

h. Cut the ends of the rafter and tie beam (ends a and b) at a 45 degree angle, as shown in Fig. 4.

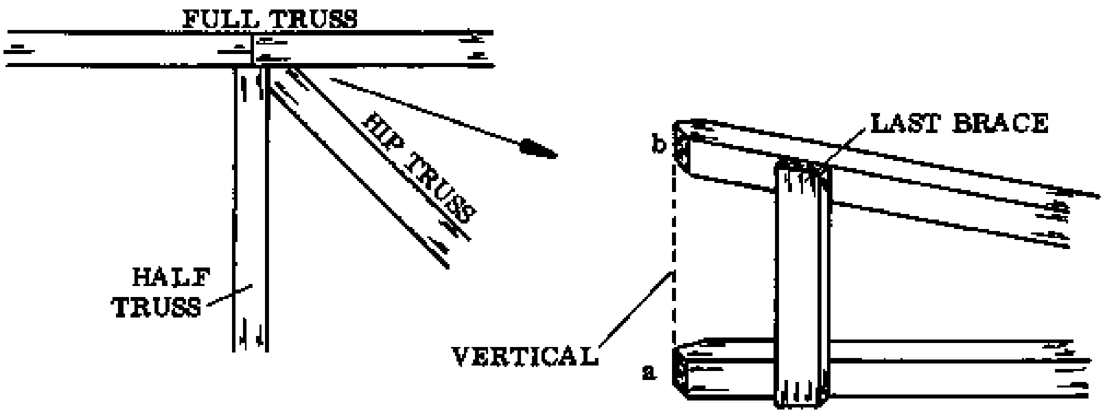

Fig. 4

i. Assemble the second hip truss on top of the first one.

NOTES:

Erecting the hip of the roof

When the half truss and hip trusses are ready, the hip structure of the roof can be erected. The connection between the tie beams of the half truss, hip trusses, and full truss can be made as shown in Fig. 1. The rafter connection is made as shown in Fig. 1 on page 208.

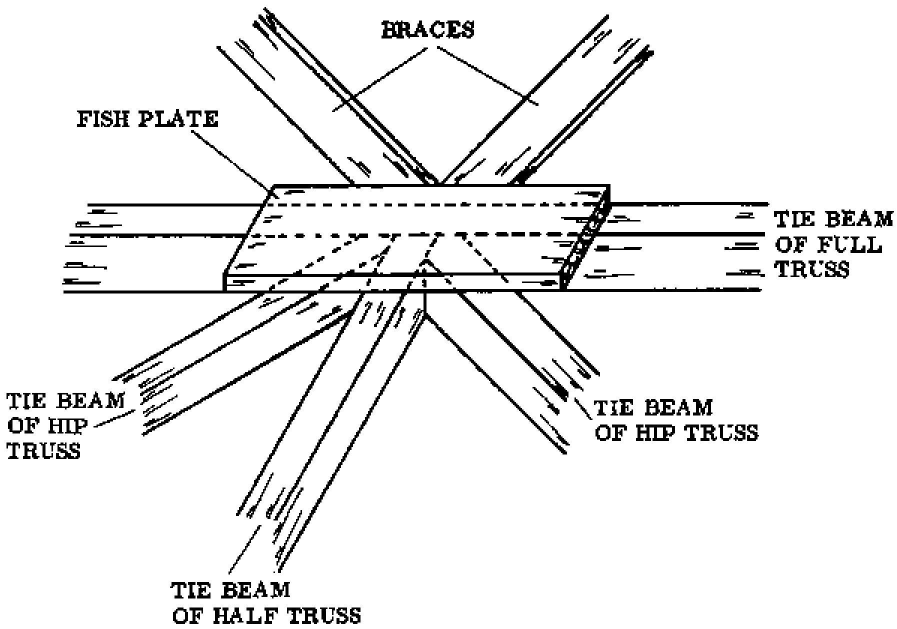

Fig. 1

- FIXING THE PURLINS: The purlins which butt against the hip rafter must be cut at exactly the correct angle so that they will fit snugly against the rafter.

- Mark the positions of the purlins on top of the hip rafters, and insert a nail at the mark to support the purlin during marking (Fig. 2).

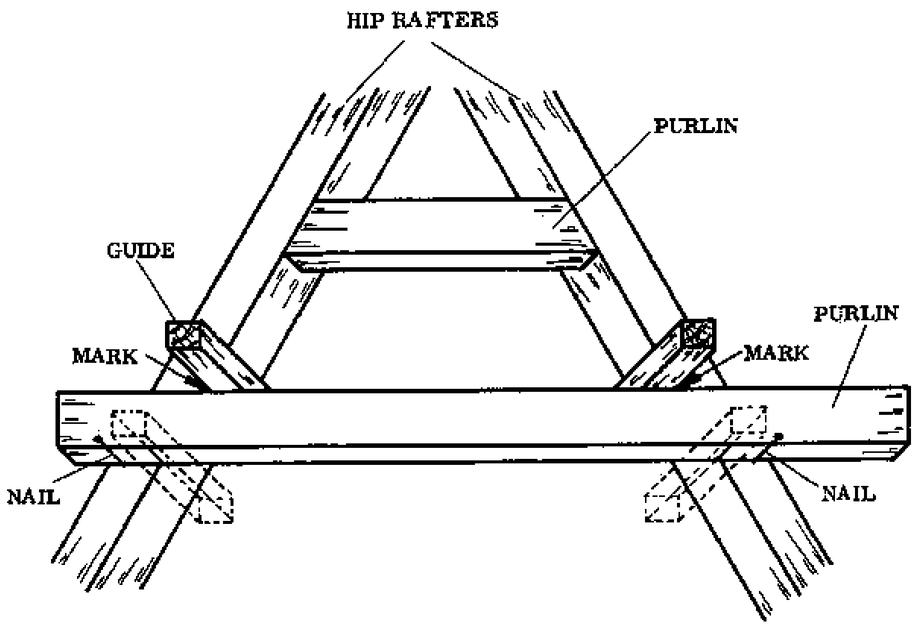

Fig. 2

- Place the purlin against the nails and mark the cutting lines. Use a short piece of wood as a guide (Fig. 2). Make the marks on both sides of the purlin at once, then mark both sides at the other end.

- Cut the butt joints and fix the purlin.

Fix the rest of the purlins in the same manner. The layout for the purlins on a roof with a single sheet length on each side is shown below (Fig. 3).

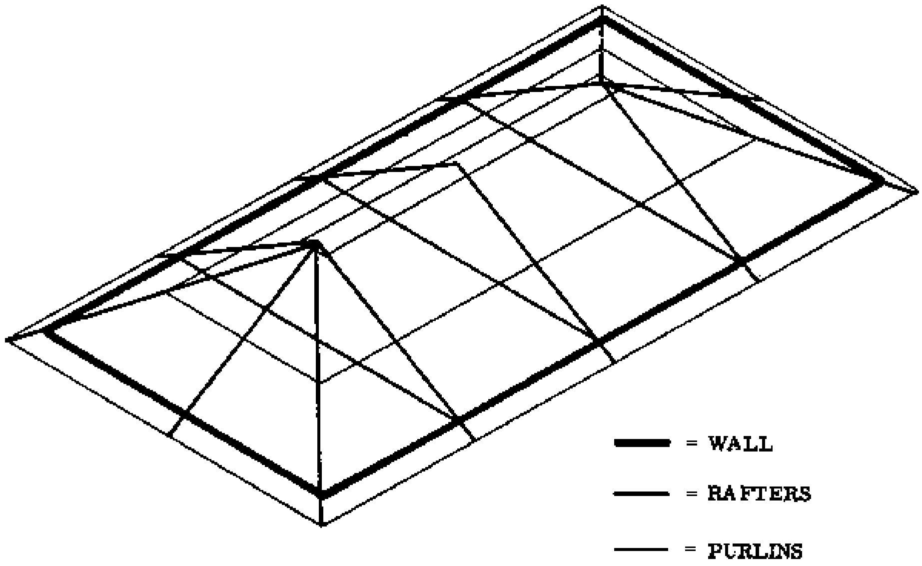

Fig. 3

Covering a hip roof

Nail two purlins parallel to the hip rafters, as shown in Figs. 1 and 2. The extra purlins provide more area for nailing the hip ridge cap.

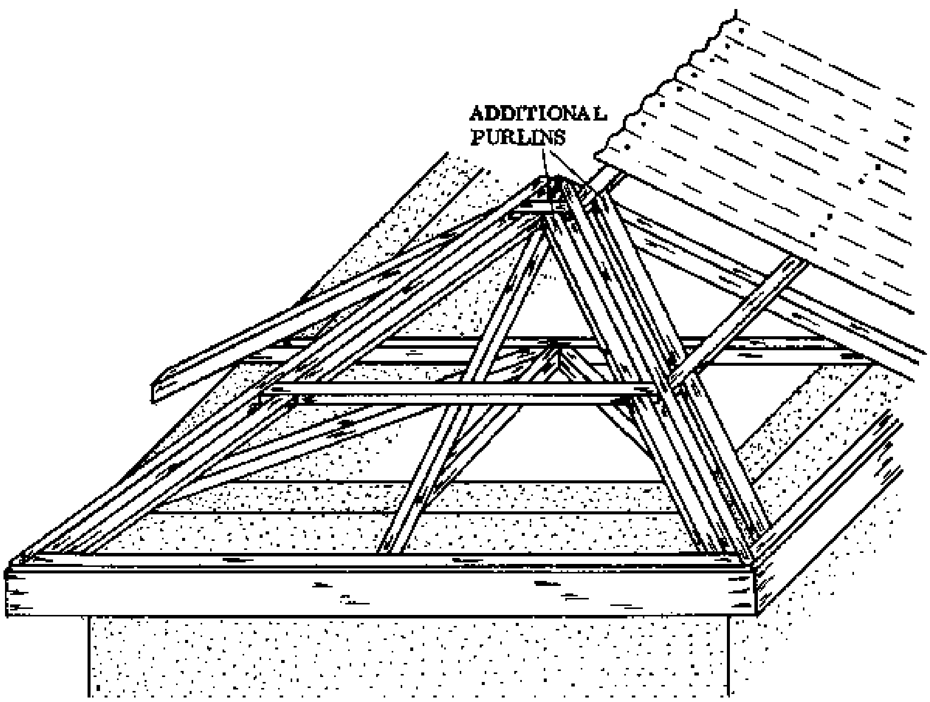

Fig. 1

- NOTE: TO MAKE THE DRAWING SIMPLER, BRACES ARE NOT SHOWN.

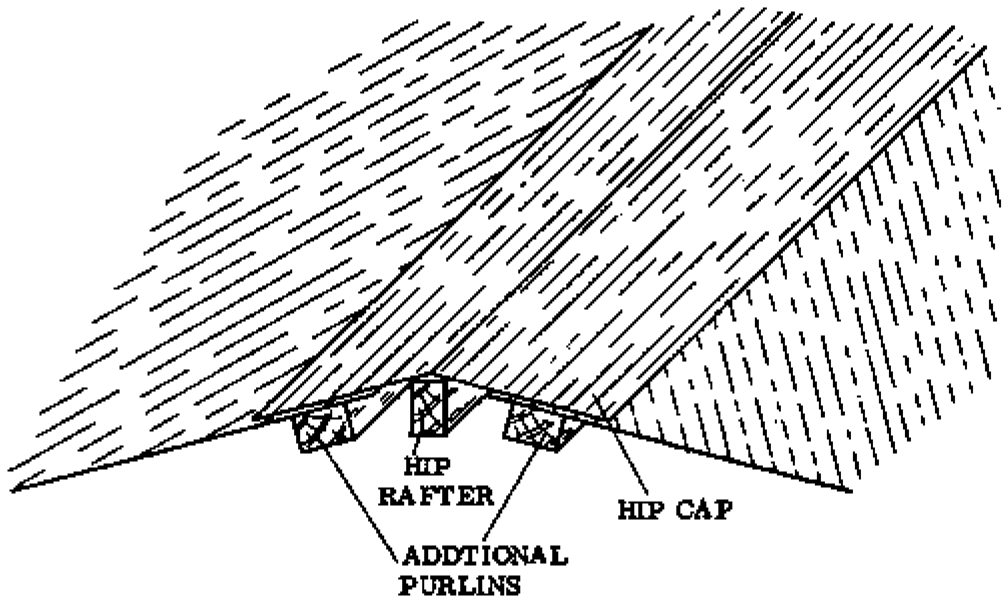

Fig. 2

Lay the first sheet at the hip rafter in position and mark with a straight edge where it should be cut. Cut the sheet and nail it in position before you mark and cut the next sheet. Continue in this way until the hip is covered.

A hip cap, similar to the ridge cap, must be used to cover the hip line, where the sheets meet. If no ready-made caps are available, one can be made as explained on page 205.

NOTES:

HIP AND VALLEY ROOF

When a roof is constructed for an L- or U-shaped building, a hip and valley roof is normally used.

The main problem of this construction is to make a truss which provides sufficient nailing area for the valley and also for the hip. This is solved by assembling two trusses, with spacers in between to connect them (Fig. 1). The spacers provide the required distance between the trusses. This distance is important, because the valley should be wide and deep enough so that rain can run down it easily and so it does not get blocked by leaves (Fig. 1).

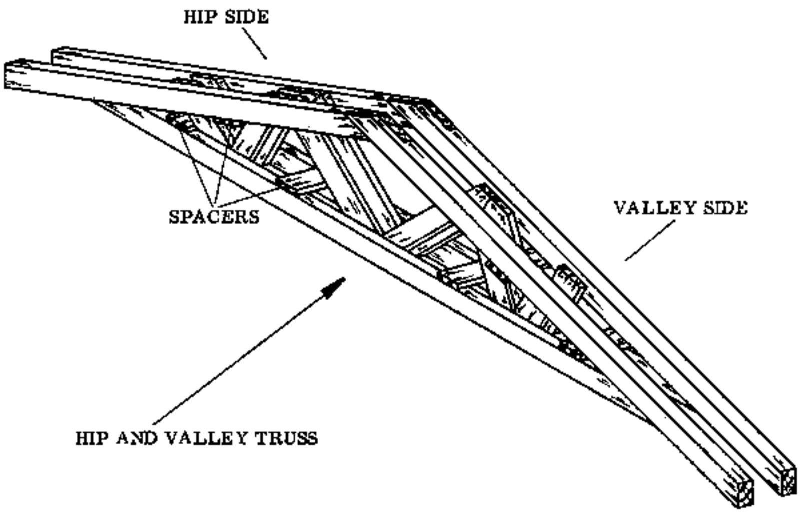

Fig. 1

As in the hip roof, the hip rafters and the valley rafters must be set higher so that the purlins meet them at the sides, and don't lie on top as they do with the other trusses.

If a large span must be covered with a hip and valley truss, it may be necessary to add some half trusses onto the hip and valley truss to provide enough support for the purlins (Fig. 2).

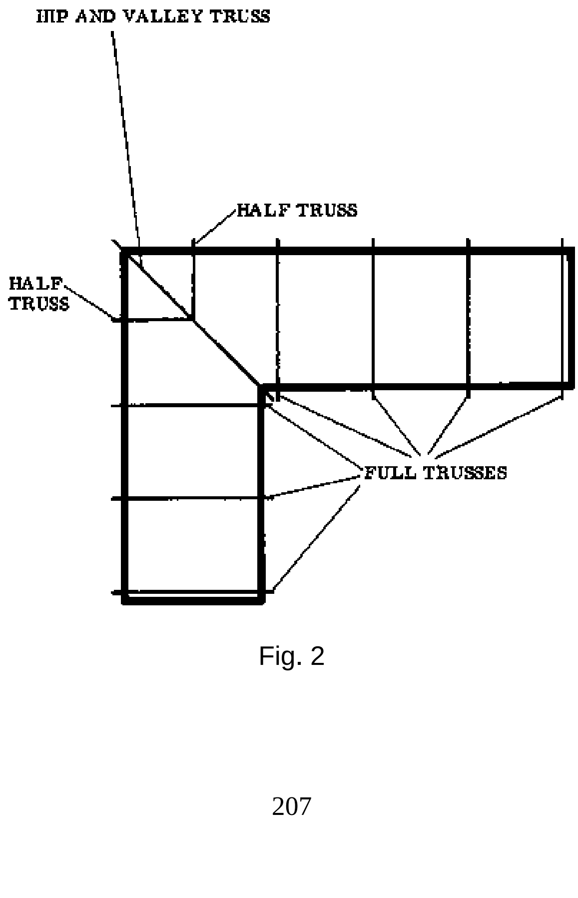

Fig. 2

NOTES:

Position and measurements of the hip and valley roof

- Start by erecting poles in the positions shown in Fig. 1, and fix lines at the ridge.

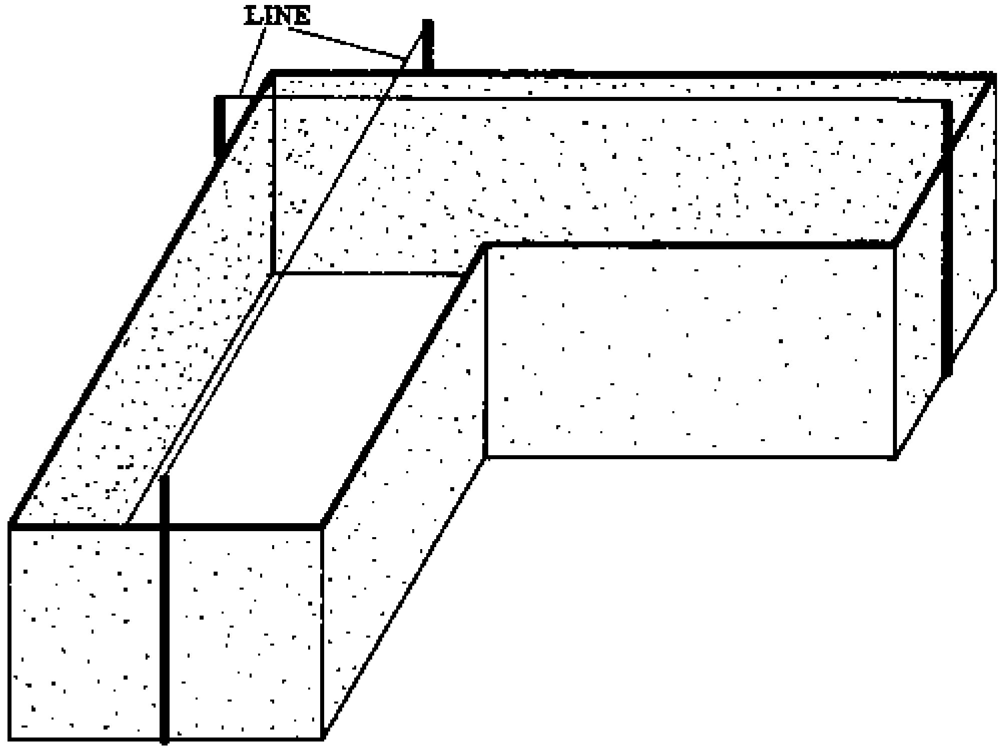

Fig. 1

- Erect the ordinary trusses according to the lines in their correct places (Fig. 2). Refer to the section on erecting a gable roof, page 191.

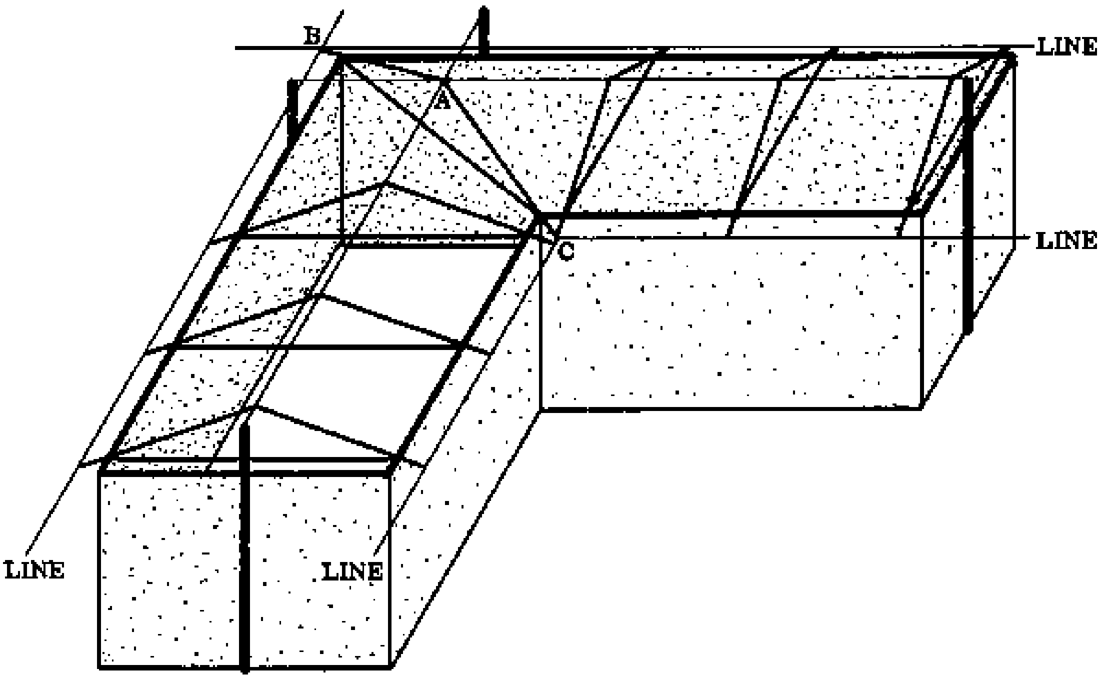

Fig. 2

- Lay purlins temporarily on top of the rafters, as was done with the hip roof (page 211).

- Fix lines parallel to the walls along the tops of these purlins, at eave height on both sides of the roof (Fig. 2).

- Set the ridge lines higher, by the amount of the purlin thickness (Fig. 2).

- Now you will have-three points where the lines cross. These are: point A at the ridge; point B at eave height, and point C on the other side at eave height (Fig. 2). These points mark the outer surfaces of the hip and valley truss.

- Next construct a lightweight, temporary model truss. Hold it in position on top of the roof (Fig. 3). Adjust it until points A, B, and C touch the outer surface of the truss.

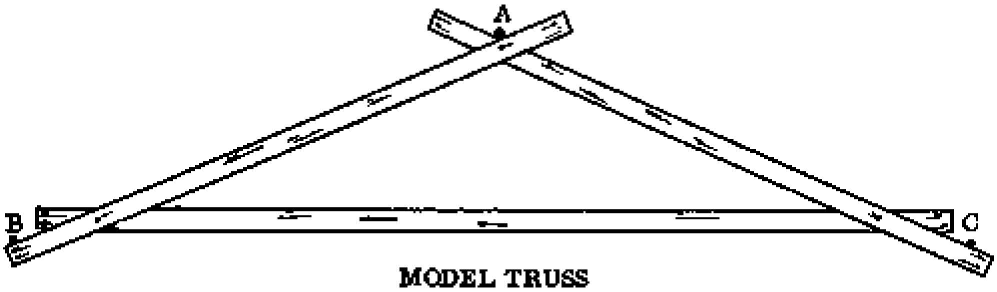

Fig. 3

- Now the model truss will have the correct dimensions and can be used as a model for constructing the two trusses of the hip and valley truss.

NOTES:

Construction of a hip and valley truss

Take the model truss down and set it on the ground in a cleared and level spot.

- Place an iron peg at each side of the model where the rafters meet the tie beam (Fig. 1, pegs 1 and 2) and one peg at the ridge (peg 3). Remove the model truss.

- Now lay the actual tie beam on the ground against the pegs.

- Lay the two rafters on the ground in the correct positions. Be sure that the members are in the correct positions with respect to the pegs, as in Fig. 1.

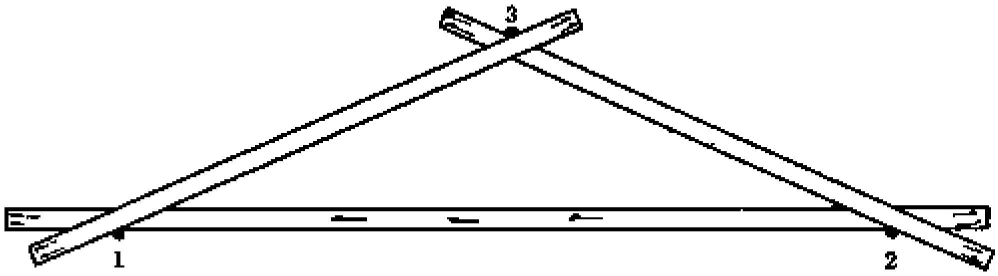

Fig. 1

- Cut the rafter-to-tie beam joint, and the ridge joint (Fig. 2).

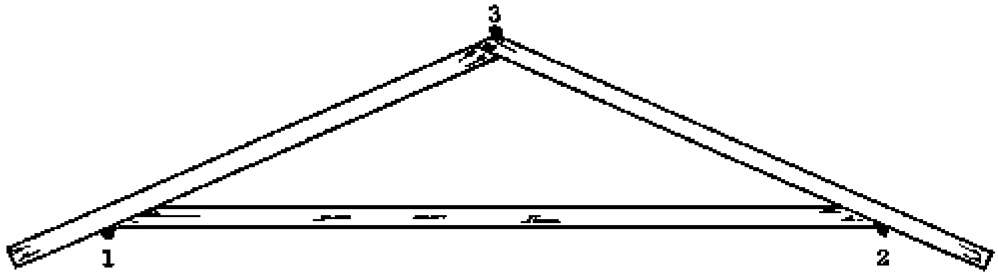

Fig. 2

- Nail the braces. Take care that the braces are set back from the top of the rafters on the valley side, so there is room to construct the valley later (Fig. 3).

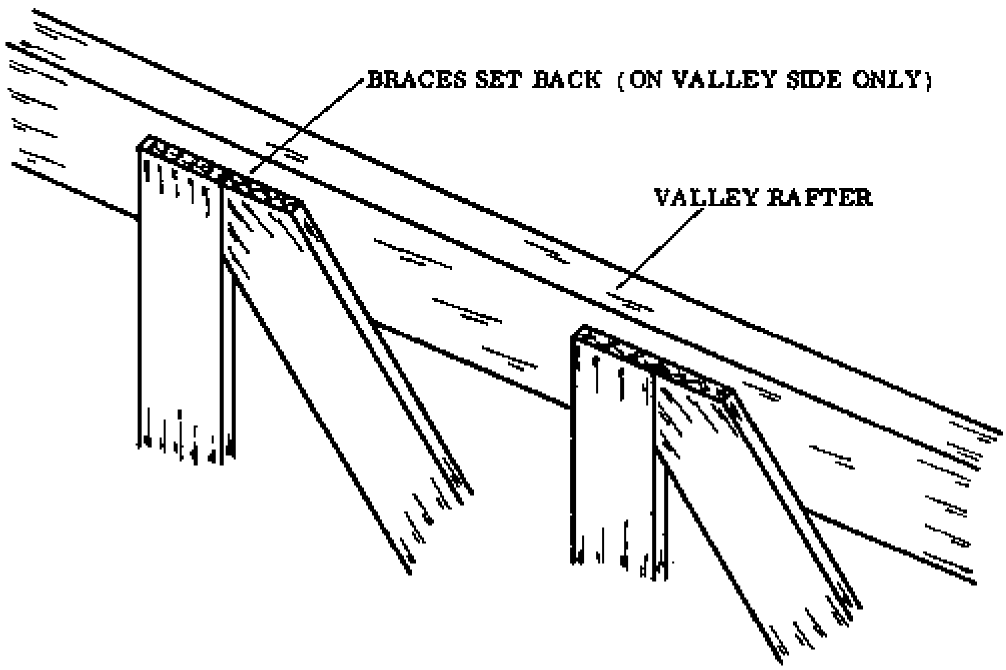

Fig. 3

- Assemble the second truss on top of the first one. Be careful to nail the braces so that later when the two trusses are combined, the braces will all be on the inside (Fig. 4).

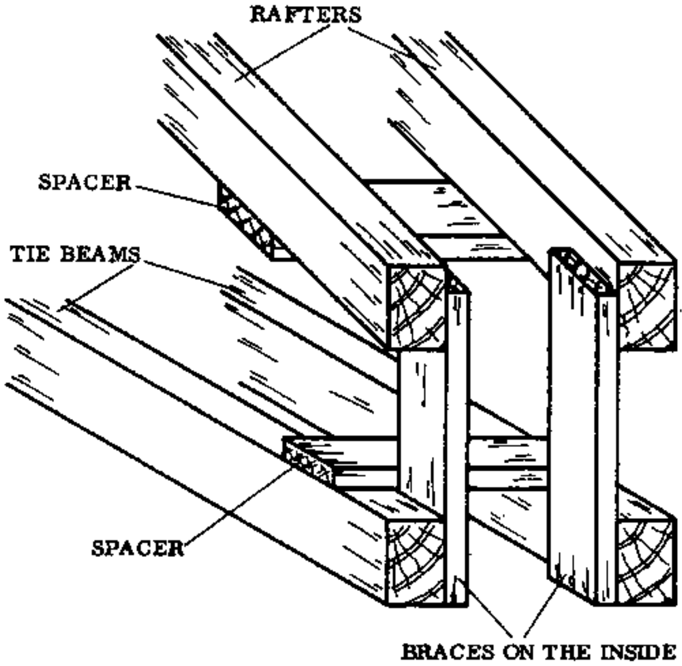

Fig. 4

- When both trusses are ready, they can be set in place on top of the wall. Then the spacers can be nailed to keep the trusses at the correct distance apart. Re member that the distance between the trusses should be wide enough (approximately 15 cm) to provide a wide valley.

Covering a hip and valley roof

First fix the fascia boards and the purlins. Fix a line at eave level and cut the rafters according to this line. Then nail the eave purlin and the fascia boards.

At the place where the fascia boards meet at the valley, cuts have to be made in the fascia boards according to the shape of the gutter (Fig. 1).

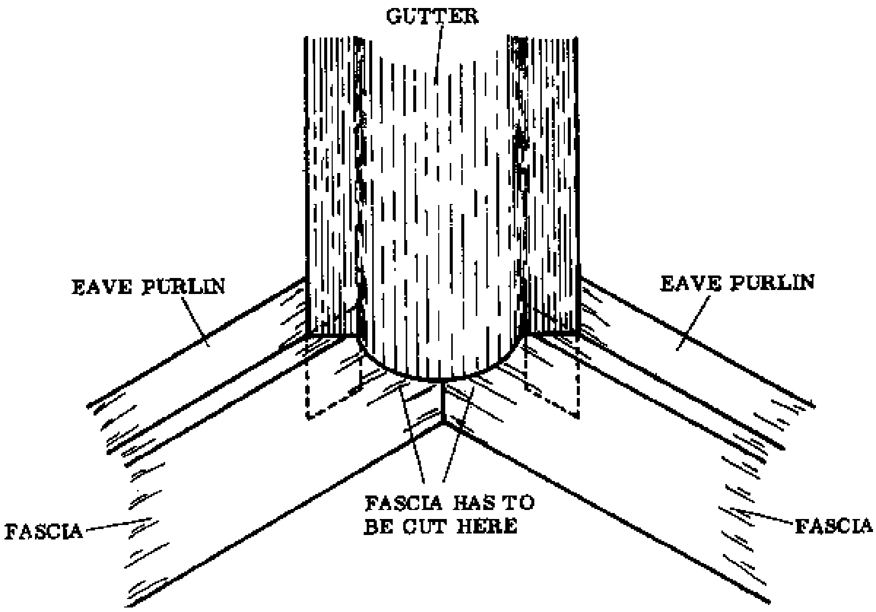

Fig. 1

Now fix the gutter in the valley. Lay a strip of sheeting metal lengthwise in the valley in the form of the required gutter. Fix it there temporarily with nails. The final fixing will be done as the other sheets are laid, since they have to be laid on top of the gutter. The overlap for the gutter sheets should be about 30 cm in the length.

Now lay the first sheet into position at the valley, mark and cut it. Nail this sheet and place the next sheet in position. Continue in this way until the hip and valley are covered.

Install the hip cap as explained for the hip roof.

The ridge cap on the main ridge is always covered last, since it has to overlap all the rest.

PLASTER AND RENDER

Plaster or render is a mortar coating over the blockwork. We call the coating on the inside walls “plaster” and the coating on the outside walls “render”. The main difference between the two is that render is generally richer in cement than plaster, because it has to be weather resistant. In the following pages we will refer to the application of either plaster or render as “plastering”.

The function of the plaster inside is to make the walls smooth so that they are easier to clean, free of insect hiding places, and have a better appearance. Also, if the house is constructed out of wood or bamboo closed up with mud or clay, the plaster acts as a protection against fire.

The render on the outside surface of the walls is essential to protect them from the influence of the weather, especially if landcrete blocks or mud blocks are used. When these blocks are exposed to moisture for long periods, they gradually become soft, expand, and finally crumble away. The render must therefore be water resistant.

- All external walls should be covered with render. The sides of the building that face the heaviest weather (in north-western Ghana, this comes from the north-east) should be covered with a somewhat richer mix (Fig. 1, a, next page).

- All so-called wet rooms such as bathrooms, toilets, kitchens, and washing areas should be plastered and painted. (Fig. 1, next page: K = kitchen; S = shower; and W = washing area.)

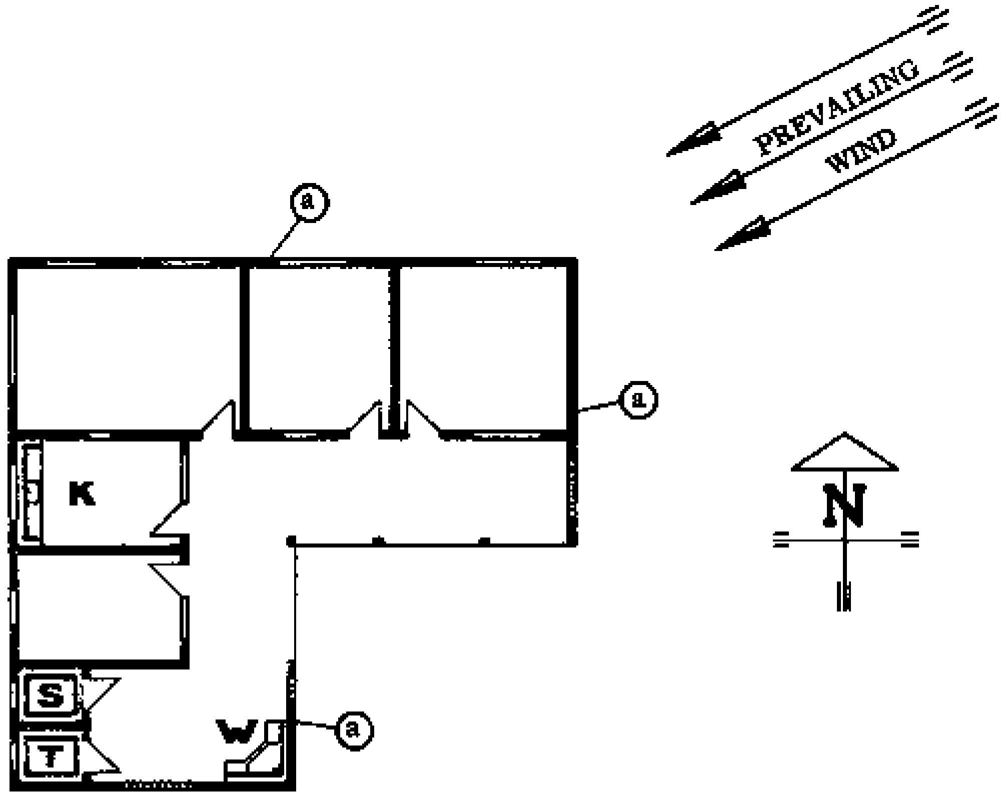

Fig. 1

Composition of plaster or render

In Rural Building, plaster or render consists of cement, sand, and water. Lime can be added to the mix, but this is not always available.

Sharp and relatively coarse sands are preferred for render, although they produce a mortar which is not easy to work with. The size of the grains should be no greater than 5 mm; the sand should be well graded (Reference Book, pages 148 and 149); and it should not contain more than 20% very fine particles (powdered sand).

The sand for plaster should be well graded, but less coarse than sand for render (see Reference Book, page 159).

- MIX PROPORTIONS: The mix proportion for plaster need not be better than 1:8, and may be as low as 1 : 12. The exception to this is the plaster for an area which is often wet, such as a bathroom or washing area. These should be plastered with a mix of about 1 : 6.

The mix proportion for render should never be better than 1 : 6; this is for the north and east sides of the building (or whatever direction the heaviest rain comes from). The other sides of the building can be covered with a mix which is at least 1 : 10 (see the Reference Book, Tables of Figures, page 234).

Exceptions are made for special structures which need waterproof plastering, such as water storage tanks, septic tanks, inspection chambers, manholes, etc. The mix proportion of the plaster used on these may vary from 1 : 3 up to 1 : 1, because the permanently moist surfaces keep cracks from developing.

- REMEMBER: The richer the mix, the more likely it is to develop cracks. Save materials and money by following the rules for correct mix proportions.

Preparing the wall for plastering

During the blockwork as the wall is built-up, the first measure is taken to prepare the wall for plastering: the joints are raked out to a depth of approximately 1,5 cm (Fig. 2). This is done immediately after each course is completed. Raking out the joints gives the plaster or render a better grip to the wall.

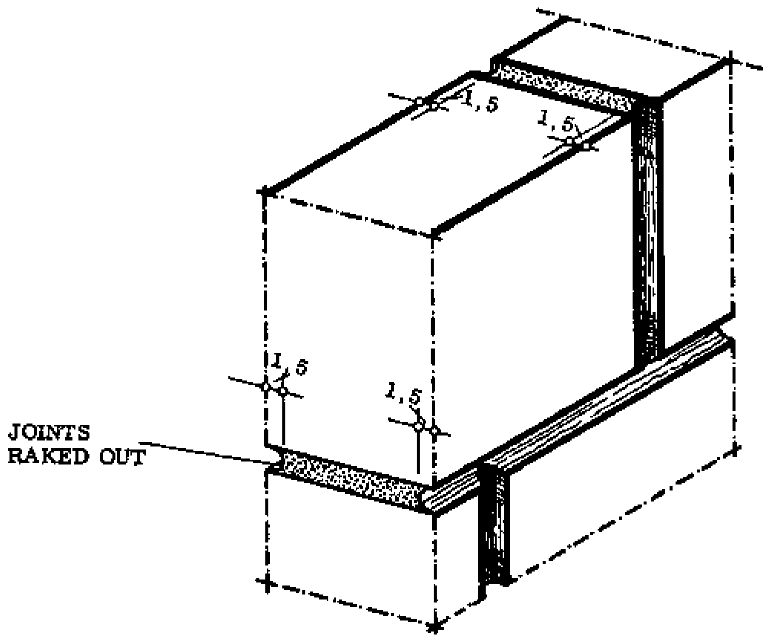

Fig. 2

Before any plaster or render is applied, the wall must be brushed to remove the dust and dirt which would weaken the grip of the mortar. The masonry must then be thoroughly watered, especially during the dry season. This reduces the absorption of water from the freshly applied mortar, so that the mortar hardens well.

- NOTE: Some experiments at NPVC have shown that the landcrete surface can be improved by leaving the walls exposed to one or two short rains before plastering. The rain washes out the finer particles, leaving a rough surface which bonds to the plaster or render better. This method is risky however, because it is impossible to tell in advance how long the rain will last and how heavy it will be.

Application techniques

- SPATTERDASH: In order to give a good grip on smooth surfaces such as sandcrete, or to reduce the amount of moisture absorbed from the freshly applied mortar, spatterdash may be applied before plastering. This is done with the spatterdash apparatus (see Basic Knowledge, page 178), using a very wet and rich mix (1 : 3, up to 1 : 1). The spatterdash layer is never more than 5 cm thick.

The plaster or render is generally applied in a single layer on top of the spatter-dash, or else directly on the blockwork surface. This layer will be 15 to 20 cm thick.

Sometimes a second coat or finish coat is applied on top of the first layer. This must be done before the first layer has hardened. The second coat is usually made where the plaster has to be very thick, for example where the wall is very uneven so that a thick coat of plaster has to be applied to get a smooth surface. The second coat should be about the same mix as the first coat, and about 5 cm thick.

Don't start plastering on a wall which is in direct sunlight. This would cause the render to dry out too quickly, resulting in a “burnt” render which is useless.

Instead, start plastering in the early morning on the west side of the building, going clockwise around the building to the north, east, and south sides so that the freshly plastered areas are always in the shade.

Areas which are too large to be completely plastered in one day are divided into smaller areas by introducing working joints (Fig. 1). The joints should always be vertical, so that water will flow away as quickly as possible from the joint.

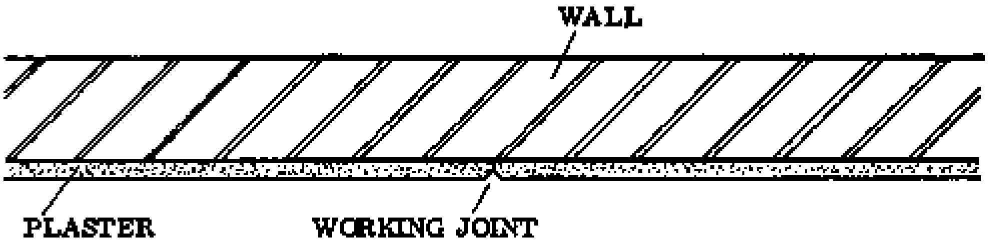

Fig. 1

In Rural Building, the inside of the building is generally plastered after the roofing is completed.

- PLASTERING THE FOOTINGS: Here we must add a note about the footings. These have to be plastered before the rising wall. This is done as shown on the left (Fig. 2; a, b, & c).

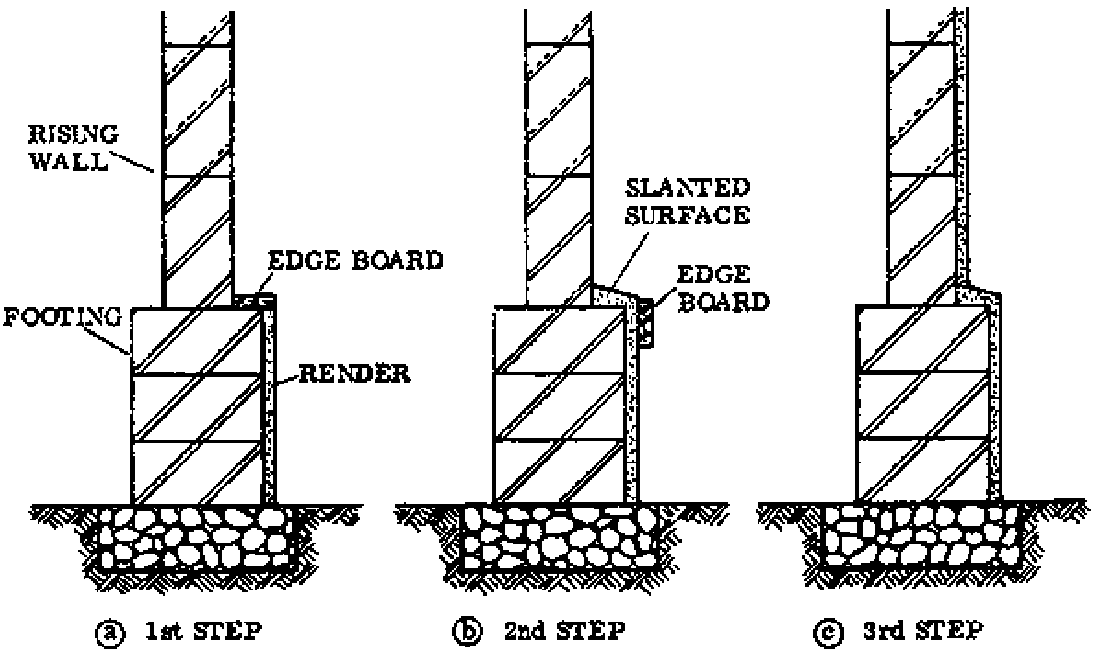

Fig. 2

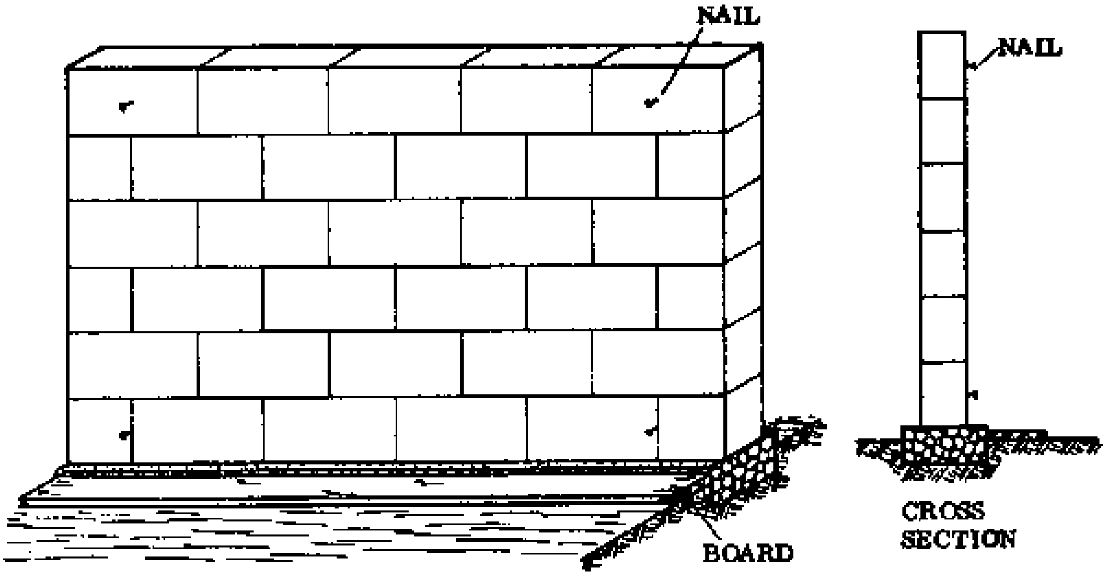
An edge board is laid on the ledge of the top of the footings, and the vertical surface below is plastered according to the procedure explained on the following pages.

Next the ledge is plastered. The render must form a slanted surface so that water runs away from the wall. It is important that this slanted surface is made before the rising wall is plastered, because otherwise the joint between the two would allow water to enter (Fig. 2; b & c).

NOTES:

Sequence of operations for plastering a straight wall



a. Study the wall which is to be plastered; notice the holes and projecting parts.

b. Clean the wall with a hard brush and chisel off any projecting blocks.

c. Soak the wall thoroughly with water; try to wash off the loose particles. Clean the wall very well, especially the area near the footings and the footings them selves.

- NOTE: In the drawings here the footings have been left out, to make the drawing simpler. The plastering of the footing - rising wall connection is made as explained on the previous page.

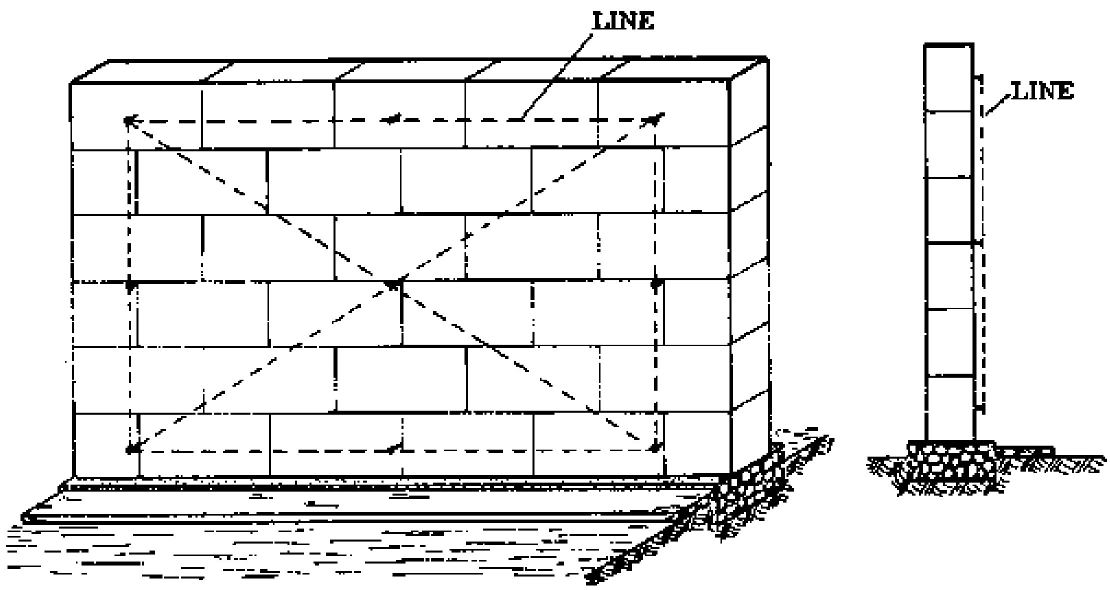
d. Place boards against the foot of the wall to catch the mortar which is dropped.

e. Prepare some mortar which is of the same strength as the wall, and use it to fill up the larger holes in the wall.

f. Make a scaffolding to work from, if this is needed.

g. Insert four nails, one at each corner of the wall.

NOTES:

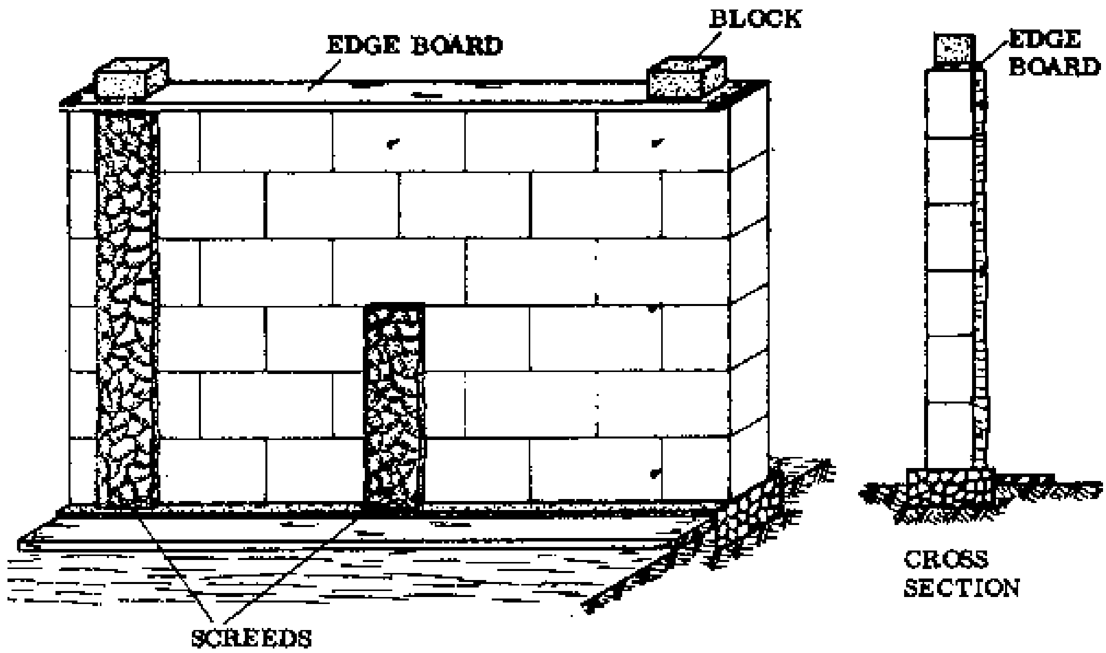


h. Fix lines around all four corners and across the diagonals.

i. The surface contained by the nail heads and the lines should be flat and plumb. Check this using the plumb bob and straight edge. Make corrections by knocking the nails in until they are ail in the same plane; this will be the surface of the future plaster layer.

j. When the four corners have been adjusted, insert more nails along the mason lines, as shown above. The heads of the nails should be at the same height as the lines. The distance between the nails should be no more than the strike board can bridge.

NOTES:



k. Fix the edge boards. The edge board at the top of the wall can be held in place with blocks on top of it. The edge boards should project by the same amount as the nails - the thickness of the future plaster layer.

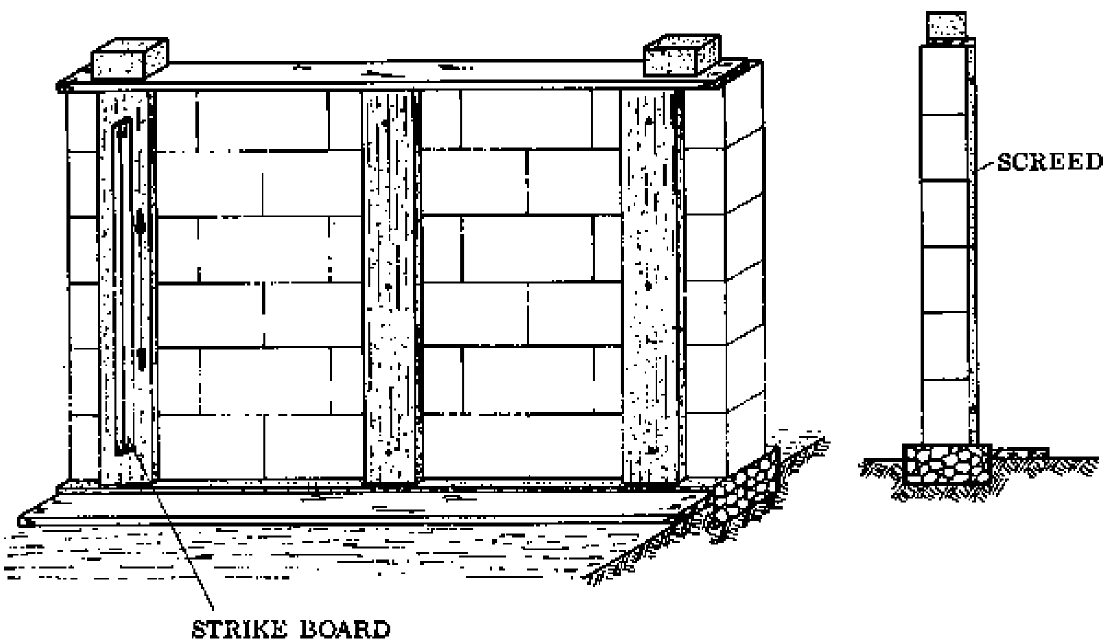
l. Now the plastering can start. Make sure that you have enough time to finish the whole area you want to plaster at once, otherwise wait until the next day.

m. Mix the mortar according to the required proportions. Take care that there are no stones in the plaster. Make up a dry mixture first and add water to this as it is needed. Do not mix too much at once, and keep the mortar covered with paper bags or other covering to keep out the sun and wind.

n. Sprinkle the wall with water again.

o. Build up screeds (guiding strips) by throwing mortar against the wall in vertical strips. The mortar should cover the nail heads completely.

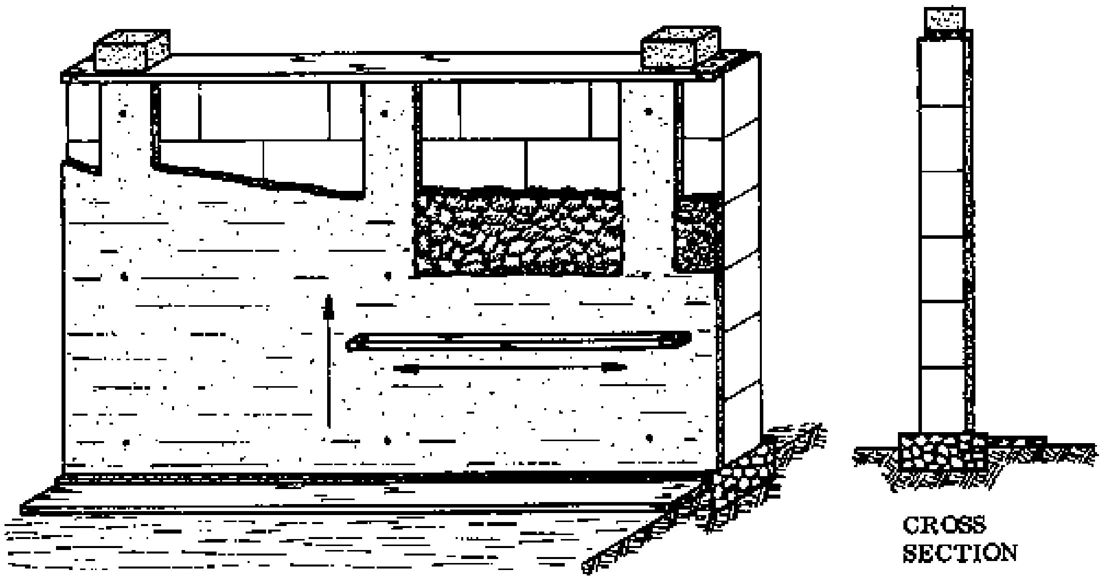
NOTES:



p. Use the strike board to smooth off the screed flush with the heads of the nails. Return any mortar which drops down to the headpan. Give the strike board an up and down movement as you move it across the screed, to obtain a good surface.

q. Let the screeds set for a while, until they are hard enough so that no mortar will be taken off by the strike board during the next steps.

NOTES:



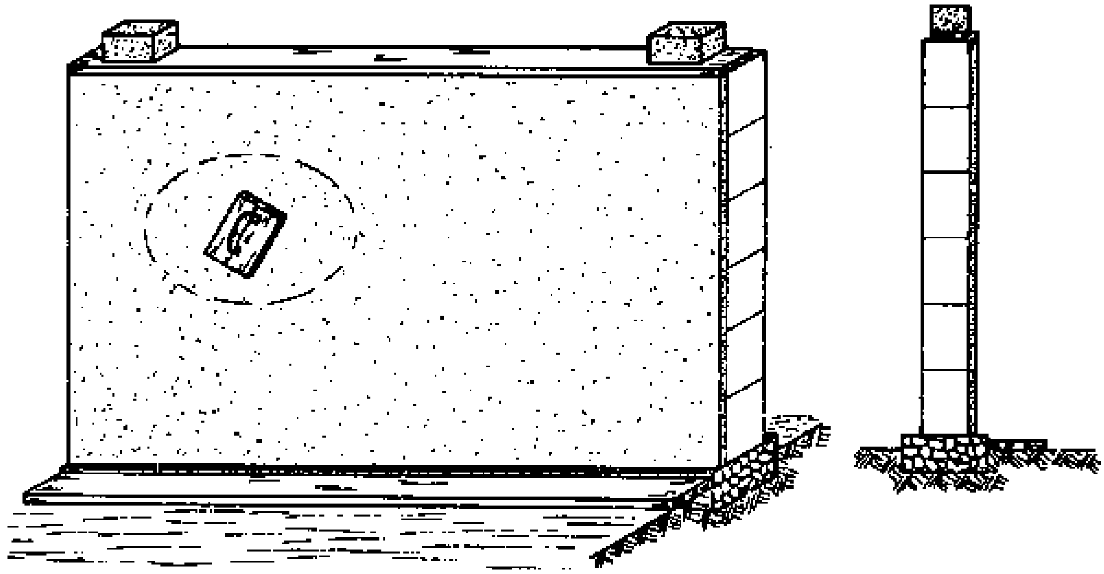
r. When the screeds are hard enough, sprinkle the wall with water again.

s. Fill in between the screeds with mortar. Throw the mortar against the wall, so that it grips well to the wall. The mortar should be a bit thicker than the screeds.

t. Press the strike board to the screed and move it up the wall, holding it horizontally. The board should remove the excess mortar so that the surface of the mortar is flush with the screeds. Make sure that the strike board does not remove any of the mortar from the screeds. Return all surplus mortar to the headpan.

It is not necessary to fill up the whole section between the screeds before you start to smooth the plaster. Fill in the plaster as high as you can comfortably reach, then smooth this and fill in the rest with the help of a scaffold so you can reach the top of the wall. Smooth up to the top of the wall. However, you should never leave a section halfway finished, because it will not join properly when you continue the next day.

u. When the whole wall has been levelled off the nails should be removed and the last finishing work can be done.



- FINISHING: If the wall should be finished with a textured surface, a wood float can do the job. Turn the float around systematically to obtain a regular texture.

If a wall should be smooth-surfaced, use a steel float and take care that the sharp edges do not remove mortar from the plastered surface.

Dip the wood float in water regularly, but don't over-wet the mortar because it could come down or “sag”.

Take care that the plaster or render comes to the footings (here, to the foundations) and cut it off properly. The edges around openings and outside corners should be rounded or chamfered.

Before stopping work, make sure that the work is finished off properly and is clean. Someone should return in the evening and sprinkle water on the freshly made plaster or render. Water the plaster or render regularly in the next few days so that it cures properly.

The edge boards can be removed the next day.

- CURING: Watering the plaster or render is very important, especially during the dry season when the harmattan is blowing. Don't watt until the whole work is finished before you put water on the parts which were done first; the fresh plaster can dry out in a few hours.

If you started on the west side of the building in the morning, be sure to water those sections in the afternoon when the sun is shining on them.

Positions of edge boards for plastering corners

Below are illustrations of the correct method for plastering around corners. In Fig, la, the first step is shown; in Fig. 1b the second step. The arrows indicate the areas which are plastered in each step. The boards project by the thickness of the plaster.

Plaster the inside surfaces of the opening first (Fig. 1), then the rest of the wall can be plastered as usual (Fig. 2).

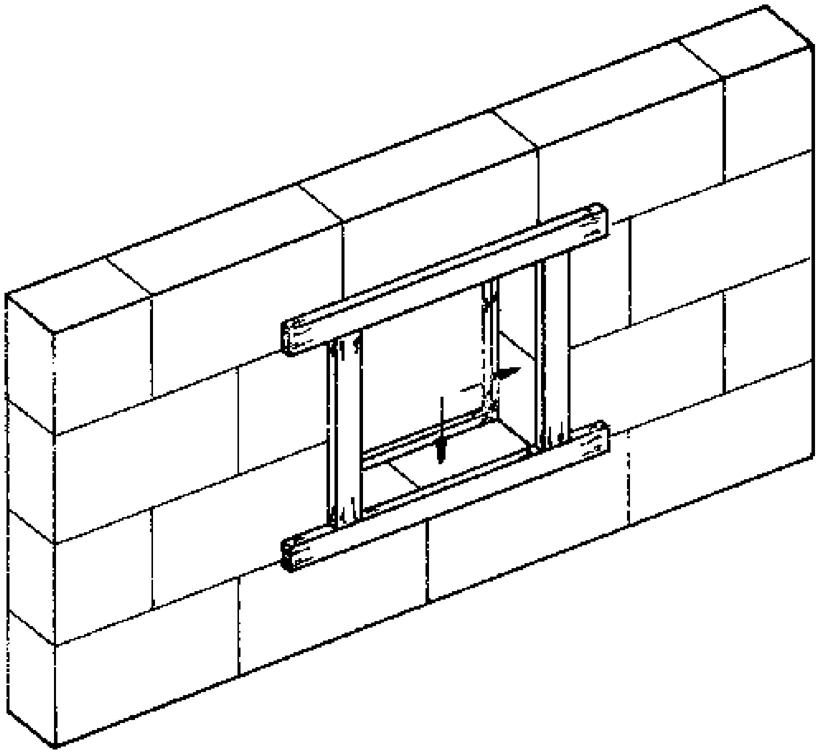

Fig. 1

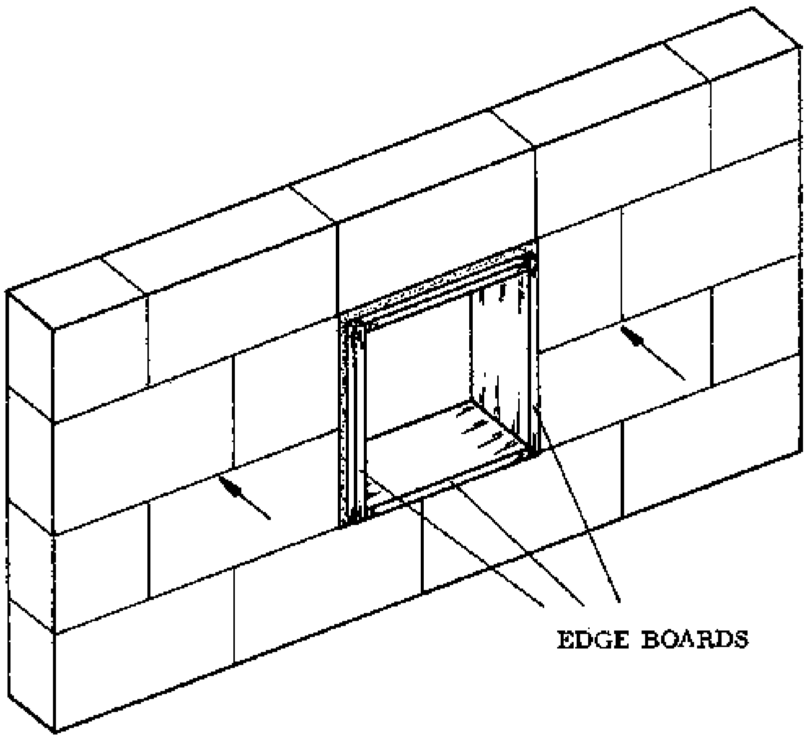

Fig. 2

FLOOR CONSTRUCTION

It is best to construct the floor after the roof covering has been completed. This makes it easier to cure the floor without problems caused by the concrete drying out too quickly and cracking.

Floors are constructed on top of the hardcore filling. There are two methods for floor construction used in Rural Building: one-course work and two-course work. One-course work means that the floor is made in a single layer; while in two-course work the floor is constructed in two layers, the base layer and the floor screed or finishing layer. For an explanation of the two methods and their respective advantages and disadvantages, see the Basic Knowledge book, page 179.

Any floor which is larger than 10 square metres should be divided into “bays” before it is cast (Basic Knowledge, page 180). The bays should be as nearly square-shaped as possible, so that the shrinkage on each side of the bay will be the same. The bays are separated from each other by edge boards during the casting. The smaller the bays, the fewer cracks will appear. In floors which are in the sun, the bays should be no more than 5 square metres in area, and expansion gaps should be made between them.

Expansion gaps and shrinkage gaps are explained in the Basic Knowledge book, page 183. Shrinkage gaps are made between the bays in either one-course or two-course work, to keep the floor from cracking as it hardens and shrinks a bit. Expansion gaps are larger gaps made in the base layer of two-course work when the floor is exposed to the sun or to large temperature changes, which can cause cracks when the floor expands with the heat and contracts as it cools.

The procedure for casting a floor is explained on the following pages.

NOTES:

Sequence of operations for one-course work

The hardcore filling is usually made well beforehand, to allow it to settle properly. It is constructed as explained on pages 59 and 60 in this book. The last 6 cm up to the top of the footings is filled with sand. The hardcore forms a firm support for the floor (Fig. 3).

a. Clean the whole area and level the sand surface (Fig. 1).

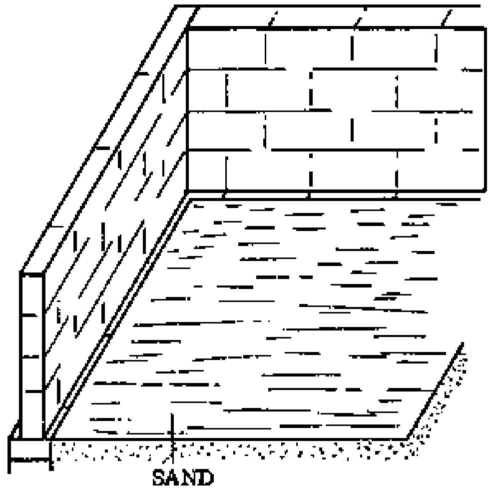

Fig. 1

b. Divide the area of the room into bays and mark the bays on the walls (Fig. 2).

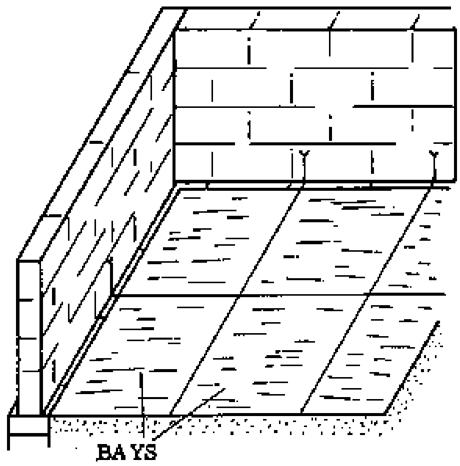

Fig. 2

c. Mark the positions of the edge boards on the sand between the marks on the walls (Fig. 2). Lines may also be fixed between the wall marks at the height of the finished floor level (Fig.. 3).

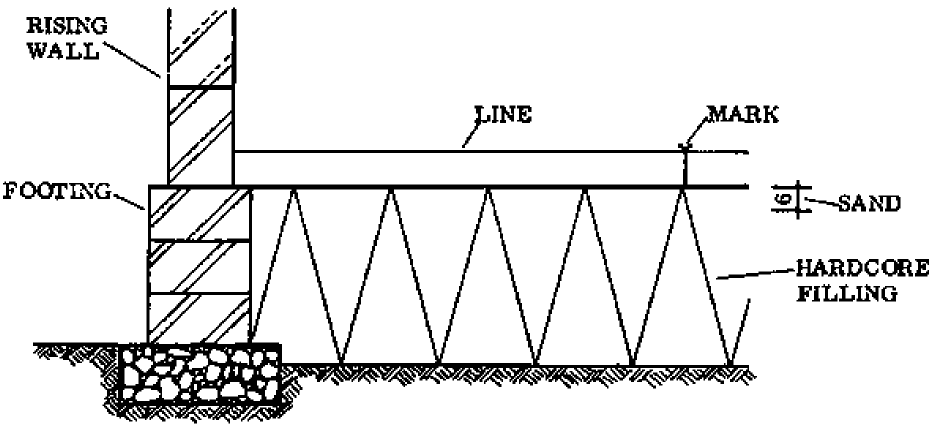

Fig. 3

d. Cut the edgeboards to the proper length. Note the arrangement of the boards shown above in Fig. 4 and in Fig. 6 below, and cut the boards so that they fit in this pattern.

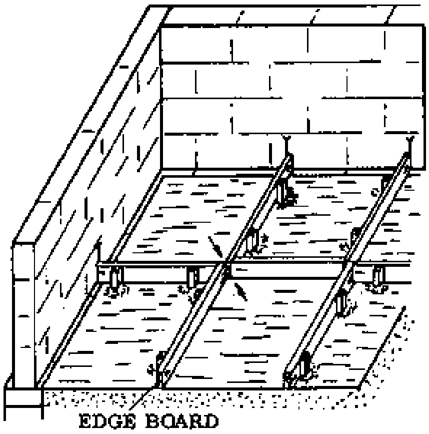

Fig. 4

e. Nail the pegs to the sides of the edge boards.

f. Place the edge boards as shown in Fig. 4, along the marks. The corners of the boards should meet as shown in Fig. 6 below.

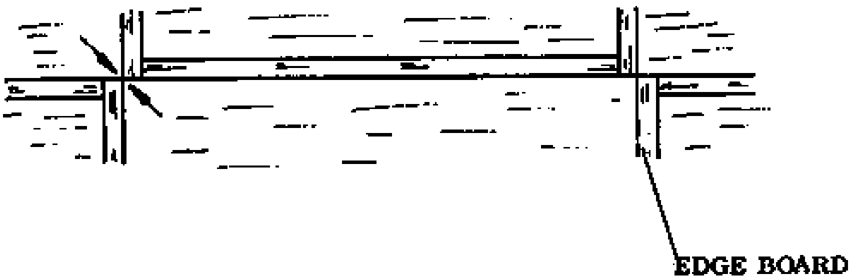

Fig. 6

g. Knock lightly on the pegs until the edge boards are level (check with the spirit level) and at the correct height (the tops of the boards should be level with the finished floor surface).

h. Pour the guide strips to the height of the base layer (approximately 8 cm) (Fig. 5). Level the tops of the guide strips (Fig. 7).

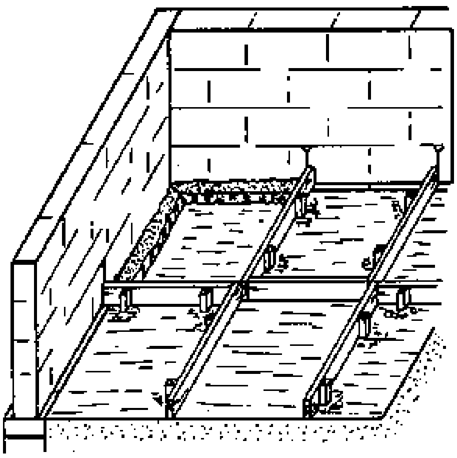

Fig. 5

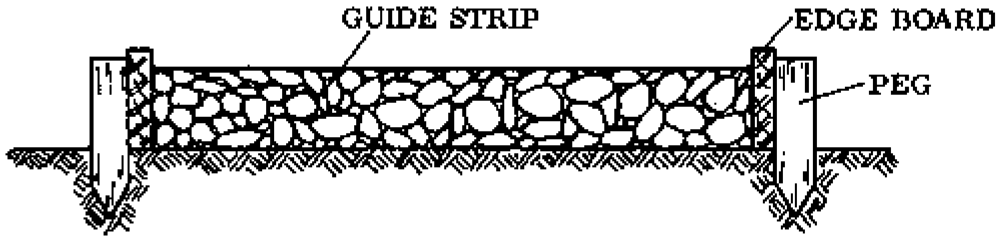

Fig. 7

i. Pour the concrete for the base layer of one bay, making sure that it is well distributed near the walls and corners especially. Mix proportions can be found in the Tables of Figures, Reference Book, page 234 (Fig. 1).

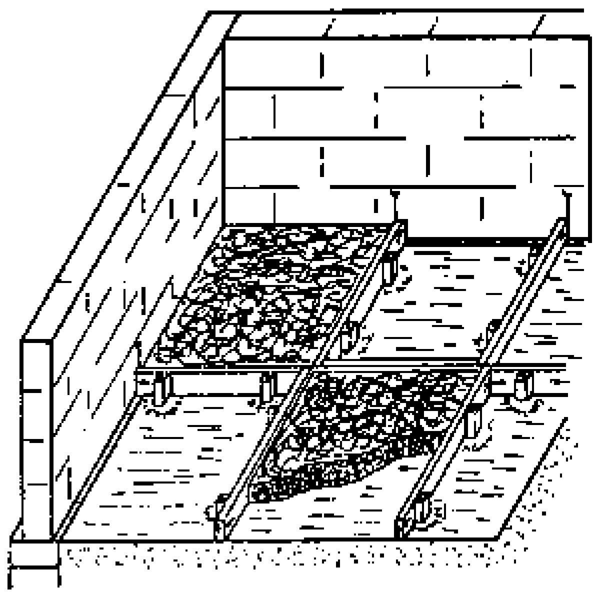

Fig. 1

j. Compact the concrete with a rammer, especially the corners and edges.

k. Use the notched strike board (Fig. 3) to level the surface by gently tamping until the layer is screed-thickness below the top of the edge boards.

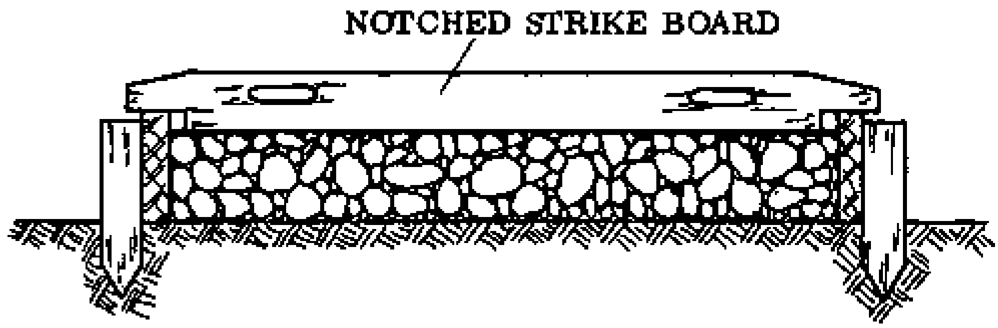

Fig. 3

l. Prepare the mortar for the screed layer. This should be moist but not wet.

m. Pour this mortar on top of the concrete. The screed is about 2 cm thick.

n. Tamp the screed down with a strike board until a level surface is obtained (Fig. 2).

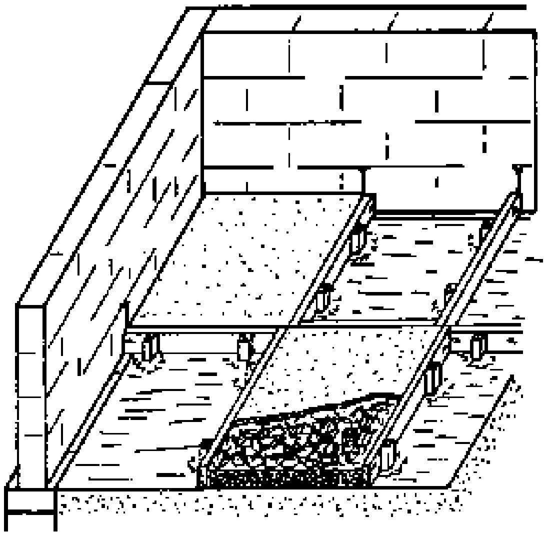

Fig. 2

o. Use the wood float to tamp the screed until the moisture from the concrete comes through. At the same time smooth the surface with the float. During this operation dip the float regularly in water and sprinkle water on top of the screed if necessary to make the work easier.

p. If a smoother surface is desired, finish off with a steel float. Make a chamfer along each edge next to the edge board to form half of the “V” groove above the shrinkage gap (Figs. 4 & 6).

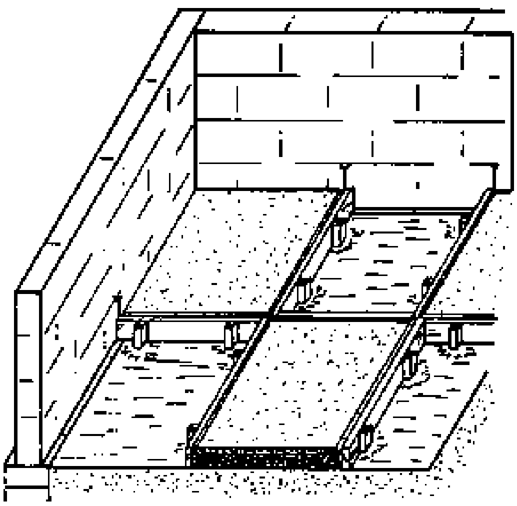

Fig. 4

Fig. 6

q. If blisters or bubbles appear when the concrete starts to harden, pop them and close the holes.

r. Let the floor harden for some hours, then sprinkle water over it. Keep the floor wet at all times.

s. The next day, put some clean sand on top of the floor and wet it thoroughly. Keep the sand wet until the hardening process is over in several days time.

t. Remove the edge boards and cast the remaining bays in the same way. Make sure that the bays are separate by putting pieces of plastic or paper between them before pouring the concrete in the other bays (Fig. 5). The tops of the finished bays act as guides for the strike boards, but be careful not to damage them (Fig. 7).

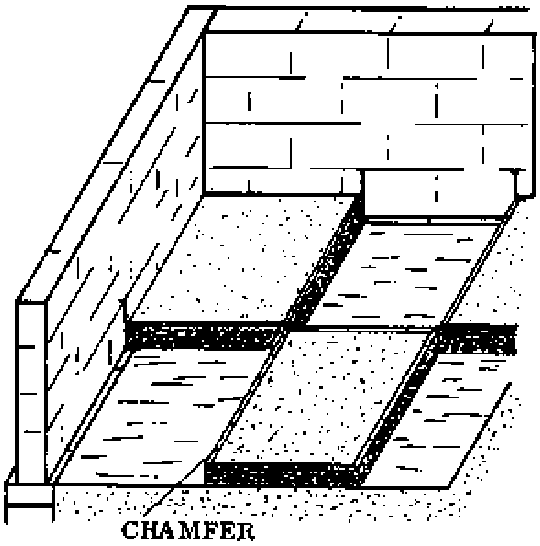

Fig. 5

Fig. 7

Verandah floors

The construction of a verandah floor is different from that of an inside floor in three particular ways.

- Usually the verandah floor is built with a small slope towards the outside so that rain water can run off quickly (Fig. 1, a).

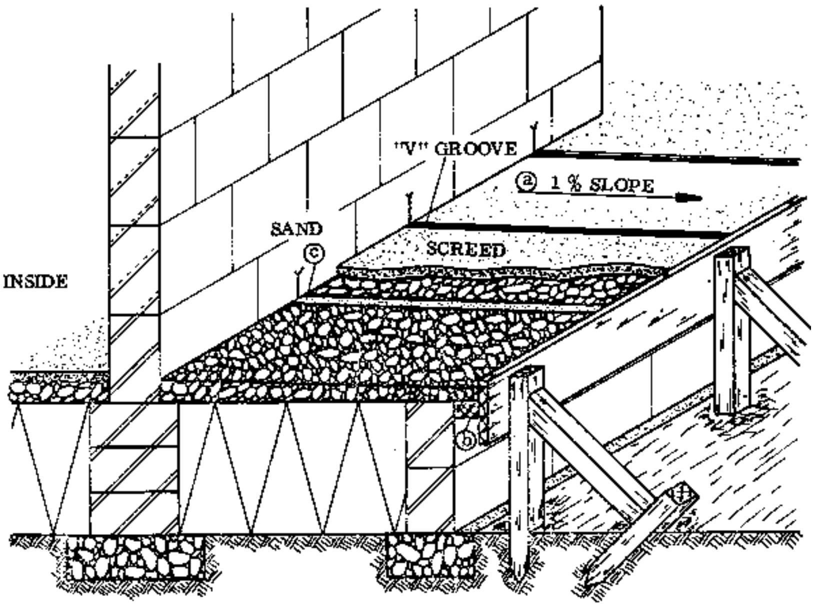

Fig. 1

- The verandah floor can have a projecting outside edge (Fig. 1, b).

- Because the floor is exposed to the sun, expansion gaps have to be made in it. This means that the floor must be made with the two-course method. (Fig. 1, c, and Basic Knowledge book, page 183).

- SLOPING FLOOR: Verandah floors may have a slope which is about 1%; no more than 2%, because this could cause problems in walking and working on it. The greater slope increases the danger of slipping when the surface is wet.

A slope of 1% means that the floor slopes 1 cm lower in every metre; in this case the slope is across the width of the floor.

The construction of the slope is done by simply setting the edge boards between the bays at the required slope.

- PROJECTING OUTSIDE EDGE: If the outside edge of a verandah floor is kept flush with the render of the footing (Fig. 2), then cracks would soon appear along the edge. This is prevented by constructing the floor so it projects past the footing by no more than 7,5 cm. The shorter the projection the better, because the floor is not reinforced.

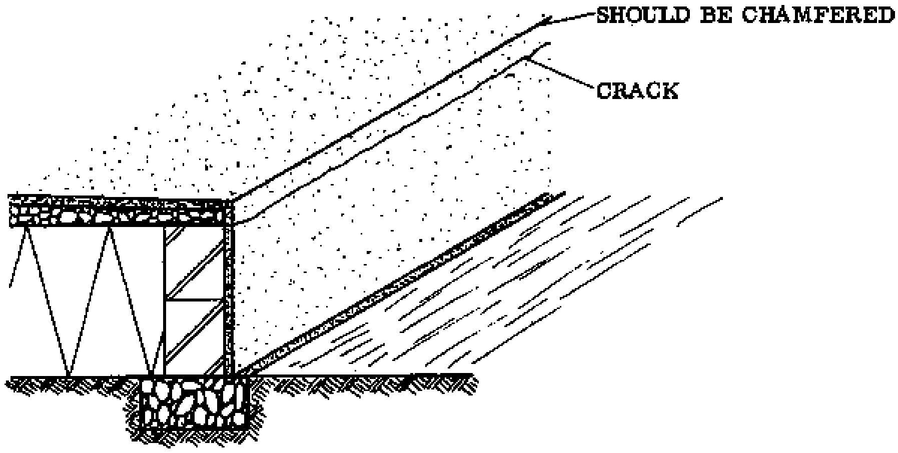

Fig. 2

NOTES:

STAIRS

A stair means a series of at least three steps, also called a flight of stairs. A stair can form the link between two storeys of a building. In Rural Building we are only concerned with one storey buildings, so the stairs are usually only needed up to the level of the floor of the building, which is normally not much higher than 60 cm above ground level.

- TECHNICAL TERMS: Fig. 1 shows the parts of a staircase.

  - TREAD: The tread is the horizontal part of the step (a).

  - RISER: This is the vertical part of a step (b).

  - GOING: This refers to the width of the tread (c). The “going” of a flight of steps is the sum of the “goings” of all the steps of the flight.

  - RISE: This is the vertical distance between two treads, equal to the height of the riser (d).

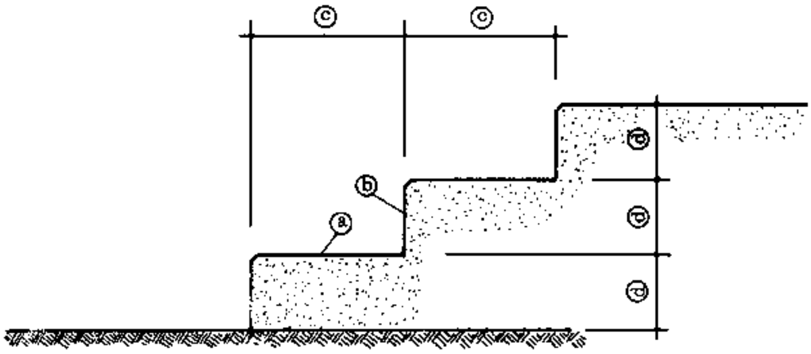

Fig. 1

Requirements

The short flights of stairs we make in Rural Building are usually built with sandcrete blocks or are cast out of concrete. Regardless of the materials and the method of construction, the steps must be all the same height and the same width. A staircase with steps of different sizes is likely to cause accidents.

The rise of the steps is usually 15 cm (approximately) and the width of the tread, the “going”, is usually about 30 cm for each step.

The steps in Fig. 2 are built with sandcrete blocks, so the rise of 17 cm is convenient because it fits in with the block size. The width of the tread can be about 28 cm, or slightly more than the half-block size.

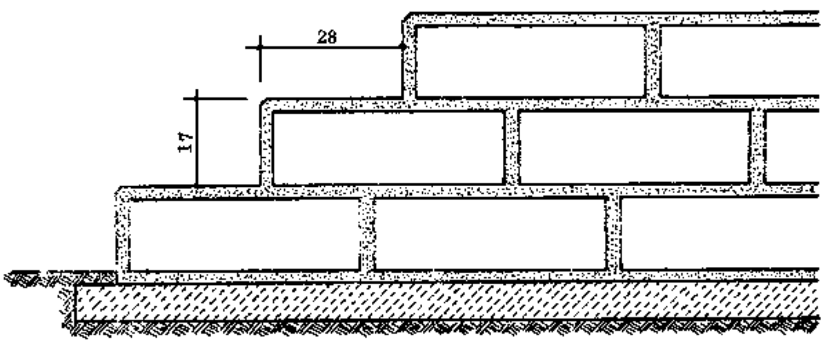

Fig. 2

Steps cast out of concrete can have any convenient rise, but normally the rise is about 15 cm high, and the width of the tread will be approximately 30 cm. The formwork for casting the steps is shown in Fig. 3.

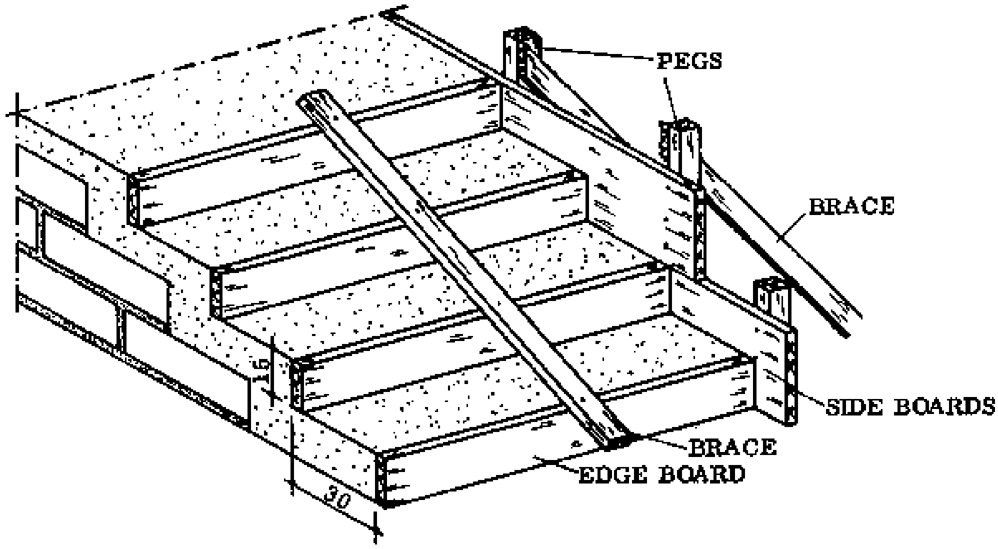

Fig. 3

Plan ahead. If the steps with a 15 cm rise do not reach the right level (measure the height before you start to make the steps) either change the height of the rise (to 14, 16, or 17 cm, etc); dig out some soil before to lower the height of the whole stair; or add a foundation slab to raise the whole construction by a few centimetres to the required height.

- REMEMBER: Never make steps of different sizes in the same stair.

FORMWORK

Formwork for copings

A free-standing wall which is not part of the building (not under the roof) needs to be protected against rain, which otherwise might penetrate at the top of the wall and damage it. This is done by adding a “coping” at the top of the wall.

- SADDLE-BACK COPING: This is placed on top of the wall as shown in Fig. 1. The formwork for the coping is shown in Fig. 2. The drip or throating is made by setting two pipes or smooth iron rods in the wet concrete. The correct position can be assured by using wooden spacers tied to the pipe (Figs. 2 & 2a).

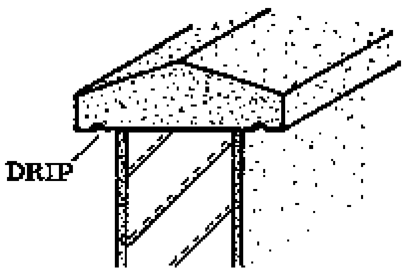

Fig. 1

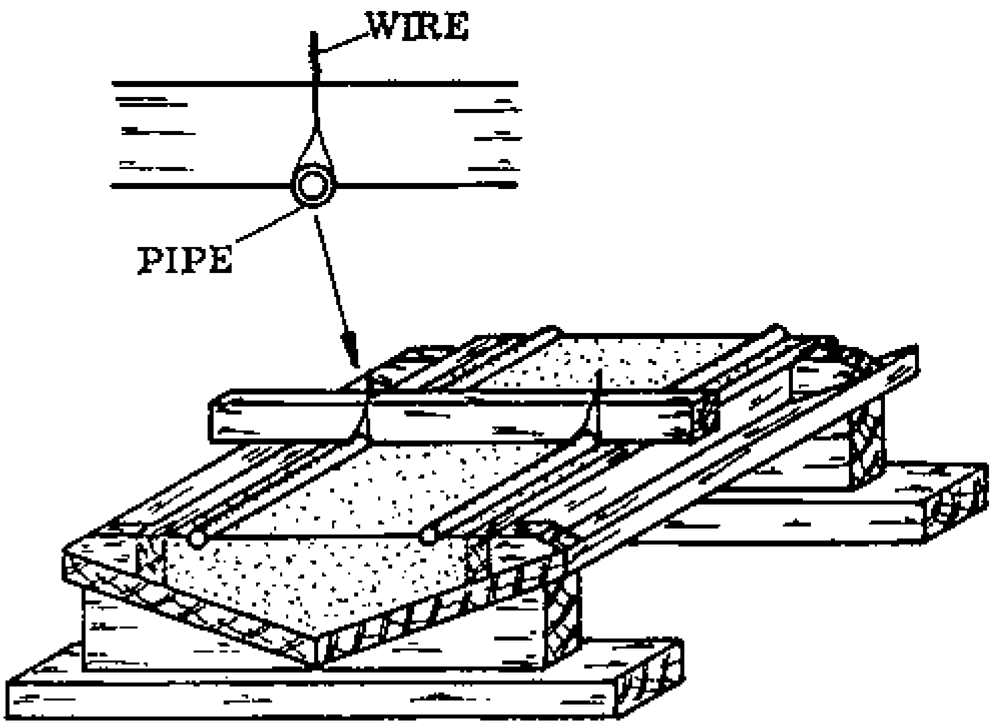

Fig. 2 & Fig. 2a

A second way of making the coping is shown in Fig. 3. A line is fixed at the height of the ridge and the surfaces are shaped with the steel float. The drip is made by fixing half-round beads onto the soffit board of the formwork (Figs. 3 & 3a).

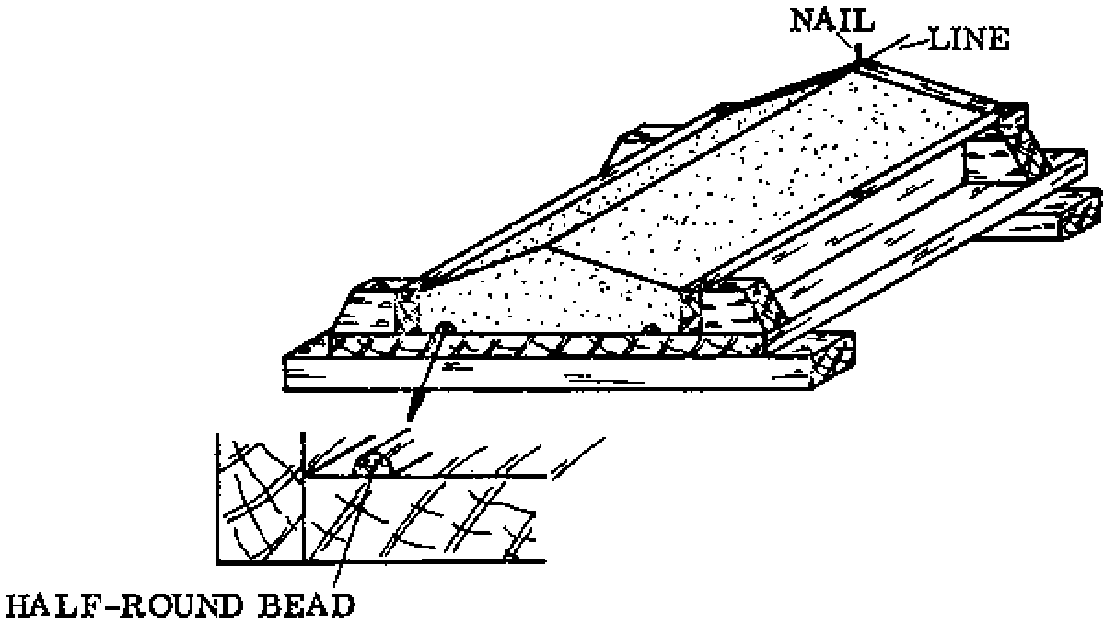

Fig. 3 & Fig. 3a

- SPLAYED COPING: The splayed coping in Fig. 4 can also be made in two ways, in a fashion similar to the saddle-back coping above (Figs. 5 & 6).

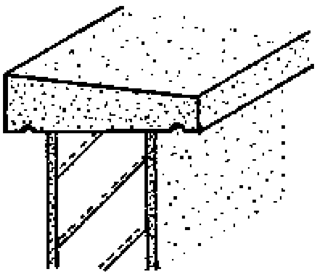

Fig. 4

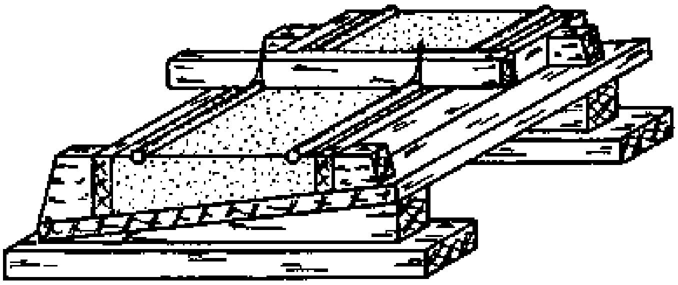

Fig. 5

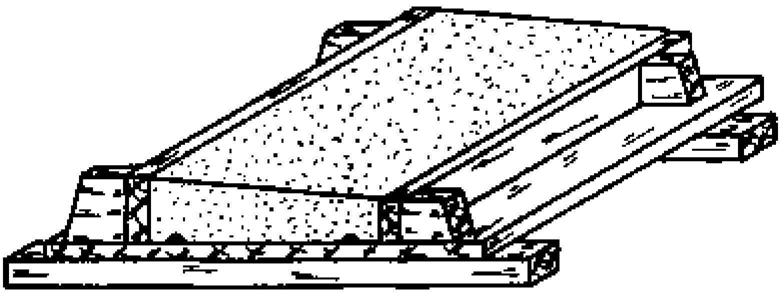

Fig. 6

Formwork for pillars

The formwork for a concrete pillar is shown in Fig. 7 below.

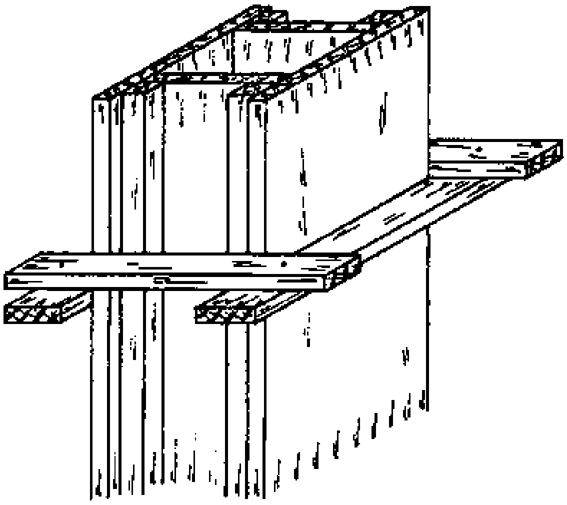

Fig. 7

Formwork for slabs

Fig. 1 shows an example of formwork for a slab. Paper should be set underneath before the concrete is cast.

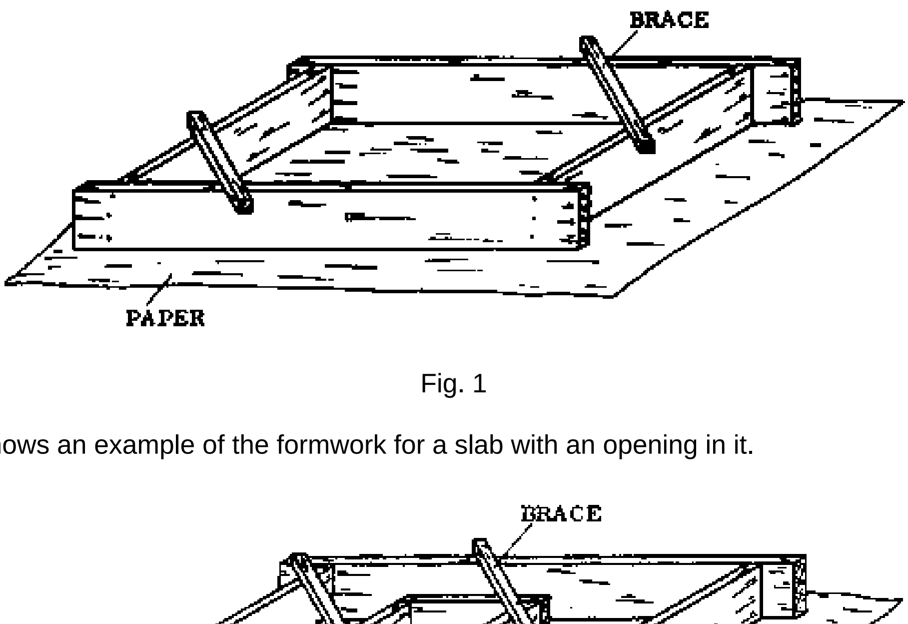

Fig. 1

Fig. 2 shows an example of the formwork for a slab with an opening in it.

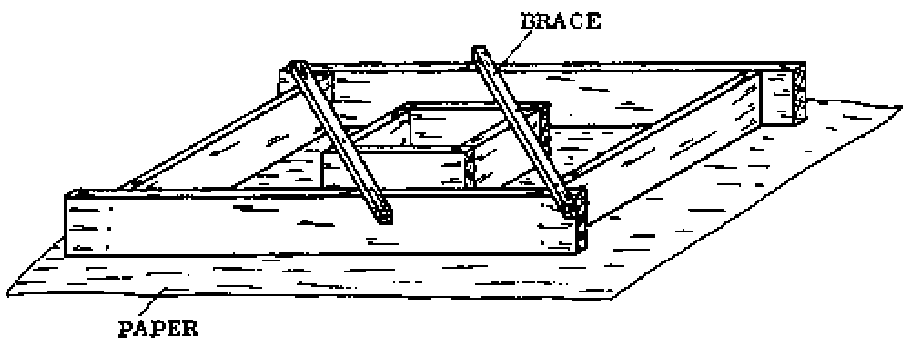

Fig. 2

General hints for formwork

- Use good, straight-grained wood.

- Make a sketch of the formwork before you start to make it.

- Design the formwork so it can be easily removed from the piece after curing.

- Use enough supports and braces to make the formwork rigid and strong.

- Be aware that the wood swells when it is in contact with the wet concrete.

- If the concrete will not be plastered later, plane the formwork members smooth where they are in contact with the concrete.

- Do not overnail the structure, and fix the nails so that they can be taken out easily.

- Oil the form lightly where it is in contact with the concrete.

- For precast members, put the form on the ground in a level spot, and put paper underneath it (old cement bags).

- Remove the formwork only when the concrete has hardened sufficiently (the time depends on the member which is cast).

- Be careful not to damage the edges and corners of the concrete piece when you remove the formwork.

- Clean off the formwork with a steel brush and take out all nails when you finish.

NOTES:

REINFORCED CONCRETE SLABS

In the northern part of Ghana a typical traditional house has a flat roof made of mud plastered over sticks, and supported by tree trunks. The flat roof is very appropriate for the area, but sometimes these traditional constructions have problems like leaking or even collapse during heavy rains.

In Rural Building we do not deal with the construction of flat roofs, even though these would be more appropriate to the local customs. The reason is because the materials to construct a safe, strong flat roof are expensive, and the construction of a reinforced concrete roof is very difficult and complicated.

Therefore, in this course we only treat the construction of relatively small reinforced concrete slabs such as manhole covers, latrine slabs, septic tanks, etc.

Construction

Reinforcement mats are a simple way of reinforcing slabs (Reference Book, page 173) but they are sometimes hard to obtain and they are expensive. The Rural Builder usually has to rely on single reinforcement bars to reinforce slabs.

Fig. 1 shows a typical arrangement for a circular slab, and Fig. 2 shows that for a rectangular slab.

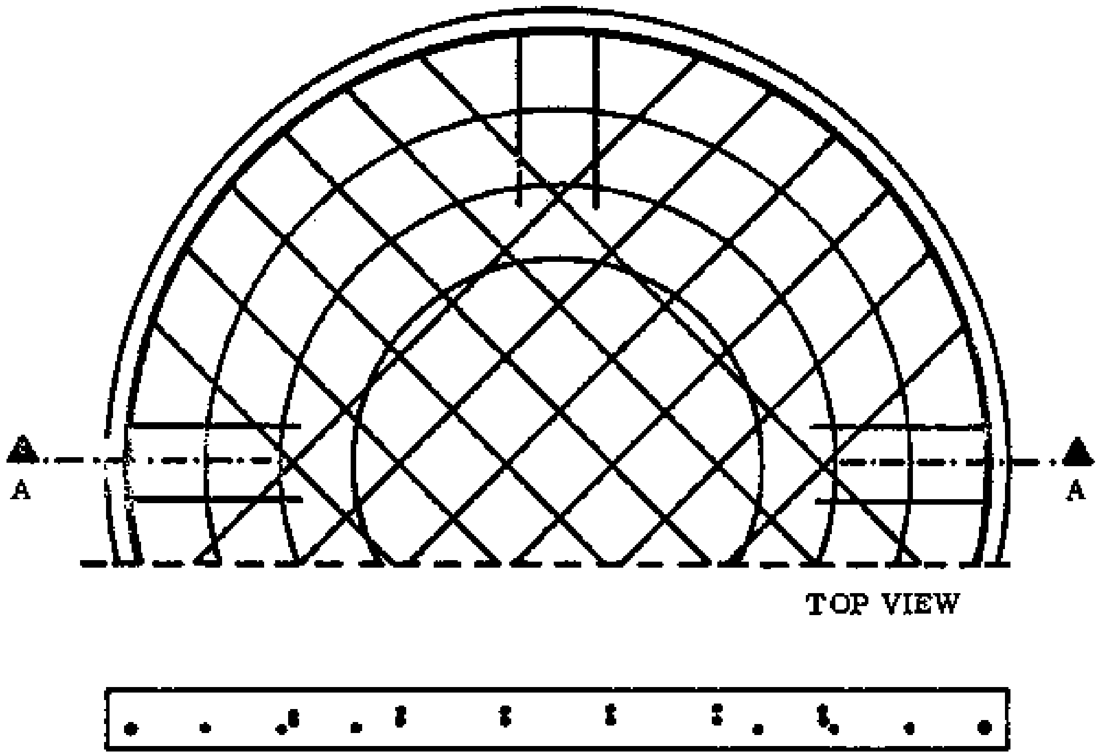

Fig. 1

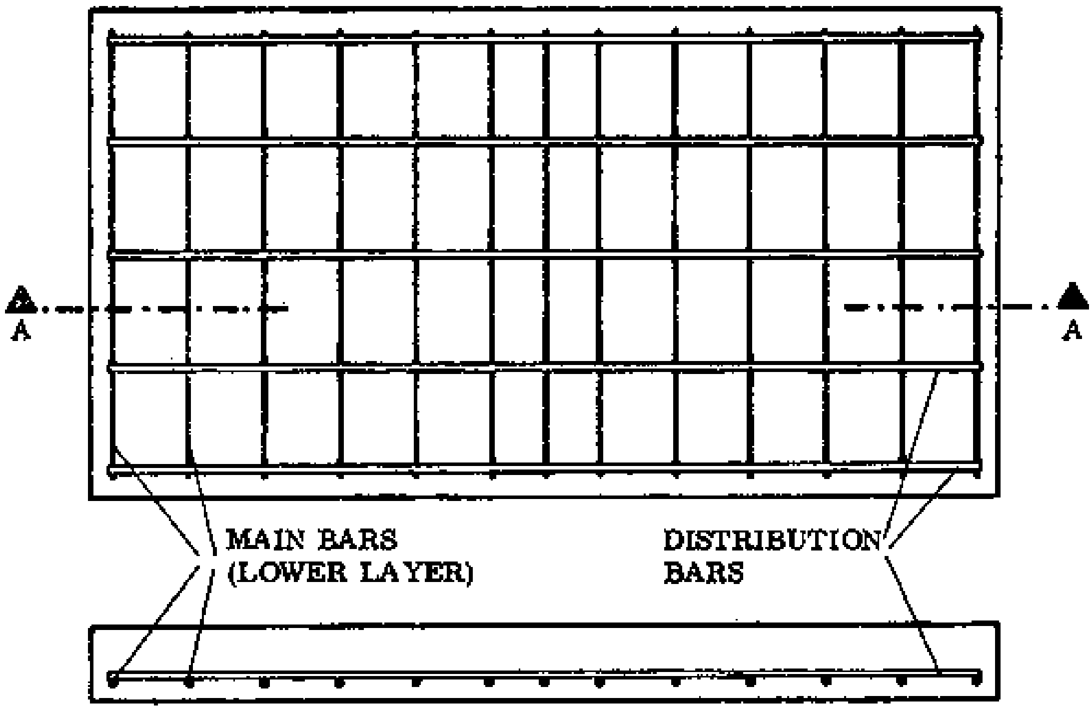

Fig. 2

The distance between the 12 mm main bars is never more than 10 cm. The thickness of the slab can vary between 7,5 cm for smaller slabs like manhole covers, and up to 15 cm for covers of septic tanks, or slabs on which people may walk.

- NOTE: This book is not meant to train engineers; it merely gives basic information. If you need to construct a larger reinforced concrete member, you are advised to seek help from a building expert.

NOTES:

HANGING DOORS AND WINDOWS

The first step in hanging a door is to make sure that the posts of the door frame are plumb. If the posts are not plumb the door will not hang properly. A door should remain in position, either open or closed, without the aid of a stop. It should not swing open or closed by its own weight. The same applies for window casements.

If the door posts are not plumb, the only solution is to fix the hinges in positions such that the door itself hangs plumb.

Hanging a door with butt hinges

Before you read the following section, look up butt hinges in the Reference Book, pages 219 to 221.

- SEQUENCE OF OPERATIONS:

a. Set the door into the door frame.

b. Check whether there is a sufficient clearance all around the door (at least 3 mm, more in the dry season).

c. Mark the positions of the hinges, then take the door down and mark the length of the hinges on the door (Fig. 1).

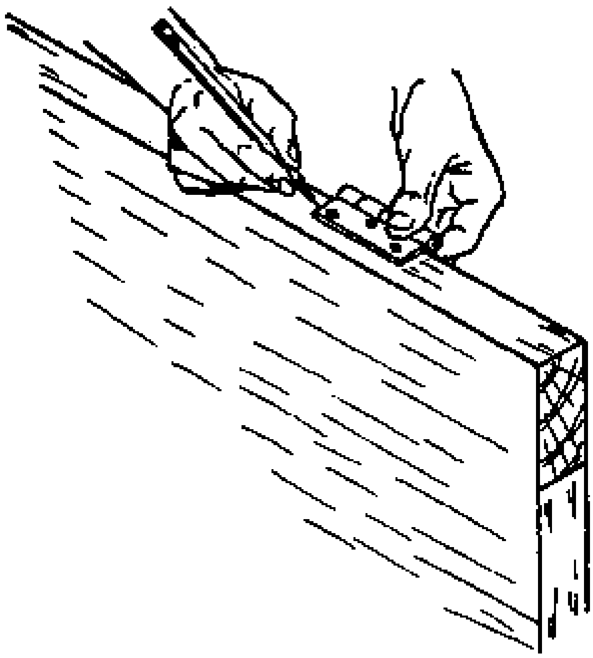

Fig. 1

d. Set the marking gauge from the middle of the pin of the hinge to the edge of the hinge leaf, and mark the distance on the edge of the door (Fig. 2).

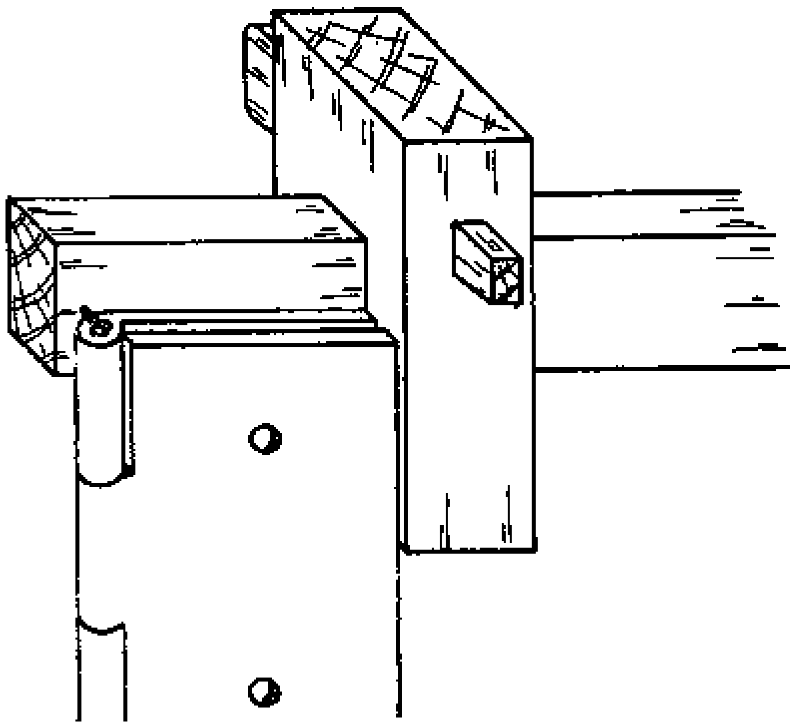

Fig. 2

e. Set the marking gauge to the thickness of one hinge leaf, and mark this on the face of the door (Fig. 3).

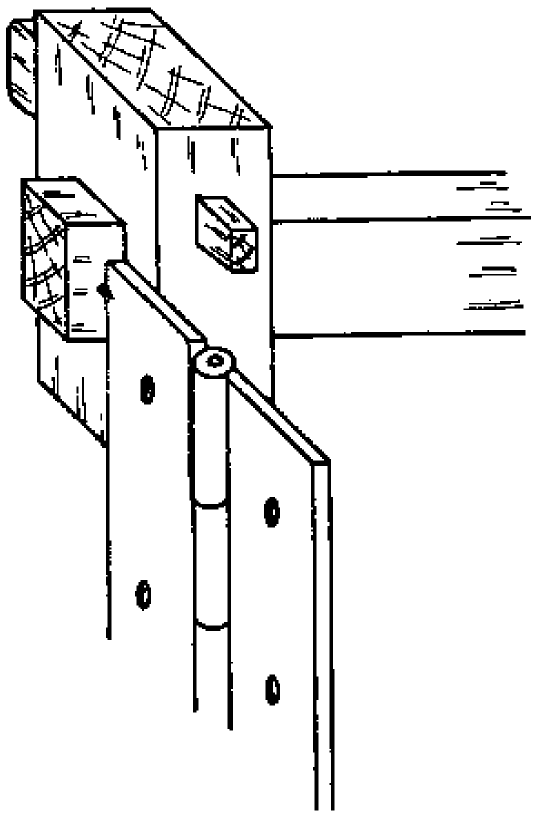

Fig. 3

f. Chisel the recesses for the hinges in the door, and fix each hinge with one screw (Fig. 4).

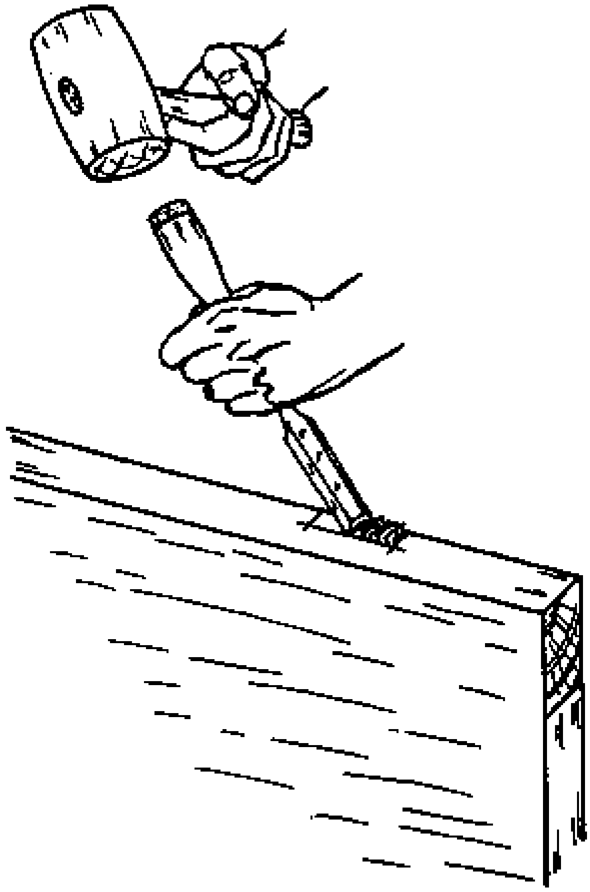

Fig. 4

g. Place the door in the door frame so that there is equal clearance around all the edges. A few thin pieces of wood between the door and frame will help to keep it in place.

h. Mark the positions of the hinges on the post. Remove the door.

i. Mark the depth and width of the hinge recess on the post, using the marking gauge.

j. Chop the recesses in the post.

k. Place the door in position and fix it to the door post with one screw in each leaf of the hinges. Close and open the door several times to see if it works smoothly. Notice in particular whether the door closes completely and does not scrape either post. It should stay closed by itself.

The same sequence as above also applies for casements.

- ADJUSTMENTS OF THE HINGES: Below are some tips for getting a door or casement to close properly.

- If one hinge recess is deeper than the other, loosen the screws and pack the deeper recess with thin strips of wood, until the depths of the recesses are the same.

- When a door binds (catches or rubs) on the hinge post, insert thin pieces of wood at the face edge of the hinges (near the pin) until the problem is relieved (Fig. 1). A strip about 1 cm wide and as long as the hinge will do.

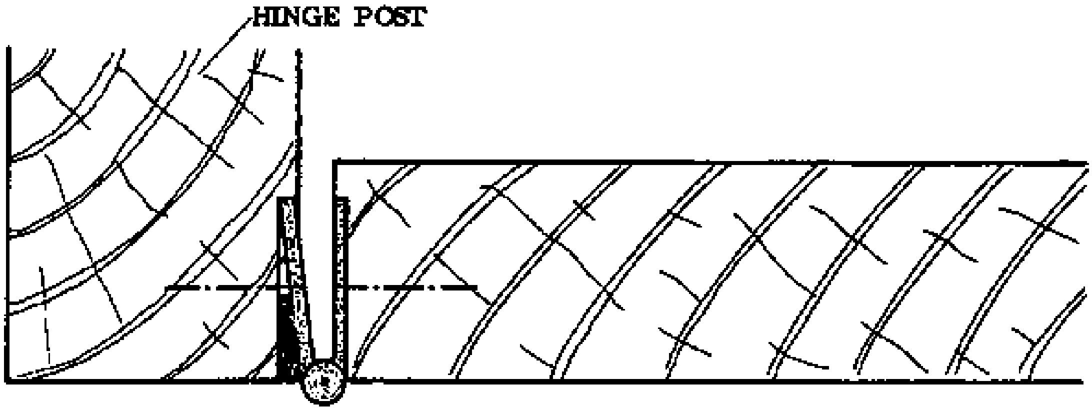

Fig. 1

- When a door binds on the locking post, insert the wood strip at the back of the hinge, to force the door away from the lock post (Fig. 2).

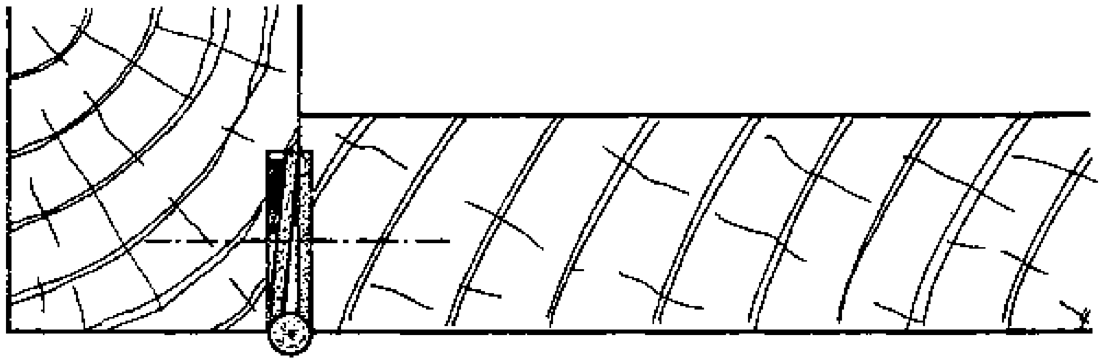

Fig. 2

- If the wood strips are not enough to relieve the problem, you will have to re move the door and plane something off, alter the hinge recesses or even move them a bit up or down.

- One possible reason that a door won't close well is that it is hinge bound/This means that the leaves of the hinges are set too deep. To remedy this, you must remove the hinge and place a thin piece of wood between the leaf and the post (Fig. 3).

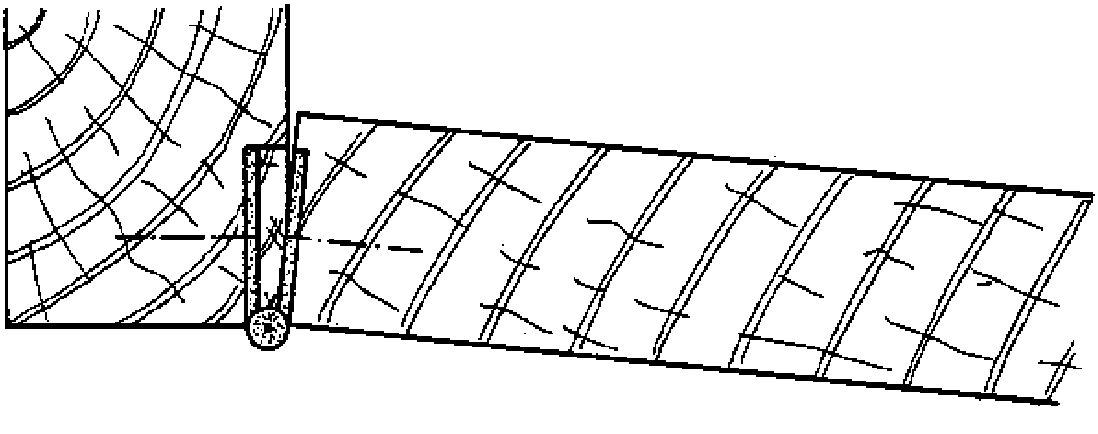

Fig. 3

- When the hinge is screw bound, the heads of the screws obstruct the door so that it can't close properly. This is often the case when the screws are too thick for the hinges, or the heads are too large. The only remedy is to fix the correct screws (Fig. 4).

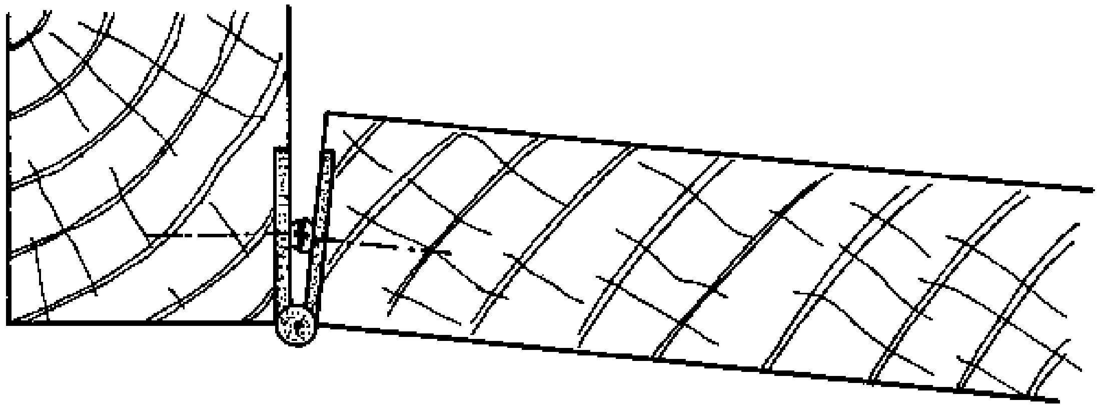

Fig. 4

NOTES:

LOCKS AND FITTINGS

Mortice lock

Before you read this section look up mortice locks in the Reference Book, pages 221 to 223. Pay attention to the names of the parts of the lock.

- SEQUENCE OF OPERATIONS FOR INSTALLING A MORTICE LOCK:

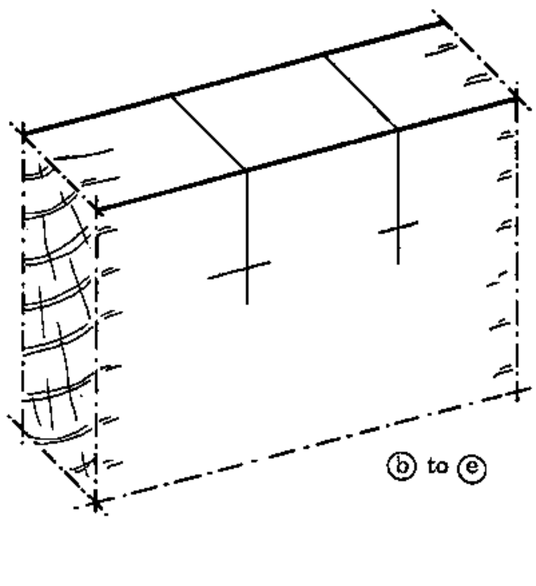
a. Place the door on edge against the side of the work bench, with one face against the bench and with the shutting stile upwards.

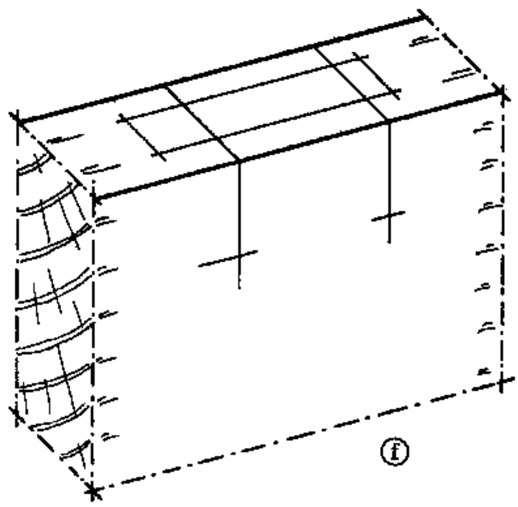
b. Mark the distance from the bottom edge of the door to the centre of the “bush” (the bush is the hole where the handle fits through, normally it is 105 cm from the bottom edge of the door).

c. Square the positions of the key hole and the bush on the face and edge of the door.

d. Set a marking gauge with the distance from the outside edge of the lock face plate to the centre of the key hole. Add 2 mm allowance for planing off later.

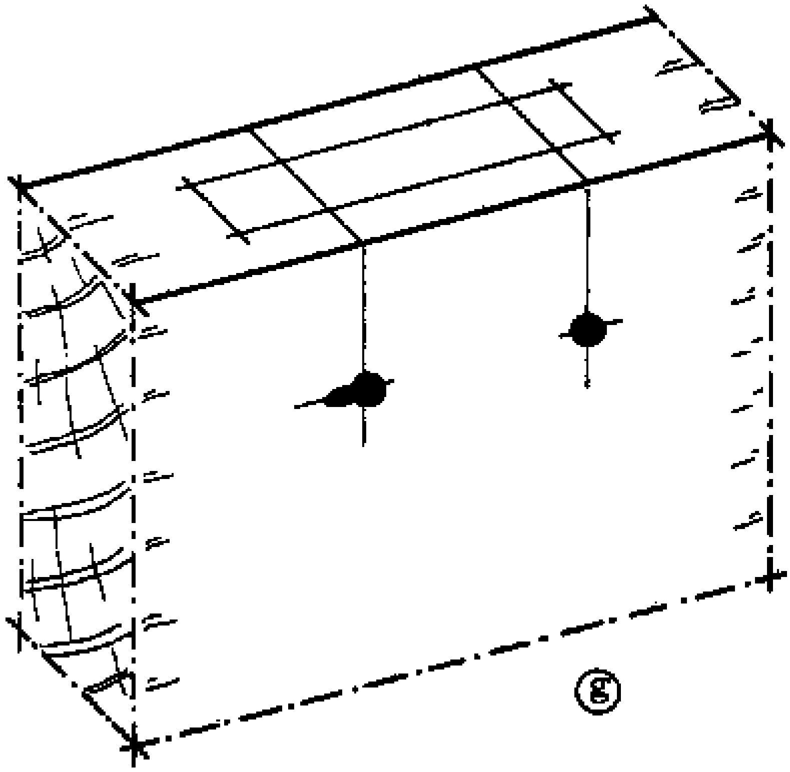
e. Mark this gauge setting on the door.



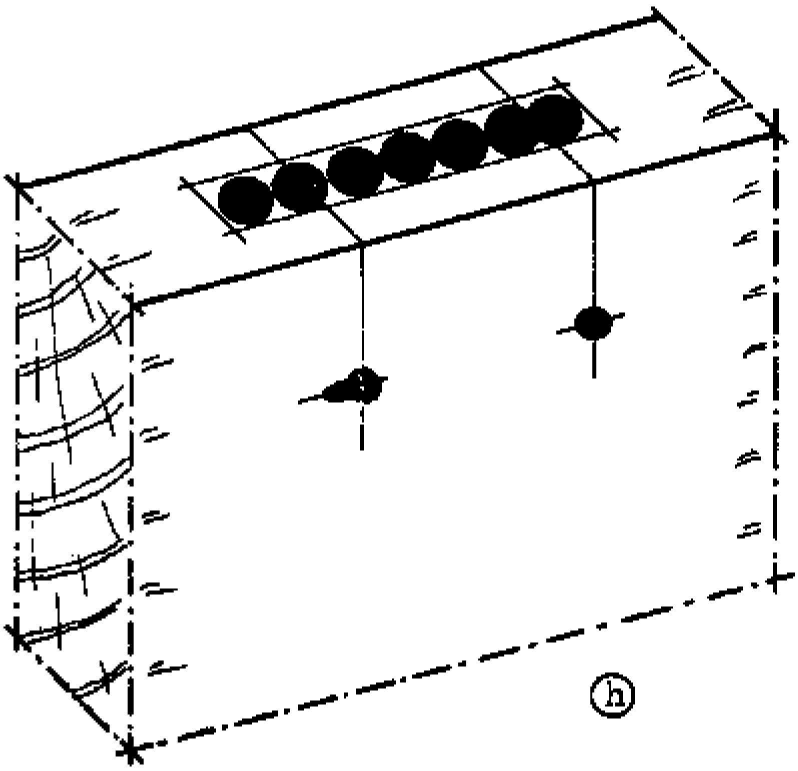


f. Mark the position of the lock stock onto the shutting edge of the door.

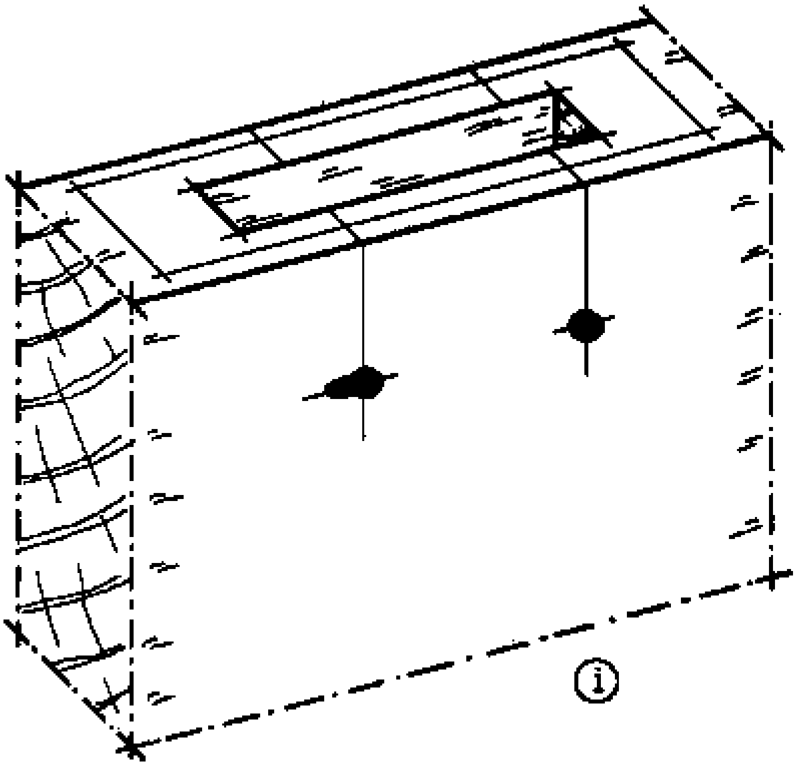
g. Clamp a piece of waste wood under the door to prevent splintering. Drill the bush hole and the keyhole. Complete the slot for the key hole with a chisel.



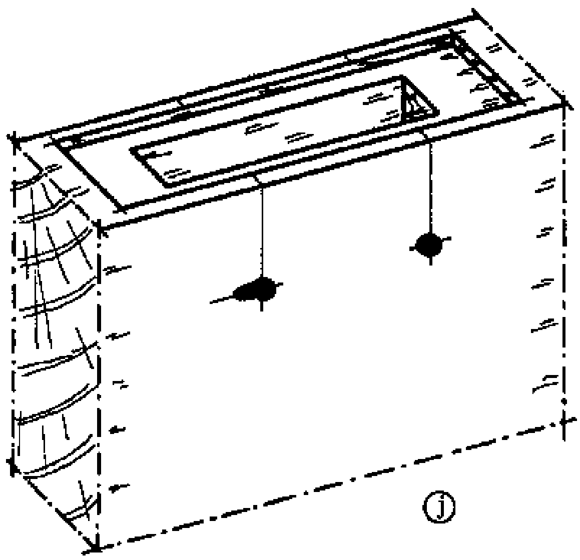
h. Chop the recess for the stock with a mortice chisel. Much of the waste can be bored away with a drill. Take care that the stock fits tightly against the sides of the mortice.



i. Drop the lock in the mortice and mark the position of the face plate on the door edge. Remove the lock.



j. Chop the recess for the face plate with a mortice chisel.



k. Drop the lock in again and insert the key and the handle with the fixed spindle. Check that there is nothing blocking the key and handle.

l. Attach the lock with screws.

m. Hold one leaf plate in position on the outside of the door. Insert the key and the handle with the spindle.

n. Attach the leaf plate to the door with screws.

o. Fix the leaf plate on the other side of the door in the same manner.

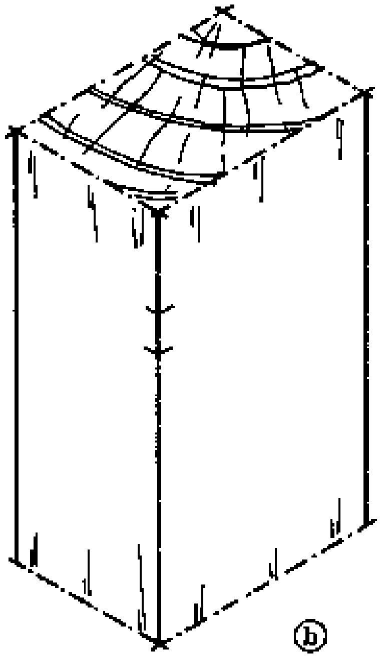
p. Secure the loose handle onto the spindle, with the pin.

The installation of a mortice lock with a cylinder is similar to the above procedure; but instead of a key hole, a hole is drilled for the locking cylinder.

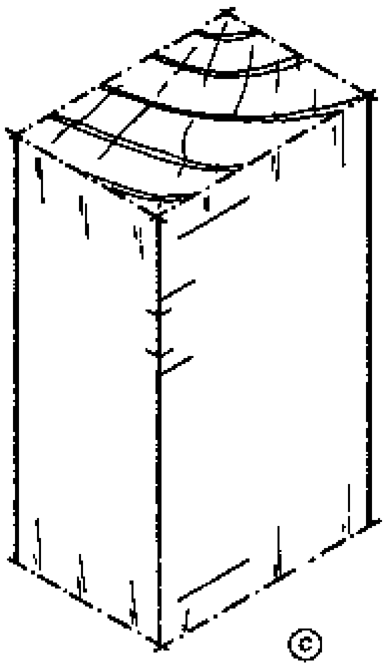
- SEQUENCE OF OPERATIONS FOR INSTALLING THE STRIKING PLATE:

a. Set the door with the mortice lock into the door frame.

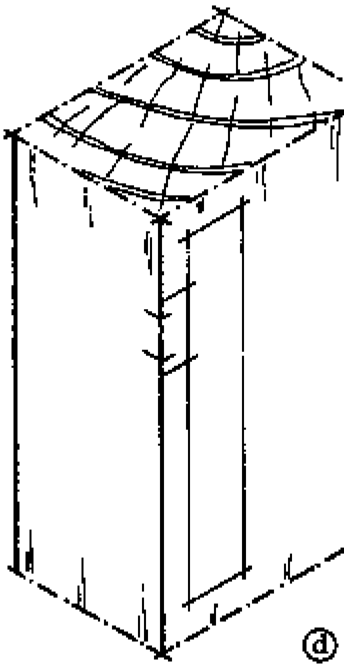
b. Mark the position of the latch bolt onto the door frame.



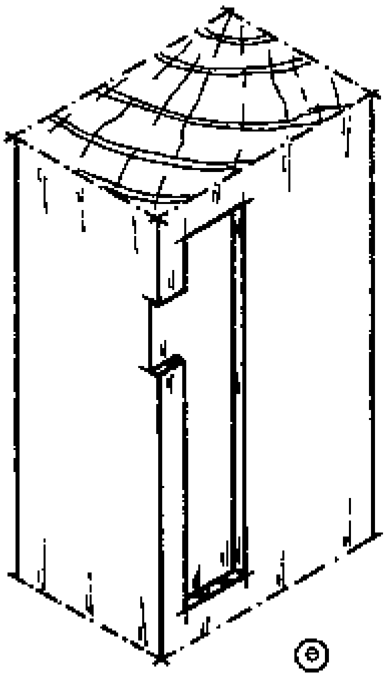
c. Hold the striking plate to the post in the correct position and mark the position on the post.



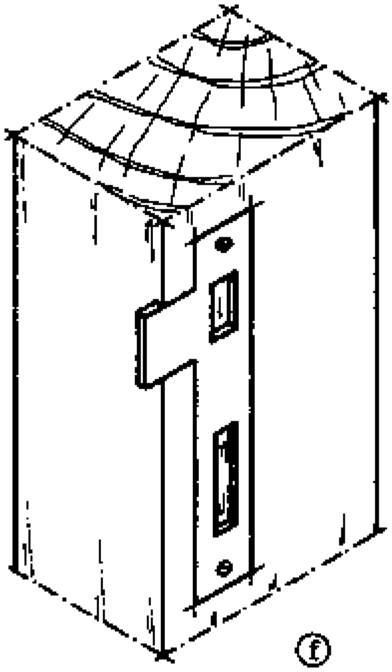
d. Set the gauge and use it to mark the vertical lines.



e. Cut the recess for the striking plate.

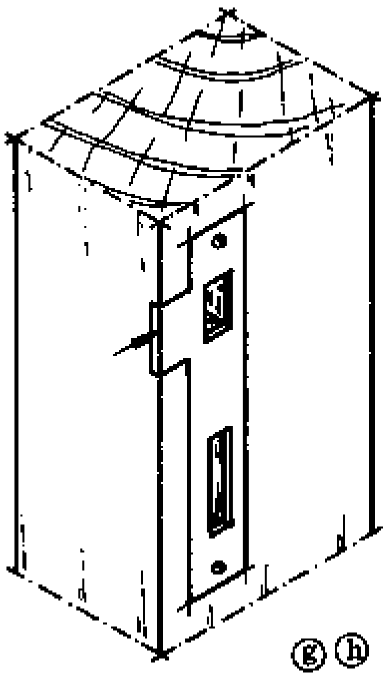


f. Fasten the striking plate to the post with screws.



g. Chop the recesses for the latch bolt and the lock bolt while the striking plate is in position.

h. Cut off the projecting lug of the striking plate (arrow).



i. Close the door and check whether the latch bolt and the lock bolt can move freely and fit into their recesses.

In the case of a door frame with beads, the beads can be fixed after the door is properly hung and the locks installed.

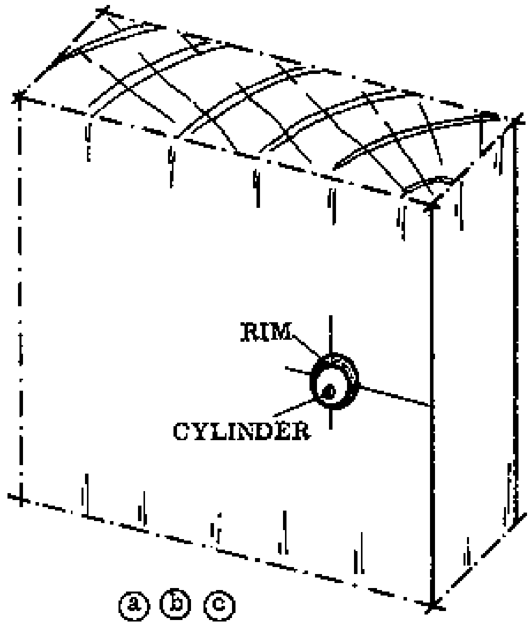
Rim lock

Look in the Reference Book, page 225, for information about this type of lock and its parts before you read on.

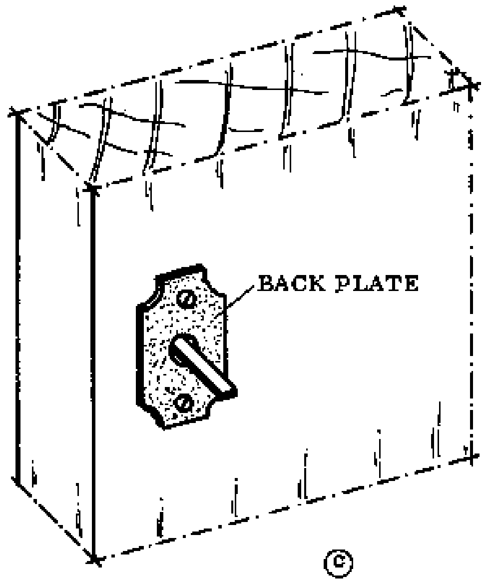
- SEQUENCE OF OPERATIONS FOR INSTALLING A CYLINDER RIM NIGHT LATCH:

a. Mark out the position of the cylinder on the door (normally 105 cm from the bottom of the door).

b. Drill a hole with the diameter of the shell.

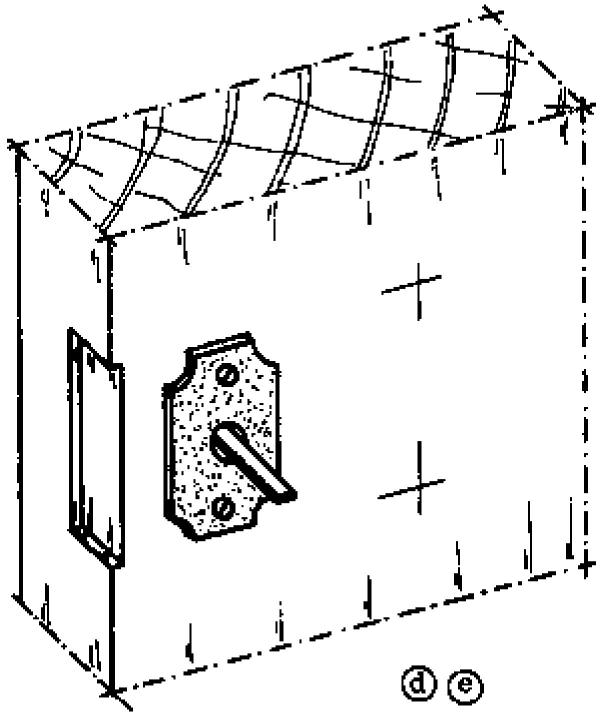


c. Insert the cylinder with the rim into the hole, and attach the back plate to the opposite side of the door with screws.

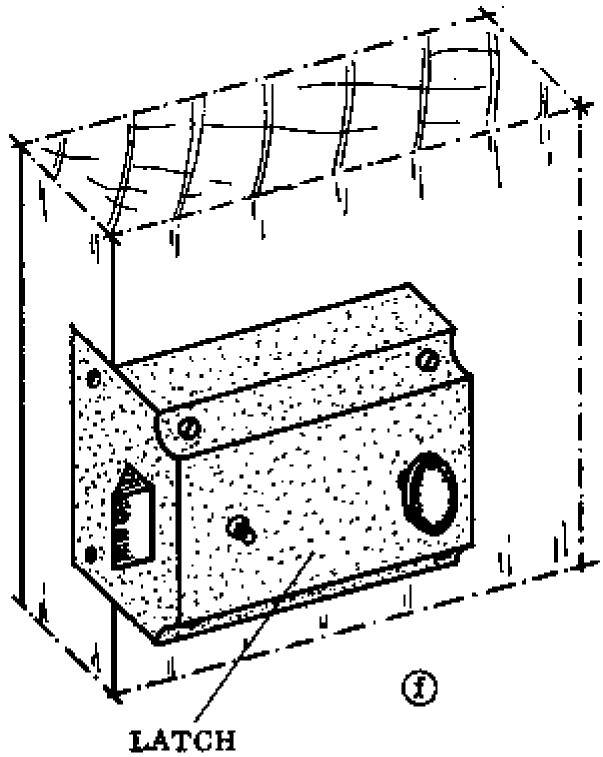


d. Mark the position of the latch and its face plate.

e. Chop the recess for the face plate.

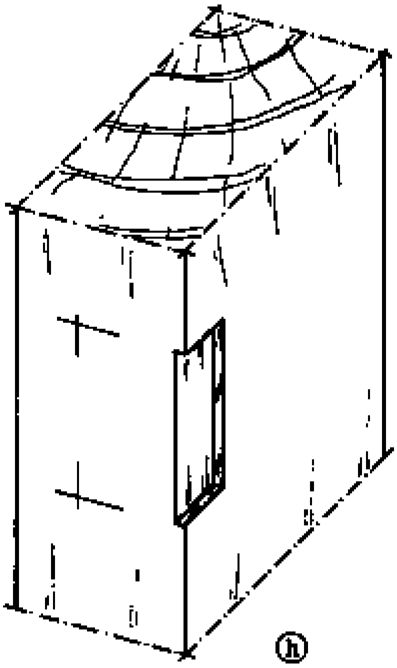


f. Attach the latch to the door with screws. Also use two screws on the face plate to attach the lock securely.

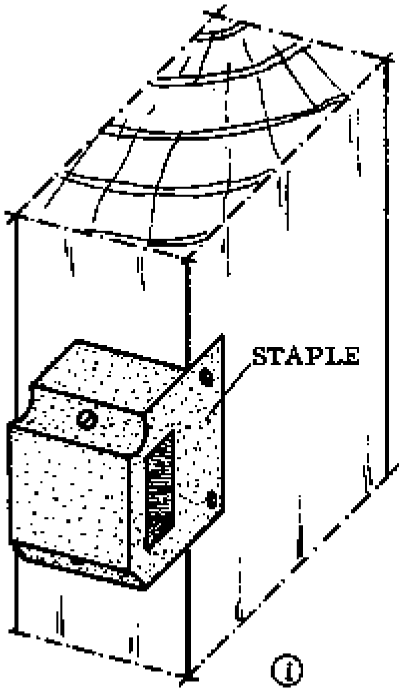


g. Turn the knob and check that the latch operates smoothly.

h. Mark the staple on the post and chop the recess for the staple face plate.



i. Attach the face plate to the post with screws.



j. Check that the bolt of the latch fits in the staple.

CEILINGS

The best method of keeping the building cool is to separate the rooms from the roof by a ceiling. The ceiling also keeps out dust and dirt, gives the room a nicer appearance, and makes it quieter.

In Rural Building, we deal only with plywood ceilings. These consist of sheets of thin plywood nailed to ceiling joists (the wooden beams which carry the ceiling). The edges where the plywood sheets join are covered by the ceiling battens (Fig. 1).

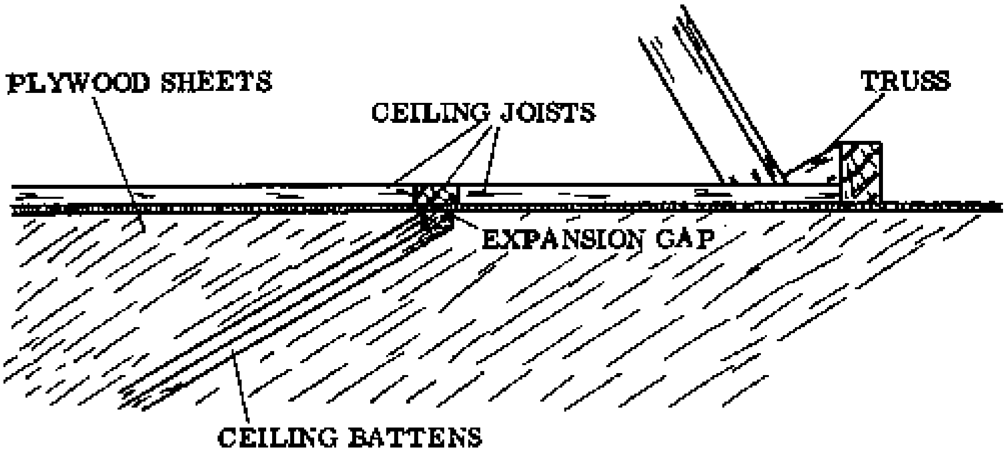


Fig. 1

- NOTE: Cross ventilation is extremely important. Every ceiling should be constructed so that there is cross ventilation between it and the roof. If this is not done, bats and other animals will make their homes above the ceiling; and also any dampness will soon cause the ceiling sheets to rot.

Cross ventilation keeps heat from building up between the roof and the ceiling, and thus the rooms are cooler (Fig. 2).

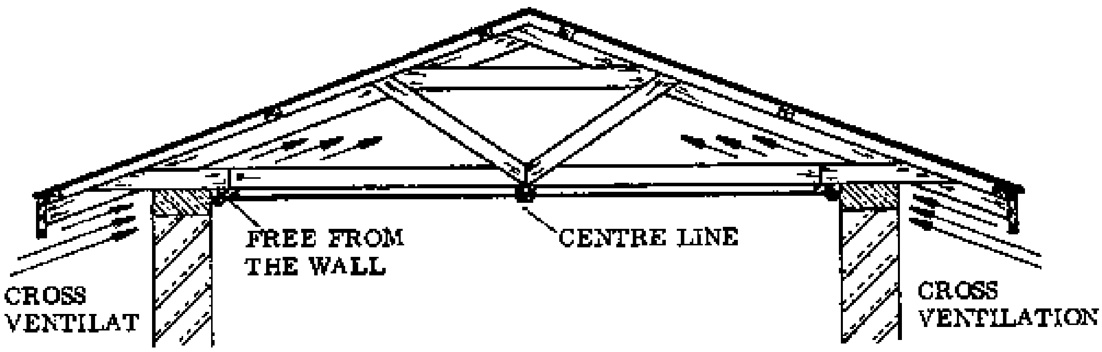

Fig. 2

Construction, parts and sizes of plywood ceilings

It is easiest to construct a ceiling under a roof with built-up trusses. If the soffits (undersides) of the trusses are level, the ceiling joists can be nailed between the tie beams. If the tie beams are not level, use battens nailed to the tie beams to build up until the surfaces are level (Fig. 3).

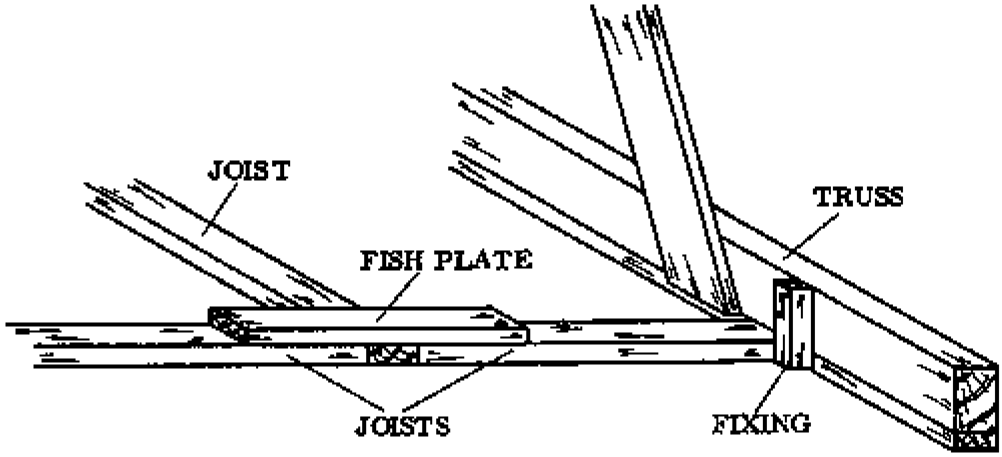

Fig. 3

If you want to fix a ceiling in a building with an ordinary pent roof (without trusses), a separate construction must be attached to the roof construction or to the wall, to provide support for the ceiling joists. Be sure to provide plenty of cross ventilation by some means (ventilation blocks could be used).

The distance between the ceiling joists should be no less than 122 cm. The joists can be left rough, because they are out of sight behind the plywood sheets.

When possible, design the rooms with the plywood sheet size in mind, just as the roof plan is made according to the size of the sheet material. Plan the size of the verandah and the positions of the inner walls so that the rooms are a convenient size and the plywood sheets fit without unnecessary waste.

NOTES:

- INSTALLING THE PLYWOOD CEILING SHEETS: Always start by fixing a line to show the exact centre of the room (Fig. 2, previous page). Start fitting sheets from this line. In case the sheets will not fit exactly in the room without being cut, start by putting one whole sheet in the centre of the ceiling, then divide the remaining space into equal areas.

There should be expansion gaps between the sheets to allow for changes in size with the changes of humidity. These gaps are covered by the ceiling battens. The battens are about 1 by 2,5 cm in size. Paint the ceiling and the battens before fixing the battens.

PAINTING

Paint preserves building materials from rot, rust, and general decay. Timber especially needs some finishing treatment, whether it is used inside or outside the building. Paint helps keep the wood from swelling or warping.

Protective finishes such as oil paints or varnish (Reference Book, pages 200 to 201) cover the wood with a protective “skin”. In order to be effective this skin must be undamaged, and so we have to repair and maintain these finishes periodically.

Which type of finish is used depends on whether the wood will be used outside or inside the building and on the particular function of the wood piece.

The selection of the colours for the inside and outside of the building is important because it affects the temperature of the building. Light colours keep the building cooler.

Preparation of surfaces for painting

Surfaces to be painted should be dry and clean; free from mud, dust, dirt, grease, rust, and old scaly paint.

All the boring, cutting, and shaping should be finished before the paint is applied.

Timbers should be well seasoned to prevent cracking. Paint with cracks in it is worse than no protection at all; water can enter the wood through the cracks, but it cannot evaporate off through the skin of paint so it causes the wood to rot.

If cracks appear in painted wood, sandpaper the wood before you apply new paint, to prevent the cracks from coming back. When you cut painted wood, don't forget to repaint the ends.

How to paint

Paint when the weather is good for drying, and when there is little or no wind or dust in the air. Paint should not be applied in wet weather or when the wood is damp. In new buildings first make sure that they are not damp. New masonry must be thoroughly dry before paint is applied to it. Drying, especially of floors, can take up to 6 months.

Mix the paint thoroughly before you apply it.

Painting is done with a brush. Dip the brush into the paint up to about 1/3rd of the length of its bristles, and remove the excess paint. Never dip the whole brush into the paint because the excess paint will drip out and be wasted.

Use long sweeping strokes and brush the paint well to form an even coating. Start at the top of a surface at one edge, and work across and down. Try to finish each day's work at a corner of the building or at a window. If you stop in the middle of a wall the mark will show where you resume painting the next day.

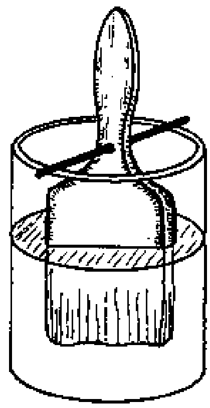
All new work, either of wood or masonry, requires three coats of paint. Surfaces which have been painted before need only two coats.

Before you apply a new coat, the previous coat has to be thoroughly dry. With most paints, the first two coats may be diluted with thinner to allow a better distribution and penetration. Only the final coat must be undiluted.

If wood is unprotected from the rain and sun, it will be necessary to repeat the application of finish from time to time. Take care that the end grain absorbs as much paint as possible.

Never allow a brush to rest upright on its bristles. If you stop work for a few minutes, remove the excess paint from the brush by wiping it on the edge of the tin, then lay it flat across the top of the tin or on a smooth clean surface.

If work is stopped for a longer time (overnight or for a few days), put the brush in a tin of kerosene. Here is an illustration of a good way to keep the paintbrushes; note that the bristles are covered with kerosene but they do not rest on the bottom of the tin. Simply drill a hole in the brush for the stick to pass through.



How to apply timber preservatives

There are two practical methods for applying timber preservatives:

- By painting (as described in the previous two pages)
- By soaking or dipping.

Different types of timber preservatives are required for different situations. The different kinds are described in the Reference Book, page 145.

- SOAKING OR DIPPING: Soaking or dipping is a much more efficient method than painting for applying any kind of timber preservative, because the chemical can penetrate deeper into the wood. This method can also be used for protective finishes such as oil paint.

Use a bucket or other suitable container to soak the wood for several hours or days. This method is only practical for smaller pieces like the ends of fence posts or frame pieces.

In cases where you are repeating the application of a preservative, use a preservative from the same group as the first application. Remember that the waterborne preservatives cannot penetrate over oil preservatives, but it is possible to apply an oil preservative over a waterborne one.

Only waterborne preservatives should be used if the wood will be painted later.

Take care that the end grain and splits absorb as much preservative as possible.

- NOTE: Be careful; most finishes are poisonous and can be fatal to human beings. Paints and paint thinners are often flammable.

NOTES:

APPENDIX

The following pages contain information and designs for constructions which do not necessarily fit under the topic of Rural Building, but which are nevertheless important for the Rural Builder to know about, at least in general. One of the purposes of this course is to prepare the Rural Builder to become a part of the development process in the rural areas, and this includes not only the construction of safe, healthy and comfortable buildings, but also the provision of safe water supplies, sanitation methods, and even the storage of the agricultural produce which is indispensable to rural life.

The following simple designs can be adapted and should be useful to almost any rural community.

NOTES:

WATER PURIFICATION

A water source is important in planning any building. The source can be a well, deep bore hole, spring, stream, or rain water collected from a roof and stored in a tank. The importance of water needs no explanation: it is worth spending both time and money to make sure that pure water is available at all times.

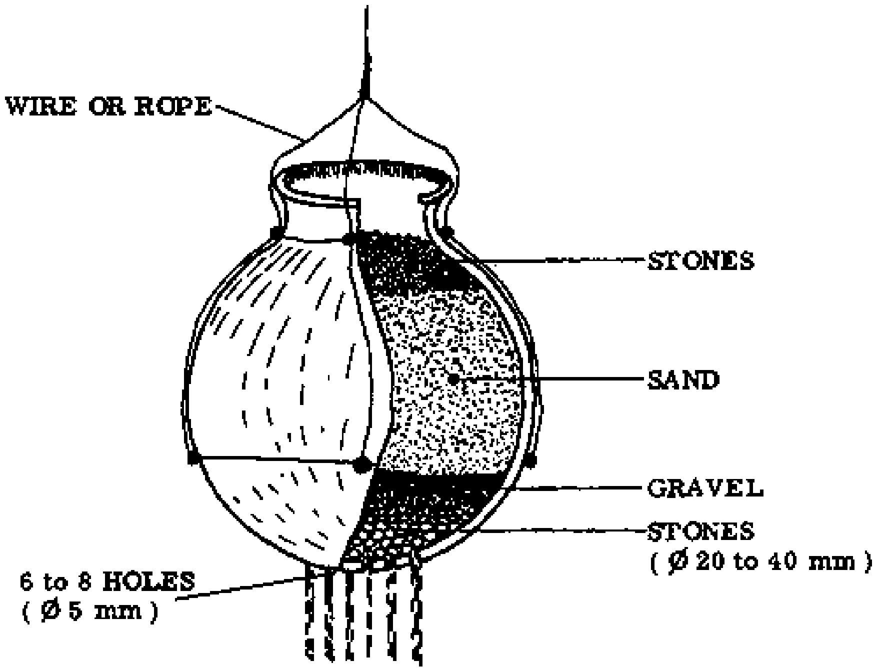
Many diseases come from drinking impure water. The danger of disease can be reduced by taking such precautions as boiling and/or filtering drinking water. Water obtained from a clean source such as a properly dug well or a borehole should carry no disease in it.

There is much that the Rural Builder can do to help the people in his community to have clean water to drink.

Small water filter

One way to improve the quality of water is to use a water filter. A simple design for a filter which can be made by anyone is shown below. It is used for small amounts of water. The filter consists of a locally made pot which hangs from wires or ropes.

The pot is partly filled with layers of fine sand, gravel and stones. The water sinks down through this and drains off through holes in the bottom of the pot. The diameter of the holes should be small enough so that the stones can't pass through.



Large water filter

A built-up water filter (Fig. 1) can be used to purify larger amounts of water. Its size depends on the amount of purified water that is needed.

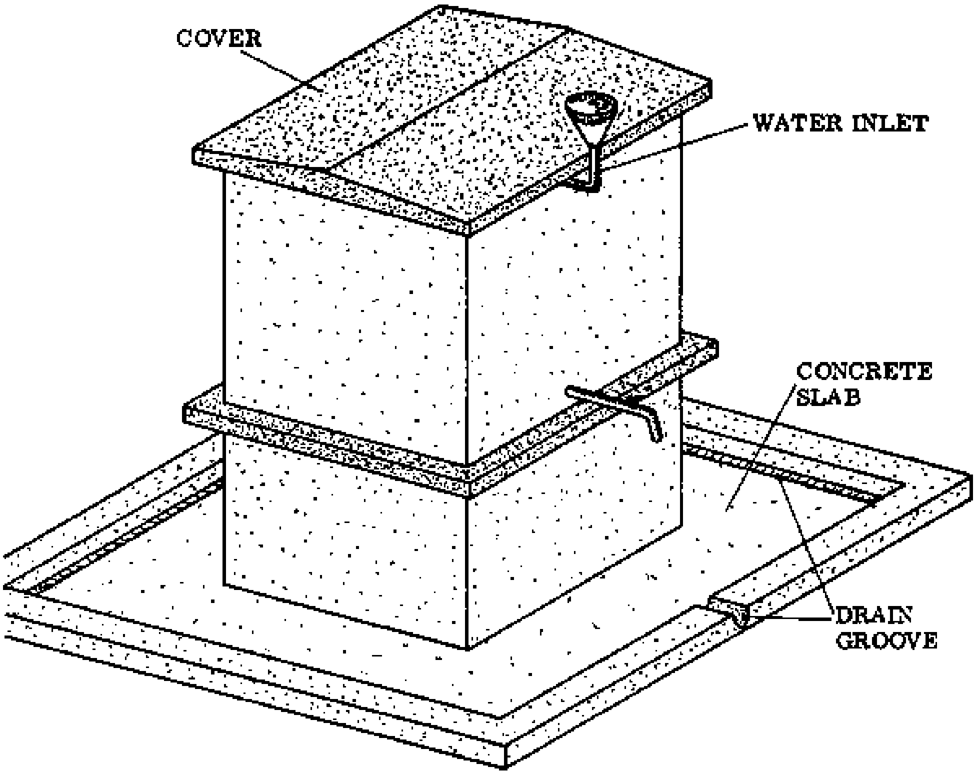


Fig. 1

The cover can be removed to allow the user to clean the filter materials and the entire inside of the tank. If the cover is very heavy it can be made in two halves.

The water inlet also acts as a ventilation opening. The top of the funnel should be covered with copper or aluminium mosquito wire to keep insects out of the tank. The distribution pipe inside (Fig. 2) has many fine holes to make sure that the water is spread evenly over the sand. If necessary install more distribution pipes so that the whole top surface of the sand can be soaked with water; thus using all of the filter materials inside the tank rather than overloading a small area.

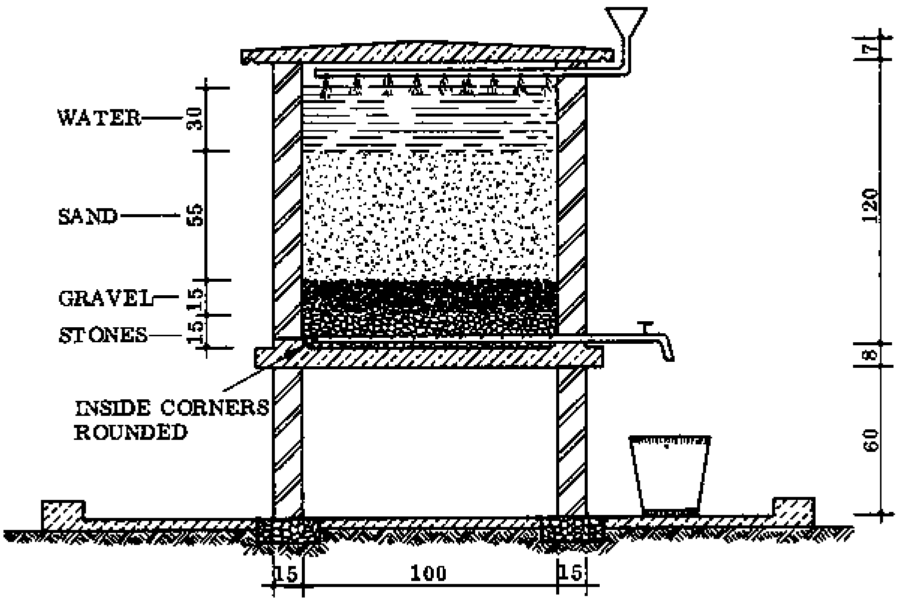

Fig. 2

The space of 30 cm at the top for water storage may be increased if necessary. The depths of the different layers of filter materials should be no less than indicated. If the layers are made deeper still the water will be filtered more thoroughly, but generally the indicated depths are sufficient (also see Drawing Book, page 120).

At the bottom of the tank a piece of pipe with holes in it allows the filtered water to drain off. There should be plenty of holes, and the diameter of the holes should be small enough to prevent the fine gravel from entering the drain pipe. At the end of the pipe a valve can be used to stop or start the flow of water. It drains into a container which is placed under the pipe.

The floor of the tank should be constructed with a rim all around (Fig. 2), which carries the walls and projects at the base of the walls, so that there is no crack between the walls and the floor. The whole inside should be plastered smooth to make it easy to clean.

The filter should be built off the ground so that the water can drain easily into buckets. It is advisable to concrete the area surrounding the filter and to provide a drain for spilled water (Fig. 1).

When the filter needs cleaning the water flow will become very slow. To clean the filter it is only necessary to take off the top 2 cm of sand and replace it with clean sand. Depending on how clean the water is at the start, the filter may need cleaning only after several weeks or even months.

NOTES:

HAND-DUG WELLS

The hand-dug well is the most common kind of well. Unfortunately, most wells are dug according to very basic “hole-in-the-ground” methods, and they can become health hazards as they are easily infected by parasites and bacterial diseases. With modern methods and materials, hand-dug wells can safely be made up to 60 m deep and will give a permanent source of good water.

Untrained workers, if they are properly supervised, can safely dig a deep well with simple light equipment. The basic method is outlined here. This information is intended to help you to dig more safely, and also to make a well that will not become contaminated by surface water. However, there are other problems concerning well digging that are not covered here, and you are advised to seek the help of an experienced well digger when you make a well by this method.

Lining wells

Masonry or brickwork are widely used in many countries to line the walls of wells. These can be very satisfactory in the right conditions. In bad ground however, unequal pressures can make the lining bulge or collapse. Building with these materials is slow, and a thicker wall is required than with concrete linings. There is also the danger of the blocks moving during the construction in loose sandy soil or shale, before the mortar has set firmly between them.

This danger is prevented with concrete linings because the form is left in place to support the lining until the concrete has set hard.

Lining (Fig. 1) prevents the hole from collapsing; keeps out contaminated surface water; and supports the pump platform if there is a pump.

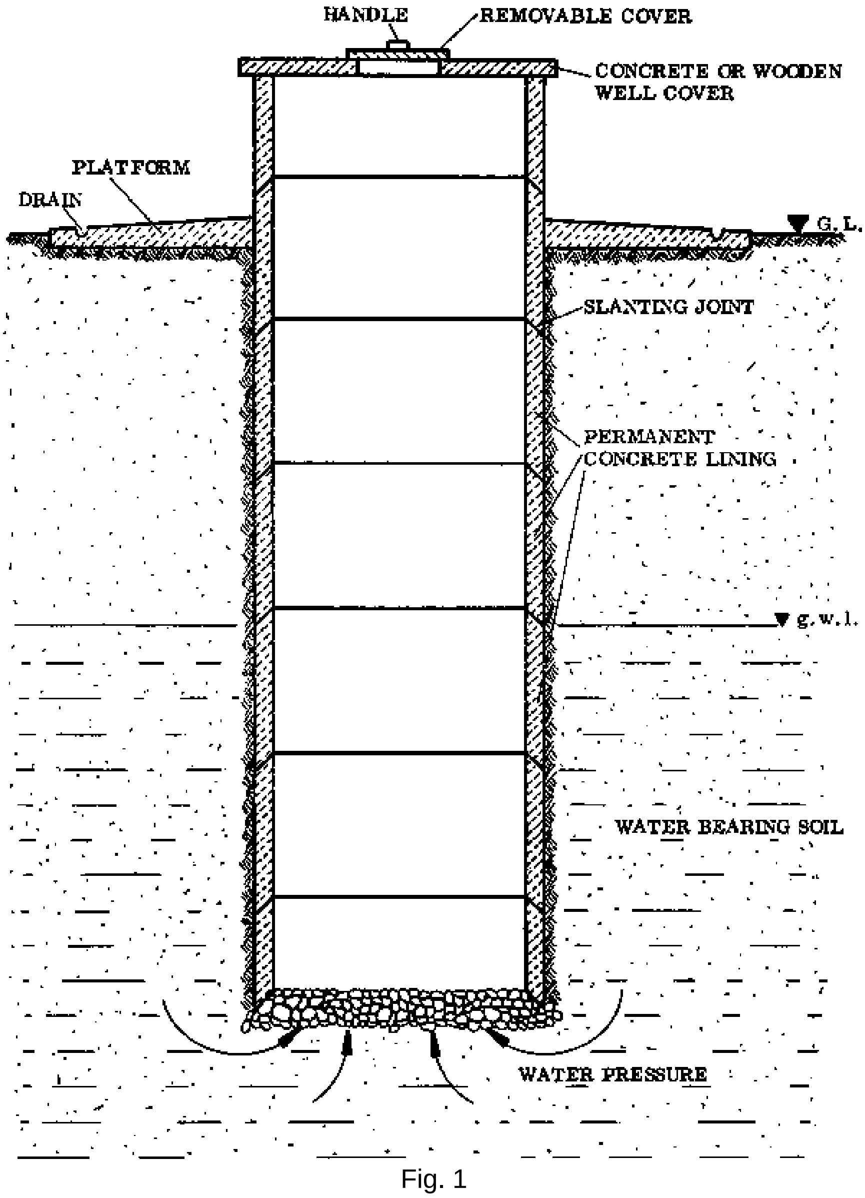

Fig. 1

It is usually best to build the lining as the well is dug, since this avoids the need for temporary supports and also reduces the danger of cave-ins during digging.

There are two methods for doing the lining:

- As the hole is dug, the sections of lining are built into their permanent positions. This is the method explained on the following pages.

- Precast sections of lining are added at the top and the whole lining moves down as the hole is dug and earth is removed from under it.

NOTES:

Tools and materials needed

- Shovels
- Pick-axes
- Buckets
- Ropes and pulley
- Steel forms and bolts
- Wooden or steel tripod
- Cement
- Reinforcement bars
- Sand
- Gravel
- Oil

Construction

Experience has shown that when one man is digging, he will be able to dig most efficiently if the well is about 100 cm in diameter. However if two men are digging together, a 150 cm diameter is best, and the two can dig more than twice as fast as one man. Thus two men in the larger hole is usually best, also for safety reasons.

- NOTE: Do not construct a well near a latrine, septic tank, or other source of contamination. The well should be as far away from these as possible; at least 30 m, and it should never be downhill from a source of contamination.

- SEQUENCE OF OPERATIONS:

a. Erect a wooden or steel tripod to support a pulley and bucket for bringing out soil from the hole.

b. Dig down until you reach ground water level (g.w.l.).

c. Make the first concrete ring section just above the g.w.l. (Fig. 1, A)

d. While the first section cures, proceed with digging the hole for the second section. The rings should be made with slanting edges as shown in Fig. 1, so that the joints between the rings slant downwards.

e. Continue constructing ring sections until the well is deep enough.

f. The other rings above ring A can be constructed during the digging.

g. When the concrete lining is completed, the walls of the whole well should be waterproof, so that surface water can't enter the well. A concrete plat form with a groove for drainage should be constructed, and a wall around the edge to keep people and animals from falling in. Either blocks or rein forced concrete can be used for the wall (Fig. 1, previous page).

h. The well is closed off with a wooden or concrete cover, with a small opening for buckets to go through (Fig. 1, previous page).

i. If possible, disinfect the entire well by adding a chlorine solution to it. Use about 1 heaping tablespoon of bleaching powder to 2 buckets of water and mix. Make up three buckets of the solution to wash the walls of the well thoroughly, and pour the remainder into the well. Make up another three buckets and put that into the well too. Leave it overnight before using the water.

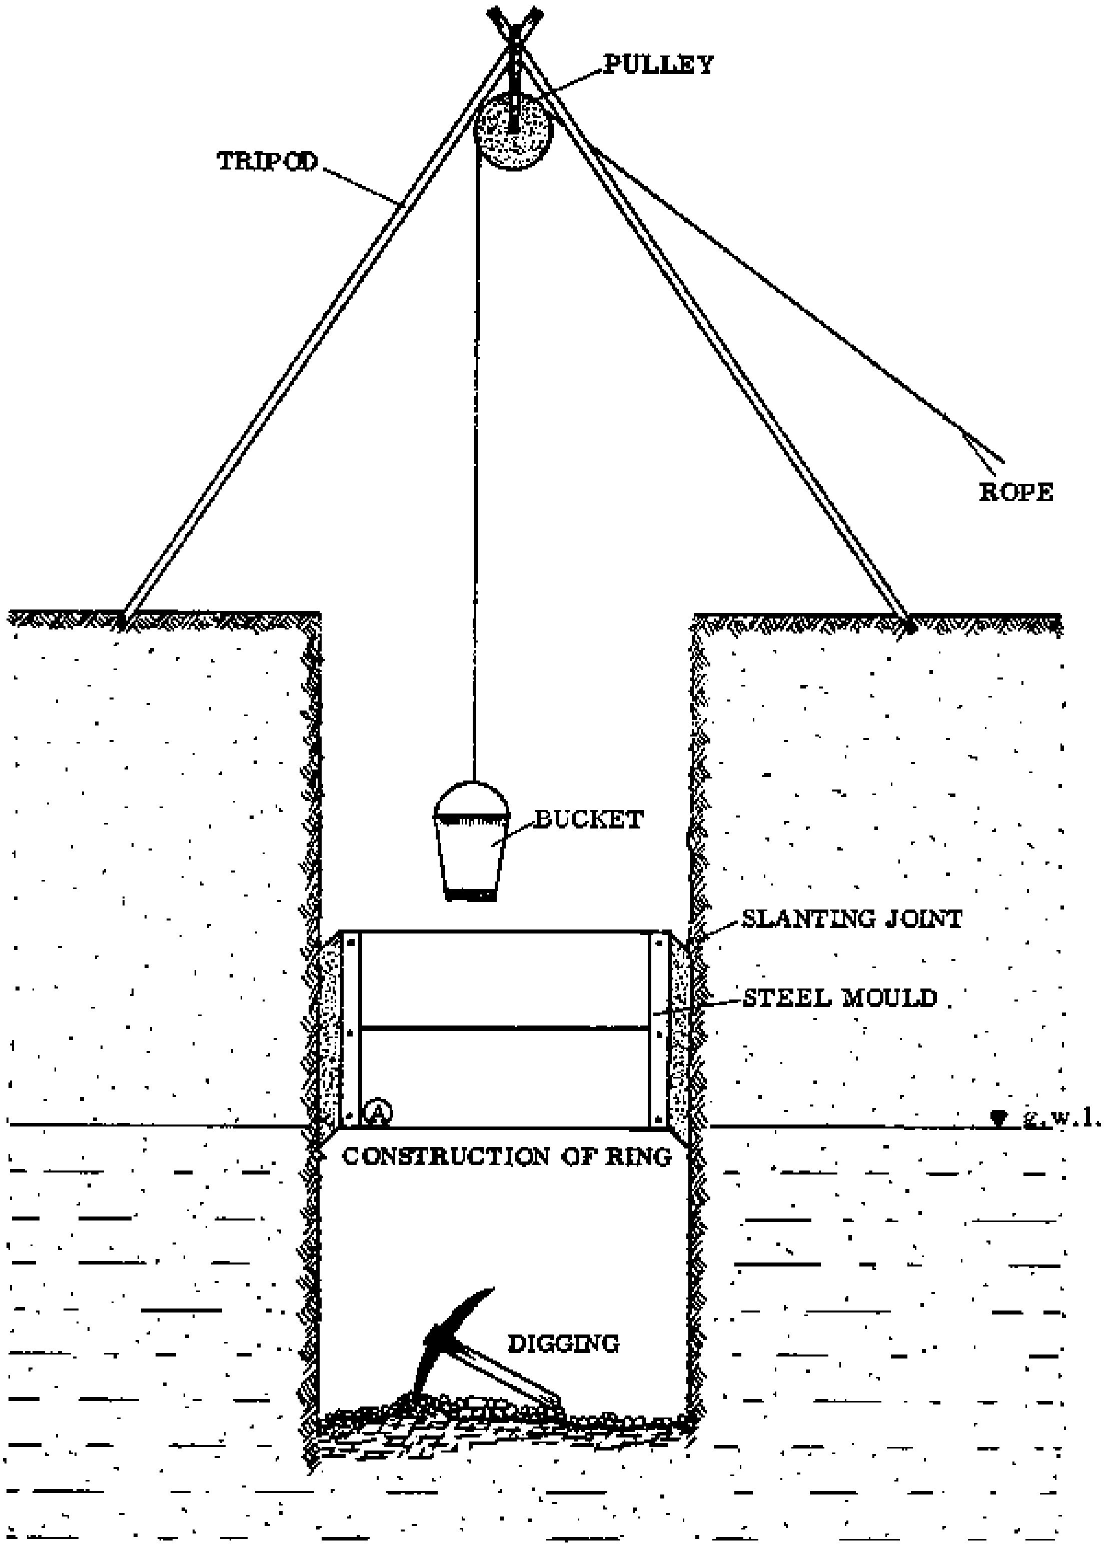

Fig. 1

- NOTE: Since there is a lot of water in the soil, don't use too much water in mixing the concrete for the lining. Be careful that there are no voids (empty pockets) in the concrete lining. These give surface water and soil a path to enter the well.

- MOULDS: A steel mould (Fig. 1) or a wooden mould (Fig. 2) is used to support the sections of concrete lining during construction and curing. After the ring has hardened sufficiently, the wooden lock pieces are removed and the mould is taken out and used for the next ring (Fig. 3).

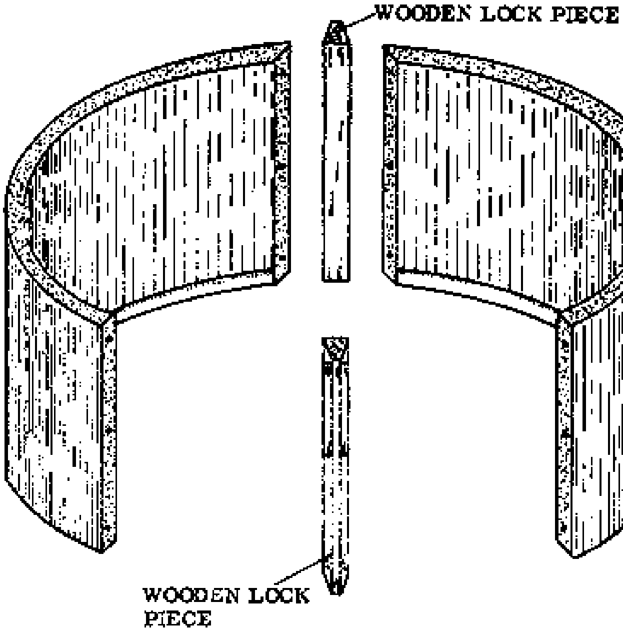

Fig. 1 STEEL MOULD

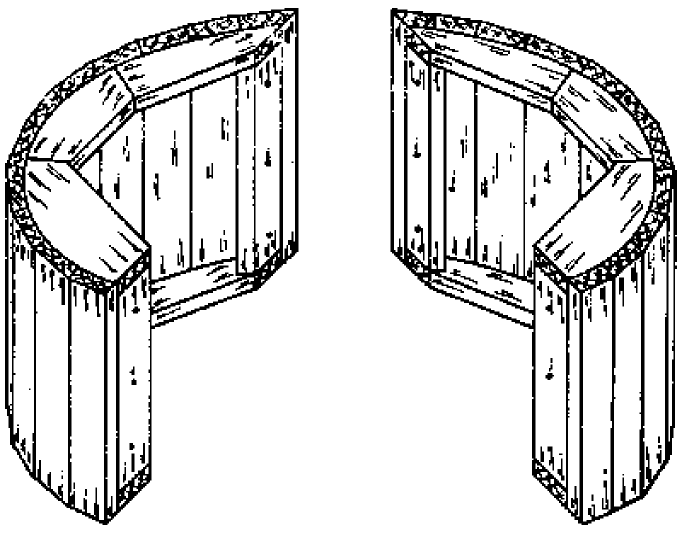

Fig. 2 WOODEN MOULD

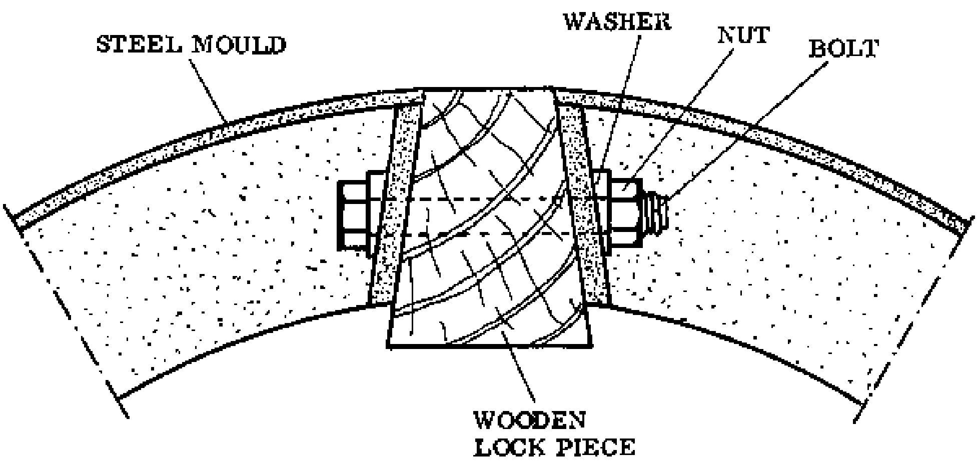

Fig. 3

When you assemble the mould, be sure that the wooden mould or wooden lock pieces are first soaked in water so that the wood does not expand when it contacts the wet concrete. If the pieces expand they will crack the concrete ring, and it will be very difficult to get the mould out again.

GRAIN STORAGE SILO

Often traditional storage methods result in the loss of valuable grain, because insects or mice etc. get into the grain. To help farmers with this problem the Garu Agricultural Station in the Upper Region has developed a new type of grain silo. This silo requires a few bags of cement plus stones or gravel to construct. It can hold between 9 and 16 bags of grain.

Compared to some types of traditional storage, the silo gives better protection to the grain against mice and insects. When the silo is closed so that no air gets in, CO_2 gas develops from the grain and stops the insects from developing.

Construction of a silo

Sun-dried laterite blocks are used for the walls of the silo. The blocks are made in the same way as any other mudblock.

Cast the topslab before starting to construct the rest of the silo, so that it will be cured and ready to use when you need it. Construct a frame for casting the slab, with an inner frame for the manhole (Fig. 1, next page). Reinforce the slab with some rods. For measurements, refer to the Drawing Book, page 118. Note that the top of the slab slopes to the outside. Also note that the edge of the slab is fitted with a groove underneath so that rainwater drips down instead of running back under the slab (Fig. 1, left).

Also make a frame for the manhole cover and cast this piece. Use a piece of iron rod set in the concrete for a handle (Fig. 1).

Place wet paper under the frames before you begin to pour the concrete. The concrete has to remain in the frame for three days. Water it twice daily so that it hardens well without cracking. After the concrete hardens (cures) remove the frames carefully so that they can be used again.

- FOUNDATION AND FOOTING: Dig out the top soil and make a concrete slab if needed (if the soil is soft). The slab will be 125 cm in diameter and about 6 cm thick. The footing is made of large stones set on the slab or on the ground. The stones should be placed in such a way that air can circulate freely between them and they should be built to a height of 30 cm above ground level. On top of and in between the large stones, small stones are used to fill in the gaps to form a surface for the floor to rest upon (Fig. 1).

- FLOOR: The floor is poured directly onto the footing. This floor is a working surface only and the top should be left rough so as to give a good grip to the slanting floor (Fig. 1, previous page).

- FIRST COURSE: Place the chute in position. The chute is a kind of open-ended box made from wood, with a sliding closure that can be locked (Fig. 1, previous page). Now proceed to lay the first blocks. The section after this one describes the procedure for laying blocks in a round structure.

- SLANTING FLOOR: Build up four courses, then pack the slanting floor on top of the rough floor. The mixture for this slanting floor should not be too rich, so it doesn't crack. After the mixture is poured into the silo, pack it down well and plaster the top of the slanting floor smoothly. To do this apply some cement powder and add some water, then smooth with a steel float.

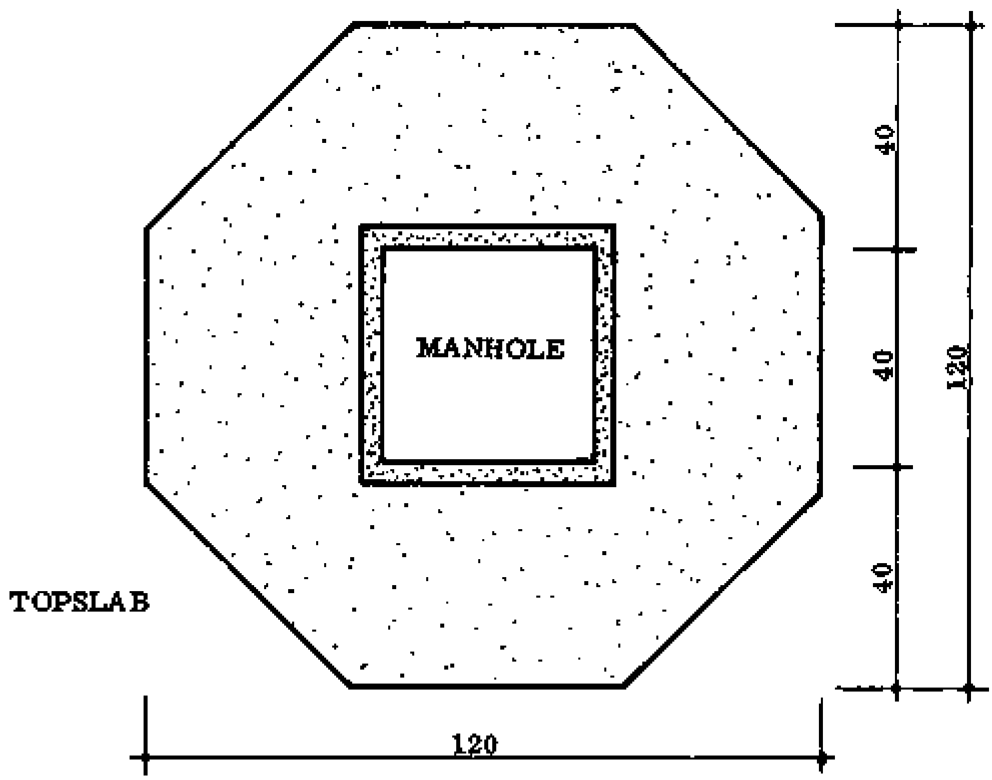
HEIGHT ACCORDING TO REQUIREMENT
8
approx. 30

Fig. 1

- WALLING: Build the walls up straight, using a plumb bob on all sides and for each course. The height of the silo depends on the required storage area. When the desired height is reached, plaster the inside of the silo. The inside plaster should be very smooth and without holes or cracks, so that the silo is airtight.

- TOPSLAB: Provide a mortar bed for the topslab on top of the wall. Then place the slab into position. The slab will be heavy, so several people will be needed for this operation. One man should be inside the silo to direct the operation.

- PLASTERING OUTSIDE: When the slab is set in position you can do the plastering on the outside of the silo. This has to make the silo waterproof, so the finish should be smooth and without cracks.



Using the silo

Dry the grain very well before you put it in the silo. Moist grain will rot, the silo will crack, and all the food will be lost. Distribute the grain well and fill the silo to the top.

Put the cover on the manhole and seal the edges with mud or cow dung. Also seal the chute so that nothing can enter the silo.

Keep the footings and the area around the silo clean.

Check the silo often for cracks, especially when it is full. Replaster any cracks immediately. The wooden chute should always close tightly and the plaster around it should not be cracked.

Paint the silo white or whitewash it. This makes it cooler inside and gives it a nice appearance.

When the silo is emptied, take care to empty it completely. Left-over grain attracts insects and rodents.

Before the silo is filled up again next year, it should be clean and insect free. Light a small bundle of grass on fire inside the silo. The smoke and heat will kill any insects or insect eggs. Sweep out the ashes and dust, and clean the entire silo thoroughly.

Circular masonry work

A section on circular work is included here because in Rural Building circular work applies mostly to structures like silos or protective walls around wells.

Here we describe a sequence which might be used to construct a silo. It may be adapted for other structures as well.

Regular blocks are used. Wedge-shaped blocks can be specially made for the job, but the shape of the wedge has to be calculated exactly according to the size of the circle.

NOTES:

Sequence of operations

a. Determine the centre of the circle. Drive an iron rod into the ground at this point (Figs. 1 & 2, a). The rod should be a little higher than the top of the first course of the future rising wall.

b. The inner and outer curves of the foundation are marked on the ground by fixing a mason line to the rod and describing circles with this at the desired radii (Fig. 1, b).

c. The foundation is completed, then the inner curve of the footings is marked on the top of the foundation using the same method (Fig. 1, c).

d. The footing blocks are laid so that the inside corners of each block touch the marked circle (d). The next course is marked on top of the first course and laid in the same manner.

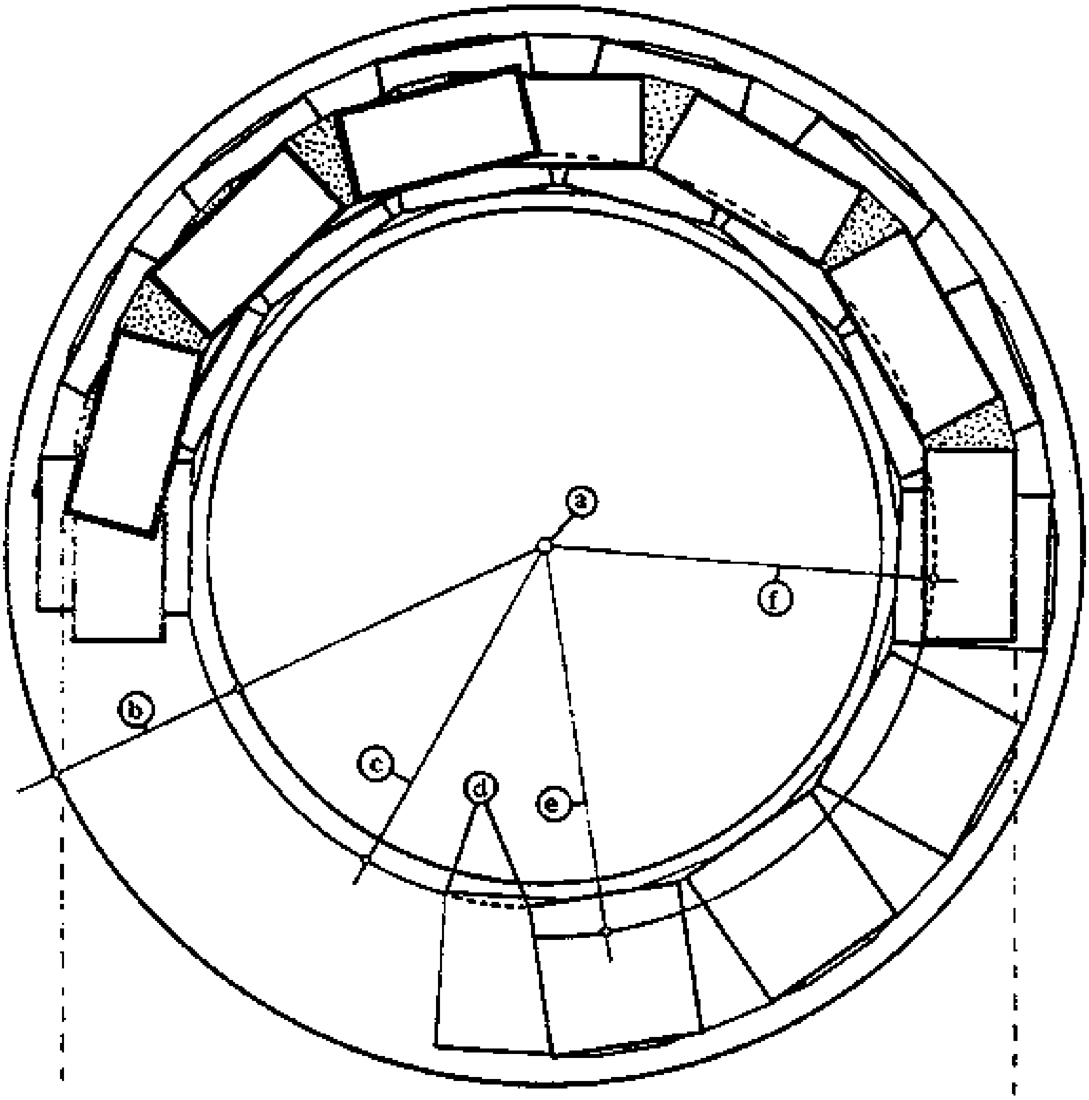


Fig. 1

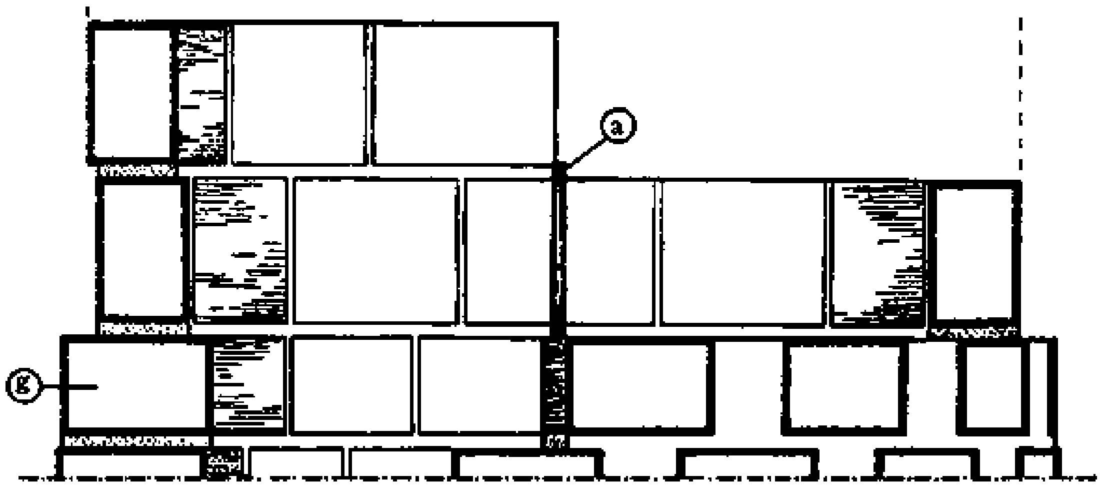

Fig. 2

NOTE: In this construction the footings are made with blocks, unlike the silo described in the preceeding pages, where the footings where made of large stones. If a silo is to be built on top of the footings, the cross joints between the blocks are not filled in; this permits cross ventilation. The space up to the top of the footings is filled in with large stones and the floor is made on top of these, as in the silo described before. Remember to set the chute in place on top of the footings before you continue with the rising wall construction. Only two footing courses are necessary to reach the required height of 30 cm for the silo floor.

e. When the footings are completed, the rising wall is laid out on top of the footings with the line and peg as before (Fig. 1, e). The blocks are positioned with the corners touching the circle as before.

f. The second course of the rising wall is laid out on top of the first course (Fig. 1, f), and the blocks are laid as before.

g. The following courses are laid with the aid of the plumb bob. All cross joints are 1 cm thick along the inner curve. Each course of the rising wall is plumbed according to the course two courses below it (3rd to 1st, 4th to 2nd, 5th to 3rd, etc.).

Fig. 2 shows a side view of Fig. 1, but only the last footing course is shown (g).

NOTES:

PIT LATRINE

Latrines, and especially pit latrines, are the most common and simple sanitation systems. A pit latrine is practical for rural areas because it is the cheapest possible system and the easiest to build.

One major problem with pit latrines is the limited capacity: only a certain number of people can use the latrine, or else it becomes full too quickly and another pit must be dug. Another problem is that the latrine, if it is improperly made or made in the wrong place, can contaminate nearby wells or surface water. Also, if the ground water level is near the surface it may not be possible to dig a deep pit.

Capacity

The volume of the pit may be planned by using the rough figure of at least 0,06 cubic meters per person per year. Thus a pit which is 1 m square and 3 m deep may serve a family of five for about 6 years, before it becomes two-thirds full and a new pit has to be dug.

Pit latrines of the type shown on the opposite page (Figs. 1 & 2) should not be used by large numbers of people unless there is space available to dig several pits. If many people use the same pit it will quickly become full, and the ground around it can become contaminated.

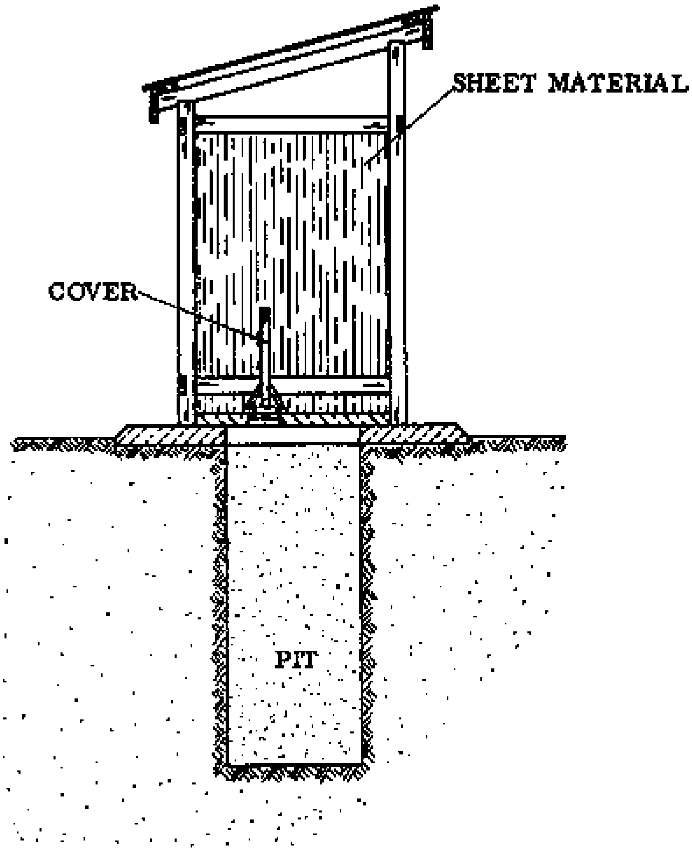

Fig. 1 ORDINARY PIT LATRINE

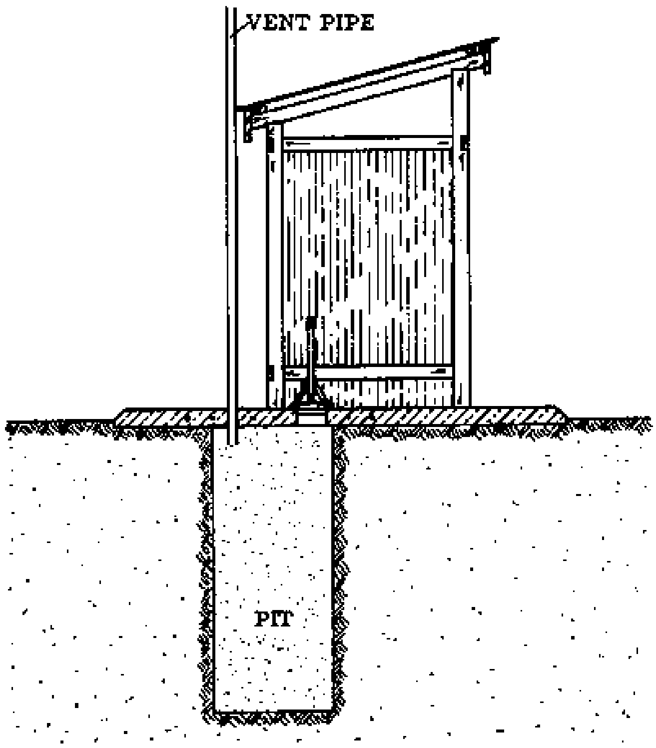

Fig. 2 VENTILATED PIT LATRINE - ADVANTAGE: LESS SMELL DUE TO VENT PIPE

It is a good idea to dig two pits at once, so that when one is 2/3rds full it can be closed, filled to the top with soil, and left there for 6 months to a year; by which time the harmful, disease-causing organisms in it will have been destroyed. The sludge can be taken out and mixed with compost, making a very valuable (and non-imported) fertilizer for gardens or farms.

- NOTE: Human wastes which have not been composted for at least 6 months should never be used as a fertilizer for food crops, because disease can be spread that way.

Location

The pit latrine should be located at least 6 m away from any house, and at least 30 m away from any water source: well, bore hole or stream. The latrine should never be located uphill from a water source - this is extremely important.

NOTES:

Design and construction of the squatting slab

The squatting slab should be designed with easy cleaning in mind. It is made out of concrete reinforced by iron rods as shown in Fig. 1. The rods should be about 8 mm in diameter.

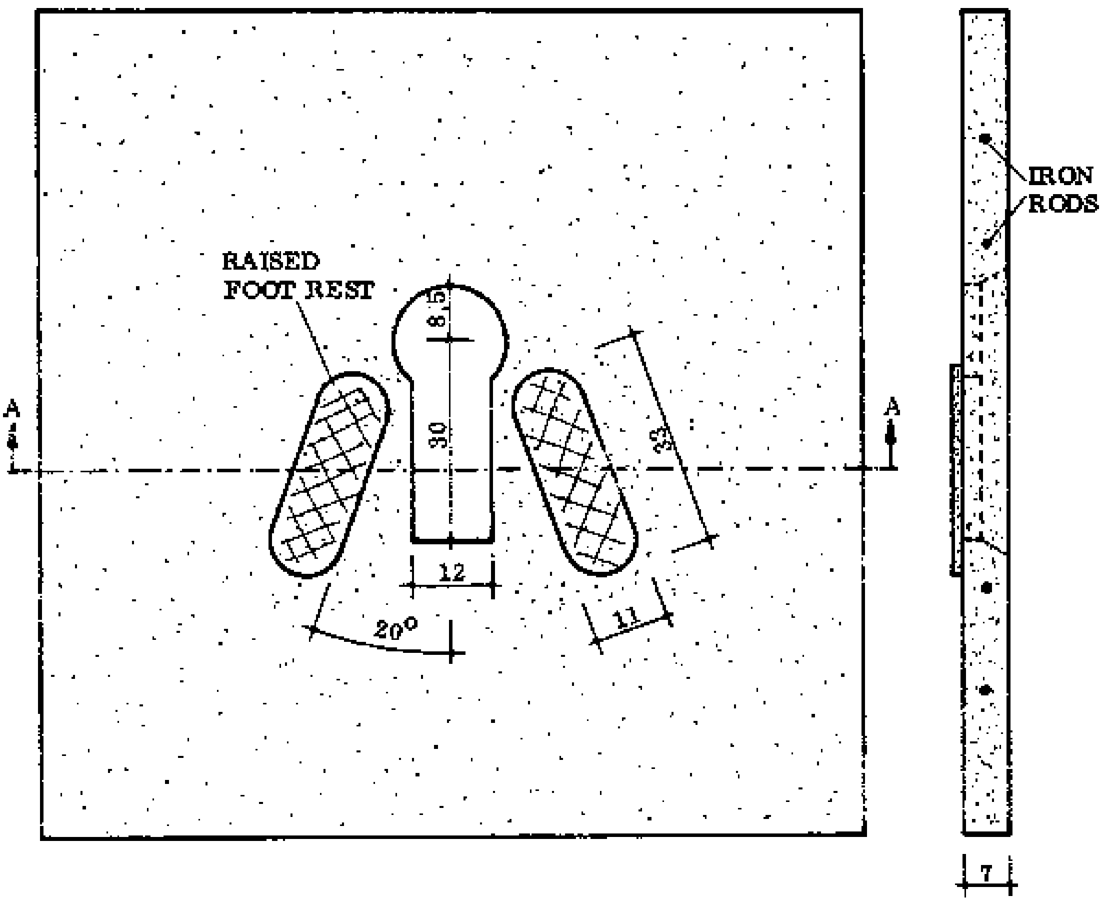

Fig. 1

The slab may be square, round, or rectangular in shape. A common size is 100 by 100 cm. The whole slab will weigh about 140 kg. The advantage of a round slab is that it can easily be rolled around the site and into place. The slab should be about 7 cm thick. The raised foot rests make the slab easier to clean. The shape of the hole and foot rests may vary; a typical arrangement is shown here. The hole should be at least 36 cm long to prevent soiling of the slab, and less than 18 cm wide so that small children can't fall through.

The distance from the back of the hole to the back wall of the latrine should be at least 15 cm, so that it is not necessary to lean against the wall when squatting.

Make a cover for the latrine hole out of wood, with a long handle (Fig. 2).

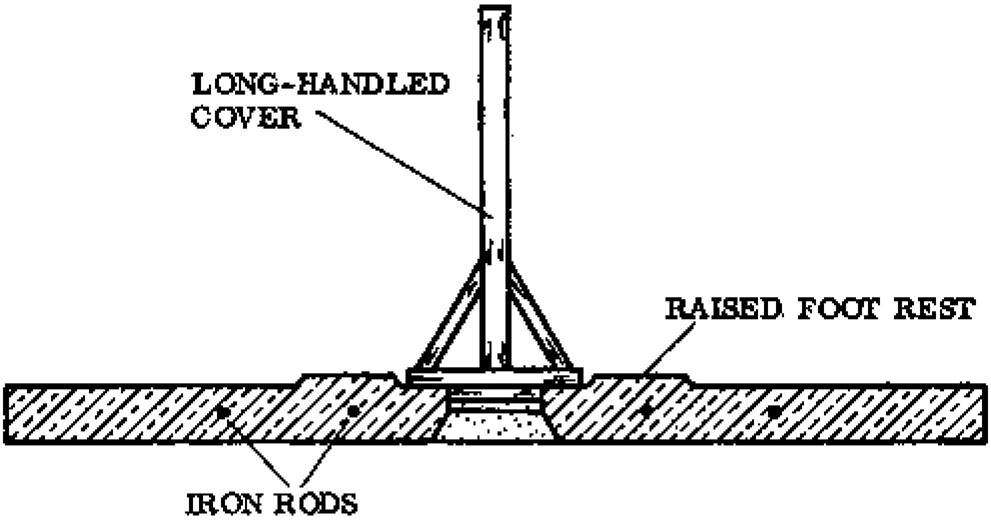

Fig. 2 CROSS SECTION A-A

NOTES:

Construction

The first step is to precast the squatting slab, as described on the previous page.

Make the hole for the latrine large enough so that it won't become full too quickly. The soil should be firm enough so that the weight of the latrine structure won't cause the hole to collapse. If the soil is firm enough, the foundation slab can be poured around the edge of the hole (first remove the top soil) (Fig. 1). If the soil is a bit soft, reinforce the foundation slab.

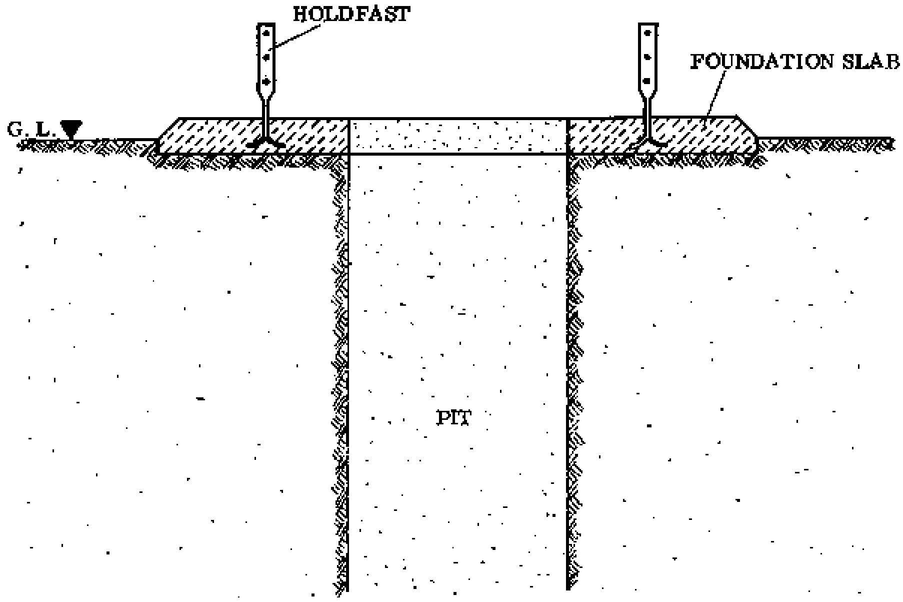

Fig. 1

If the soil is very soft, it will not be able to bear the weight of the construction. Then it will be necessary to construct a lining for the hole to be sure that it will not collapse. The lining can be made with blocks; or in a round hole with concrete rings, as described under the section on wells, page 279. The foundation slab then rests on top of the lining and cannot sink down into the soft soil (Fig. 2).

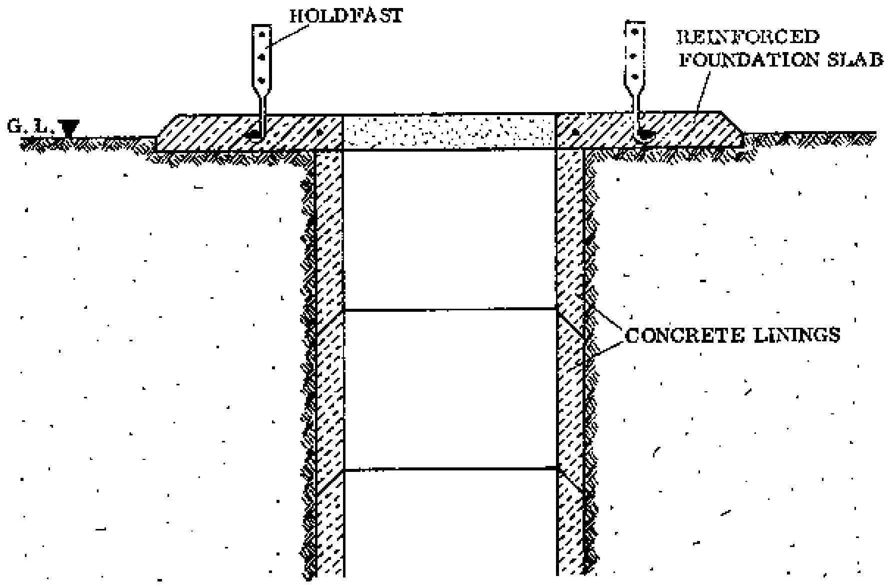

Fig. 2

When you construct the foundation slab, fix some steel rods or holdfasts in the concrete, as shown in Figs. 1 & 2. These can be used later to anchor the wooden structure of the toilet.

When the foundation slab is cured, place the precast squatting slab on top of the foundation and secure it in place with a weak mortar (Fig. 3).

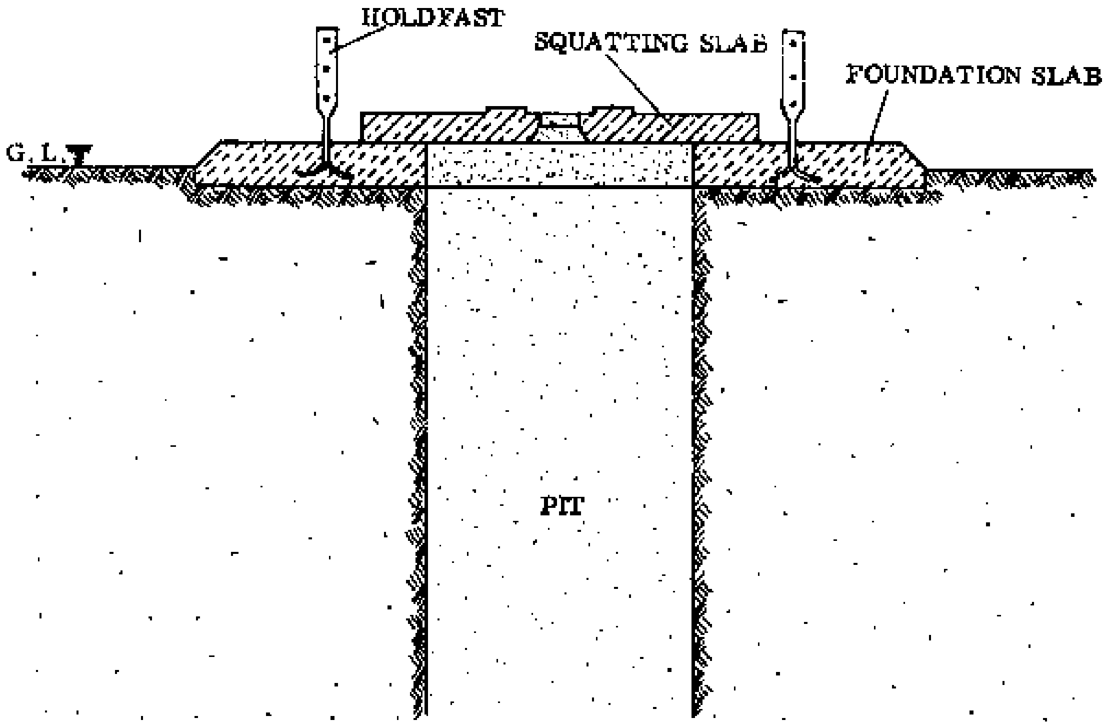

Fig. 3

Toilet room

The toilet room can be built from mud or landcrete blocks, and plastered with mud. However, be sure that the foundation can support the walls because they are heavy, and in soft soil they may sink down and collapse the hole. Also, when the hole is full and a new one has to be dug, the walls have to be built completely new.

Because of the above problems with block walls, it is advisable to construct a light-weight structure out of timber and metal sheets. The light-weight structure can be removed when the pit is full and installed again over a new pit. The squatting slab can also be re-used (Fig. 1).

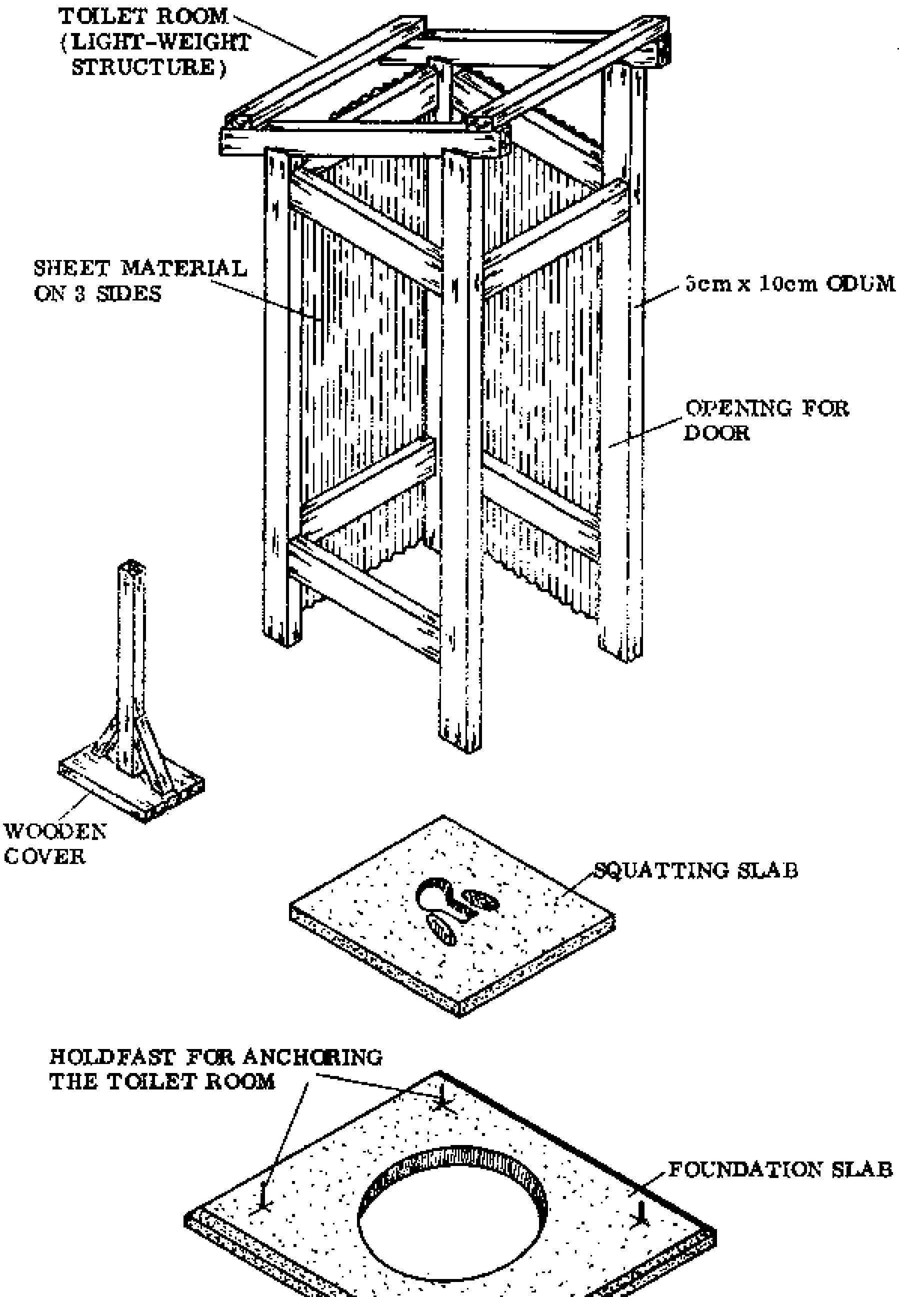

Fig. 1

The structure must be anchored well to the foundation slab so that it is not blown away in strong winds.

Toilet partitions

If a community latrine with several compartments is needed, use the system drawn on page 124 of the Drawing Book.

First do the setting out. Then dig the round pits and make foundation slabs around the pits. Construct arches or lay a reinforced concrete beam across the center of each pit.

There are four squatting slabs over each pit. Lay each one carefully so that one edge rests on the concrete beam and two other sides rest on the foundation slab. Use some weak mortar between the slab and the supports, to ensure that the slabs are flat and stable.

The partitions between the toilets should be light-weight structures of timber and metal sheets or waterproof plywood. The outside walls can be constructed from landcrete blocks or mud.

Many of the materials from the above structure can be re-used after the holes become 2/3rds full and new pits are dug. The light-weight partitions, the squatting slabs and the reinforced beams can all be taken out and used in the new construction.

NOTES:

Permanent latrine

If the latrine is constructed so that the pit can be cleaned out when it becomes two-thirds full, then it is no longer necessary to dig a new pit every few years. In the design explained here, the pit contents are removed through a manhole from the outside of the toilet room.

Make a reinforced concrete beam or an arch across the pit (Figs. 1 & 2) to support the back wall of the toilet, the floor, and the concrete manhole cover (see also the Drawing Book, pages 121 and 124).

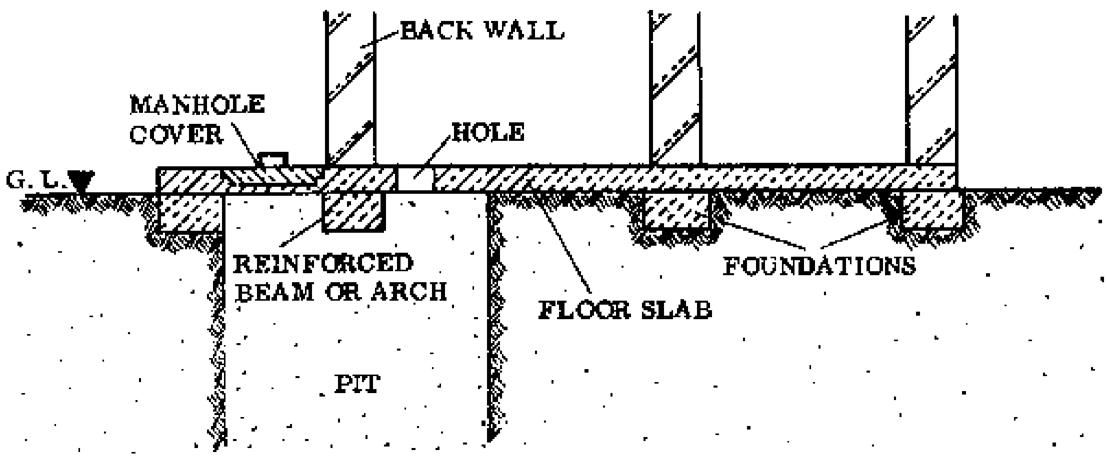

Fig. 1

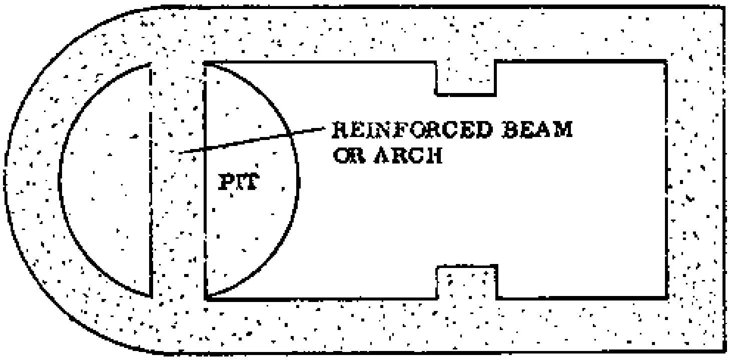

Fig. 2 FOUNDATIONS

Cast the foundations around the pit and under the future walls of the toilet (Figs. 1 & 2). On top of the foundations cast the floor slab with the openings for the manhole and toilet. The toilet can be made with the same squatting slab design as the other latrines, or a seat may be constructed above the hole (Fig. 3).

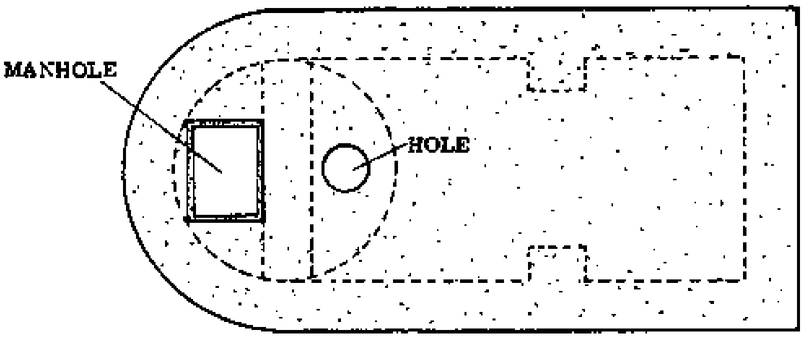

Fig. 3 FLOOR SLAB

The rising walls are constructed directly on top of the floor slab (Fig. 4). They may be built out of mud, sandcrete or landcrete blocks, since the structure will be permanent. Make sure that the toilet room is well ventilated and the roof is securely anchored to the building. The wall in front of the entrance can be built up to about 180 cm high (Fig. 4).

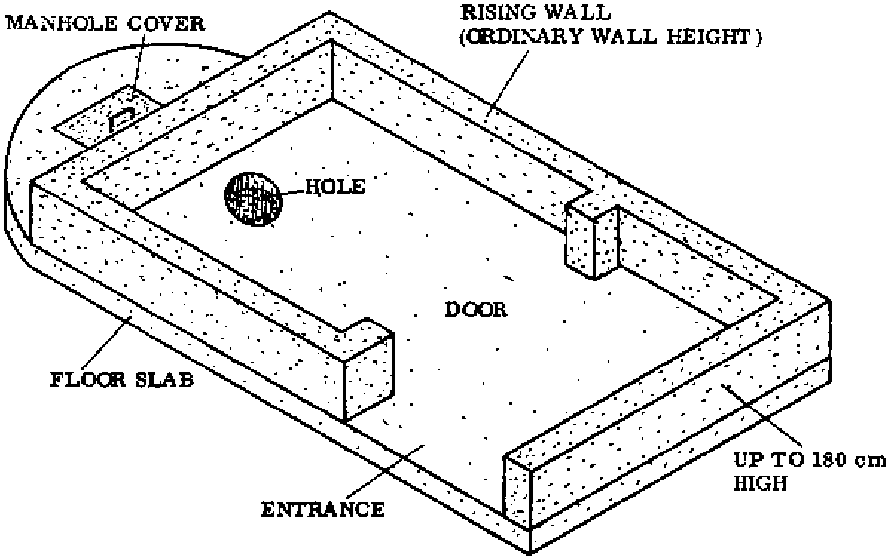

Fig. 4

BUCKET LATRINE

One of the oldest and generally least cleanly systems for waste removal is the bucket latrine. As in the cross section in Fig. 1, the squatting slab is set over a collection chamber with a bucket. The chamber should be closed off with a removable fly screen. The bucket should fit into a niche on the floor, so it is always returned to position directly under the hole in the slab when it is replaced after cleaning.

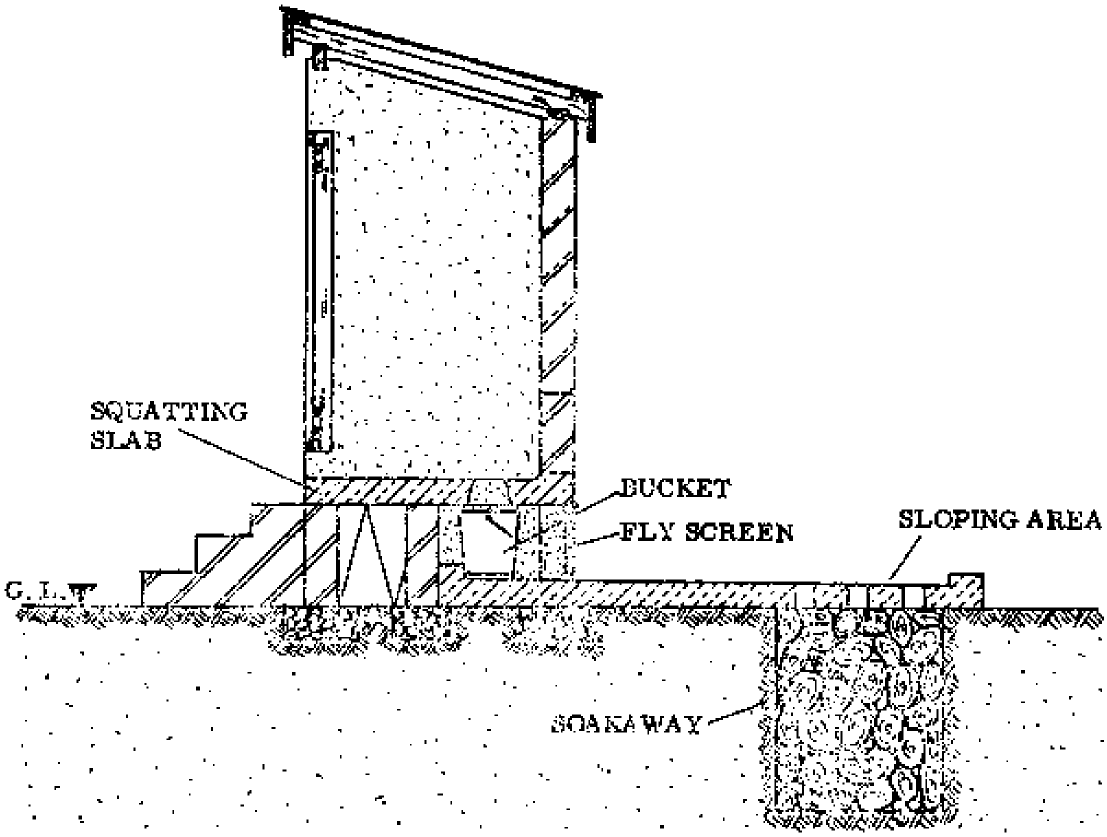

Fig. 1

The area behind the latrine should be paved, and a drain and a soak away should be made to get rid of the water used for cleaning the toilet and collection chamber.

The bucket latrine system is only possible where there is an organized system for regular collection and disposal of the bucket contents. This is usually not possible in rural areas.

AQUA PRIVY SYSTEMS

An aqua privy is basically a septic tank directly under a latrine. Its advantages are that it has fewer problems with smells, flies, and disease spreading than a regular latrine. However, at least two buckets of water must be poured into the privy every day for it to operate properly, and this can be a problem where there is no water source nearby.

An aqua privy for the use of one family may have a pit which is about 1 cubic meter in volume (about 0,15 cubic meters per person). The manhole should be large enough so that the sludge can be removed from the pit from time to time; whenever the tank is one-third full. If the tank is not emptied in time the drain pipe will become blocked and the system will fail.

Add some reinforcement to the squatting slab over the tank to support the back wall of the toilet. Make sure that the inside of the tank is waterproof, because if it leaks the water level cannot be maintained and smells can pass through the chute. If necessary paint the inside walls of the tank with waterproof paint. Make sure that there is a good ventilation system, with a fly screen over the end of the pipe which ventilates the tank (Fig. 2).

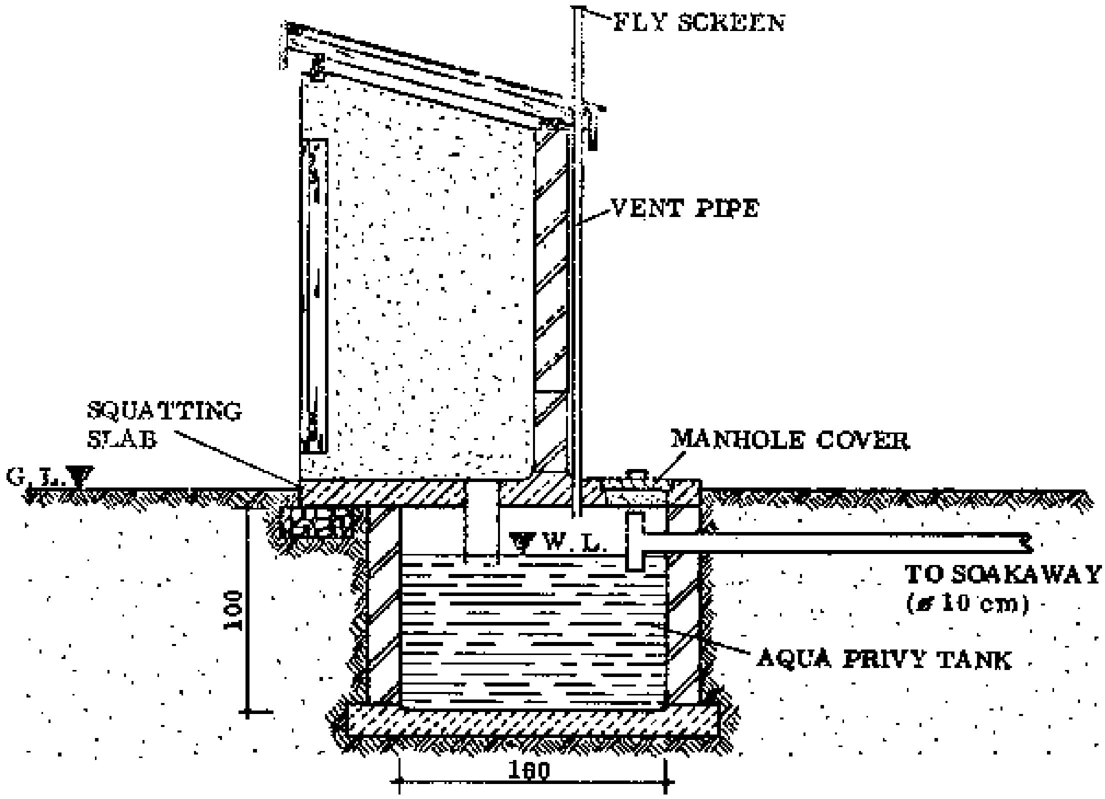

Fig. 2

It is very important to maintain the water level within the tank. If possible, washing facilities can be made nearby and connected with the tank, so that the water from the sink or shower room goes into the tank and maintains the water level.

SOAKAWAYS

A soakaway is basically a hole in the ground filled with stones, through which water can seep away into the surrounding soil instead of forming a pool on the surface of the ground where mosquitos can breed.

Dig a hole and fill it with large stones at the bottom and smaller ones at the top. Drain pipes from bathing areas, etc. can lead into the pit; they should end up in the centre. Cover the soakaway with soil, but make sure that the soil does not enter between the stones and block the drainage pipe. The soakaway can be covered with a layer of concrete to keep the top soil out (Fig. 1, previous page).

Soakaways should be at least 30 m away from wells or streams, and never uphill from a water source.

MANHOLES

Sometimes manholes are needed where long pipes have to be inspected at intervals. Manholes give easy access to the pipe junctions. A typical manhole layout is shown in the Drawing Book, page 125. This manhole can also serve as a kind of junction hole, from which more than one pipe can cross. The slope should be the same for pipes entering and leaving the manhole (Figs. 1a & 1b).

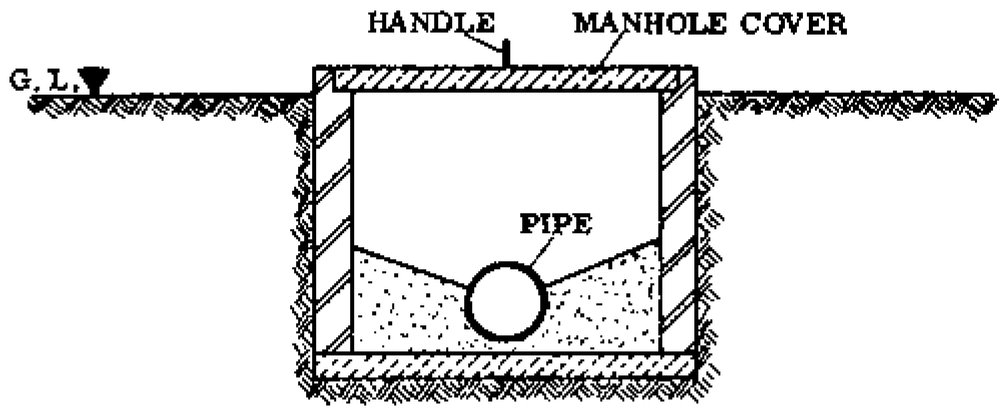

Fig. 1a

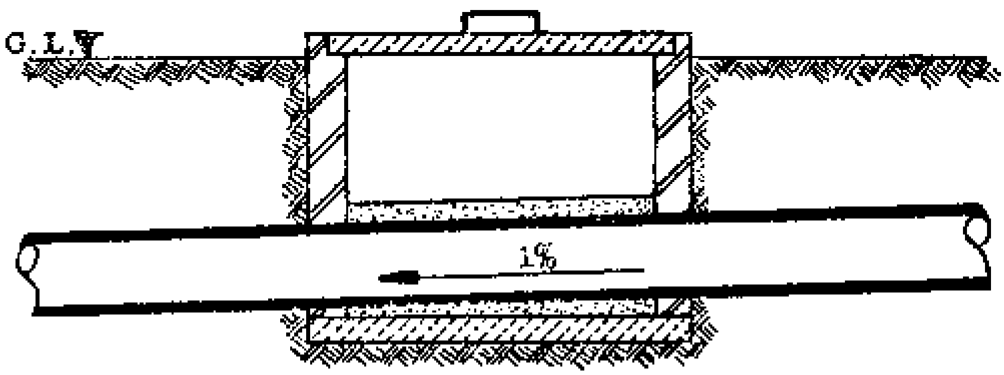

Fig. 1b

SEPTIC TANKS

Septic tanks are designed in such a way that the water takes at least 24 hours to pass through the system. During that time the heavier solids will settle to the bottom, forming the sludge. In the tank the solids are gradually broken down and become much reduced in volume.

Septic tanks should have two compartments (Fig. 2). The first compartment is twice the size of the second compartment. Intermediate walls are sometimes made in order to reduce the speed of the water flow, and to make the distance that the water has to travel longer (Drawing Book, page 126).

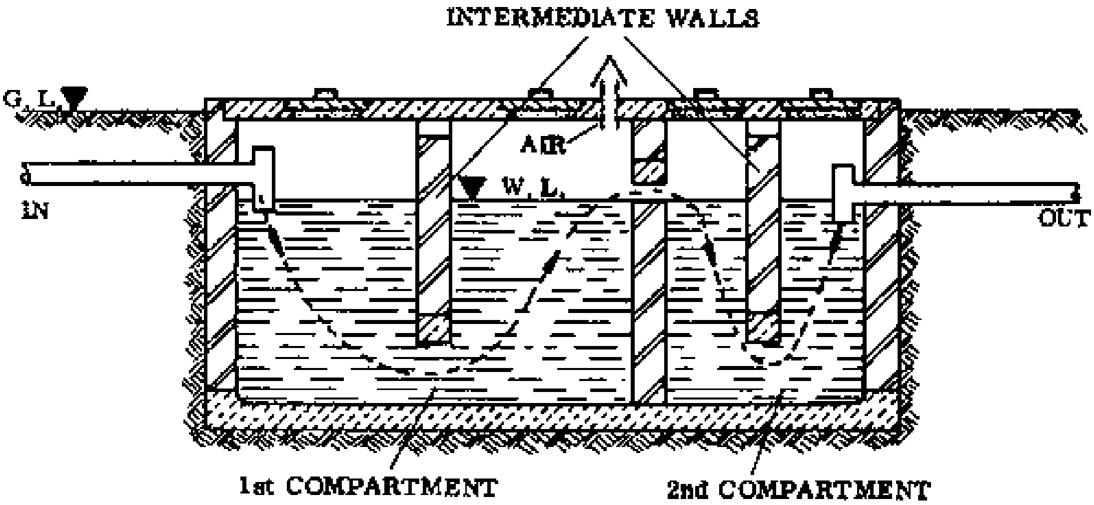

Fig. 2

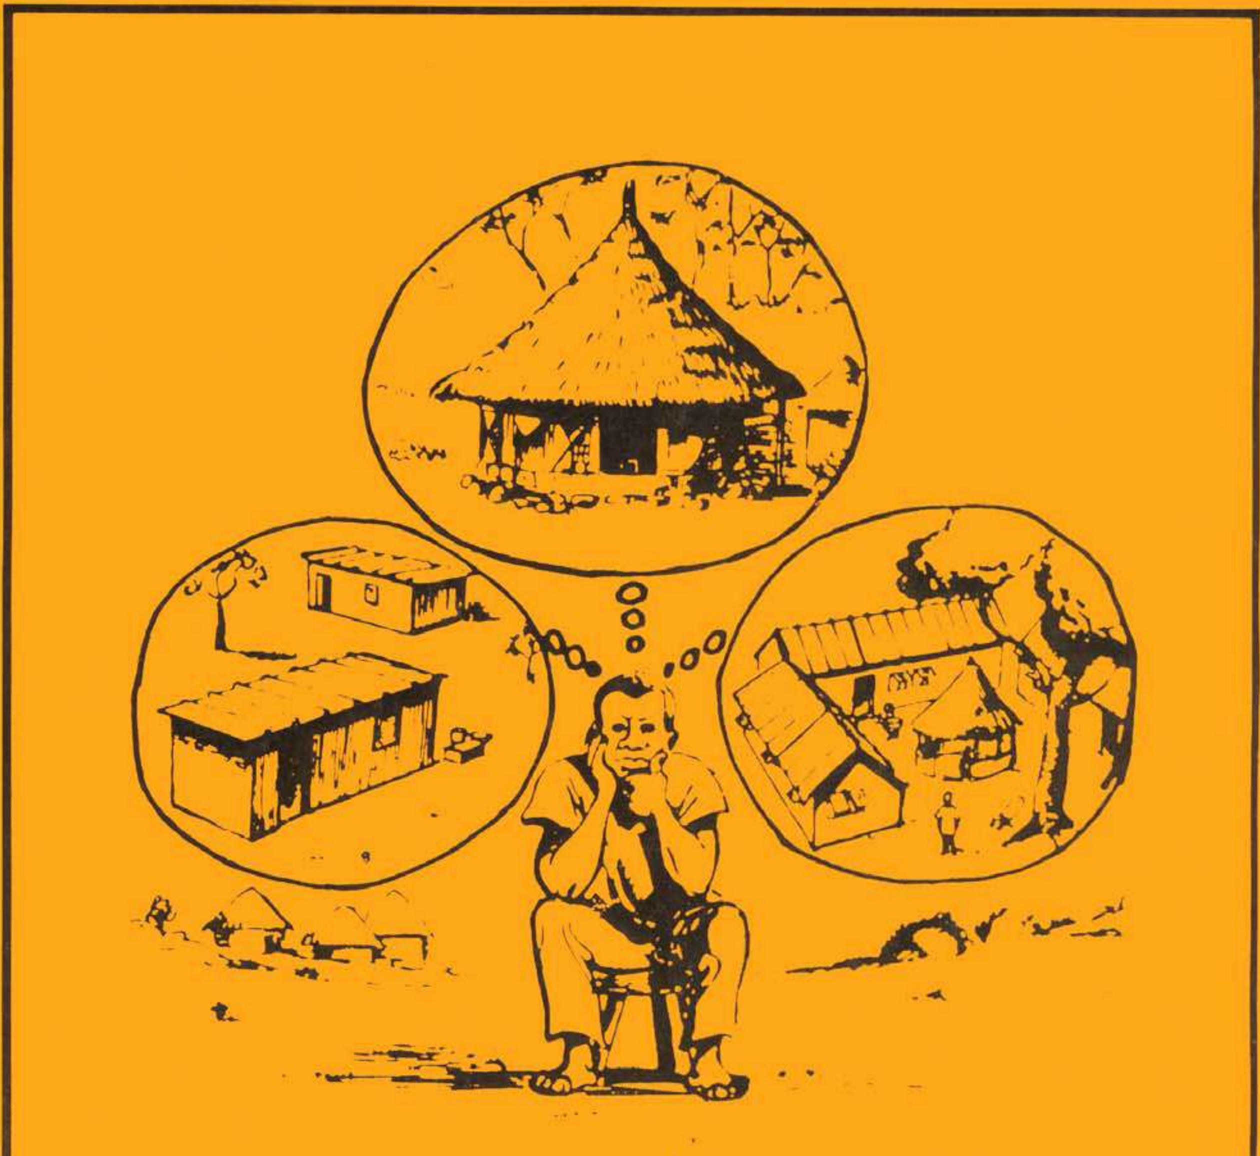
The sludge has to be removed from the tank every few years, whenever it becomes 1/3 full. This sludge will not be safe to use as fertilizer until it has been composted for several months. The water flowing out from the tank will also be contaminated with bacteria and disease organisms.

NPVC

RURAL BUILDING



BASIC KNOWLEDGE

PREFACE

This official text book is designed purposely to meet the needs of trainees who are pursuing rural building courses in various training centres administered by the National Vocational Training Institute.

The main aim of this book is to provide much needed trade information in simple language and with illustrations suited to the understanding of the average trainee.

It is the outcome of many years of experiment conducted by the Catholic F.I.C. brothers of the Netherlands, and the German Volunteer Service instructors, in simple building techniques required for a rural community.

The National Vocational Training Institute is very grateful to Brothers John v. Winden and Marcel de Keijzer of F.I.C. and Messrs. Fritz Hohnerlein and Wolfram Pforte for their devoted service in preparing the necessary materials for the book; we are also grateful to the German Volunteer Service and the German Foundation For International Development (DSE) - AUT, who sponsored the publication of this book.

We are confident that the book will be of immense value to the instructors and trainees in our training centres.

DIRECTOR: National Vocational Training Institute, Accra

INTRODUCTION TO A RURAL BUILDING COURSE

Vocational training in Rural Building started in the Nandom Practical Vocational Centre in 1970. Since then this training has developed into an official four year course with a programme emphasis on realistic vocational training.

At the end of 1972 the Rural Building Course was officially recognised by the National Vocational Training Institute. This institute guides and controls all the vocational training in Ghana, supervises the development of crafts, and sets the examinations that are taken at the end of the training periods.

The Rural Building programme combines carpentry and masonry, especially the techniques required for constructing housing and building sanitary and washing facilities, and storage facilities. The course is adapted to suit conditions in the rural areas and will be useful to those interested in rural development, and to farmers and agricultural workers.

While following this course, the instructor should try to foster in the trainee a sense of pride in his traditional way of building and design which is influenced by customs, climate and belief. The trainee should also be aware of the requirements of modern society, the links between the old and new techniques, between traditional and modern designs - and how best to strike a happy medium between the two with regard to considerations like health protection, storage space, sewage and the water supply. The trainee should be encouraged to judge situations in the light of his own knowledge gained from the course, and to find his own solutions to problems; that is why this course does not provide fixed solutions but rather gives basic technical information. The instructor can adapt the course to the particular situation with which he and the trainee are faced.

This course is the result of many years of work and experimentation with different techniques. The text has been frequently revised to serve all those interested in Rural Development, and it is hoped that this course will be used in many vocational centres and communities. It is also the sincere wish of the founders of this course that the trainees should feel at the completion of their training that they are able to contribute personally to the development of the rural areas, which is of such vital importance to any other general development.

We are grateful to the Brothers F.I.C., the National Vocational Training Institute and the German Volunteer Service for their assistance and support during the preparation of this course.

Bro. John v. Winden (F.I.C.)
Wolfram Pforte (G.V.S.)
Fritz Hohnerlein (G.V.S.)

LAY-OUT OF THE RURAL BUILDING COURSE

The Rural Building Course is a block-release-system course, which means that the trainee will be trained in turn at the vocational centre and at the building site. The period of training at the centre is called “off-the-job” training, and the period on the building site is called “on-the-job” training. Each will last for two years, so that the whole course will take four years and will end with the final test for the National Craftsmanship Certificate.

<u>BLOCK RELEASE SYSTEM</u>

YEAR	TERM 1	TERM 2	TERM 3
1	X	X	X
2	O	O	O
3	O	X	O
4	X	O	X

X = OFF-THE-JOB TRAINING
O = ON-THE-JOB TRAINING

The total “off-the-job” training period is approximately 76 weeks, each week 35 hours. During this training about 80% of the time is spent on practical training in the workshop. The remaining 20% of the time is devoted to theoretical instruction.

The total “on-the-job” training period is approximately 95 weeks, each week 40 hours. During this period the trainee does full-time practical work related to his course work. In addition some “homework” is assigned by the centre and checked by the instructors.

A set of books has been prepared as an aid to the theoretical training:

A - Rural Building, Basic Knowledge (Form 1)
B - Rural Building, Construction (Forms 2, 3, 4)
C - Rural Building, Drawing Book (Forms 1, 2, 3, 4)
D - Rural Building, Reference Book

All these books are related to each other and should be used together. The whole set covers the syllabus for Rural Building and will be used in the preparation for the Grade II, Grade I, and the National Craftsmanship Certificate in Rural Building.

CONTENTS

BOOK INTRODUCTION

Rural Building, Basic Knowledge is your first construction book. This book plus most of the Reference Book (Rural Building Tools, Maintenance of Tools, Materials and Building Products) will be treated in the first year of centre training.

This book is divided into three parts:

PART 1: BASIC MASONRY TECHNIQUES

This part covers the very basic techniques of masonry. These include the preparation of mortar, blocklaying, the proper arrangement of blocks, and building up walls. Some of the techniques mentioned in the section on the arrangement of blocks are techniques used mainly for bricklaying and therefore only apply to areas where bricks are available.

PART 2: BASIC CARPENTRY TECHNIQUES

The basic techniques covered here include planning construction pieces, preparing wood for construction pieces, ways of fastening the pieces and the important types of joints and how to construct them.

PART 3: PREPARATION FOR ON-THE-JOB TRAINING

This part is meant to be a preparation for the trainee's first year of on-the-job training. It should enable him to follow the basic procedures he is confronted with on a building site, and to understand the technical terms used there. This part of the book doesn't attempt to give detailed information about technical problems but merely to give an idea of them and to enable the trainee to understand the terms and deal with situations on the building site. Most of the procedures will be treated more intensively in the Construction and Drawing books.

At the beginning of both the carpentry and masonry sections there is a list of the terms you will need to know, together with explanations.

You will often be asked to refer to one of the supplementary books for additional information. Especially in the first part of the course, much of the basic knowledge you will need about tools and materials and products will be found in the other books.

You should prepare yourself for each lesson by reading the material before class and looking up the references given in the text for the Reference Book or Drawing Book. If you are not familiar with a tool that is mentioned, now is the time to look in the Reference Book and learn about the tool and how to use it.

There is ample space provided in the book for making notes and sketches.

SAFETY FIRST

When you first start doing construction work it is essential to realize the importance of being safety conscious. You must develop safe working habits in order to prevent injuries to yourself and others.

Accidents can generally be avoided by using ordinary care and skill. Most accidents are a result of thoughtlessness or carelessness on the part of some person.

To practise any kind of craftwork you need your hands, your legs and feet, a healthy body, and most of all your head.

Safety first means that you use your head and think out what you are going to do before going ahead with the job. By first thinking the operation through, you will discover that there is a correct way of doing the task, and some other ways of doing it that may cause danger to yourself and others. Look in the beginning of your Reference Book for a list of general safety rules.

Follow the safety rules, but also use your own sense. When you realize that certain actions can be dangerous, you can plan to prevent accidents and injuries. Look ahead to find the dangerous points of a task and plan to make them safe by taking proper precautions. We can make hundreds of safety rules, but they are useless unless we understand why they are needed and we all cooperate in following them.

One of the most important safety precautions is learning to use the right tool for the job, and in the correct way. The correct way is the safest way.

RESPECT OTHER PEOPLE: RESPECT YOURSELF!

PART 1: BASIC MASONRY TECHNIQUES

TECHNICAL TERMS

Before describing the methods used in bonding it is necessary to briefly define and explain a few of the technical terms commonly used.

- SUN-DRIED TRAINING BLOCKS: These blocks, as the name implies, are dried in the sun, because they do not contain cement (Fig. 1). They are often used by beginners during their first terms of in-centre training, as they are easy to make and to handle.

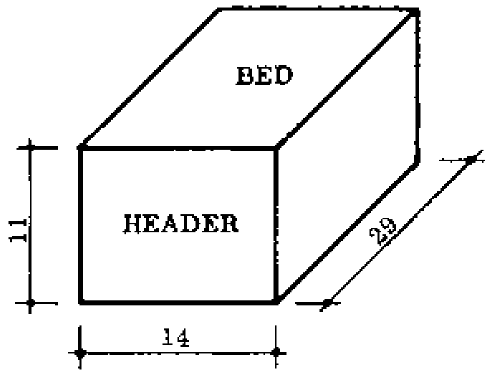


Fig. 1 SUN-DRIED TRAINING BLOCK

The dimensions of these blocks are approximately 29 cm × 14 cm × 11 cm, which allows us to construct complicated bonds with them. They can be used to make an excellent inside wall also, as the following chapters will describe.

- LANDCRETE BLOCKS: These are blocks used for actual building (Fig. 2).

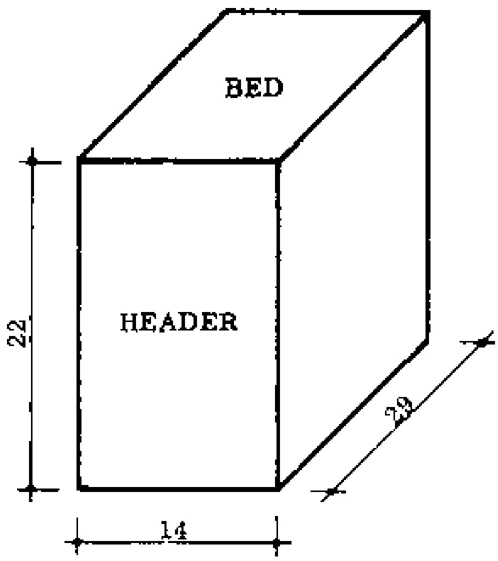

Fig. 2 LANDCRETE BLOCK

- SANDCRETE TRAINING BLOCKS: These are specially made small sandcrete blocks with the approximate dimensions of 24 cm × 14 cm × 11, 5 cm; so they can be used to teach the making of more complicated bonds (Fig. 3).

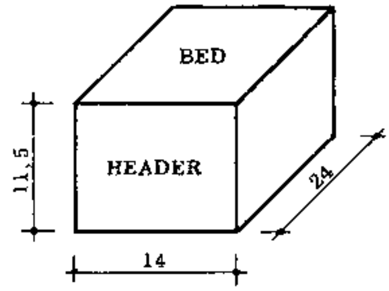

Fig. 3 SANDCRETE TRAINING BLOCK

Like the sun-dried blocks, they are often used in training because they are easy to handle. As they are made with cement they can be used for a long time before they wear out.

- SANDCRETE BLOCKS: This type of block is used for actual building (Fig. 4).

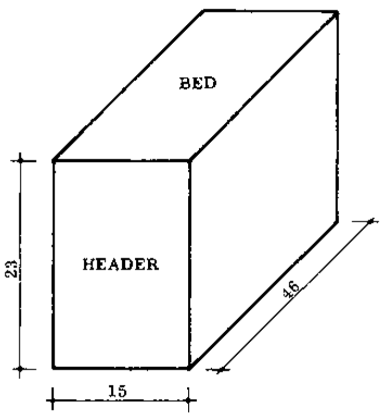

Fig. 4 SANDCRETE BLOCK

- 3/4 - 1/2 - 1/4 - BLOCKS: These are parts of blocks obtained by cutting a block through either the centre line or the quarter line, less half the thickness of the joint (Fig. 5). The cut is made along the width, not along the length. A special block gauge may be used for marking off the different sizes.

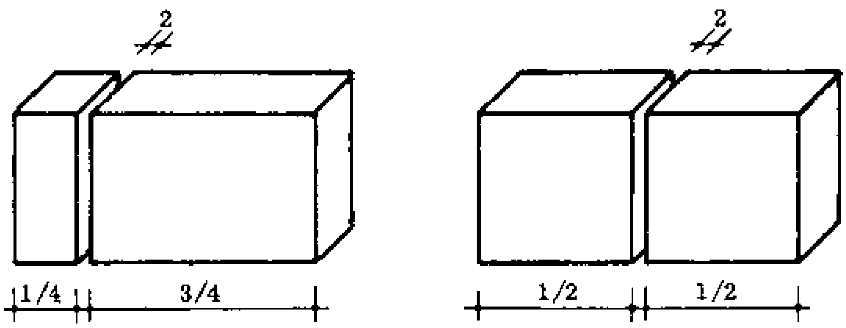

Fig. 5 1/4 - 1/2 - 3/4 BLOCKS

- HEADER: A block is known as a header when it is placed in a wall so that its smallest face is exposed (Fig. 1, next page).

- BED: The under-surface of a block, or the mortar on which the block is laid.

- STRETCHER: If the biggest face of a block is exposed, the block is called a stretcher (Fig.

1, next page). This is the way most blocks are laid in Rural Building, and we say that the block is laid edgewise. If a block is laid flatwise, so it is actually showing the top face, it is also called a stretcher (Fig. 1, next page).

- COURSE: This is the term applied to each layer or row of blocks, with the bed joint included (Fig. 1, next page).

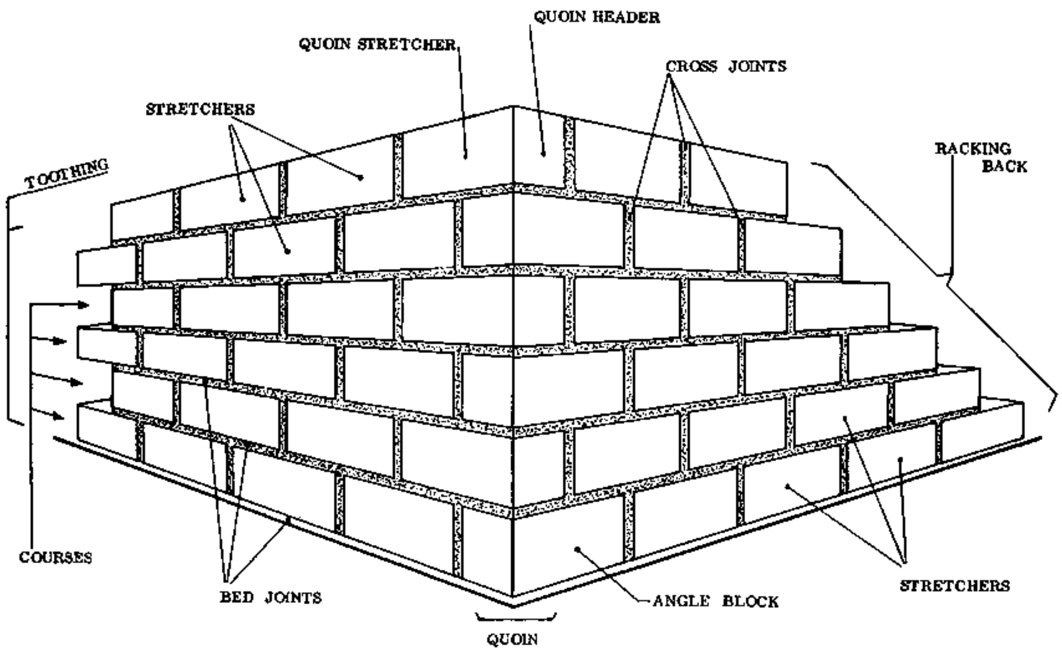

Fig. 1

- BED JOINT: This is the horizontal mortar joint between two courses (Fig. 1).

- CROSS JOINT: The vertical joints between the blocks (Fig. 1).

- QUOIN: The quoin is the outside corner of a wall or the external angle on the face side of the wall (Fig. 1).

- ANGLE BLOCK: This is the block which actually forms the corner in each course (Fig. 1).

- STOPPED END: A plain vertical surface which forms the end of a wall (see page 21).

- TOOTHED END OR TOOTHING: The form produced at the end of a wall by recessing every other course by half a block (Fig. 1) in order that the wall may be extended later using the same bond.

- RACKING BACK: As an alternative to toothing, the end of a wall may be set back half a block at each course (Fig. 1). This is also done so that the wall may be extended later using the same bond.

- BUILDING UNIT: This refers to the dimensions of a full block, plus one joint. For sandcrete blocks the building unit is 25 cm high by 48 cm long (2 cm joints).

- FOUNDATION: The base, usually concrete, on which the building rests. It is usually set below ground level, and is the only part of the building in direct contact with the ground.

- FOOTINGS: The courses laid directly on top of the foundations; usually three flatwise courses of sandcrete blocks (see page 35).

- PLINTH COURSE: The edgewise course of sandcrete blocks laid on top of the footings (see page 35).

- RISING WALL: The edgewise courses of sandcrete or landcrete blocks which build up the rest of the wall (see page 35).

NOTES:

BONDING OF WALLS

The practise of blocklaying requires a complete understanding of the correct arrangement of the blocks forming a wall. This correct arrangement of blocks, regardless of the method, is known as bonding.

The blocks are placed so that they overlap each other and care must be taken to ensure that as far as possible no vertical joint is immediately above another vertical joint in the course below.

General effect of bond

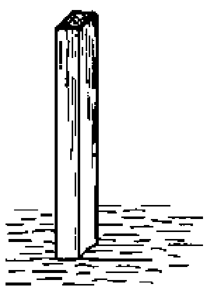

Fig. 1 POLE GIVES WAY AND SINKS DOWN

Fig. 1 shows a wooden pole placed vertically on soft ground. If this pole has to carry a heavy load it will sink down into the soil, because the total area on which the pole rests on the ground is far too small to support it (Fig. 2).

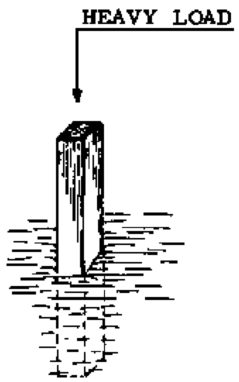

Fig. 2 POLE GIVES WAY AND SINKS DOWN

A possible solution to the problem is shown in Fig. 3: a board is laid flat on the ground and it now carries the pole with the load. In this way the total load is distributed over a larger area of ground and it is impossible for the pole to sink down.

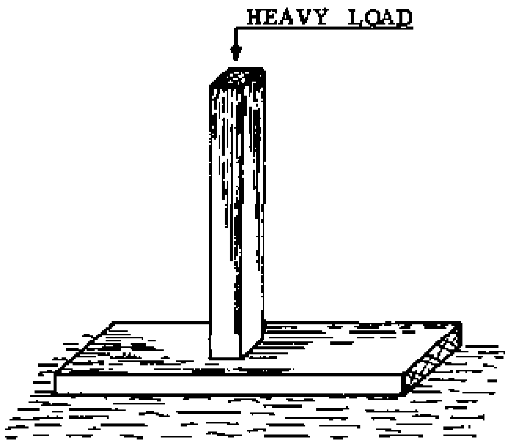

Fig. 3 LARGER AREA OF BOARD PREVENTS POLE FROM SINKING DOWN

If a wall is built up by simply placing blocks directly above each other, we say the wall is built without bond. If a heavy load is put on top of this wall (Fig. 4) the column of blocks immediately under the load tends to give way and sink down.

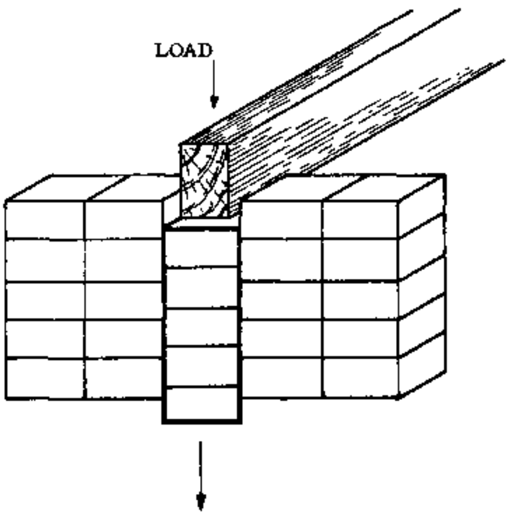

Fig. 4

In order to make the wall stronger in itself and able to distribute loads properly, the Rural Builder applies the so-called half-block bond.

A properly bonded wall which receives a heavy load will distribute the pressure over a large number of blocks and therefore over a much greater area (Fig. 5).

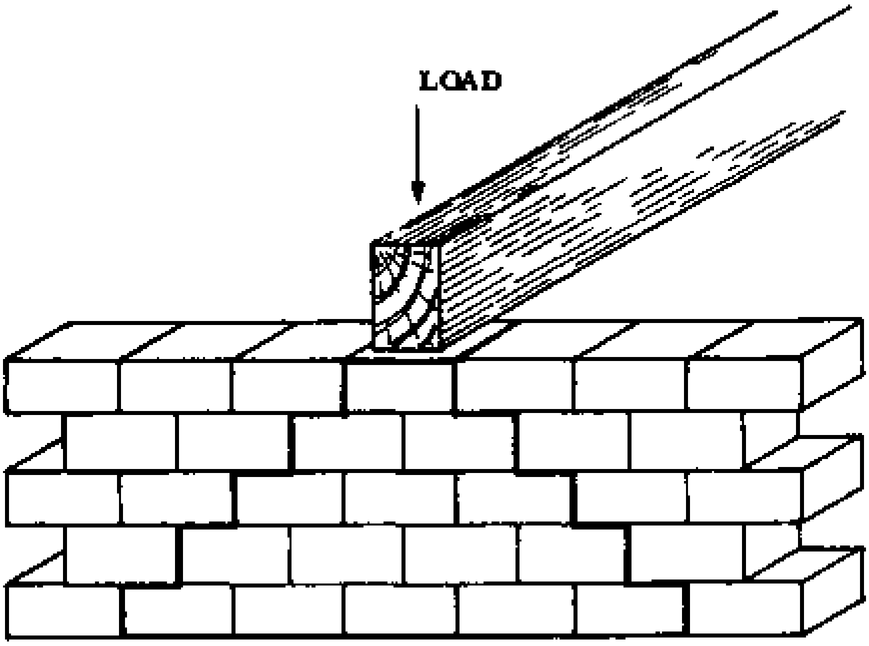

Fig. 5

NOTES:

Half-block bond

The simplest form of bonding is that where all the blocks are laid down as stretchers, each block overlapping the one below by half its length (Fig. 1).

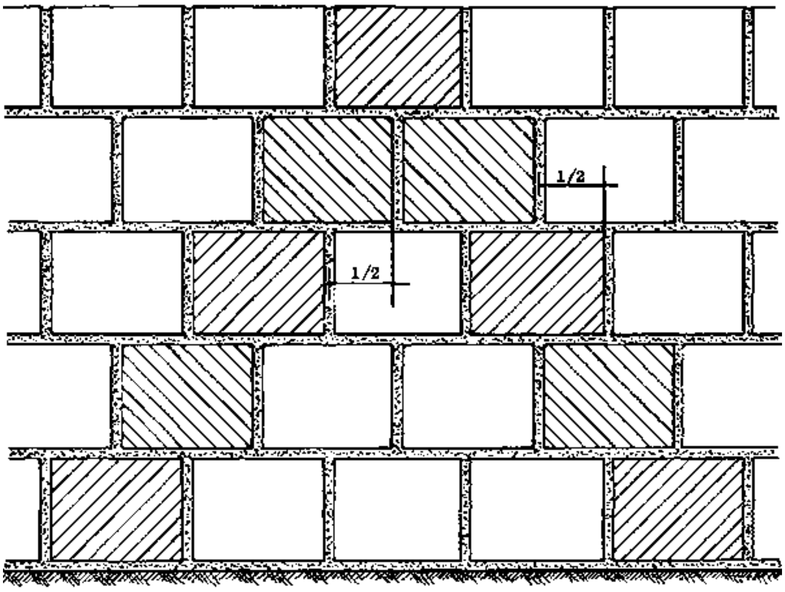

Fig. 1 HALF-BLOCK BONDING (LANDCRETE)

SCALE 1: 10 (cm)

This form of bonding is only suitable where a one-block thickness of the wall is sufficient. In Rural Building the most common wall thickness is 14 cm when landcrete blocks are used and 15 cm when using sandcrete blocks; provided that they are laid edgewise.

If for some reason a thicker wall is required, the blocks may be laid flatwise. By doing this the wall thickness will be increased to 23 cm, 29 cm or even 46 cm depending on the type of block and the way the blocks are laid.

Other types of bond

There are many types of bond in use, the two most common being the English Bond (Fig. 2) and the Flemish Bond (Fig. 3), both of which are used with bricks.

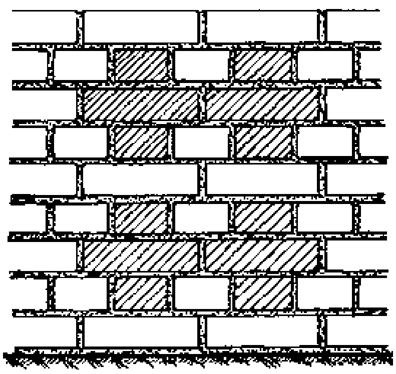

Fig. 2 ENGLISH BOND SCALE 1: 10 (cm)

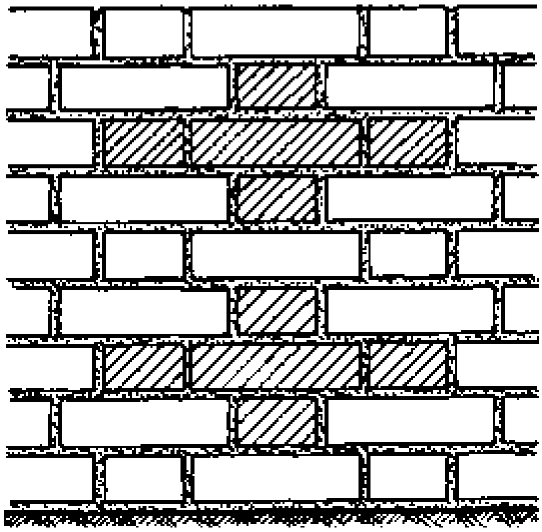

Fig. 3 FLEMISH BOND SCALE 1: 10 (cm)

Bricks are smaller blocks with approximate dimensions of 24 cm × 11, 5 cm × 7 cm.

- ENGLISH BOND: This bond consists of alternate courses of headers and stretchers. The centre of any stretcher is in line with the centre of the header in the courses above and below.

- FLEMISH BOND: This bond consists of alternate headers and stretchers in the same course. Again, the centre of any stretcher is in line with the centre of the header in the courses above and below.

NOTES:

HANDLING THE TROWEL

In the process of laying blocks, the brick trowel is used to perform a series of operations during which the trowel is seldom put down or changed from one hand to the other.

All operations require free and easy manipulation of the trowel from the wrist and it is therefore essential to master the correct handling of the trowel.

Fig. 1 illustrates the correct grip on the handle, with the thumb resting on the ferrule. The thumb must be in this position in order to manipulate the trowel skillfully.

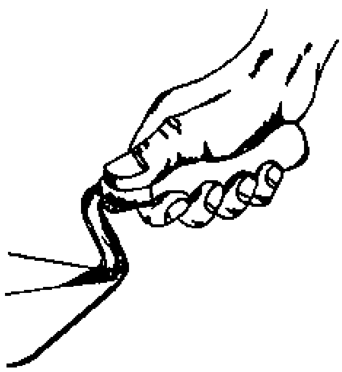

Fig. 1 CORRECT GRIP

The amount of mortar picked up from the headpan will depend on the nature of the job, but for the trainee it is advisable to pick up a sufficient amount to lay one training block, i.e. a heaped trowel. Later, when working with the common big blocks, it will become necessary to pick up two trowelfuls of mortar.

Preparing the bed joint

Place the mortar in the middle of the wall or the marked position of the first course and spread it out by a pushing movement with the back of your trowel, into a layer about 3 cm thick (Fig. 2).

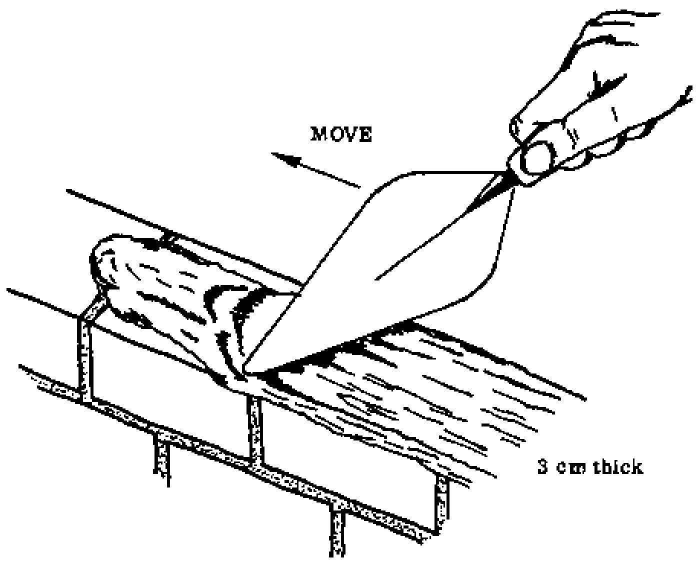

Fig. 2

Next draw the point of your trowel through the centre of the layer, making a mortar bed suitable for the block (Fig. 3).

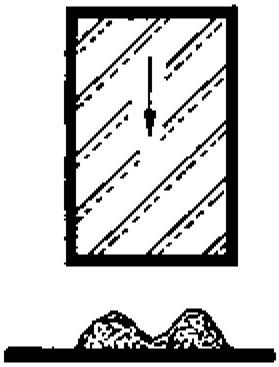

Fig. 3

A block laid on a bed prepared in this way will at first rest on the two outer edges, but when it is pressed down to its correct position it will not only squeeze mortar from the front and back of the block but will also squeeze it into the valley in the centre. In this way a solid bed is formed (Figs. 3, 4, & 5).

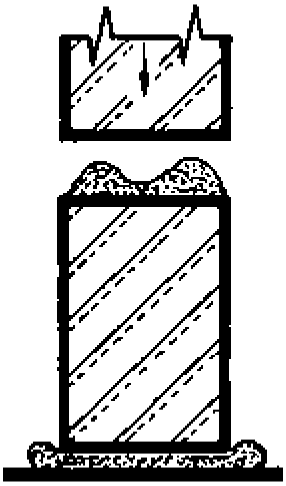

Fig. 4

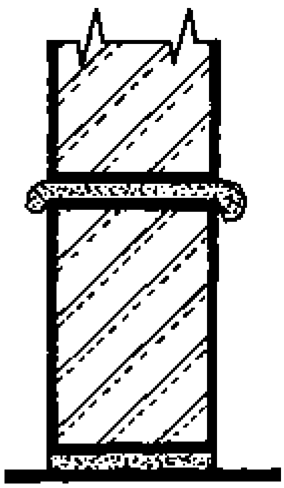

Fig. 5

- NOTE: All the tools mentioned in this section on masonry techniques are described in the Rural Building Reference Book, pages 3 to 15.

NOTES:

Removing surplus mortar

Before and after the block is layed, a certain amount of mortar will project from both sides of the wall. This must be removed before it drops down, as one of the most important principles of the Rural Builder is to work as economically as possible. This means saving materials. Fig. 1 shows the position of the trowel for these operations.

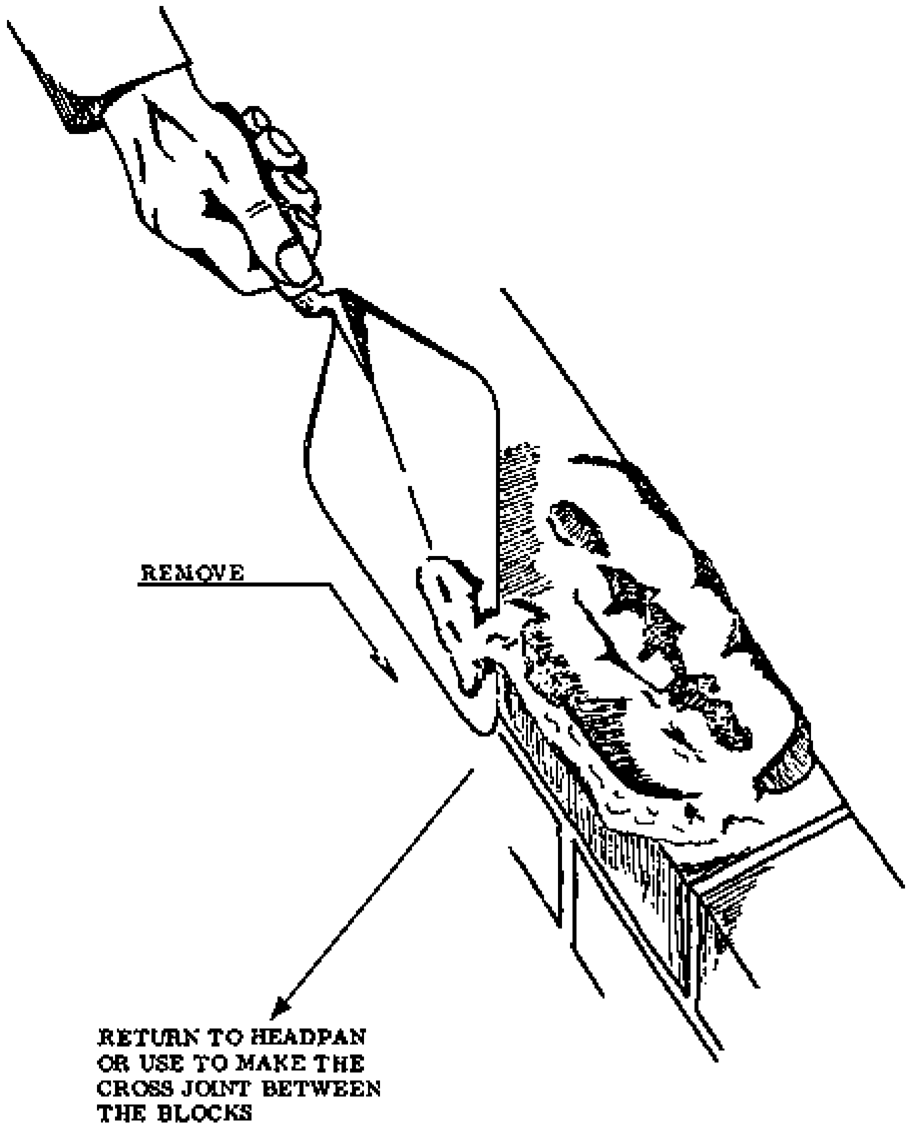

Fig. 1

The surplus mortar recovered on the trowel is usually taken to form the cross joint between the last laid block and the previous one, or it is returned to the headpan.

NOTES:

THE FIRST WALL

Setting out

Before actual building operations are started, you must know the correct position and dimensions of all the parts of the building.

This information is given in the plan or drawing of the building, which of course must have been already prepared and at hand.

The positions of the walls, for instance, have to be marked on the ground according to the measurements given on the plan before any building operation starts.

This operation is called “setting out” and we will deal with it repeatedly here, because it is one of the most important preparatory steps in building.

Organizing the work

The workplace has to be well organized in order to operate smoothly and safely.

Building materials such as blocks and mortar should be neither too close nor too far away from the wall being erected. A working space of about 90 cm will usually be all right. The blocks should be neatly stacked, not just thrown in a heap; and there should always be an adequate supply available, so that work is not delayed by waits for materials.

Keep your tools together and near your workplace so they are within easy reach. When you use a tool, put it back immediately afterwards so that it cannot fall off the wall etc. and injure you or other workers. Make a habit of putting your tools down in a way that prevents accidents.

- NOTE: You cannot expect to produce a good job with your tools and materials always scattered around. Neatness and orderliness show the professional.

Never throw, kick or drop tools as you might damage them.

Work on one side of the wall only. As the wall becomes higher, you won’t be able to move from side to side anyway.

NOTES:

Preventive measures

Almost all of the building in the Northern and Upper Regions of Ghana is done during the dry season, with its high temperatures and low humidity. These conditions are important and our building procedures must take them into consideration to prevent problems with drying out.

Before you put the mortar down and spread ft, thoroughly wet the top of the foundation or the already laid course.

Do the same thing with the block that you are going to lay next. This is to prevent the block from absorbing too much moisture from the mortar. The porous landcrete or sandcrete blocks quickly suck in any moisture they come into contact with. This process is known as absorption. If the blocks absorb too much moisture from the mortar, it will not be able to set properly, and the joints will be weak. By sprinkling sufficient water onto the blocks, we ensure that there will be enough moisture left in the mortar to allow it to harden properly.

It is also important to never spread too much mortar at one time. Some masons prepare the mortar bed in advance for five, six or even more blocks in order to speed up the work. This is wrong.

While the first blocks are placed, lined-out, and levelled, the rest of the mortar is exposed for too long to the sun and air.

Due to the high temperatures and the low humidity, the mortar dries out very fast. As a result the mortar becomes too stiff, making it difficult to lay the last blocks and weakening the grip between the mortar and the block. The end result is a weak wall.

The Rural Builder should always keep in mind the dry climate and never spread more mortar than is actually needed.

NOTES:

The first blocks

After you have wetted the block and the area where it is supposed to be set, spread the mortar according to the method described on page 12. Set the block immediately onto the mortar bed and press it down firmly and evenly (Fig. 1).

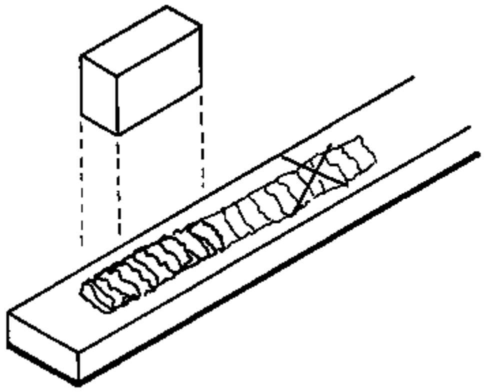

Fig. 1 SET THE BLOCK ON THE MORTAR

If the bed has been spread correctly, only a few taps with the handle of the trowel will be needed to adjust the height of the block. The height is checked by comparing the height of the block with the gauge marks on the straight edge (Fig. 2).

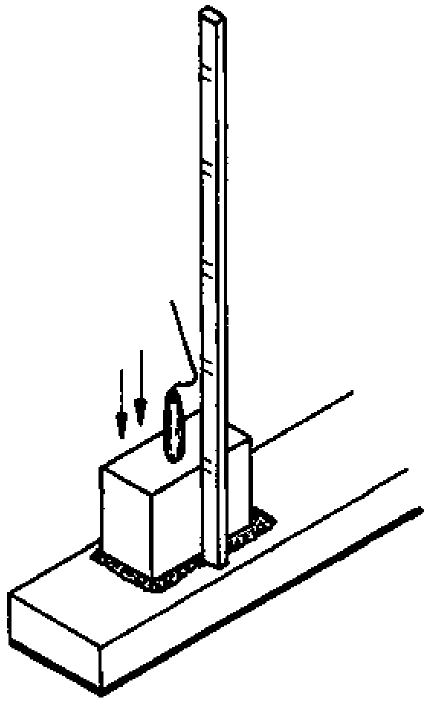

Fig. 2 CHECK THE HEIGHT

Next, plumb the block with the spirit level along the stretcher face and the header face as shown in Fig. 3. The pressure on the block will have squeezed out some of the mortar. Trim off this excess, collect it on the trowel and return it to the headpan.

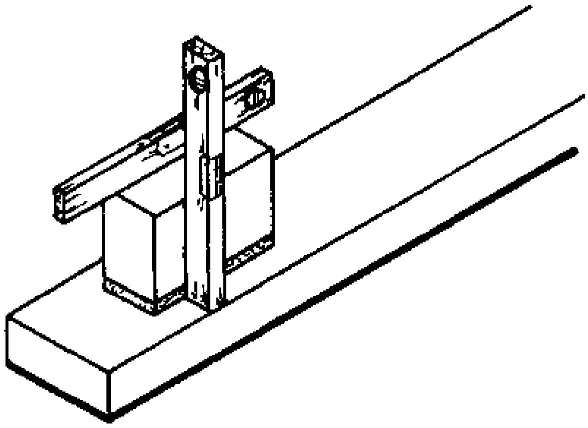

Fig. 3 PLUMB AND LEVEL THE BLOCK

If you don't use enough water to make the bed, the block will not come up to the required height; it will sit too low. If on the other hand too much mortar is used, the block will sit too high.

Do not try to correct problems like this by pushing some mortar from the edges towards the inside of the bed using your fingers; or by knocking hard on the top of the block to try and force it down. These are very poor practices. Instead, Simply remove the block and re-spread the mortar.

At the beginning of the training you will have to re-lay blocks quite often. As you gradually gain experience you will be able to spread just enough mortar to lay one block, without any of the problems mentioned above.

Lay the second block at a distance of four building units and one joint away from the first block (Fig. 4). Hold the straight edge against the stretcher faces of the two blocks to make sure that they are in line.

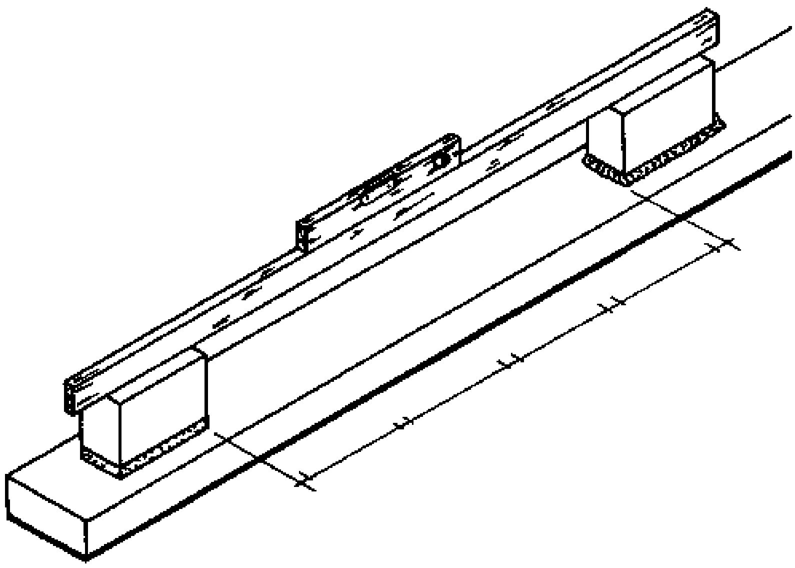

Fig. 4 LAY THE SECOND BLOCK MAINTAIN THE CORRECT DISTANCE OF 4 BUILDING UNITS PLUS 1 JOINT.

NOTES:

The first course

Because the first two blocks are in line and at the same height, we can complete the course without using the spirit level, only using the straight edge. Starting from either block (but still working on only one side of the wall) more blocks are inserted between the first two (Fig. 1).

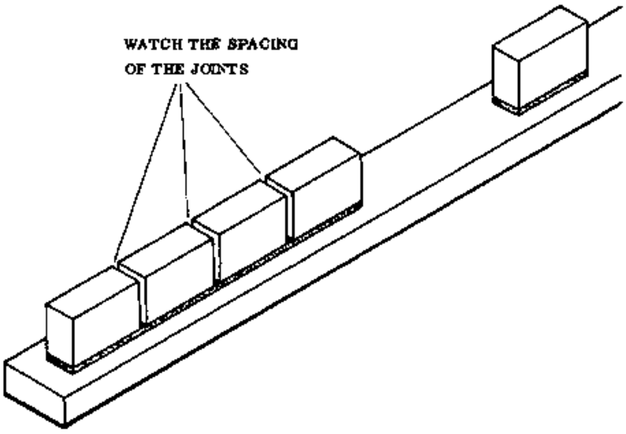

Fig. 1 LAYING THE FIRST COURSE

Their height is adjusted by placing the straight edge on top and pressing the blocks down until the top surfaces of all the blocks touch the straight edge equally, along their whole length.

Line out the course (make it perfectly straight) by holding the straight edge against the stretcher faces and moving the blocks until they touch it along their full length.

During these operations take care to maintain the proper distances between the blocks. The next step is to fill the remaining open gaps between the blocks with mortar, thus forming the cross joints. This job is done by closing the back of the gap with the aid of a small wood float while carefully pushing the mortar down into the joint with the trowel (Fig. 2).

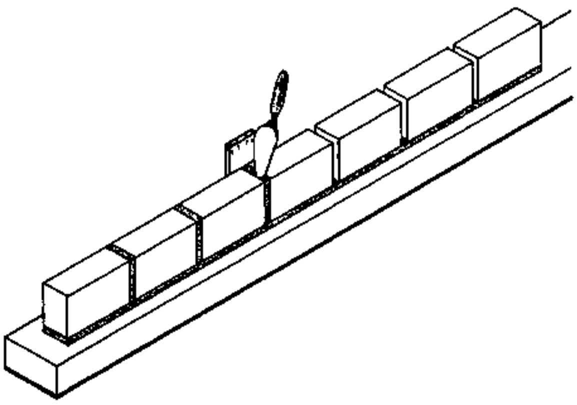

Fig. 2 FILLING UP THE CROSS JOINTS

REMEMBER: RETURN SURPLUS MORTAR TO THE HEADPAN!!

All cross joints must be completely filled up with mortar so that no holes are left, which would reduce the strength of the course and the whole wall.

All the excess mortar which has dropped down or was squeezed out of the bed must now be collected and returned to the headpan to be mixed with the rest of the mortar.

NOTES:

The second course

Lay the first block of the second course with its centre exactly above the first cross joint so that it overlaps both blocks below equally.

No matter what sort of wall-ending is desired, the first block of the second course is always a full block laid above the first cross joint between two stretchers. This is known as the 1-2-1 rule. By doing this you maintain the half-block bond throughout the wall (Fig. 1)

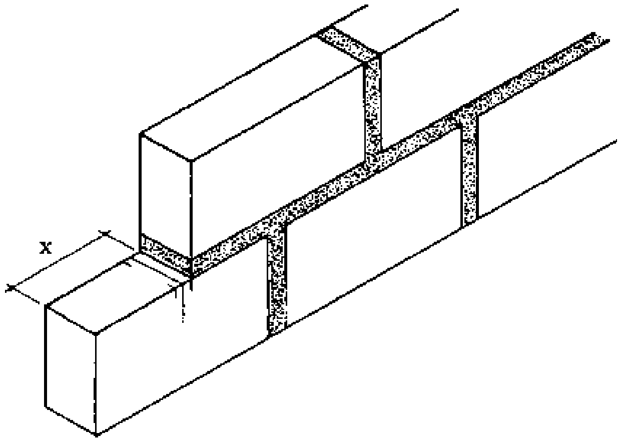

Fig. 1 SECOND COURSE X = HALF BLOCK PLUS HALF JOINT

After you check the height of this block, you must plumb its face. Hold the spirit level vertically along the face of the lower block with one hand, while with the other hand you move the upper block until its face is also in full contact with the spirit level, and the bubble is in the centre of the tube.

Follow the same operation with the second block, laying it above the last cross joint in the lower course. Insert the remaining blocks between them according to the method used for the first course.

The construction of any subsequent course is merely a repetition of the above operations and will result in a wall with racking back at both ends (Fig. 2).

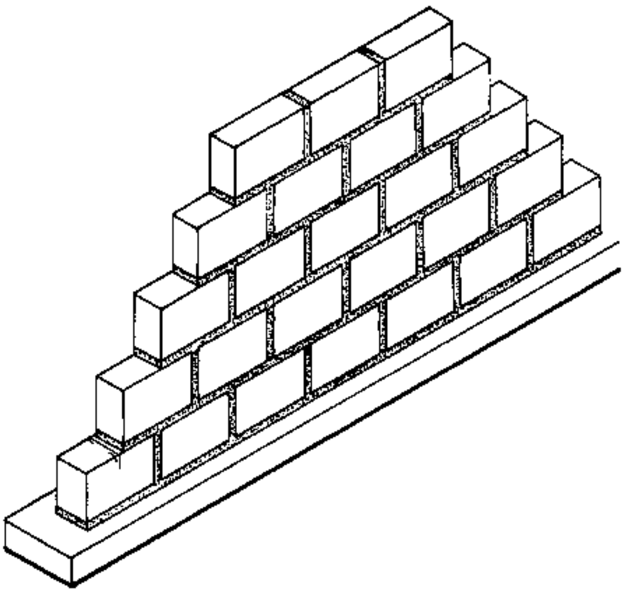

Fig. 2 RACKING BACK

- NOTE: If the Rural Builder has a choice between racking back and toothing, racking back should be the preferred method. This is because the joints used in toothing are difficult to fill properly when completing the wall, which often results in a weak grip all along the joints.

NOTES:

Toothed end

The construction of a wall with a toothed end starts with the same operations used for a wall with a racking back. After you lay the first block of the third course, the next block you lay forms the toothed end. As this block projects past the one below by more than half its own length, it should normally tip over on its projecting end. To prevent this, a temporary support must be provided until the block is overlapped by the first block of the fourth course and the mortar has set hard. This temporary support is preferably a short piece of board cut to the height of the block plus two bed joints. The upper and lower ends of the supporting board may be chamfered slightly to keep it from wedging between the blocks when it is removed (Fig. 1).

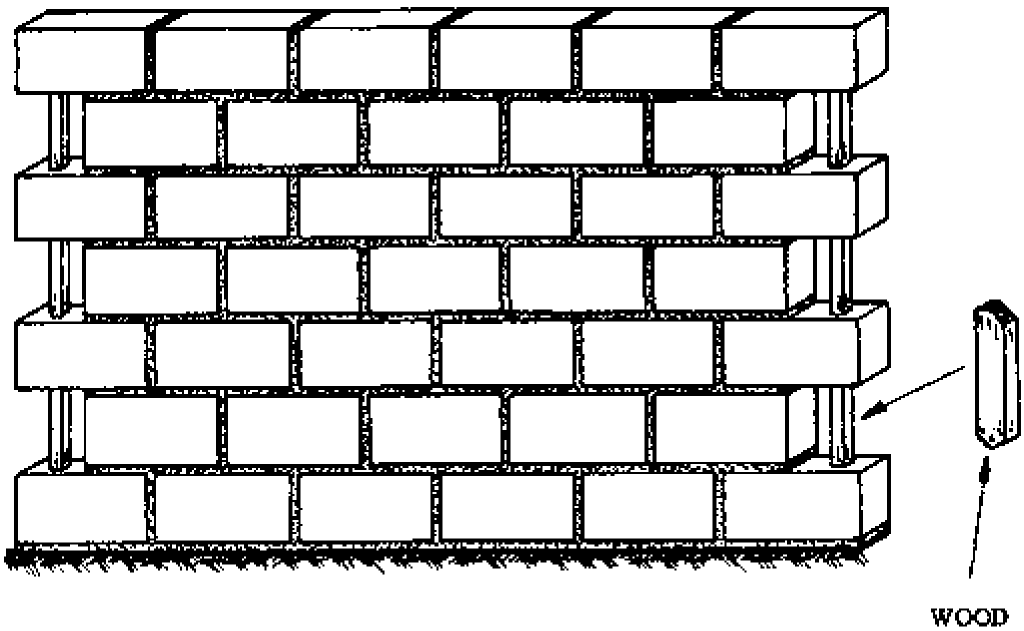

Fig. 1 TOOTHED END

This block must be exactly above the first block of the first course. To ensure this, hold the spirit level against both header faces and make any necessary corrections. It is not necessary to level the top face if the stretcher and header faces have been plumbed.

The construction of further courses is again only a repetition of these operations.

Stopped end

The construction of a wall with a stopped end is very similar to that with a toothed end. The sequence of operations is exactly the same except that instead of the supporting board, half a block is added at the end of the second course before the third course is laid (Fig. 2).

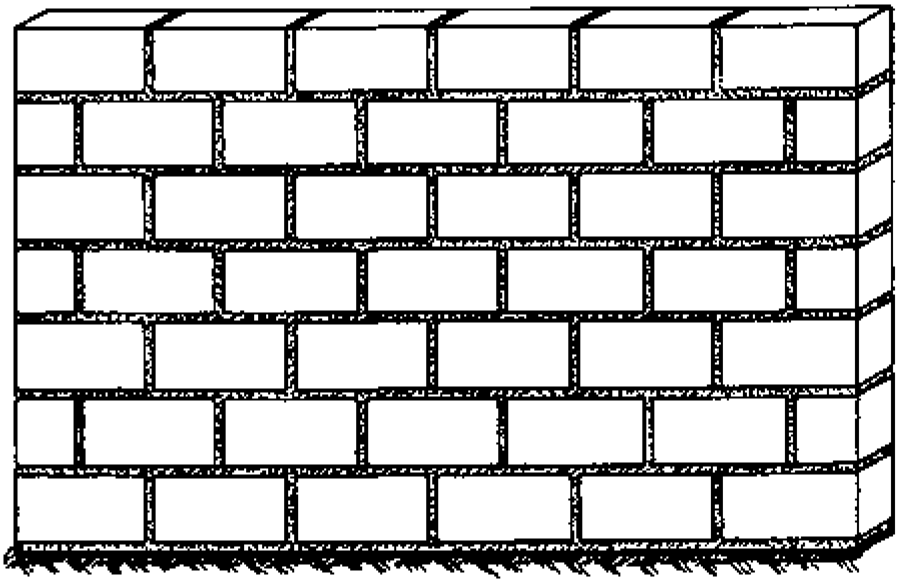

Fig. 2 STOPPED END

This means that there are no gaps left as in the toothed end, so it is called a stopped end.

NOTES:

Marking and cutting blocks

It is usually not possible to construct walls using only full blocks. In most cases 1/4, 1/2, and 3/4 blocks or intermediate sizes are also required. The previous description of the stopped end, for example, has shown the need for 1/2 blocks.

This does not mean that 1/2 blocks are obtained by simply cutting a full block into two identical halves. This is because the cross joint and its thickness must be considered.

Therefore, the 1/4, 1/2, and 3/4 blocks are actually that part of a full block minus half the thickness of the cross joint (Fig. 1).

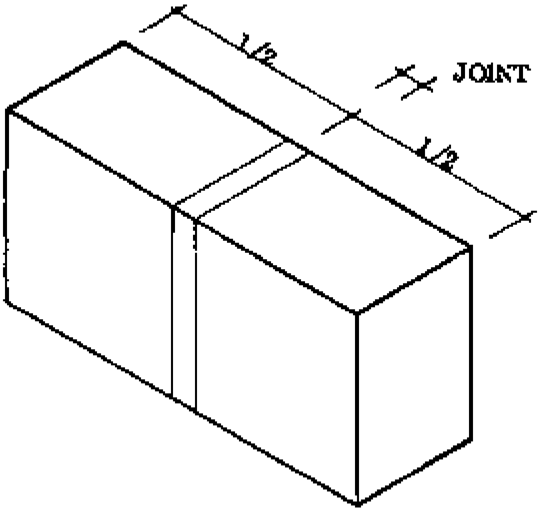

Fig. 1 MARKING THE BLOCK

Before cutting a block, mark the required size around all the faces. To prevent mistakes and to speed up the work, use a block gauge (see Rural Building Reference Book, Tools, page 12). Position the appropriate setting of the gauge against the block, then mark off the measurements on the block face using a pencil or a nail.

Set the marked block on a small heap of sand and then cut it with the block scutch by repeatedly and carefully knocking along the mark, making a groove in the surface. Direct the blows close to each other all around the four faces and continue until the block breaks apart along the groove (Fig. 2).

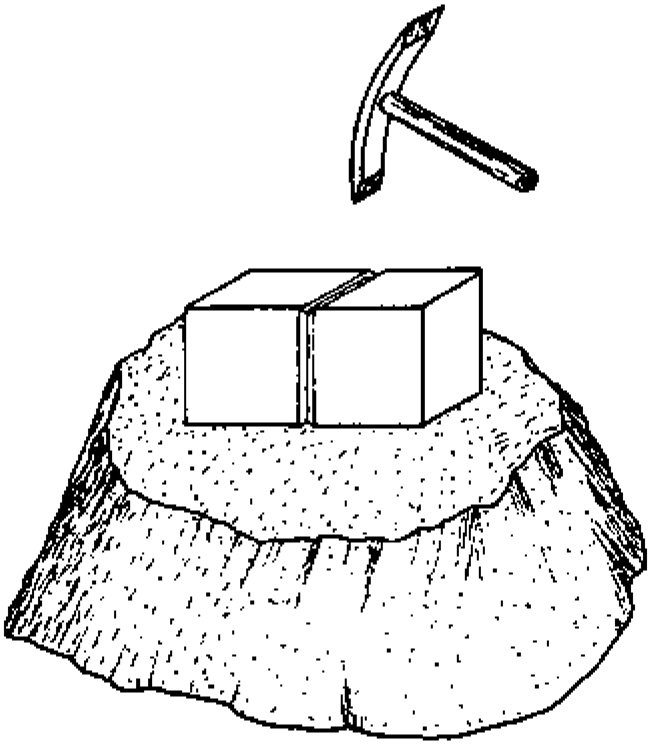

Fig. 2 CUTTING THE BLOCK INTO HALF BLOCKS

Trim the resultant rough header faces, if necessary, with the edge of your trowel blade (for landcrete blocks). When cutting sandcrete blocks, you should use the block scutch for trimming (Fig. 3).

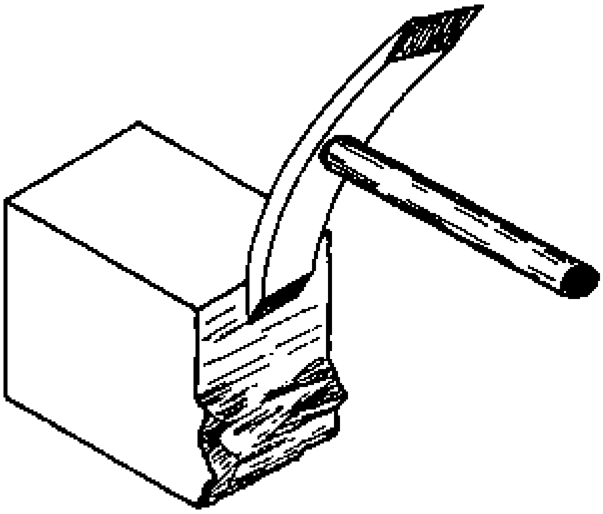

Fig. 3 TRIMMING OF HEADER FACE

- NOTE: Avoid cutting blocks on hard ground: they can easily break into irregular pieces and be wasted.

Never cut blocks on a scaffold for the same reason, also because they might fall and injure someone below.

It is always better to prepare in advance the number of blocks that you think will be needed that day.

Do not use blocks which are cracked; these must be replaced by good blocks or the wall will be weakened.

NOTES:

QUOINS

When external walls are constructed the corners or quoins are built first, to a height of several courses. Usually it is best to build six courses as this will reach to about 1,5 m high, the so-called scaffold height; and in most cases this will be half of the total height of the wall. The walling between the courses is completed later, course by course. The accuracy of the whole wall is determined by the corners, so great care must be taken to build them properly.

At the beginning of training, the positions of the quoins are determined by marking them out on the floor using the mason square.

A quoin is constructed in the following manner:

Blocks are sometimes not correctly shaped, so the first block or angle block must be chosen carefully so that all its faces are square to each other.

As you lay the angle block, stand close to the foundation with your head vertically over the block. You should be able to see that both outer faces of the block are aligned with the mark below (Fig. 1). After this the block has to be accurately levelled and plumbed.

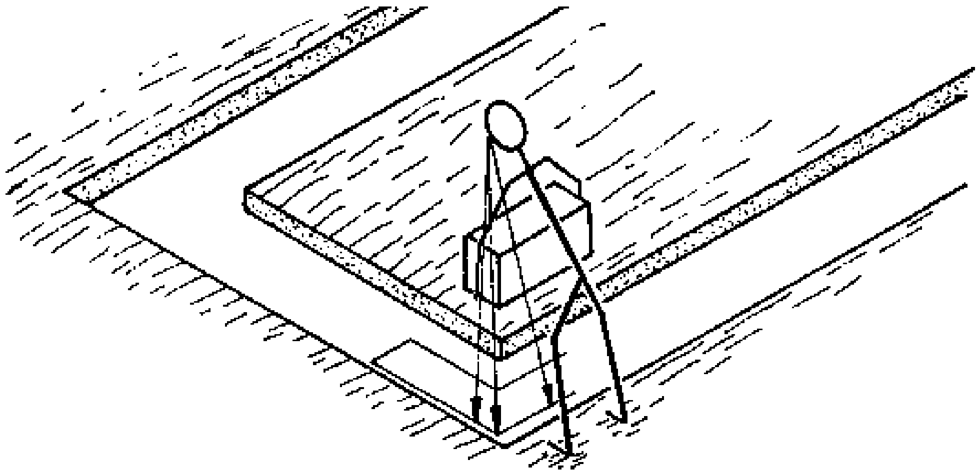

Fig. 1 ALIGN BLOCK WITH THE MARKS

Use the straight edge with gauge marks to ensure that the block is laid at the correct height. Hold the straight edge vertically against the block; the top edge of the block should correspond to the gauge mark (Fig. 2).

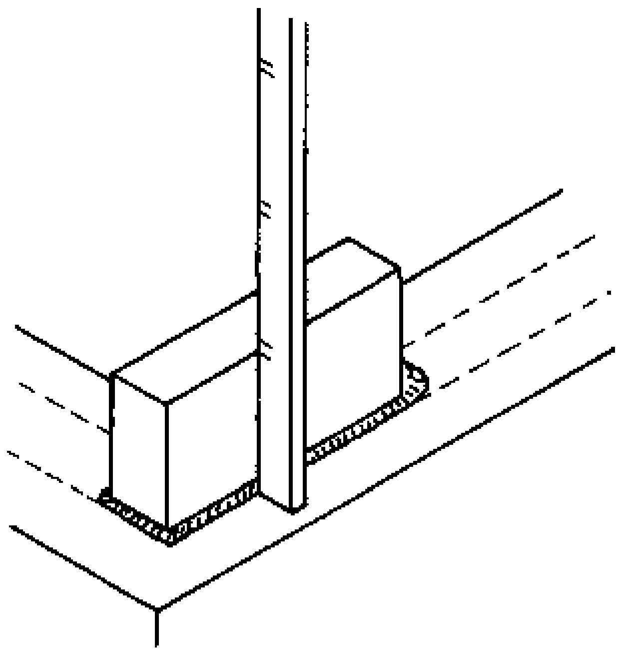

Fig. 2 CHECK CORRECT HEIGHT

Now you have to make certain that the header face and the stretcher face are truly vertical. To do this hold the spirit level against one face about 5 cm from the corner, keeping it in this position while with your other hand you move the block until the bubble in the tube is centered. This operation must be repeated with the other face of the block (Figs. 3 & 4).

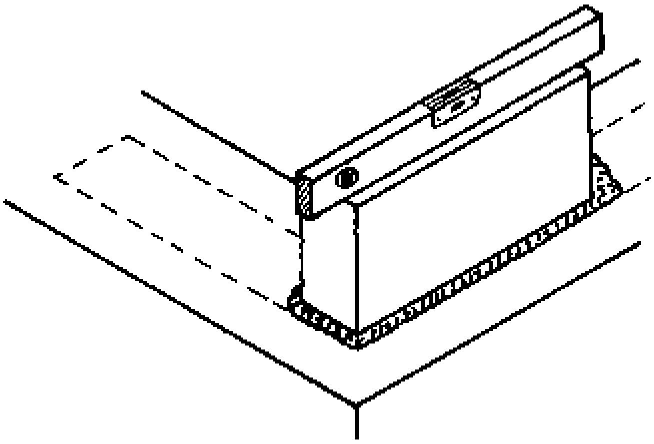

Fig. 3 LEVEL THE BLOCK

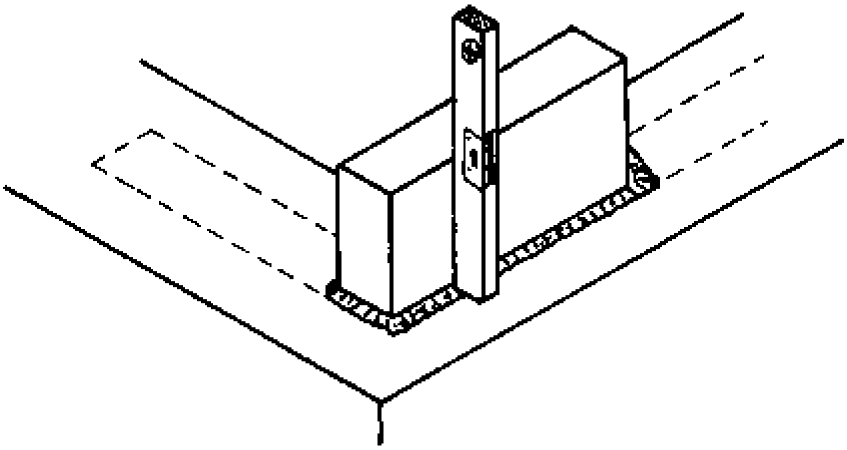

Fig. 4 PLUMB THE BLOCK

NOTES:

Now lay several blocks in each direction according to the method described before. On the quoin stretcher side three more blocks should be laid; followed by four on the header side of the quoin. This will be a sufficient base for building up a height of six courses with either a toothed end or racking back (Fig. 1).

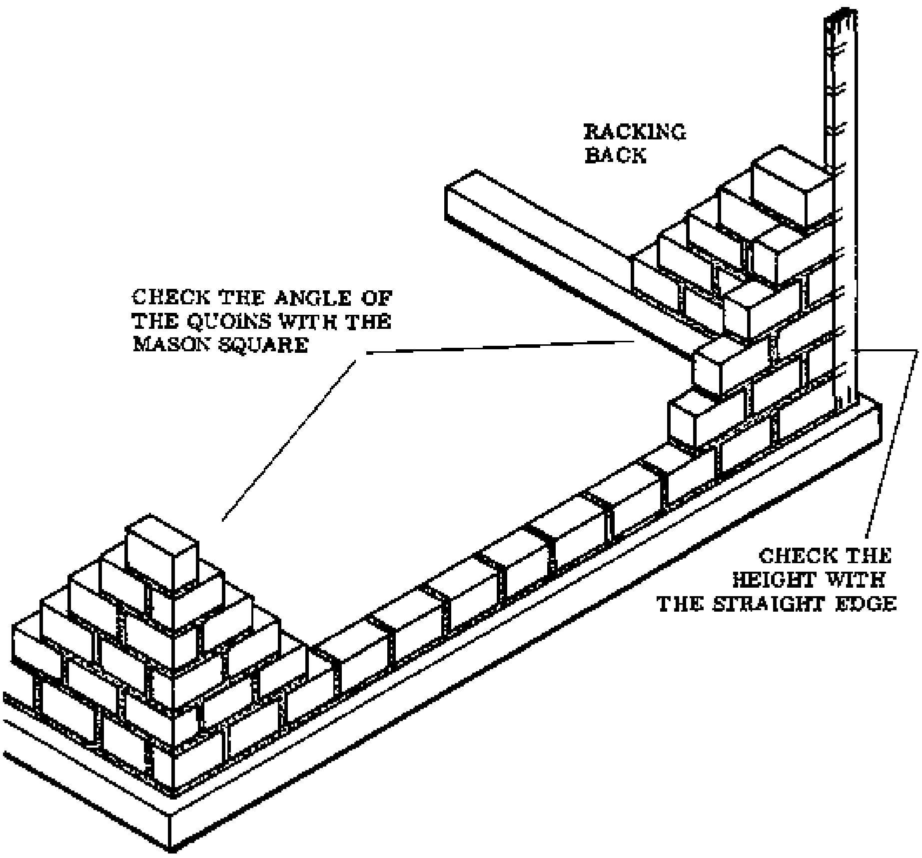

Fig. 1

Use the mason square to make sure that the quoin has an angle of 90 degrees. Hold it against the quoin so that both of the blades fully touch the faces of the blocks. Repeat this operation after turning the square around, so that the direction of the blades is reversed.

Second course

Following the 1-2-1 rule, the first block of the second course will not be the angle block; but the one covering the cross joint between the quoin stretcher and the adjoining stretcher. If the angle block were laid first it could get pushed out of position when the other blocks are laid. The correct method fixes the angle block in position by the cross joint between it and the first block. A further reason for this procedure is that the cross joint between the quoin headers and the adjoining stretchers has a different thickness than the other cross joints. This problem will be explained later when we come to bonding problems.

To complete the second course use the same method as described for the construction of the first course.

- NOTE: The arrangement in any course is repeated in the courses two above or two below it. Therefore only two alternating block arrangements are used.

Walling between quoins

When both corners of a wall have been built up to a height of six courses, it is necessary to fill in the blockwork between them. This is done with the aid of the mason line and either nails, pins, or line bobbins.

Fixing the mason line

If nails or pins are used, insert one of them in the bed joint at one corner so that the line will be level with the upper edge of the course (see Rural Building Reference Book, Tools, page 6). Fix the mason line to the nail or pin without using a knot, as shown in Fig. 2. This is so that later it can be easily removed.

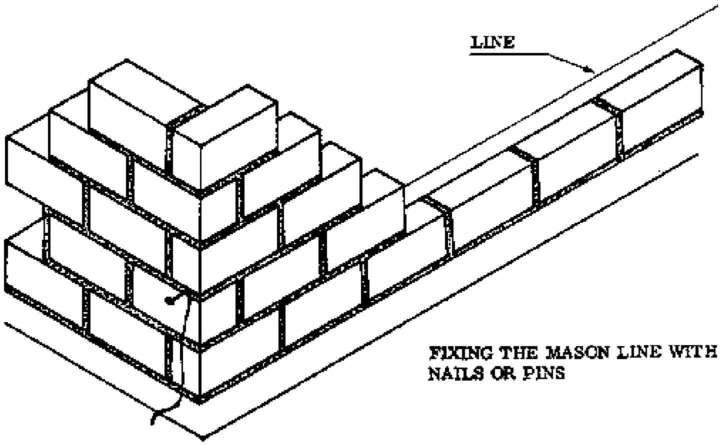

Fig. 2

Stretch the line taut to prevent any sagging, and push the second nail or pin into the corresponding bed joint in the opposite quoin. The line should now be level with the top of the course to be built; and about 2 mm or the thickness of a trowel blade away from the blockwork. Put a wedge of paper between the wall and the line to keep the distance of 2 mm. The line should be horizontal.

If you use line bobbins instead of pins, take one with the line fastened around the screws and engaged in the saw cut; and position it with the notch against the corner of the quoin so that the line is level with the top edge of the course to be built. At the opposite quoin insert the line in the saw-cut of the second bobbin and set it at the correct height against the corner. Stretch the line taut and secure it by winding around the screws (Fig. 1).

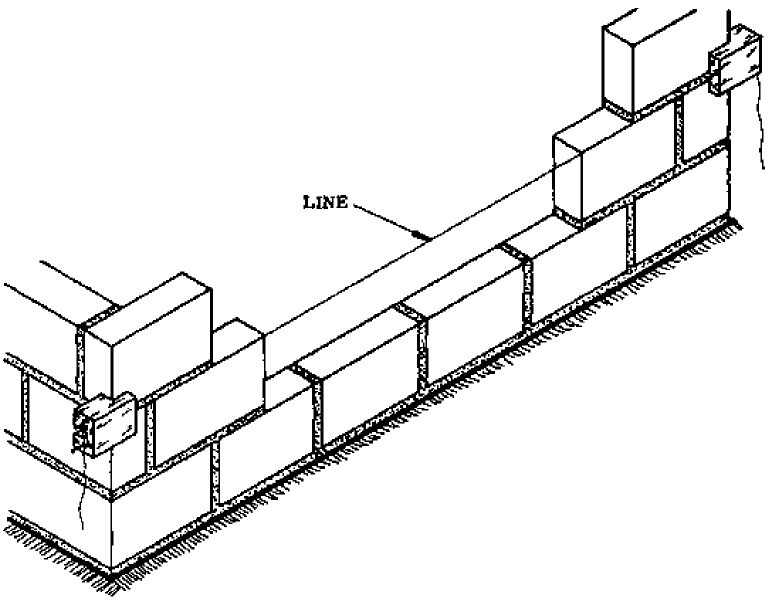

Fig. 1 LINE BOBBINS

The tight mason line holds the bobbins against the corners, keeping them in position. Once the line has been fixed in this manner no further adjustment is needed, unless the line starts to sag and needs tightening.

After one course is completed, simply slide the bobbins up the corners to the level of the next course.

Use of the tingle plate

If the line is stretched over a longer distance, it will tend to sag and will no longer provide a straight guide. In the case of a long wall where the distance between the bobbins exceeds 6 m, it becomes necessary to use one or more tingle plates (Fig. 2). This is done to keep the line from sagging. The tingle plate must be set on a so-called tingle block. Lay this block plumb, in position and at the correct height in the course to be built. This block keeps the tingle plate at the required height to support the mason line. Place the plate flat on the block, and weight it down with a half-block. The taut line is passed under the outer nibs and over the centre nib (Fig. 2).

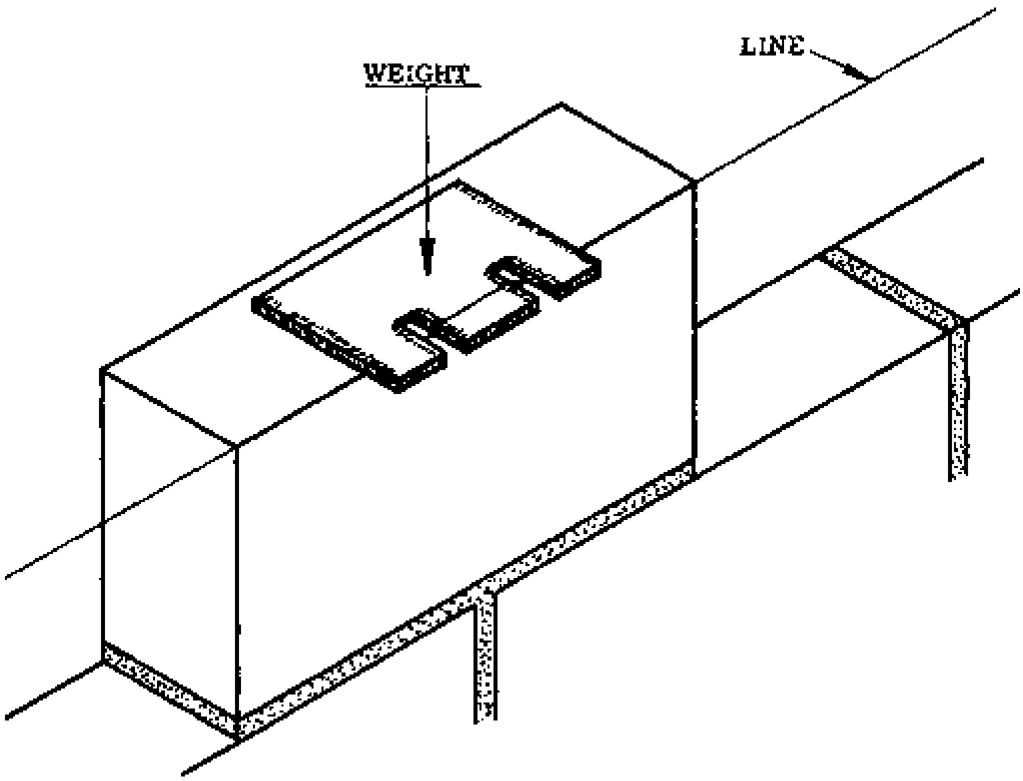

Fig. 2 TINGLE PLATE

Completing the course

Now lay the blocks to complete the course. Take care that the outer top face edge of each block is level with the line.

At the same time be sure to keep the lower stretcher face edge in line with the edge of the course below. Avoid the tendency to lay the blocks too close to the line; the 2 mm distance must be maintained and checked from time to time by sliding the trowel blade between the line and block.

If the blocks are laid correctly, plumbing and levelling are not necessary. It is advisable however to check the face of the wall for a possible overhang, using the straight edge.

After you have filled the cross joints, carefully rake out all the joints of the freshly laid courses to provide an additional grip for the plaster.

BONDING PROBLEMS

Problems arise when we use different types of blocks in the same wall. Usually in Rural Building we use sandcrete blocks for the lower courses of a wall to avoid problems with dampness, and landcrete blocks for the higher courses. Unfortunately the dimensions of sandcrete blocks and landcrete blocks do not match up well to each other. This means that it is not as easy to maintain a half-block bond as it is in a wall made up of only one kind of block.

For example, a sandcrete block has dimensions of 46 × 23 × 15 cm. A sandcrete half-block has the dimensions 22 × 23 × 15 cm. Even when the sandcrete blocks are cut in half they still will not match up exactly to the landcrete blocks (see the table below).

	Full block	**Half block**
Sandcrete	46 × 23 × 15	22 × 23 × 15
Landcrete	29 × 22 × 14	13,5 × 22 × 14

The dimensions of the 1/4 and 1/3 blocks also do not correspond, so in order to maintain the half-block bond between the sandcrete and landcrete courses we would have to make quite an adjustment.

Practically this means that although it would be better, we cannot maintain exactly a half-block bond between the sandcrete and landcrete. They must be considered as separate parts of the wall, properly bonded in themselves but not necessarily showing a half-block bond between them.

CORNER BONDS

Corner bond for footings

The materials used for footings are sandcrete blocks which must be laid flatwise, giving a wall thickness of 23 cm. Since this measurement exceeds the length of a half-block by 1 cm, the first cross joints following the quoin stretchers must be 3 cm wide instead of the normal 2 cm. All the other joints are still 2 cm thick. By doing this the half-block bond is maintained (Fig. 1).

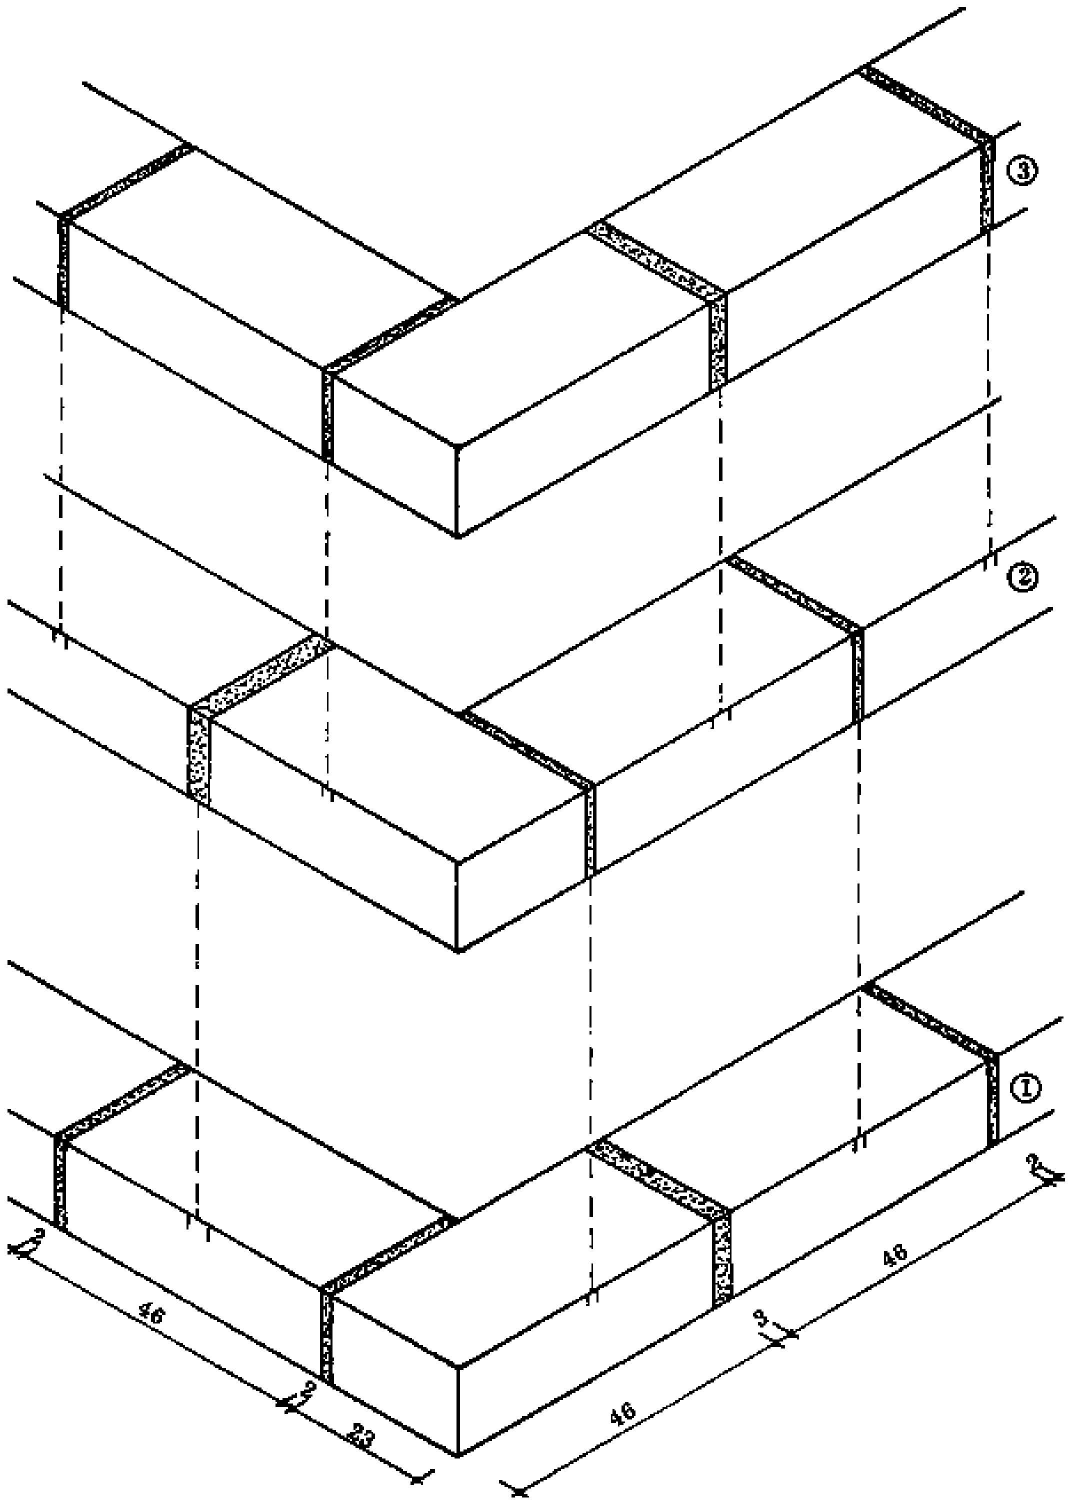

Fig. 1

There are of course two other ways to maintain the half-block bond:

- All the cross joints directly following the quoin header could be reduced to a thickness of only 1 cm. The effect would be the same but these joints would be difficult to fill properly, which could result in a weak quoin.

- All stretchers following the quoin headers could be cut to a length of 45 cm. This takes time and may damage the blocks.

In general, it is best not to use these last two methods.

Corner bond for a rising sandcrete wall

So-called wet rooms such as kitchens, showers and toilets must be built with sandcrete blocks. This is to avoid any damage to the walls caused by moisture.

If landcrete blocks are exposed to moisture for a long time the blocks will start to expand. This pushes the plaster off the walls and makes them weaker and weaker until finally they collapse under their own weight.

Rising walls in Rural Building are generally built by laying the blocks edgewise. When sandcrete blocks are used the wall has a thickness of 15 cm.

In order to avoid making too many cross joints within the quoin area, each quoin header as well as each quoin stretcher is followed by a full block.

To maintain the required half-block bond, a 7 cm lack of overlap has to be made up. This is done by inserting a 5 cm block between the first two stretchers that follow the quoin headers (5 cm plus 2 cm joint equals 7 cm). Almost every building project uses thin blocks for copings or rain gutters etc., and these specially made blocks can be simply cut in half and used to fill the gaps (Fig. 1).

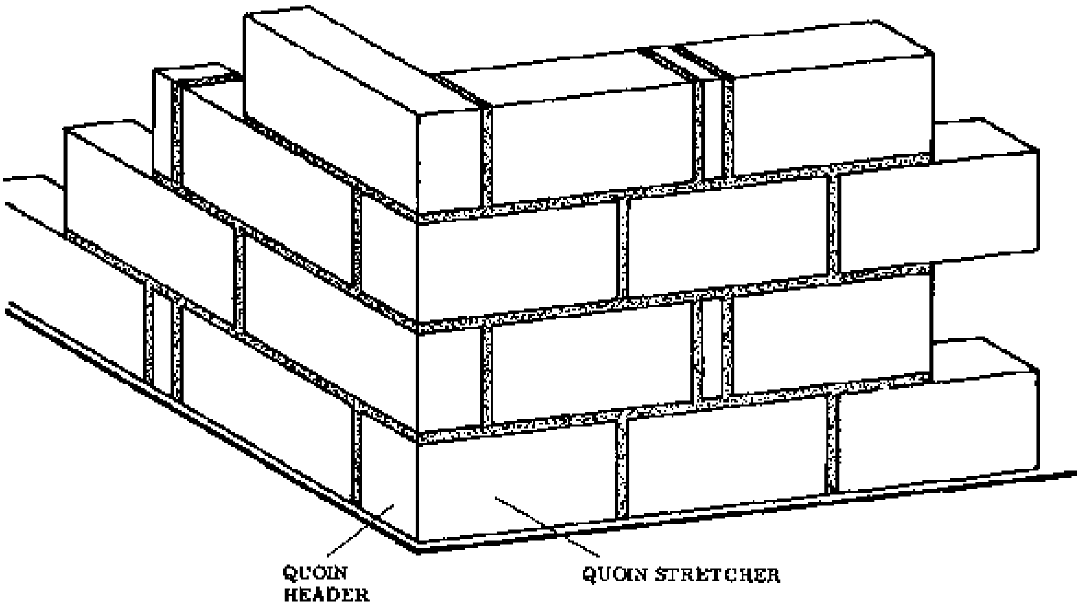

Fig. 1

NOTES:

Corner bond for rising landcrete wall

As far as bonding is concerned, the footings, the plinth course and the rising landcrete wall are all regarded separately. They are properly bonded in themselves but don't necessarily show a half-block bond, especially between the plinth course and the landcrete wall.

As Fig. 1 illustrates, a half-block bond between footings and plinth course (both sandcrete) is possible despite the 4 cm setting back (c) and should be maintained.

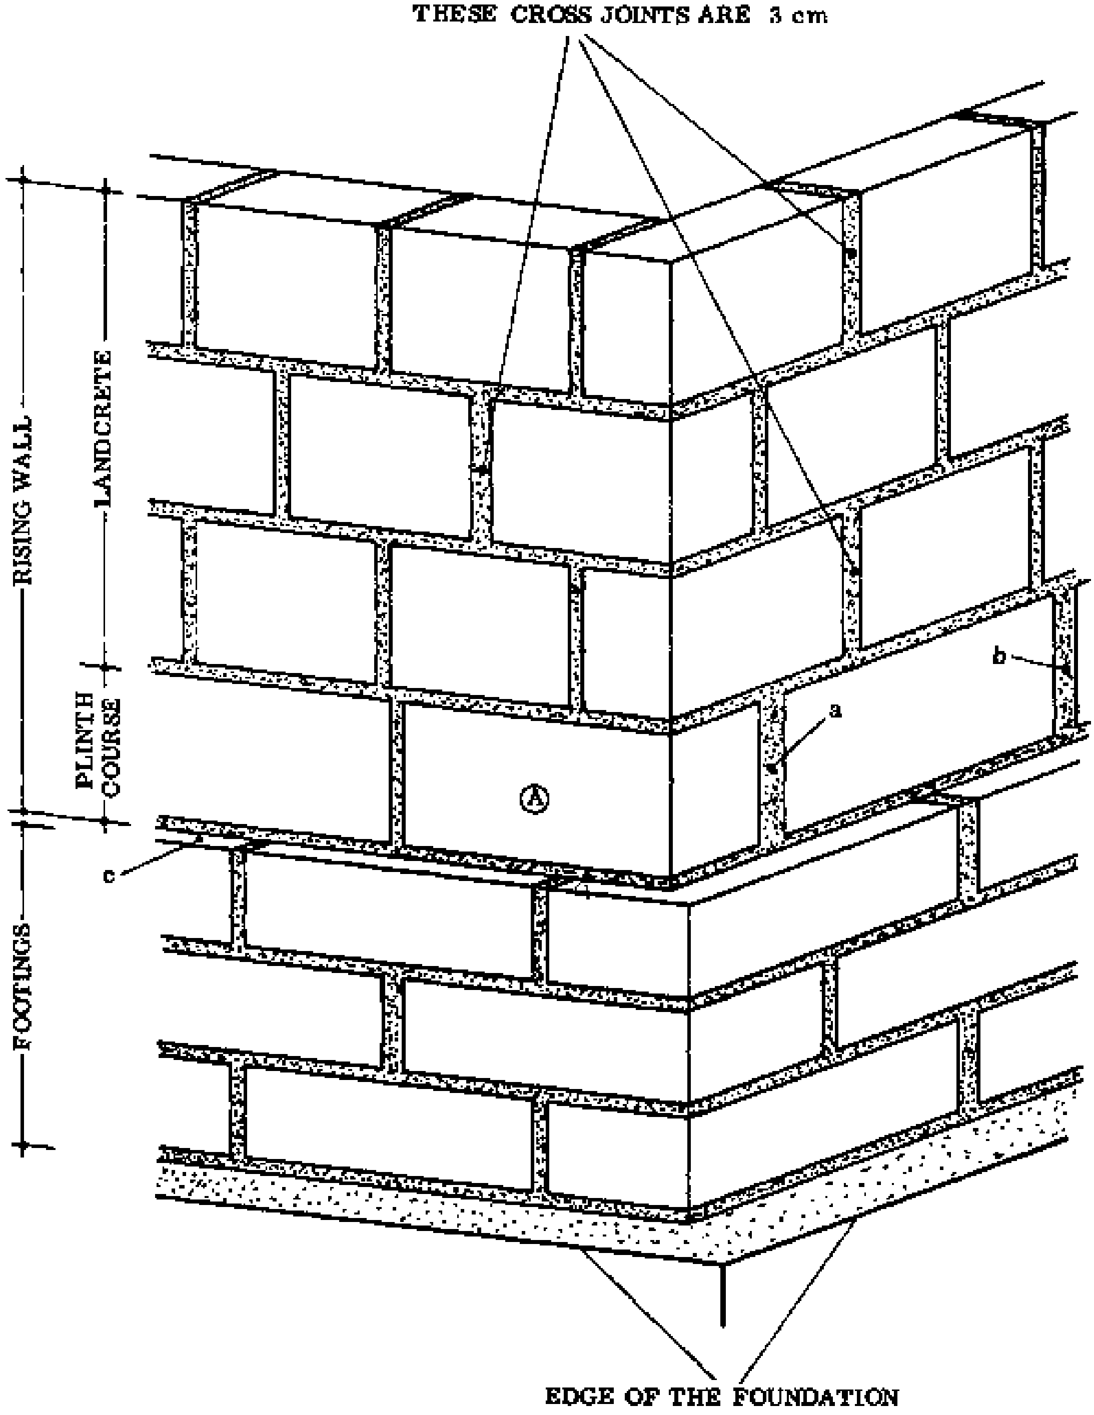

Fig. 1

- PLINTH COURSE: Since the rising wall is erected exactly in the middle of the footings, the plinth course has to be set back 4 cm from both faces: 23 cm (thick ness of footings) minus 15 cm (thickness of plinth course) divided by 2 equals 4 cm (at both sides).

The angle block (A) has to be shortened by 3 cm because of the setting back, thus we automatically make the correct half-block bond on the quoin stretcher side. The first two cross joints (a & b) following the quoin header must be widened to 4 cm each to overcome a lack of 4 cm in overlap. By doing this we distribute the lack of 4 cm over two joints equally.

- RISING LANDCRETE WALL: As already stated, the rising landcrete wall is regarded separately from the plinth course. This is because the dimensions of the landcrete and sandcrete blocks prevent the construction of a half-block bond between them.

However, one important rule must be observed: No matter what part of the construction or what material it consists of, each quoin header must be overlapped by a quoin stretcher; each quoin stretcher is automatically followed by a quoin header (Fig. 1).

To maintain the half-block bond within the landcrete wall, all the cross joints directly following the quoin stretchers must be widened to 3 cm. All other joints remain the same.

NOTES:

T-JUNCTION BONDS

The term T-junction is given to connections between walls which form a T shape, although it is not essential that the angles be right angles. This situation occurs most often where outside walls are met by inside walls.

T-junction bond for footings

Like quoins, the T-junctions are built first or at the same time as the quoins, and the walling between them is completed later.

The first block to be laid is the first block (A) of the inside wall: it will be seen as a header in the face of the outside wall (Figs. 1 & 2). This followed by a 1/4 block (B) at one side of it in the direction of the outside wall, and by a full block (C) on the other side (Fig. 2). This is followed by laying full blocks in all three directions.

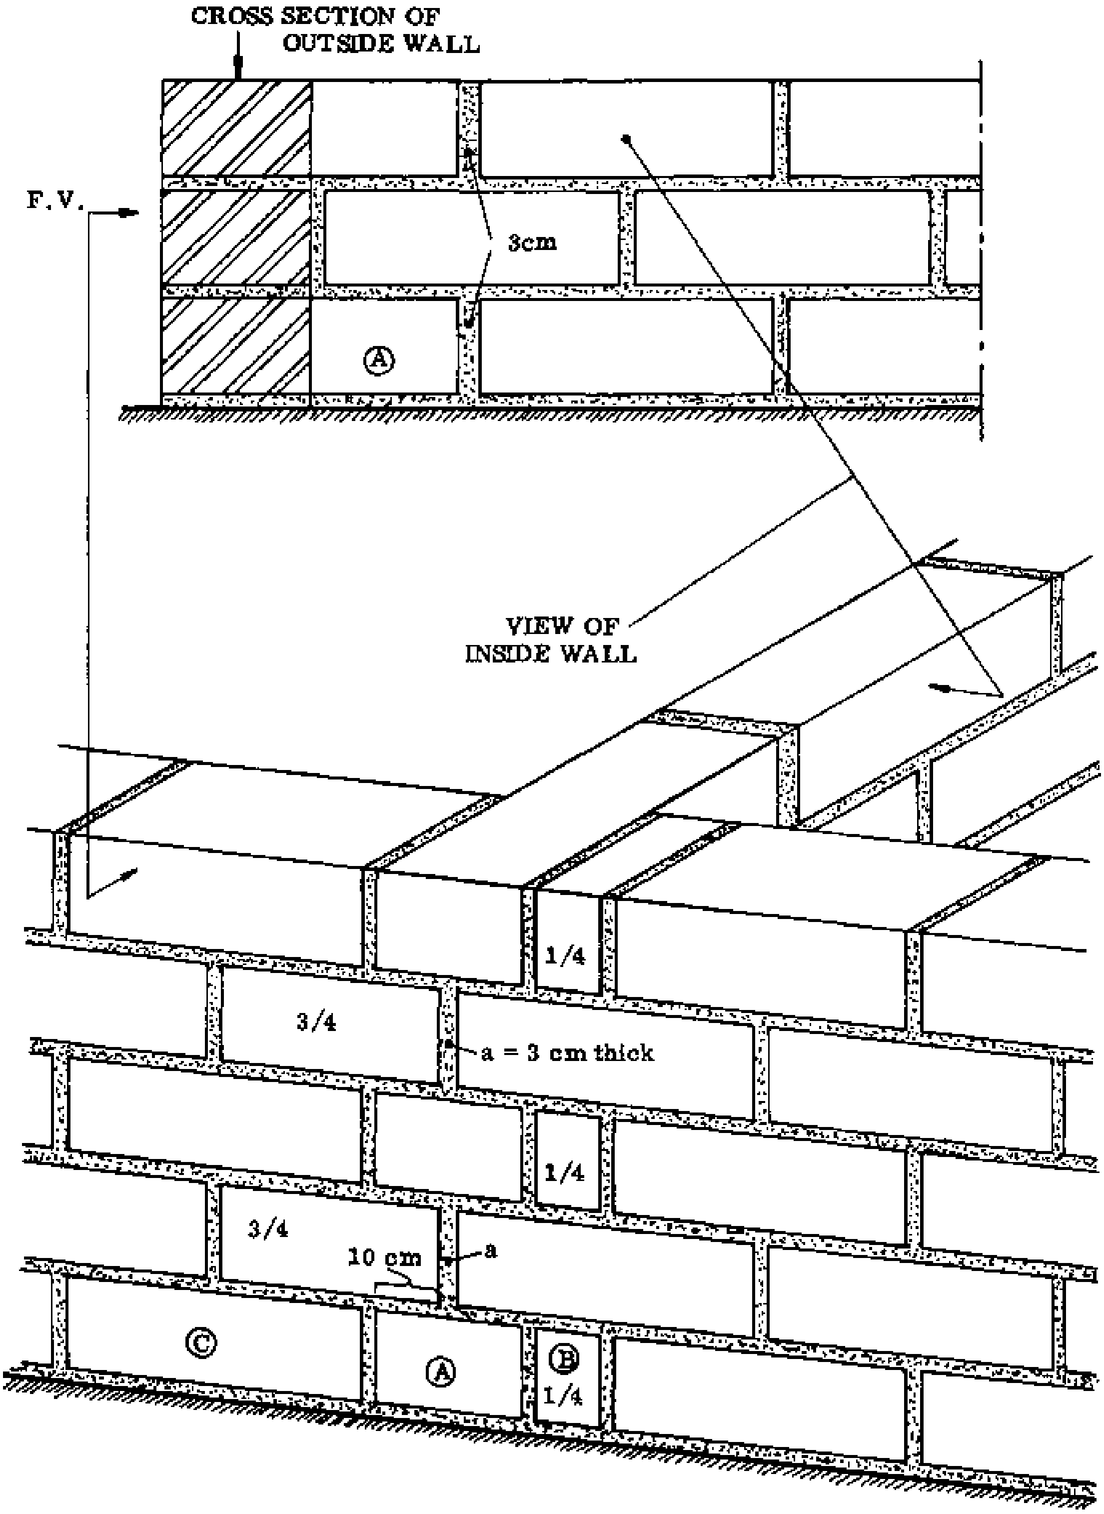

Fig. 1 & 2 COMBINED SECTION OF OUTSIDE WALL AND VIEW OF INSIDE WALL

The second course, and all the alternate courses, go through in the direction of the outside wall, that is, they do not share a block with the inside wall. Thus the inside wall is bonded to the outside wall only at alternating courses: at the 1st, 3rd, 5th etc. courses (Figs. 1 & 2).

The second course starts with a 3/4 block overlapping the header below by 10 cm but from the side opposite from the 1/4 block below. This is followed by full blocks in all three directions (Figs. 1 & 2).

The cross joints between the headers of the inside wall (a) are 3 cm thick and must be exactly in line with the centre of the headers (Fig. 1). The cross joints directly following the blocks which are bonded to the outside wall are also 3 cm thick (Fig. 2). All the other joints are 2 cm thick.

- NOTE: All courses with odd numbers (1st, 3rd, 5th etc.) share one block with the inside wall; these blocks are seen as headers in the face of the outside wall, each one next to a 1/4 block.

All courses with an even number (2nd, 4th, 6th, etc.) go through in the direction of the outside wall and contain a 3/4 block at the opposite side of the 1/4 block below and above.

NOTES:

The illustrations on the opposite page show three other possible constructions for T-junctions in footings, all of which maintain the half-block bond (Figs. 1, 2, & 3).

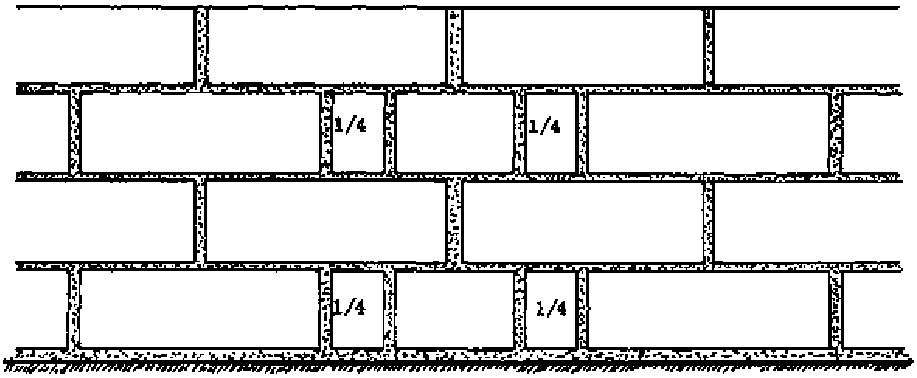

Fig. 1 2nd CONSTRUCTION

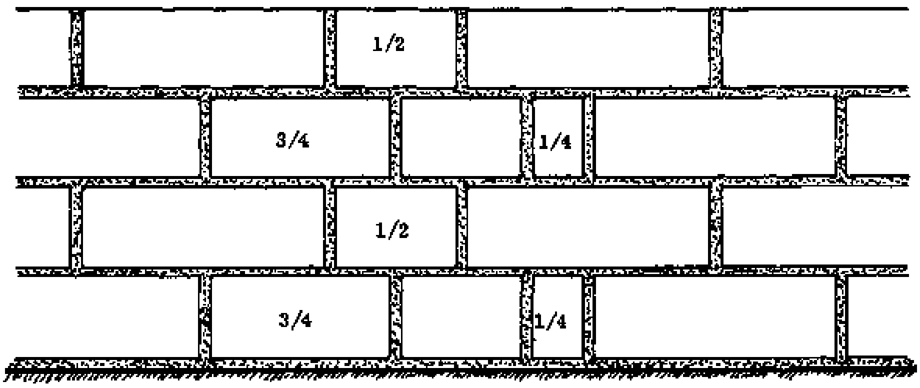

Fig. 2 3rd CONSTRUCTION

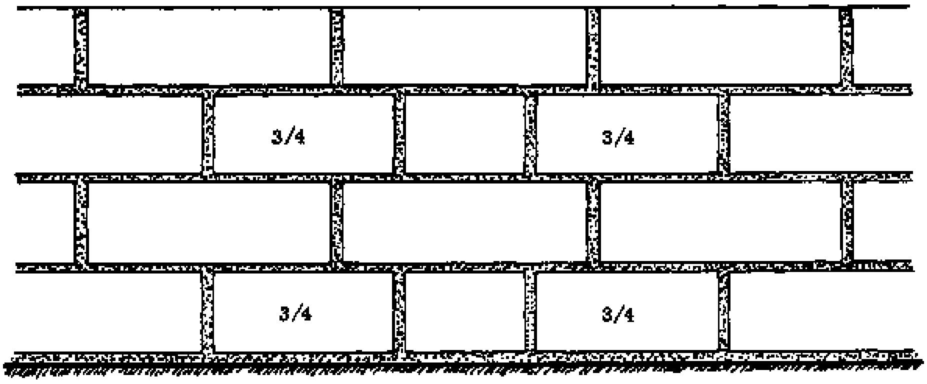

Fig. 3 4th CONSTRUCTION

Which method is used depends on factors such as the distance between the junction and the next quoin, or the next junction.

One way to find out the best choice is to lay out the first course of blocks without mortar, and try different arrangements. In this way the builder can decide what will be the best final arrangement.

If two or more constructions are possible the Rural Builder should chose the most efficient method. This is the method that wastes the least time and materials.

Specifically, the more blocks that have to be cut the more time will be needed; and if for example only 3/4 blocks are needed, the remaining 1/4 blocks are wasted unless there is a need for them somewhere else.

By comparing the four possible constructions (Figs. 1 & 2 on page 37, and Figs. 1, 2 & 3 at left) we see that the first three can be carried out without any waste of blocks while in the last case (Fig. 3) all the 1/4 blocks are left-over.

As far as efficient work is concerned, we see that for the first method (page 37) only one cut needs to be made for two courses as both parts of the block are used. The alternatives shown in Figs. 1, 2 and 3 need two cuts for two courses.

By considering carefully the advantages and disadvantages of the four, we see that the first construction is the best, the 2nd and 3rd constructions are less good and the 4th construction is the worst. Therefore the first type should be used whenever possible.

NOTES:

T-junction bond for rising sandcrete walls

Since the footings are normally 3 courses high, the third course of the footings contains the block which bonds the inside wall. Thus the first course of the rising sandcrete wall must go through in the direction of the outside wall to cover the header of the footings (see previous pages).

The first block of the rising wall is placed so that it extends past the header below by 12 cm on one side (Fig. 2, block A). Don't forget to set this block back from the face of the footings by 4 cm. This block is followed by full blocks on either side (Fig. 2, blocks B). The inside wall starts with a 1/4 block (Fig. 1, block C), this too is followed by full blocks.

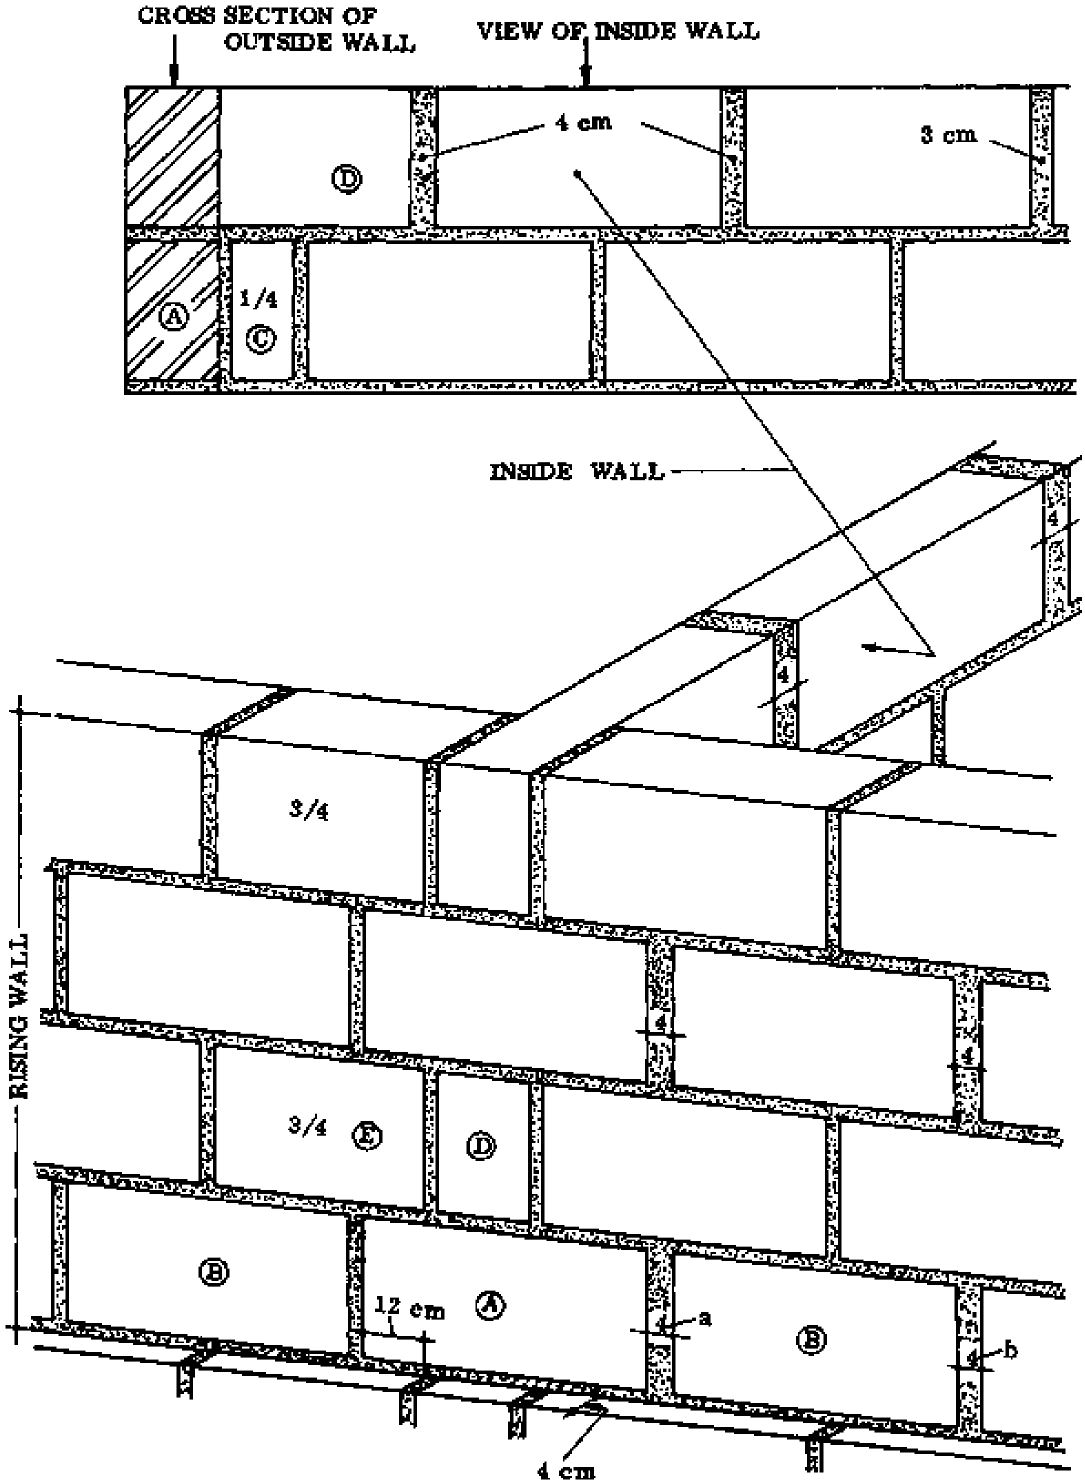

Fig. 1 & 2

The second course of the T-junction begins with the full block of the inside wall that is bonded into the outside wall (Figs. 1 & 2, block D). This is followed by a 3/4 block (Fig. 2, block E) on the same side of the header where the stretcher (block A) below projects by 12 cm. Continue with full blocks in all three directions.

The odd-numbered courses of the outside wall contain widened cross joints to catch up with the half-block bond. The first two cross joints opposite the 12 cm projection (Fig. 2, a & b) are 4 cm thick, followed by one more joint which is 3 cm thick (not shown). In this way the half-block bond is maintained.

The same must be done with the first three cross joints following the bonded block of the inside wall (Fig. 1).

NOTES:

T-junction bond for rising landcrete walls

- PLINTH COURSE: Except that the blocks are laid edgewise rather than flat, the plinth course is simply a repetition of the footing course two courses below (Fig. 1, blocks A & B).

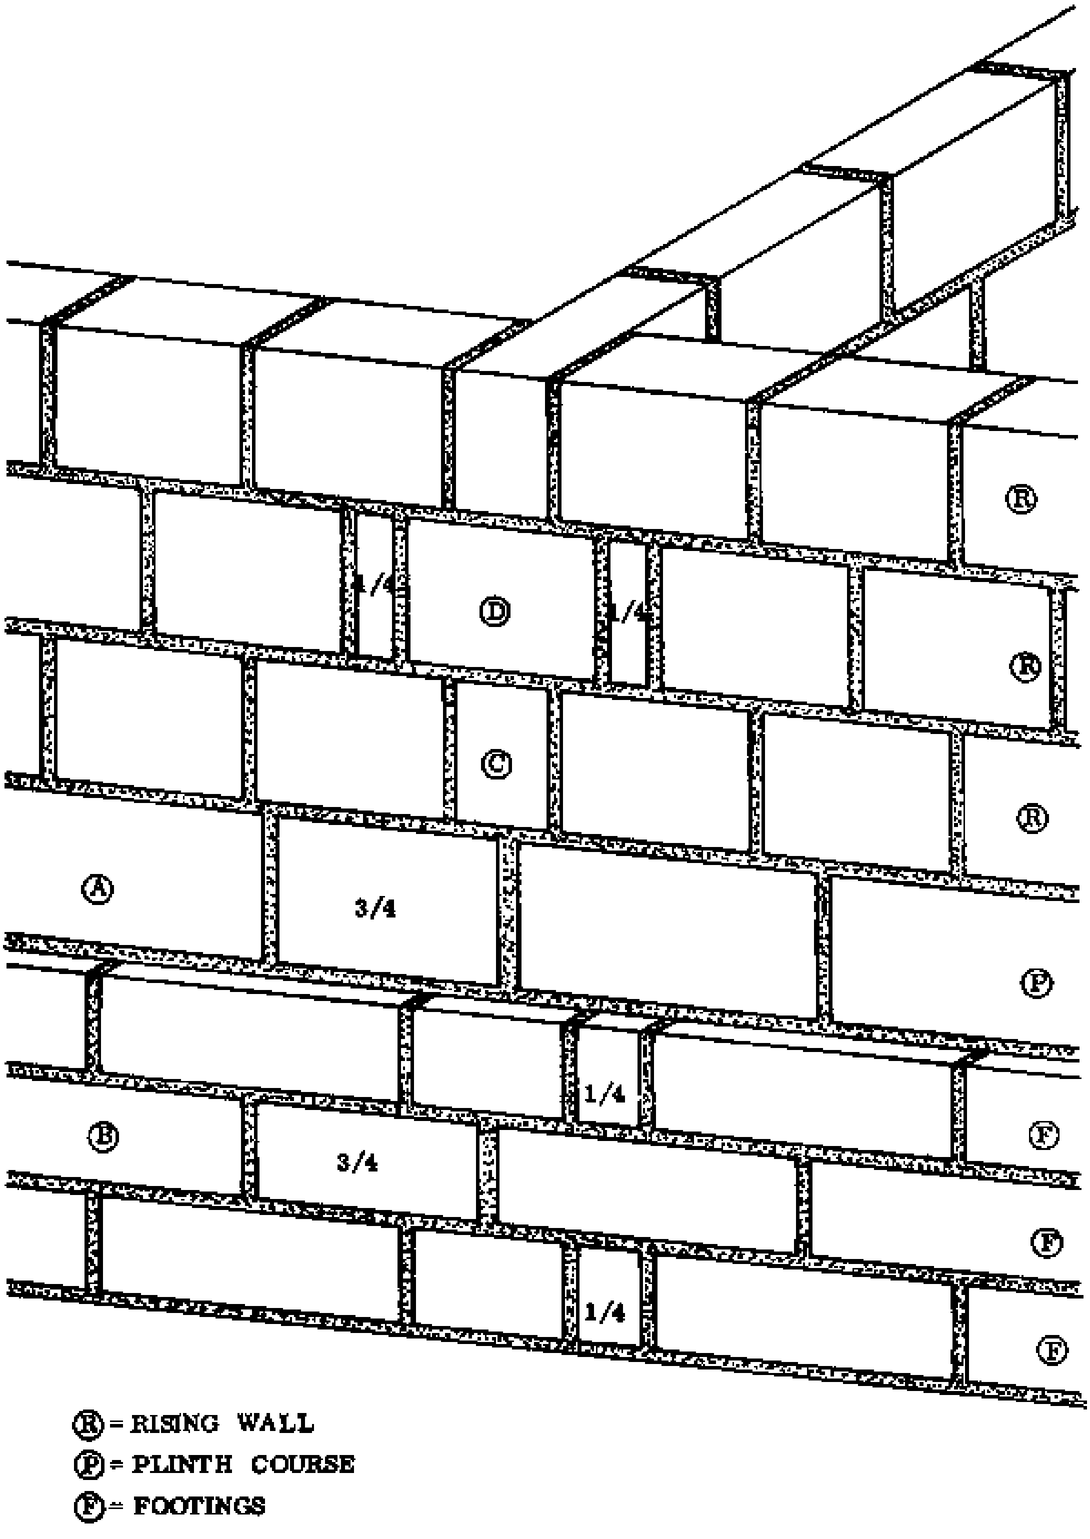

Fig. 1

The only difference is that the first two cross joints in the inside wall are widened to 4 cm each, in order to maintain the half-block bond in relation to the footings.

Do not forget to set the plinth course back from the face of the footings by 4 cm.

- RISING LANDCRETE WALL: Since the landcrete wall is 1 cm thinner than the plinth course, it is essential to continue the “good” face of the plinth by setting the landcrete blocks flush with the outside face of the plinth. The Rural Builder should choose one face of the inside wall to be the “good” face; where the surface of the plinth course is flush to that of the rising wall. This is the face from which the plumbing and levelling are done; the Rural Builder should always work from this face. On outside walls the “good” face is normally the outside face.

The first block of the landcrete wall is the one which is shared by the inside and outside walls and covers two cross joints (Fig. 1, block C). It is followed in all three directions by full blocks.

The second course of the rising landcrete wall begins with a full block centred exactly over the header below, with 1/4 blocks on either side (block D). All of the other courses in the rising wall are repetitions of these two courses.

NOTES:

CROSS JUNCTION BONDS

A cross junction, also called an intersection, consists of two continuous walls which intersect, or cross each other.

The following are only a few examples out of many methods for bonding at a cross junction. In actual practice the dimensions of the building will not always permit the use of these particular bonds. In such cases some adjustments must be made.

The essential requirements for a cross junction always remain the same:

- avoid making continuous cross joints; and
- try to use a minimum number of cut blocks.

Cross junction bond for footings

The first course consists entirely of full blocks (Fig. 1). The through-going block (A) projects equally from both sides of the crossing wall. This block has cross joints of 2, 5 cm on each end, but all the other joints are still 2 cm thick (Fig. 1).

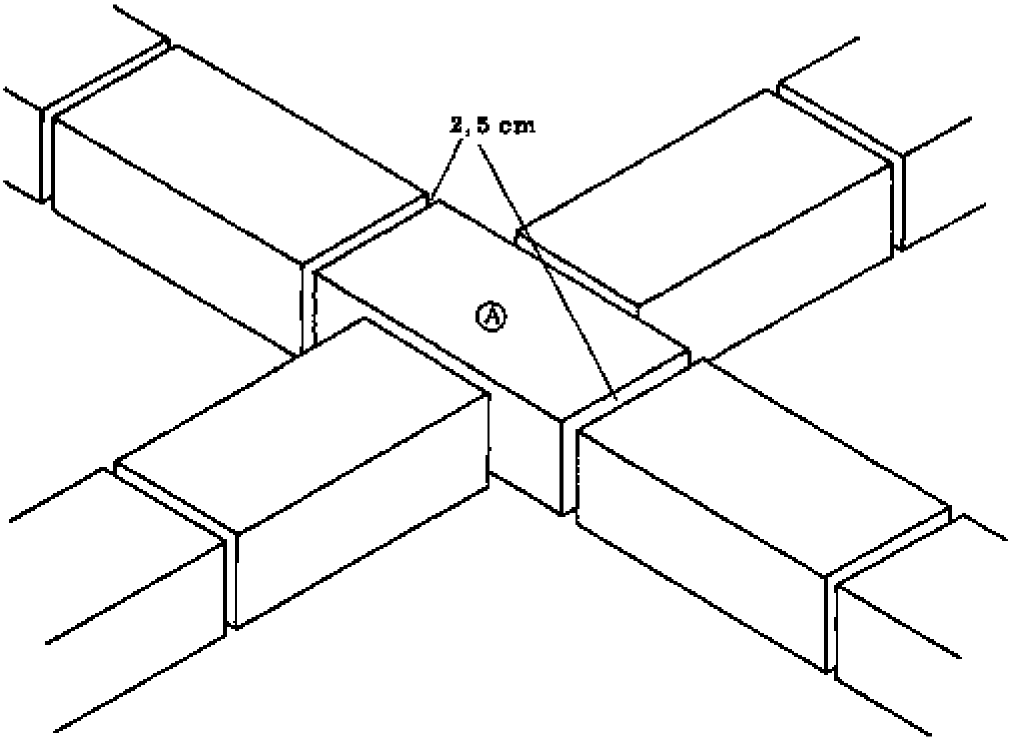

Fig. 1

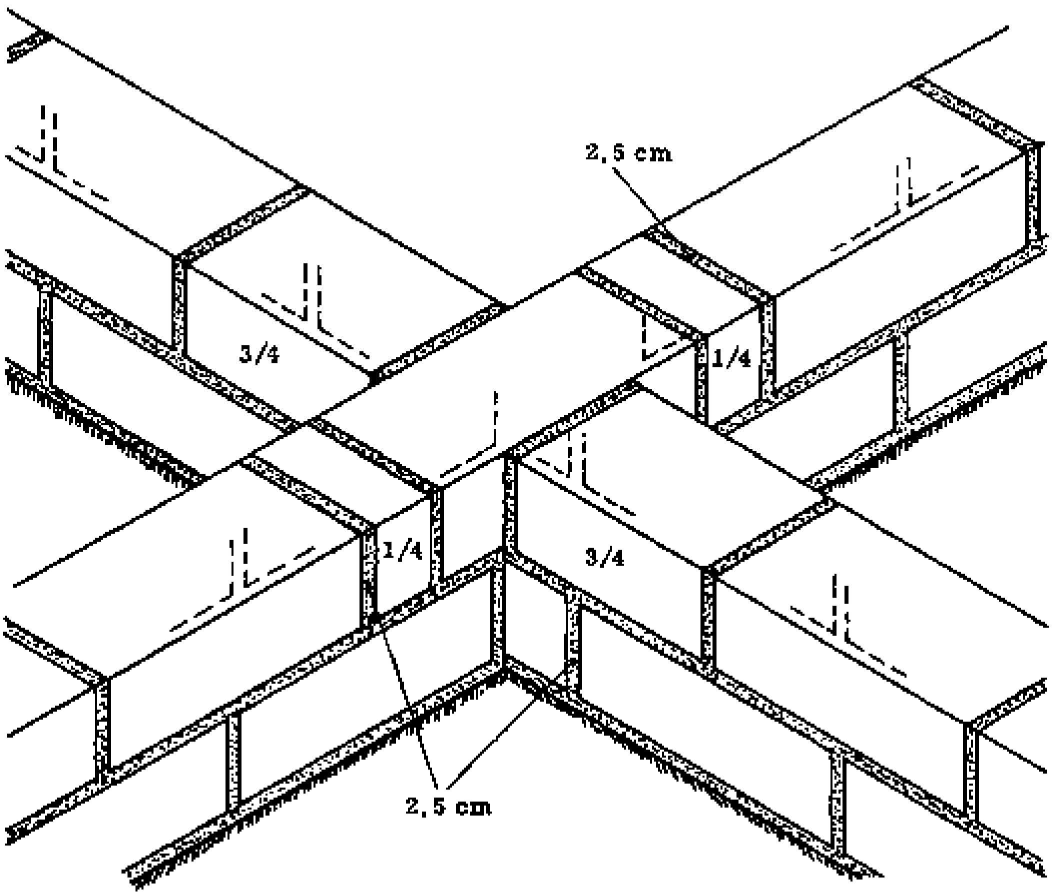

Fig. 2

The second course starts with a full block centred over the through-going block below. This block is followed by 1/4 blocks on either end. The 1/4 blocks each have one cross joint which is 2, 5 cm thick. All other joints are still 2 cm thick.

The second course of the crossing wall continues with 3/4 blocks on both sides. This is followed by full blocks in all four directions.

NOTES:

The second possible construction is where the crossing walls enclose a cross joint (Fig. 1, a). In this case two 3/4 blocks are used in the first course while the remaining 1/4 blocks are kept aside for the second course (Fig. 1).

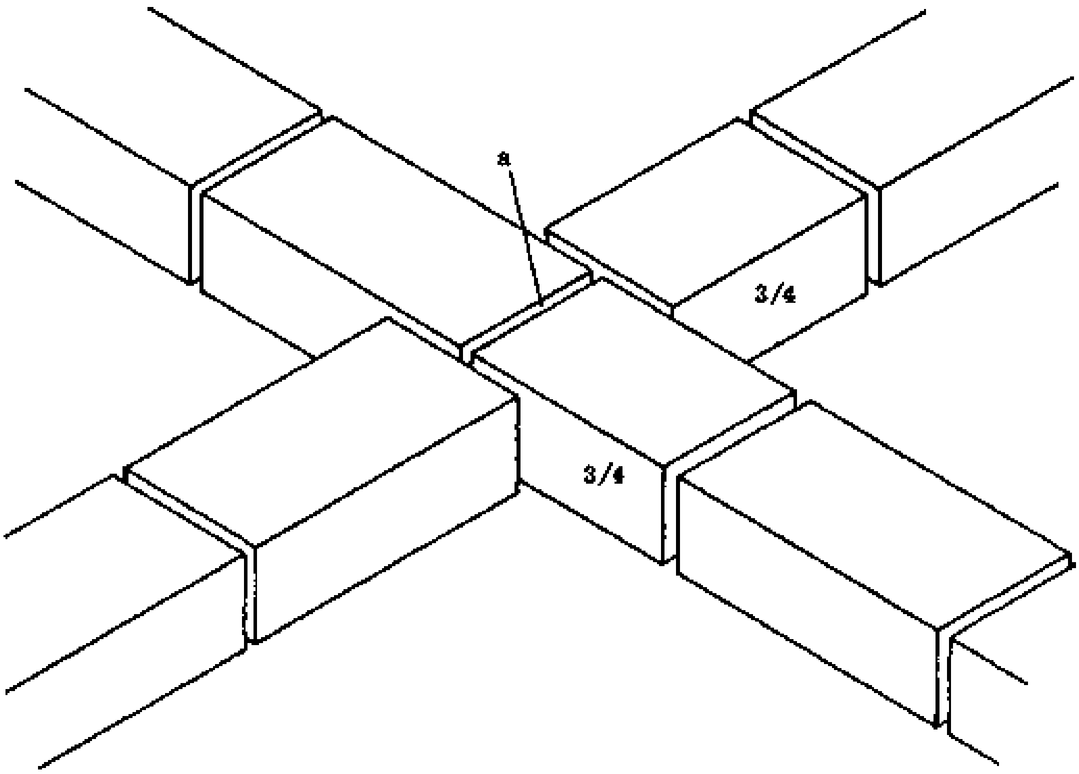

Fig. 1

The two 3/4 blocks of the first course are arranged so that they are at right angles to each other. One of the 3/4 blocks always starts from the middle of the crossing wall while the other is placed on either the right or left side of it. This is followed in all four directions by full blocks (Fig. 1).

The second course begins with a full block crossing the through-going wall below and overlapping equally at both sides. This block covers three cross joints at once instead of two as in the last method. The first block is followed by the 1/4 blocks placed on opposite sides from the 3/4 blocks below. The second course is continued with full blocks in all four directions (Fig. 2).

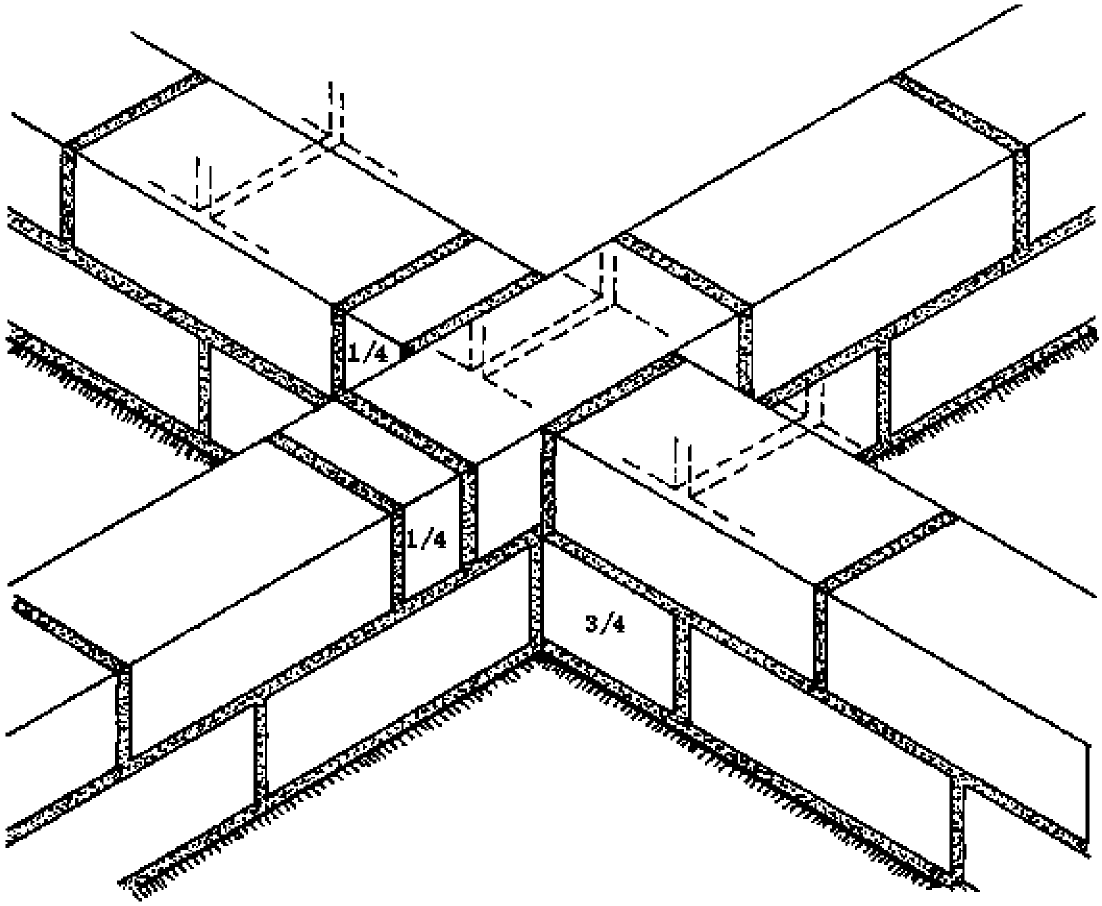

Fig. 2

Each 1/4 block must have one cross joint of 2,5 cm; all other joints remain the same, 2 cm thick.

Try to figure out more possible ways to do a cross junction bond, and discuss the results with your fellow trainees, your instructors, and your foreman on the building site.

NOTES:

Cross junction bond for rising sandcrete walls

The smaller wall thickness in relation to the block length makes it necessary that all cross junction bonds for rising sandcrete walls contain a block that is 5 cm thick (compare with corner bonds for rising sandcrete walls, page 34).

The opposite illustrations show the most economical method for constructing a cross junction. Apart from the one 1/2 block and one 5 cm block, both the first and second courses contain only full blocks.

Fig. 1 shows the first course. The through wall consists of only full blocks, while the crossed wall starts on one side with a 1/2 block combined with a 5 cm block. This is continued in all four directions with full blocks. The through-going block (A) must extend past the crossed wall by 24 cm, which is the length of a 1/2 block plus the joint.

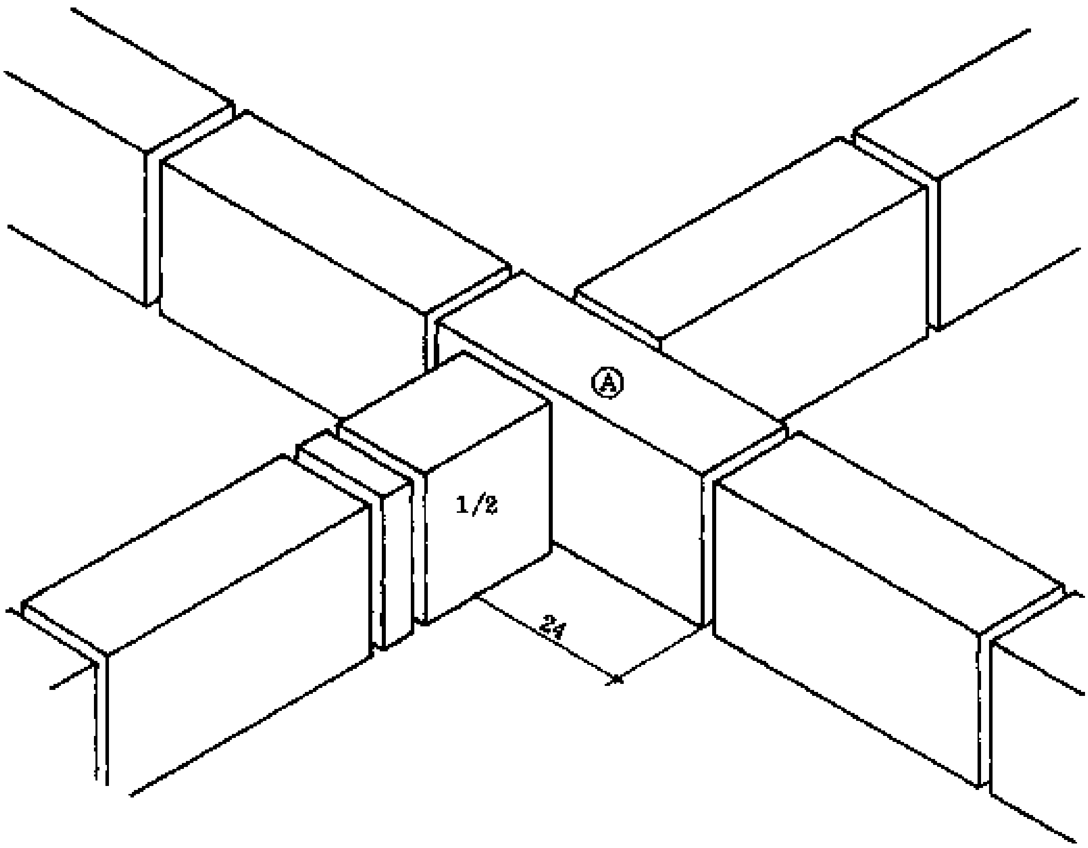

Fig. 1

In the second course, the wall which was crossed in the course below now goes through. The through block (B) again extends past the crossed wall by 24 cm, but on the side opposite from the 1/2 block in the course below. Block B is followed on its left-hand side by a 1/2 block (C) combined with a 5 cm block. This is continued in all four directions with full blocks (Fig. 2).

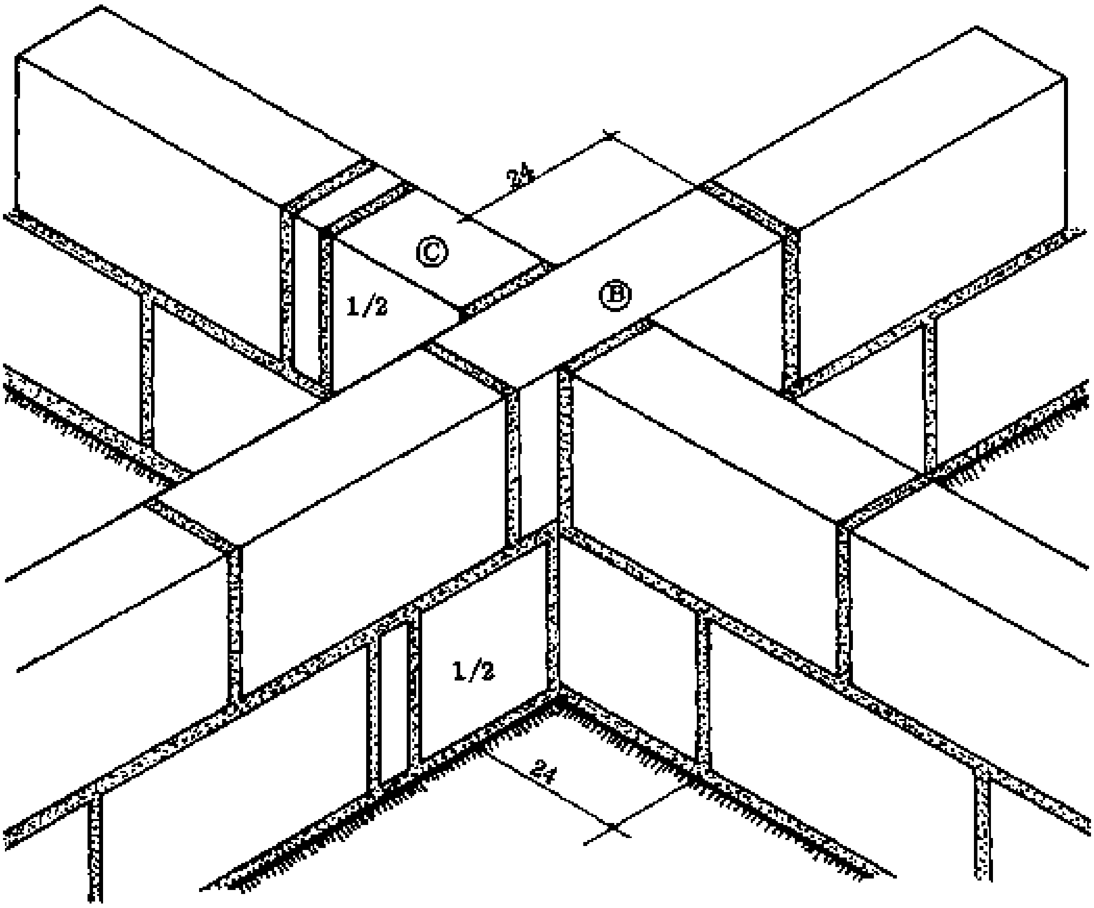

Fig. 2

In the first course the crossing block and the 1/2 block form a corner. This is also true in the second course but the corner is diagonally opposite from the one in the first course below.

- REMEMBER: All through courses in either wall consist of full blocks only. All crossed courses in either wall contain one 1/2 block combined with a 5 cm block.

NOTES:

The second method of making a cross junction in a sandcrete wall is different from the first method because 3/4 and 1/4 blocks are used instead of 1/2 blocks.

Because of this the rules for this bonding method are also different:

- All through blocks (Figs. 1 & 2, blocks A & B) project from the crossed wall by 12 cm at one end (12 cm is 1/4 block plus the joint). These blocks are followed by 1/4 blocks at the other end (Figs. 1 & 2).

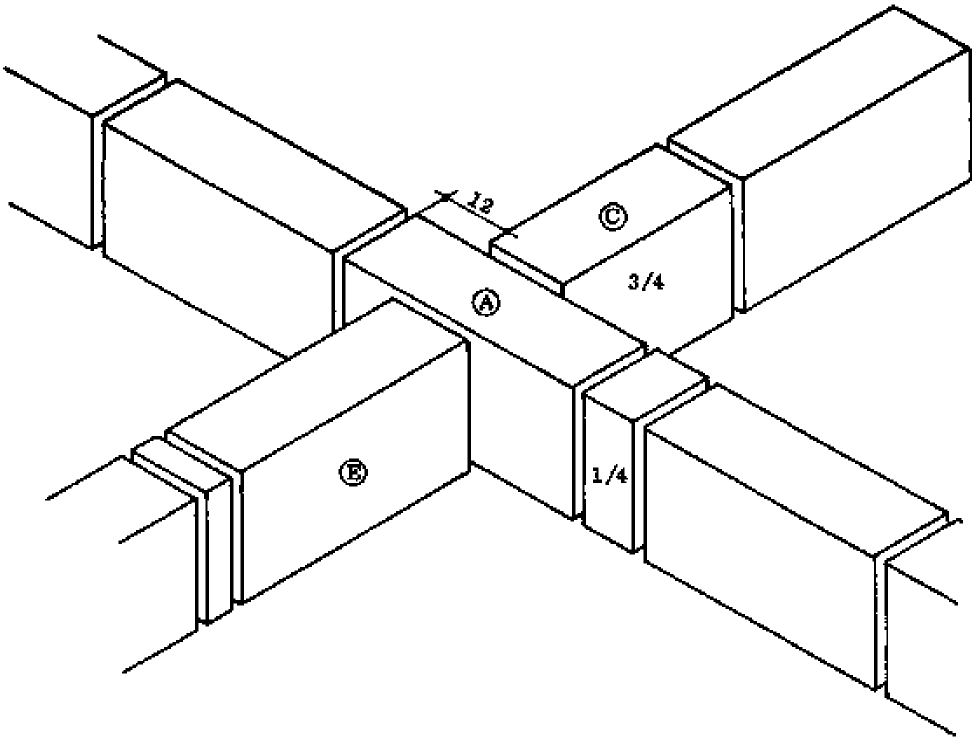

Fig. 1

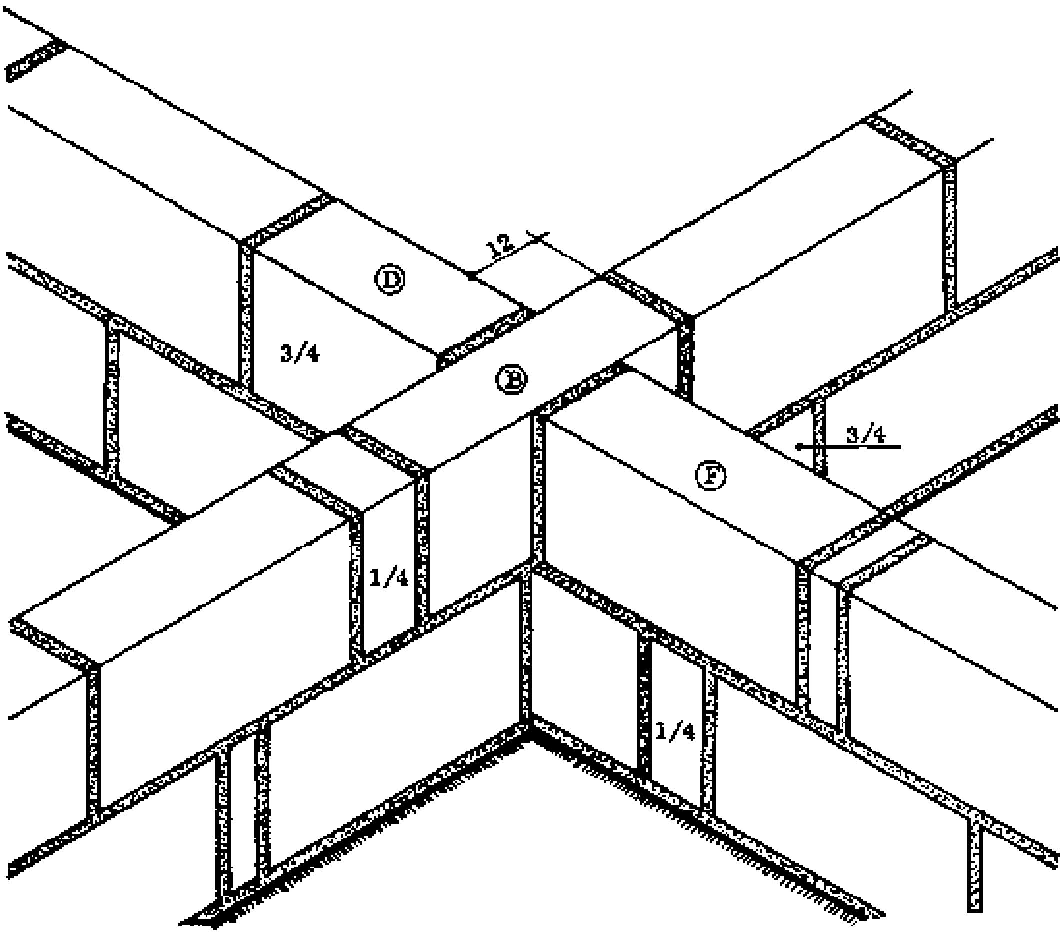

Fig. 2

- All crossed walls contain a 3/4 block (Figs. 1 & 2, blocks C & D) set directly against the through-going block. This 3/4 block is on the opposite side from the 1/4 blocks in the course below (Fig. 1). The crossed wall continues with a full block (Figs. 1 & 2, blocks E & F) and a 5 cm block, on the other side from the 3/4 block.

- NOTE: The above method involves a lot of block-cutting, which makes it less efficient than the other method.

Try to figure out more possibilities and discuss them with your fellow trainees, your instructors and your foreman on the building site.

NOTES:

Cross junction bond for rising landcrete walls

The arrangement of blocks to construct a cross junction with landcrete blocks is almost the same as for the footings (see previous pages).

Fig. 1 shows the bond for all courses with an odd number (1st, 3rd, 5th, etc.). These consist of full blocks only. The through block (A) is set exactly in the middle of the crossed wall.

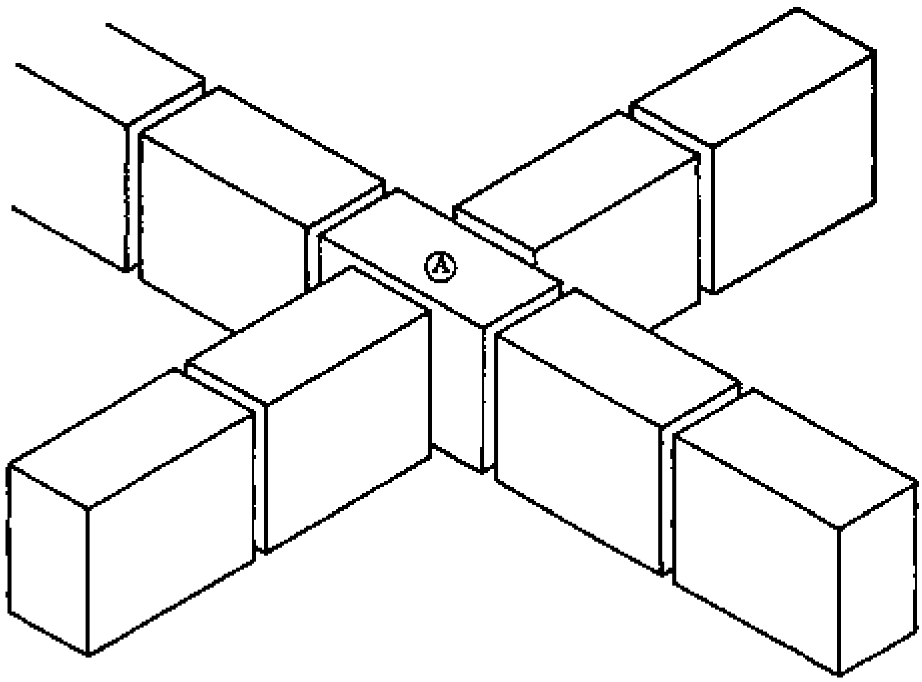

Fig. 1

The arrangement for courses with an even number (2nd, 4th, 6th, etc.) is shown in Fig. 2. These courses also start with a full block (B) set exactly across the middle of the through-going block below. This block is followed by 1/4 blocks on its ends and 3/4 blocks on its stretcher sides. This is continued in all four directions with full blocks.

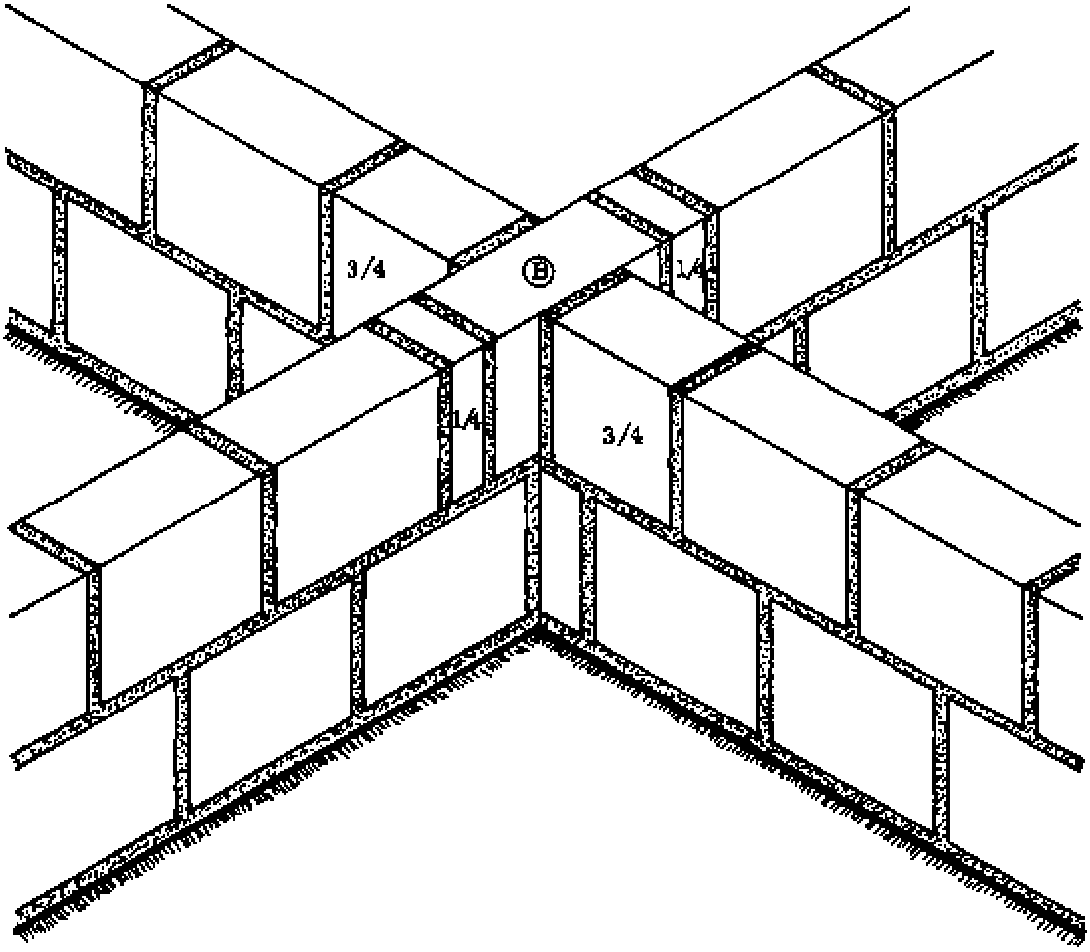

Fig. 2

NOTES:

Another method of bonding uses the cut blocks in alternate courses, unlike the last method which used all cut blocks in the same course. There is no waste in either method.

The first crossing (Fig. 1) is formed by two 3/4 blocks which project equally from the crossed wall, meaning that the joint between them is exactly in the centre of the crossed wall. The course is continued in all four directions with full blocks.

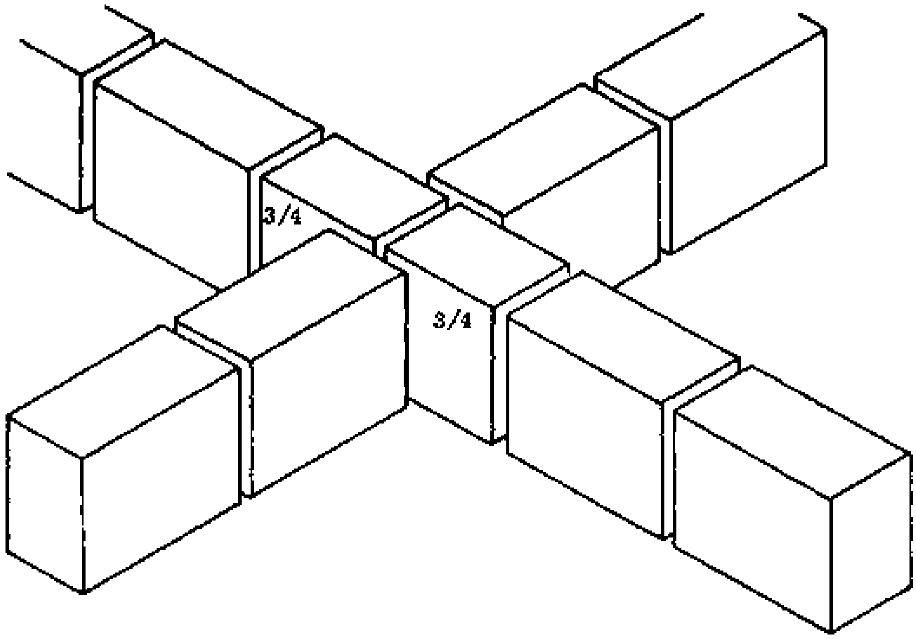

Fig. 1

The second course begins with a through-going block (Fig. 2, block A) set exactly in the middle of the crossed wall. In this way, three cross joints are covered by the block, instead of two as in the last method (Fig. 2).

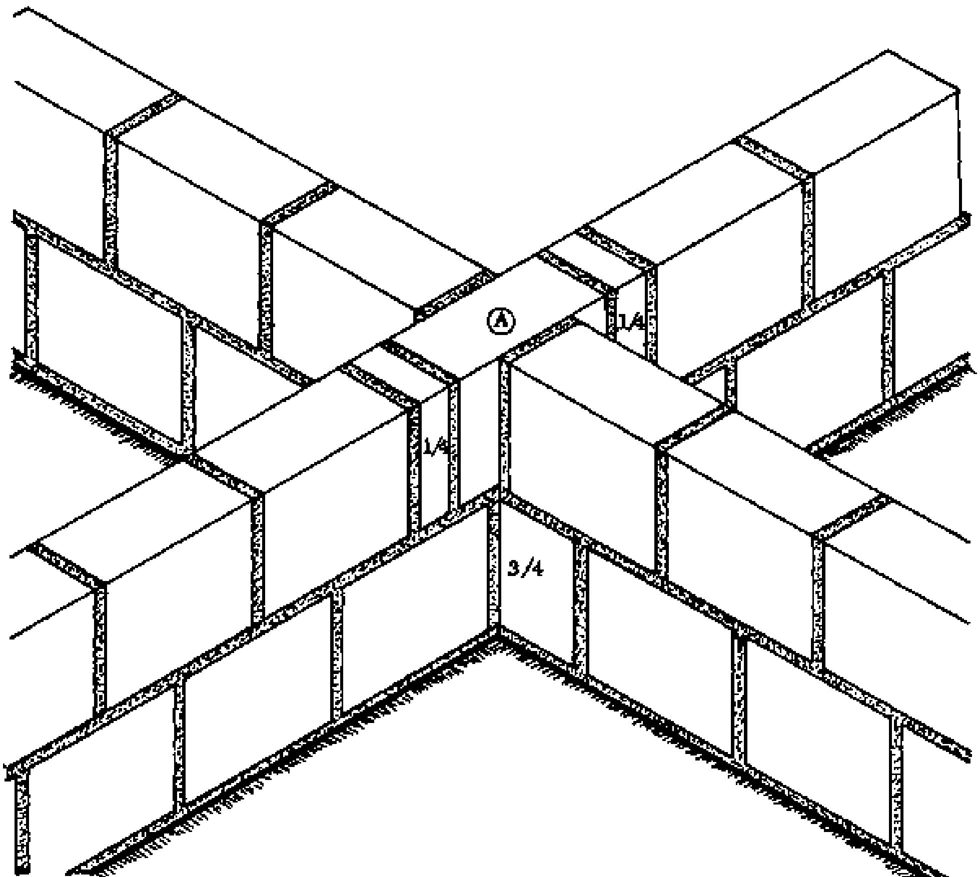

Fig. 2

The through-going block is followed by 1/4 blocks on its ends but then the course continues in all directions with full blocks.

Try to develop more possibilities but do not forget the requirements mentioned on page 46.

NOTES:

Footings - Plinth course - Rising landcrete wall

The illustration opposite shows what a cross junction will look like during the construction (Fig. 1).

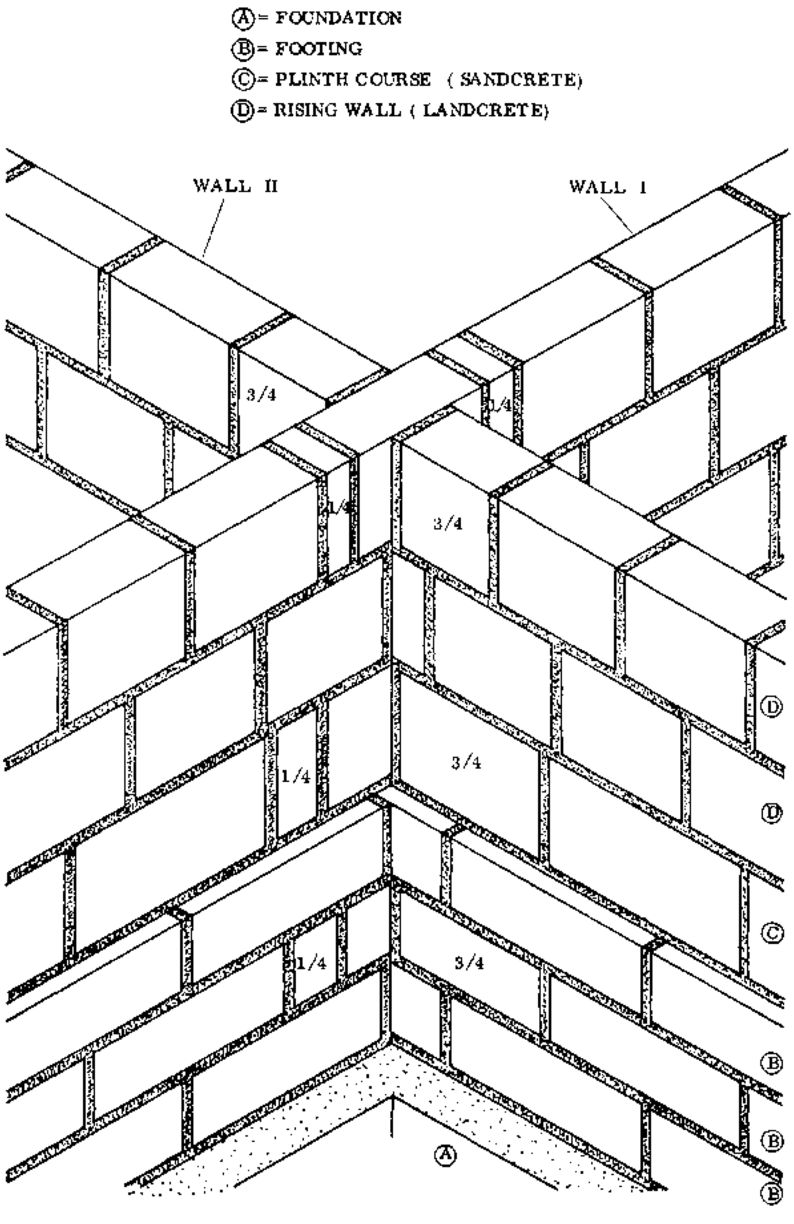

Fig. 1

Again, it is possible to maintain the half-block bond between the footings and the plinth course in wall I, as described on the previous pages. The bonding of the plinth course is a repetition of the bonding of the second footing course.

However, it can be seen that the half-block bond between the footings and the plinth course is not perfectly maintained in wall II. This is because of the 4 cm setting back on both sides as well as the reduced wall thickness.

The bond of the rising landcrete walls is the same as described on the previous pages. Only two courses are shown because the rest of the courses are repetitions of these two.

If you compare the bond of the rising landcrete wall with the plinth course, you will see that the half-block bond is not maintained between them. The only way it could be maintained is by cutting more blocks and changing the thicknesses of some of the joints. This would weaken the entire wall as well as wasting materials, so the Rural Builder should consider this bonding all right as it is shown here.

- REMEMBER: The rising landcrete wall is 1 cm thinner than the plinth course. Do not forget to maintain the "good" faces of the walls by laying the landcrete blocks flush with the plumbed faces of the plinth courses below.

NOTES:

PIERS

Attached piers

Attached piers; also called engaged piers, wall piers, blind piers or pilasters, are piers partly sunk into a wall and properly bonded into it.

Normally the visible part of a pier projects only slightly from the wall, but in Rural Building the projection may be as much as the thickness of the wall or even more.

Formerly, attached piers were most often used as decorative elements. The Rural Builder, however, uses attached piers chiefly to strengthen walls. At the same time he saves valuable materials such as cement, reinforcement bars and timber for formwork that would be needed for a reinforced concrete pillar.

The construction of an attached pier is very similiar to that of a T-junction. The only difference is that the wall which joins the front wall is very short, and with a stopped end, thus forming an attached pier (Fig. 1).

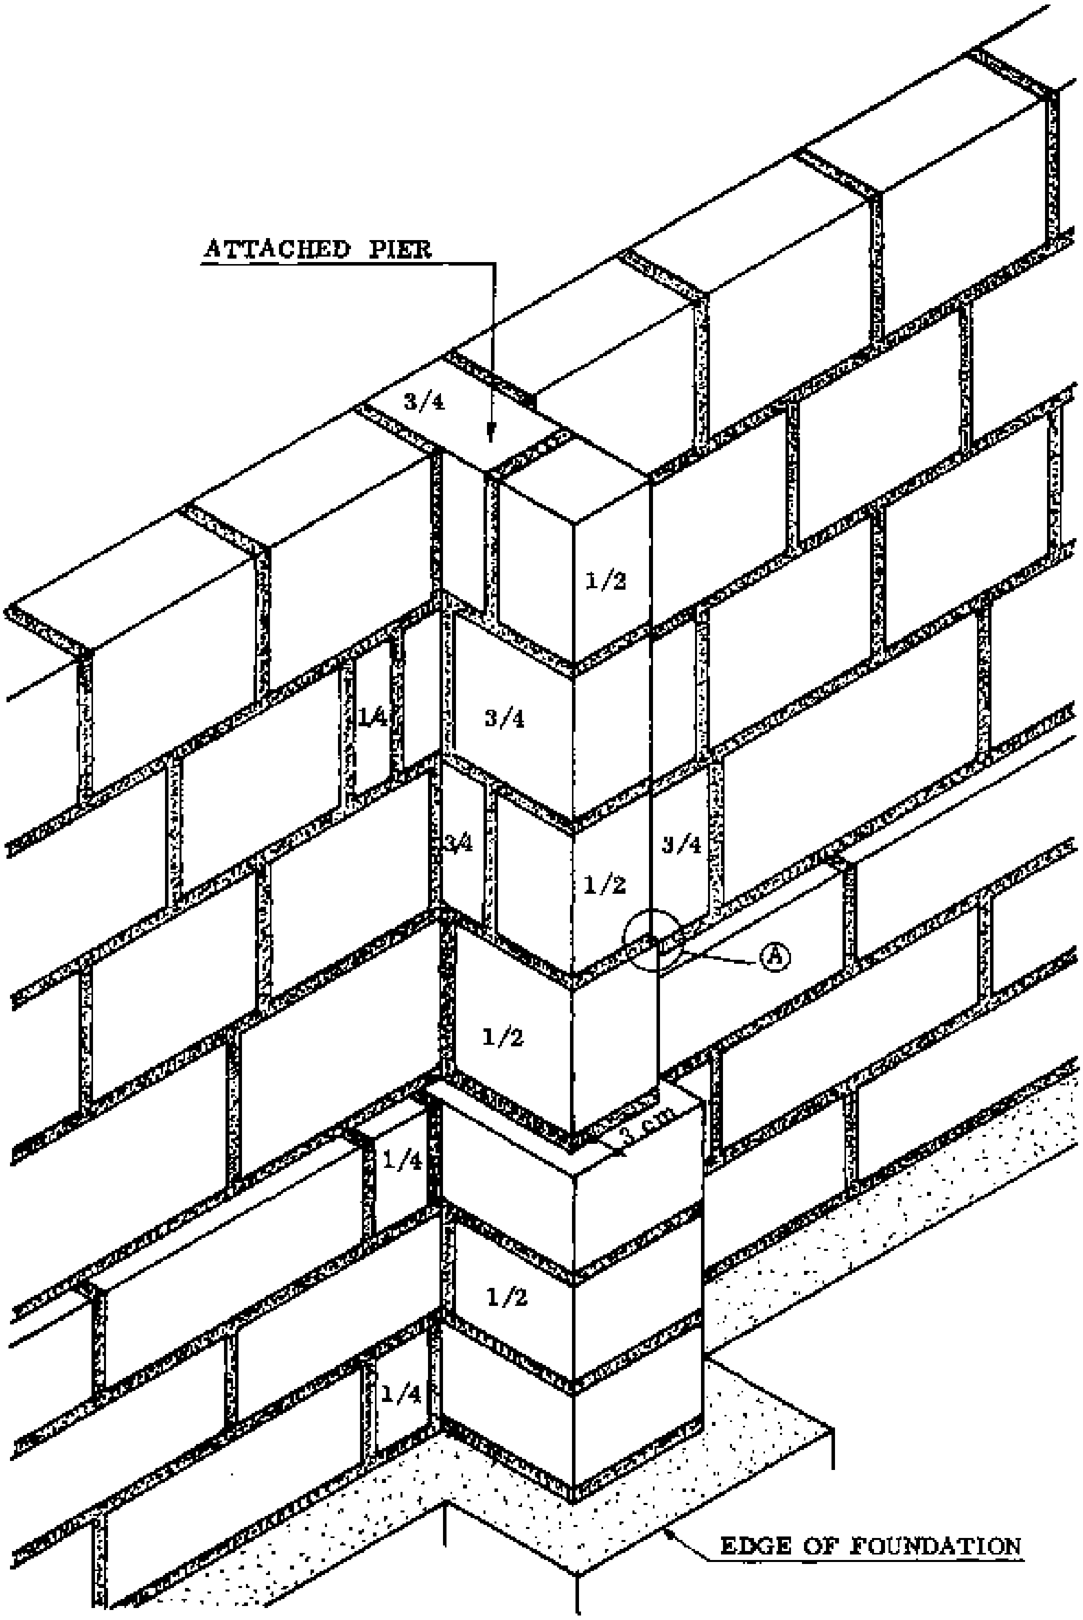

Fig. 1

The illustration shows that the bonds used to construct this pier are the same as those introduced in the chapter on T-junction bonds. Compare it with the text and illustrations from pages 38 to 44.

- NOTE: The plinth course is set back everywhere from the footings by 4 cm, except on the back side of the attached pier where it is set back only 3 cm (Fig. 1).

Do not forget to build the landcrete blocks flush with the plumbed (good) face of the plinth course. This means that on the other face of the wall there will be a 1 cm set-back caused by the 1 cm difference in size between the sandcrete blocks in the plinth course and the landcrete blocks in the rising wall (Fig. 1, point A).

NOTES:

Simple piers

A pier is a pillar-shape of brickwork, blockwork or stone which usually has a square or rectangular section, and supports a load. In Rural Building its mass also helps to anchor the roof structure.

The easiest way to construct a pier is by simply laying full blocks flatwise one above another (Figs. 1 & 2). This will be sufficient in situations where the pier does not have to carry a very heavy load.

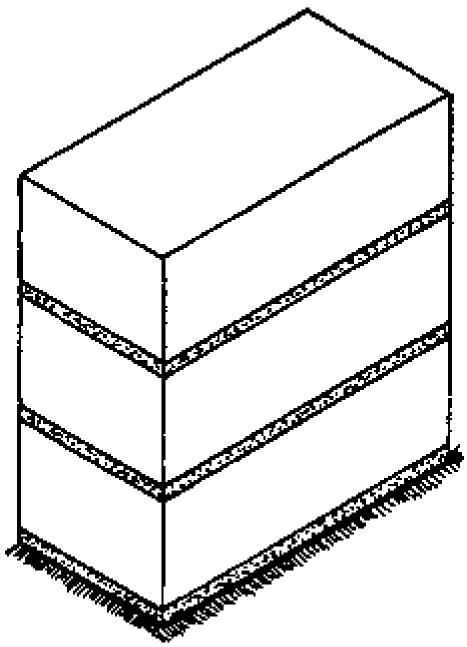

Fig. 1 SAND CRETE PIER

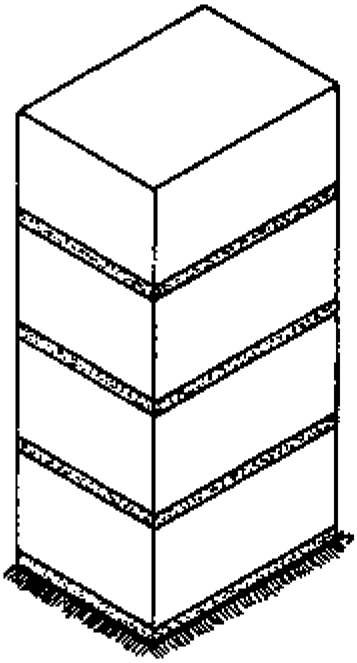

Fig. 2 LANDCRETE PIER

The disadvantage of this construction is that any roof anchorage must be fixed to the sides of the pier.

The best way to anchor a member of the structure to a pier is through the centre of the pier.

So-called perforated blocks can be made by using a specially made wooden mould (Fig. 3). In contrast to the common type of perforated block which has many smaller holes, this type has only one large hole through its centre. It is also called an open block.

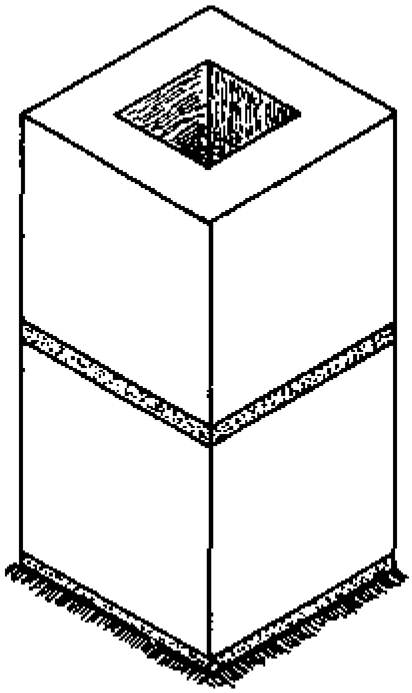

Fig. 3 PIER BUILT WITH OPEN BLOCKS

Open blocks are made by casting mortar between two frames (Fig. 4). The bigger frame is made similarly to the wooden mould described in the Reference Book, Tools section, page 29. The smaller frame is tapered and has a handle to make it easier to remove from the block.

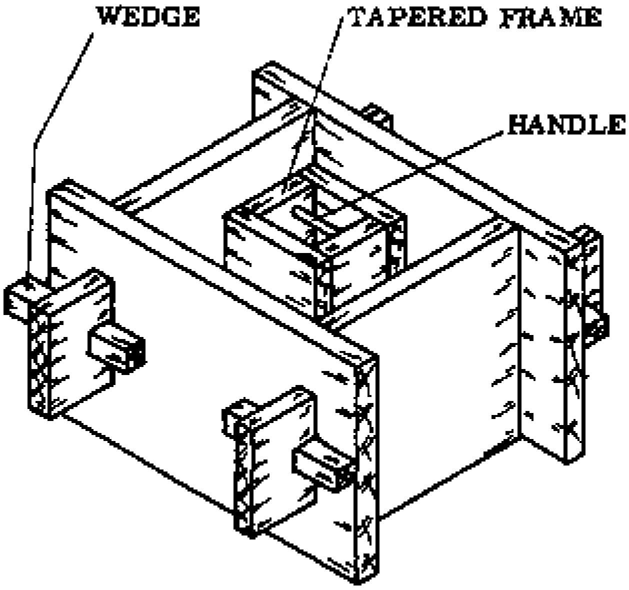

Fig. 4 WOODEN MOULD

After the pier is built, the anchoring bar is inserted in the hole and the remaining space is filled up with mortar or concrete.

NOTES:

Footings for piers

There are situations where piers are needed which not only have to carry heavy loads but also have to be very heavy in themselves. This is to anchor the roof against the suction of strong winds.

In order to save valuable building materials such as cement, reinforcement bars and timber, as well as to reduce the construction time, blockwork piers are often built.

There are several possible bonding arrangements. The bonds introduced in this chapter represent only a few types, but they will meet the requirements of the Rural Builder.

The type of bond which is used depends largely on which materials are available and on the size of pier which is desired.

The opposite illustrations show a bond for footings with sandcrete blocks laid flatwise. Refer to page 67 for another footing method. Both bonds can also be used to build up an entire pier, in case a heavy duty pier is desired.

All the courses in the illustration on the left consist of a pair of blocks which are set 2 cm out of line with each other at the header sides. You can see this 2 cm difference at points A, B, C, D in Figs. 1 and 2.

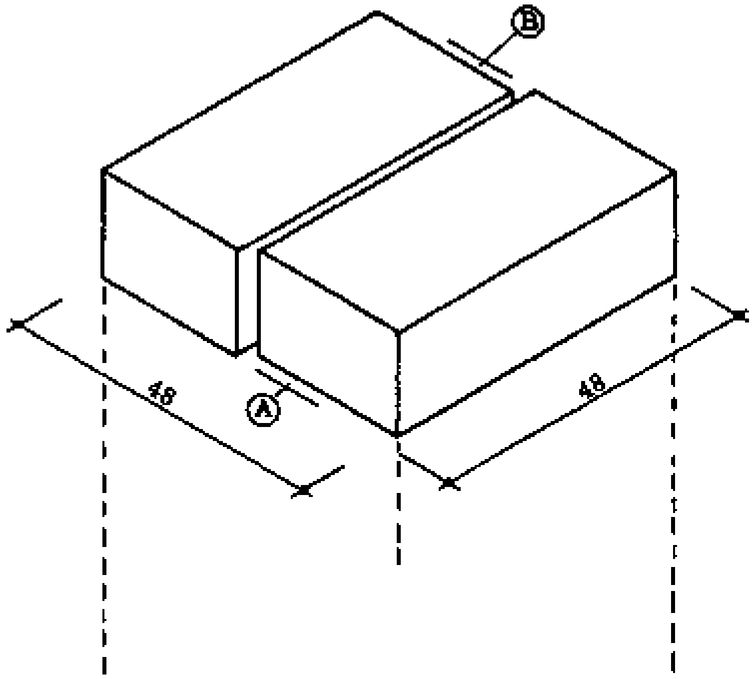

Fig. 1

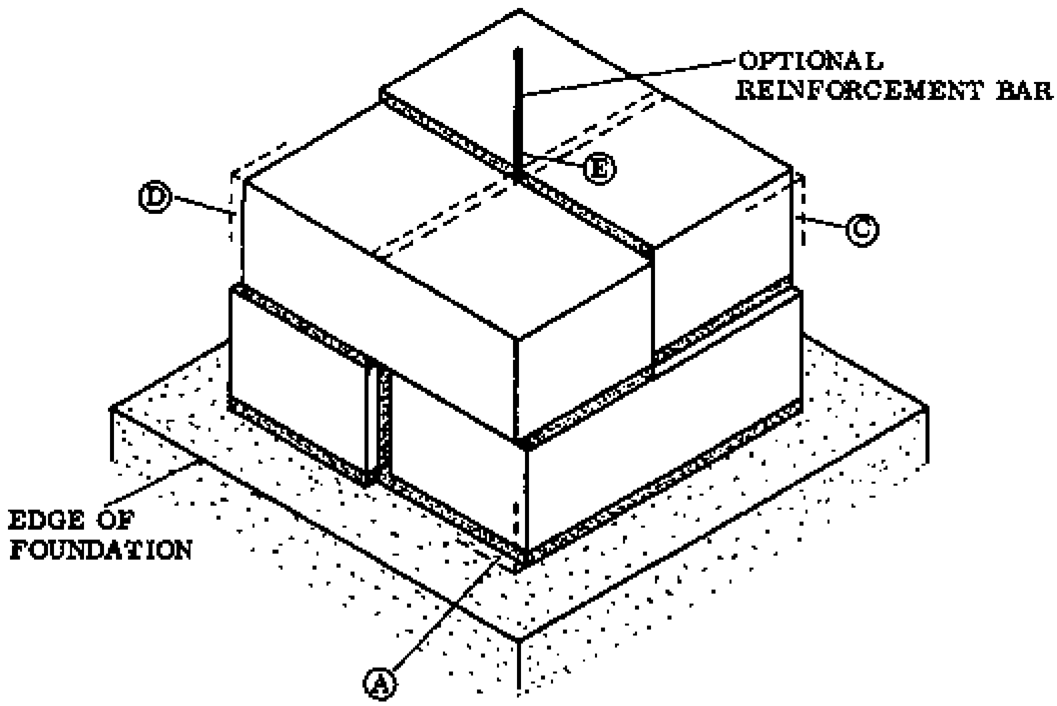

Fig. 2 FOOTING FOR PIER

This is done to maintain a square shape of 48 cm by 48 cm, since the width of the two blocks plus a joint is 48 cm, while the length of each block is only 46 cm. Since the courses cross each other, a reinforcement bar for anchorage could be built-in between the cross joints (Fig. 2, E).

NOTES:

Bonds for sandcrete piers

The following two bonds are also square-shaped but have shorter dimensions than the footing bonds: 34 cm by 34 cm.

Fig. 1 shows the best bond for a pier with the above measurements. This is because each course uses a total of 1 1/2 blocks, which means that there is no waste.

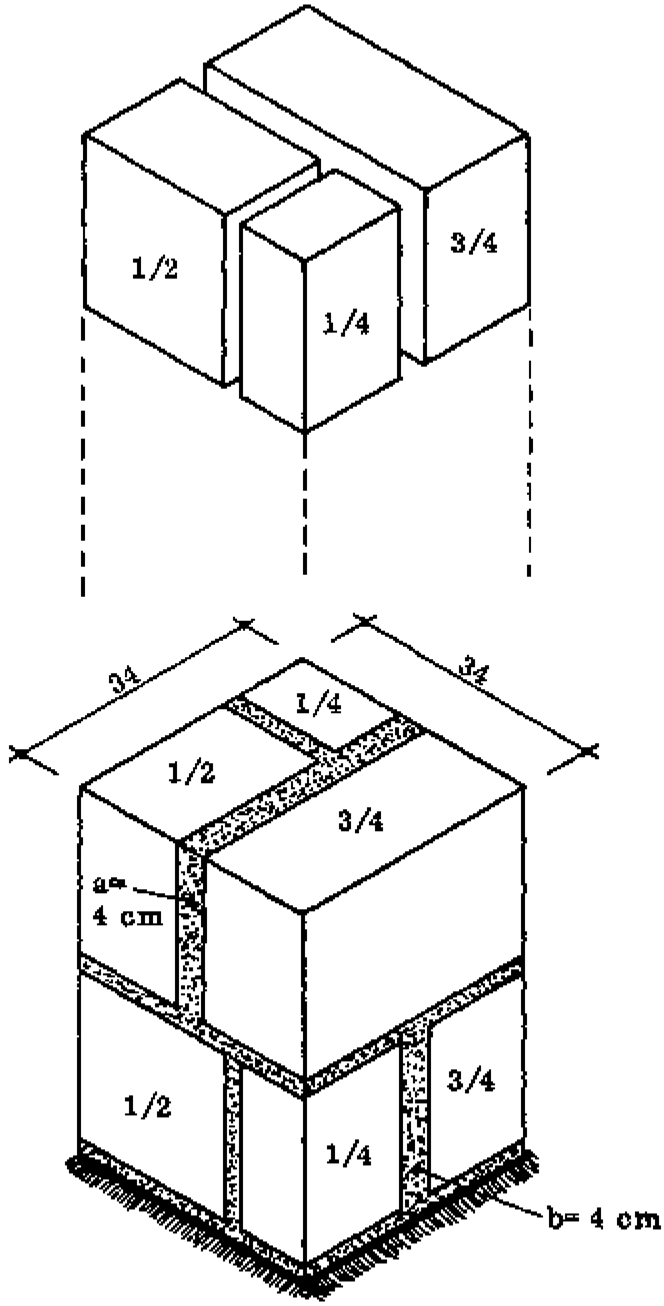

Fig. 1 SANDCRETE PIER EDGEWISE

The through-going cross joints in each course must be widened (Fig. 1, a & b) to 4 cm in order to obtain a width of 34 cm across the two blocks; 34 cm is the length of the 3/4 blocks.

The 3/4 block in each course is set over the 1/4 block below, and across the 4 cm joint, making an alternating arrangement as shown (Fig. 1).

Fig. 2 shows another bond for a sandcrete pier. The pier is built entirely of 3/4 blocks. The cross joints all go through and all have a 4 cm thickness.

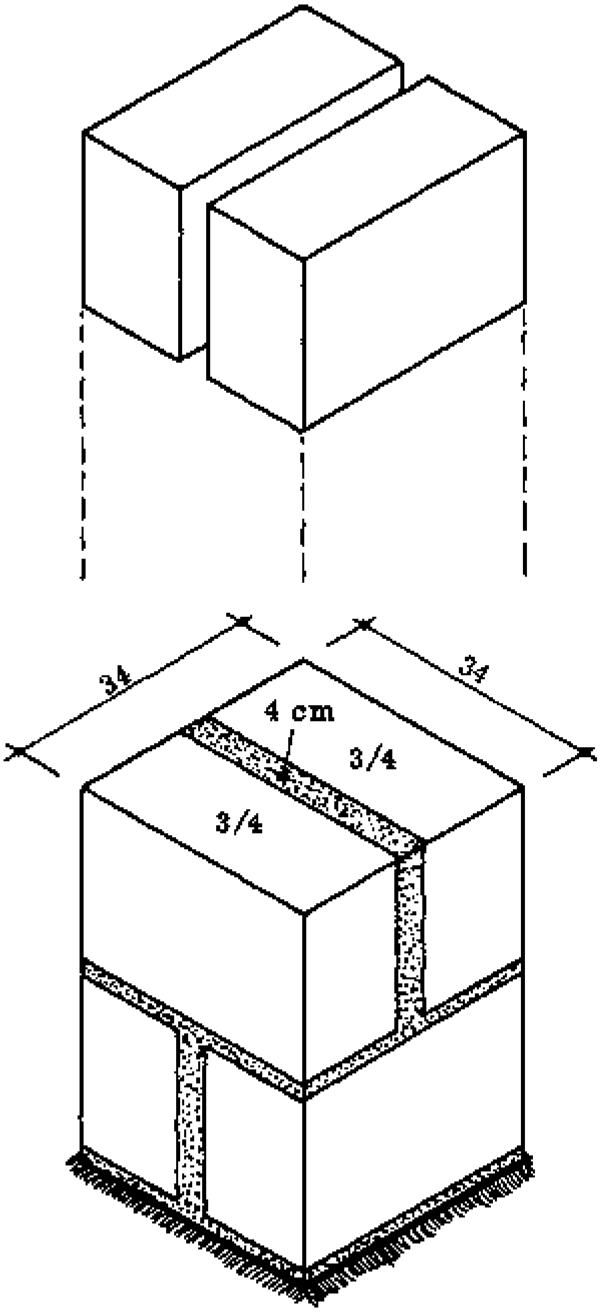

Fig. 2 SANDCRETE PIER EDGEWISE

It is obvious that this type of pier should be built only if there are a lot of 3/4 blocks left-over from another construction, because otherwise all the 1/4 blocks are left-over and wasted.

NOTES:

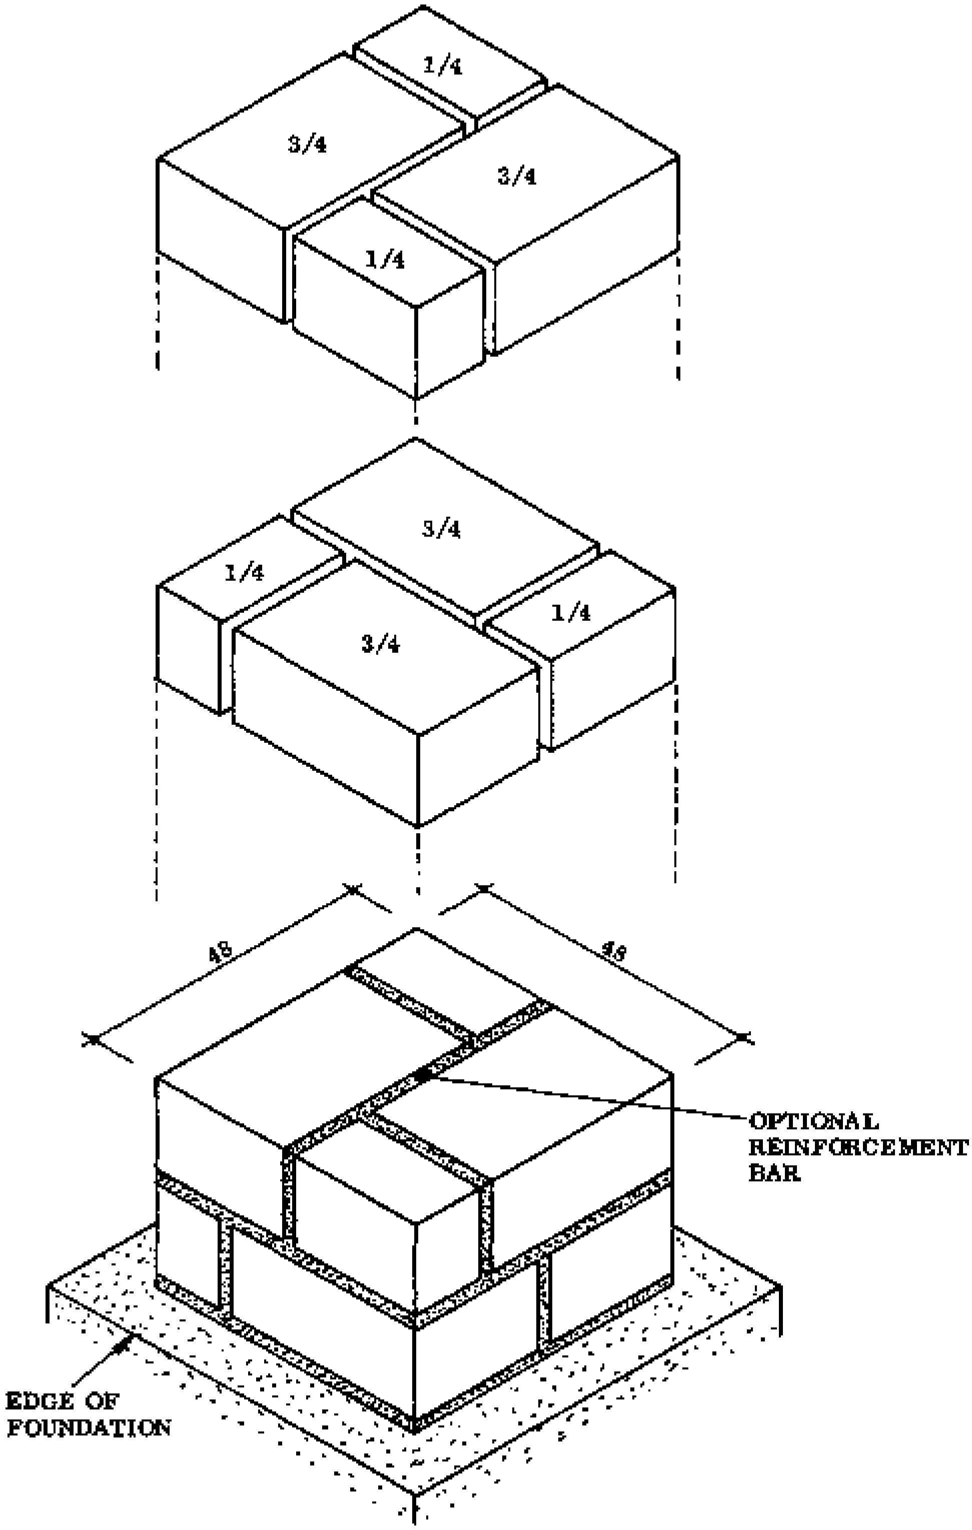

Fig. 1 SANDCRETE PIER FLATWISE

Bonds for landcrete piers

The examples of bonds for landcrete piers shown on pages 68 and 69 are similar to some of the bonds already explained. Fig. 1 shows a bond which is basically the same as the footing bond on page 63, except the blocks are laid edgewise.

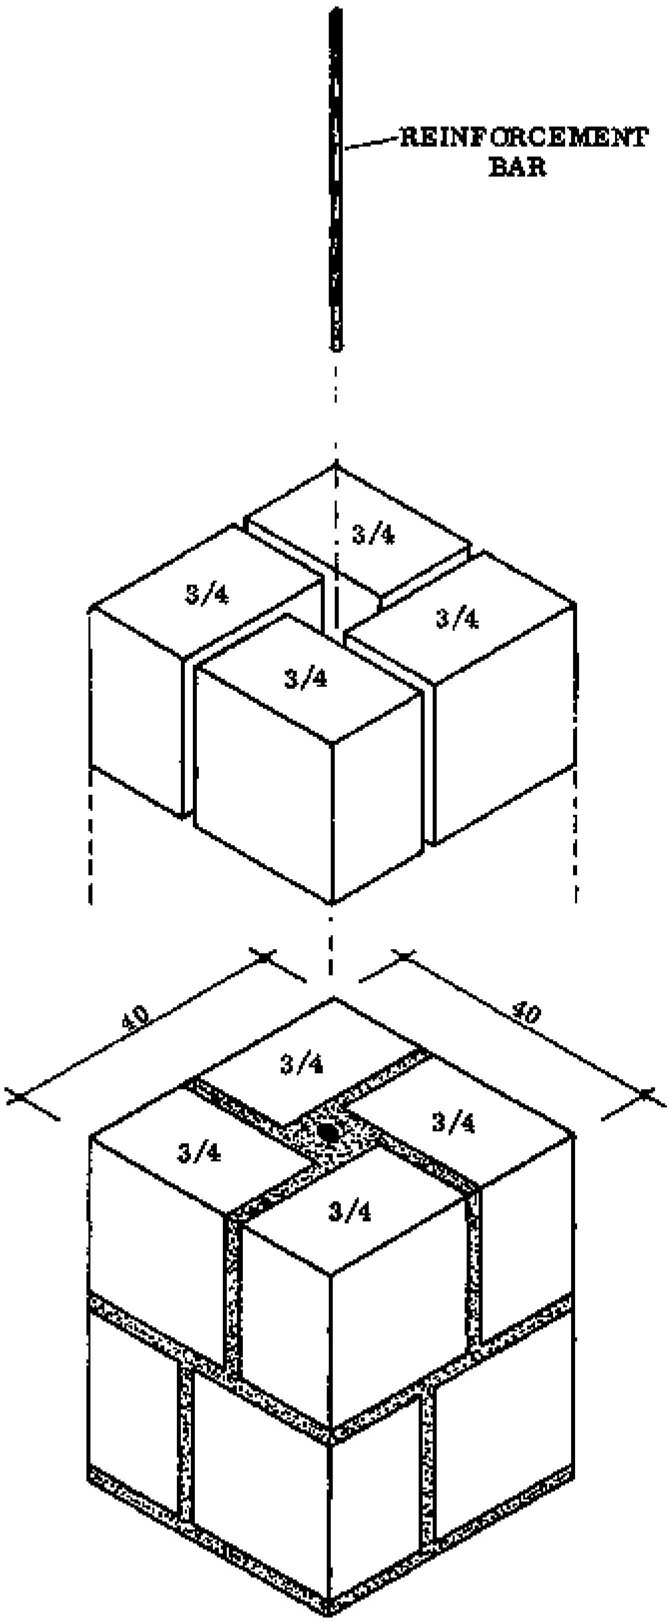

Fig. 1 LANDCRETE PIER EDGEWISE

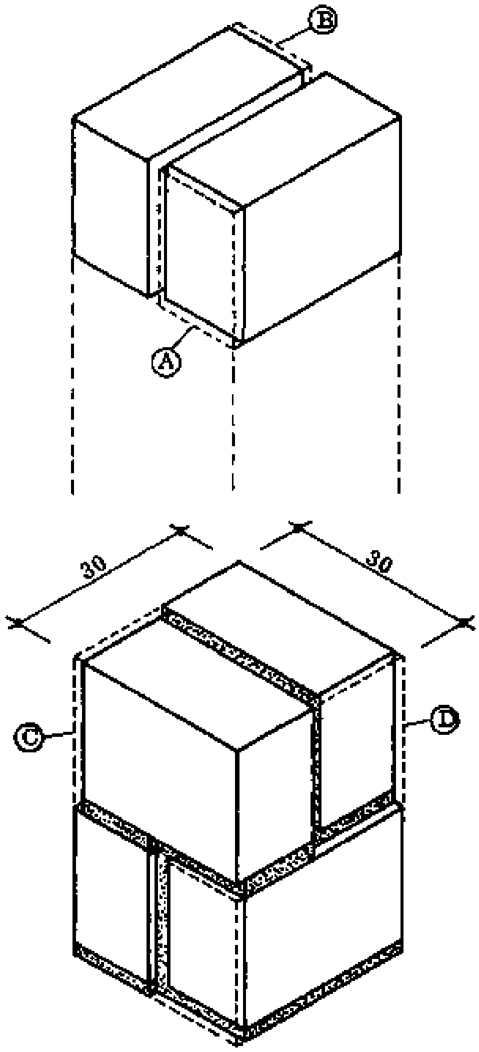

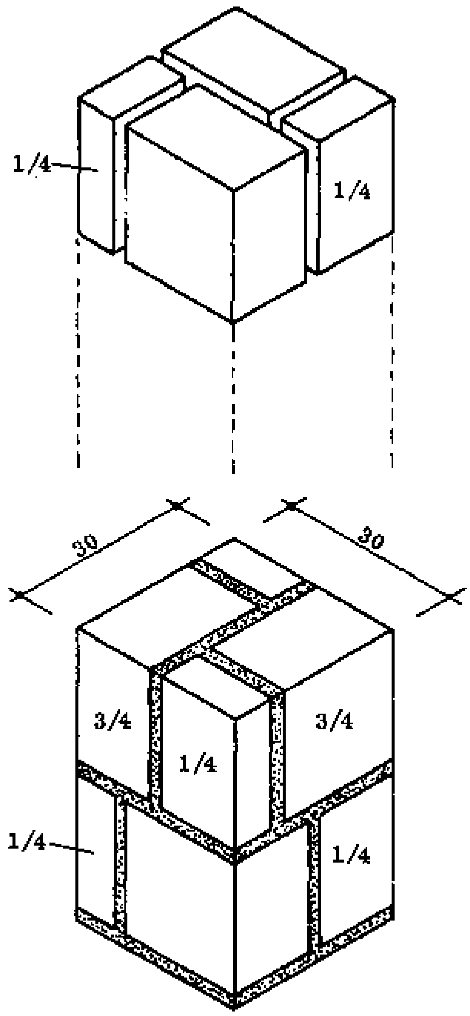

Fig. 1 LANDCRETE PIER EDGEWISE

Fig. 2 LANDCRETE PIER EDGEWISE

Each course consists of two full blocks laid edgewise and across the course below. In order to maintain a square shape of 30 cm by 30 cm, the blocks are set 1 cm out of line with each other at their header sides (see points A, B, C, & D).

The bonding method seen in Fig. 2 requires cutting two blocks per course and results in a rather weak bond. The Rural Builder should avoid making this type of pier except when he needs to use up some part-blocks left over from another construction.

Fig. 1 on page 68 shows another bonding method for landcrete piers with the blocks laid edgewise. This method has the advantage that an iron rod can be set into the centre of the blocks, either to reinforce the pier or to act as an anchor, or both.

- NOTE: Landcrete piers should not carry heavy loads such as a truss or a concrete beam, because they are too weak. They may be used to support and anchor overhanging rafters of a roof above a verandah.

If a landcrete pier has to carry heavy loads, its dimensions should be increased to a minimum of 55 cm by 55 cm.

NOTES:

PART 2: BASIC CARPENTRY TECHNIQUES

TECHNICAL TERMS

- GRAIN: This refers to the direction of the wood fibres. Length is measured along the direction of to grain. Width is measured across the grain at right angles to the length. When wood is cut across the grain, END GRAIN is exposed.

- WITH THE GRAIN: This term is used in connection with planing. If the fibres are cut cleanly and smoothed down by the cutting iron, the wood is said to be planed with the grain; like stroking a dog's coat so the hair lies down smoothly.

- AGAINST THE GRAIN: This means that the plane goes in the opposite direction, lifting and breaking the wood fibres and leaving a rough surface; as if a dog's coat were brushed the wrong way and roughened.

- STRAIGHT GRAIN: The wood fibres lie straight and parallel to the length of the piece of wood. Such wood planes smoothly and easily.

- CROSS GRAIN: The wood fibres do not lie parallel to the length of the piece.

This makes the wood hard to work.

- BEVEL: This is made by planing off the sharp edge to form a new surface which is not at right angles to the side of the piece of wood. A CHAMFER is a special bevel, cut at 45 degrees. A "through" chamfer or bevel runs the whole length of the edge (Fig. 1). A "stopped" chamfer or bevel is stopped at one or both ends (Fig. 2).

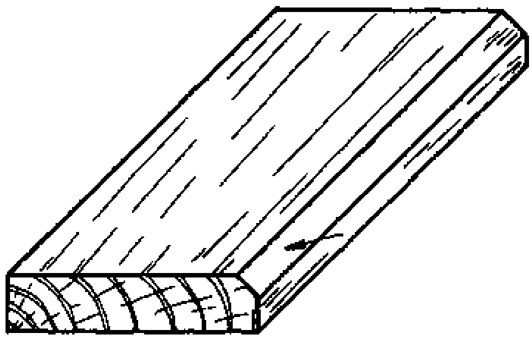

Fig. 1

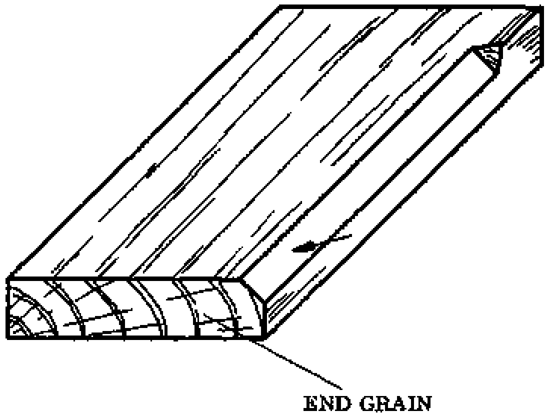

Fig. 2

- GROOVE: This is a recess cut along the grain. A “through” groove runs the whole length of the piece (Fig. 3, a); while a “stopped” groove is stopped at one or both ends (Fig. 3, b).

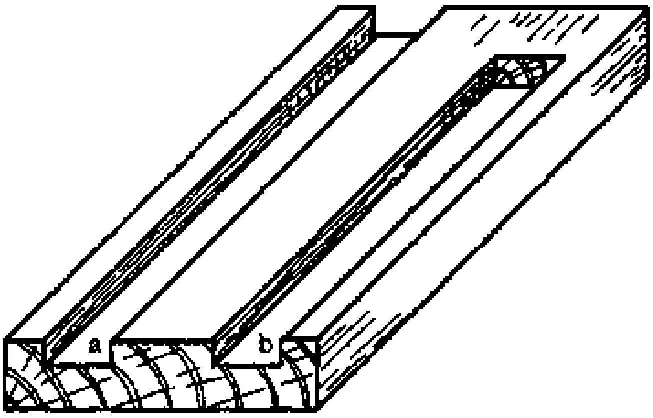

Fig. 3

- TRENCH: This is a recess cut along the grain. A trench can also be either through (Fig. 4, a) or stopped (Fig. 4, b).

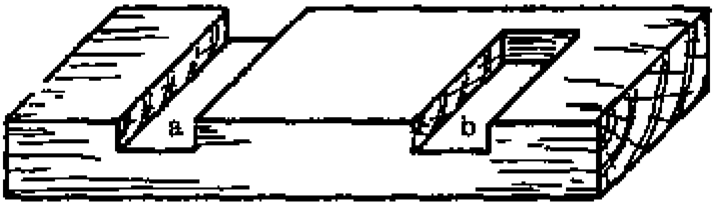

Fig. 4

- REBATE: This is a recess cut along the edge or across the end of a board as in Figs. 5 & 6.

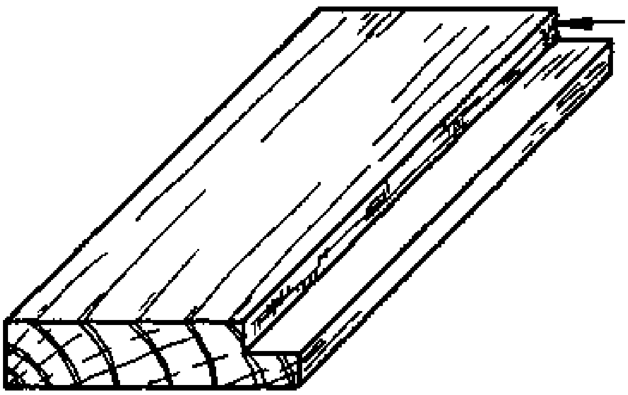

Fig. 5

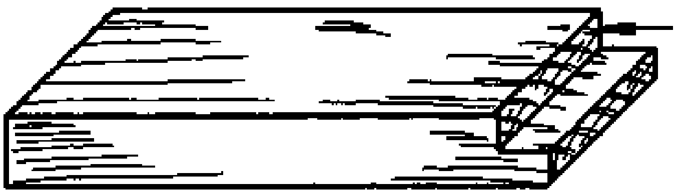

Fig. 6

- TRUE: In woodworking this indicates that a surface is flat and perfectly level.

- SQUARE: Square angles are exact 90 degree angles. “Square” is used to describe pieces in which all the corners and edges have 90 degree angles.

- SHOULDER: The vertical portion of a trench or rebate (arrows, Figs. 5 & 6).

TESTING BOARDS

When you prepare a board for use in some project, you must make certain tests on it to make sure that it is flat and true in all directions and that the angles and corners are all square. These tests are made during the actual preparation of the timber, but we describe them here separately because they are generally useful techniques which you will need again and again in your work.

Before you continue reading, look in your Rural Building Reference Book, Tools section, page 36, and read about the try square, which is one of the tools you will need for testing boards. You will also need winding strips (Fig. 2) and a straight edge (Fig. 1), which is usually a piece of wood with one long edge that you are sure is perfectly flat and straight.

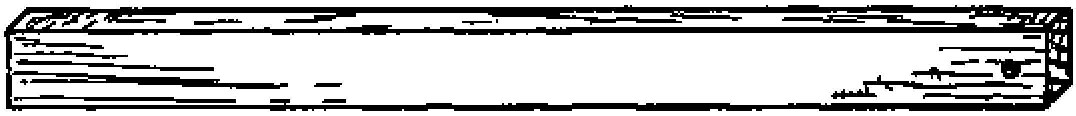

Fig. 1

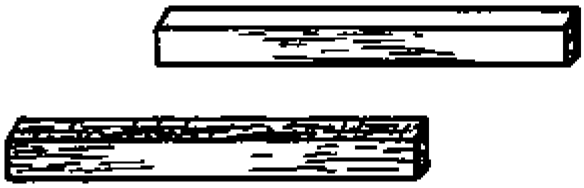

Fig. 2

Also look in the Reference Book, Materials section, page 132 and find out what is meant by the words: twisting; cupping; and bowing.

Winding strips

These are used as an aid to help you to see if a board twists or “winds”. They are two strips of wood about 35 cm long, 2,5 cm wide and 1, 5 cm thick. The top edge has a bevel and all the edges must be perfectly straight. One of the two strips may be made darker so that sighting along them is easier (Fig. 2).

How to test small work pieces

Test with the try square or the edge of a jack plane in different positions for flatness. Also test the squareness of the edges with a try square at a few different spots (Fig. 3).

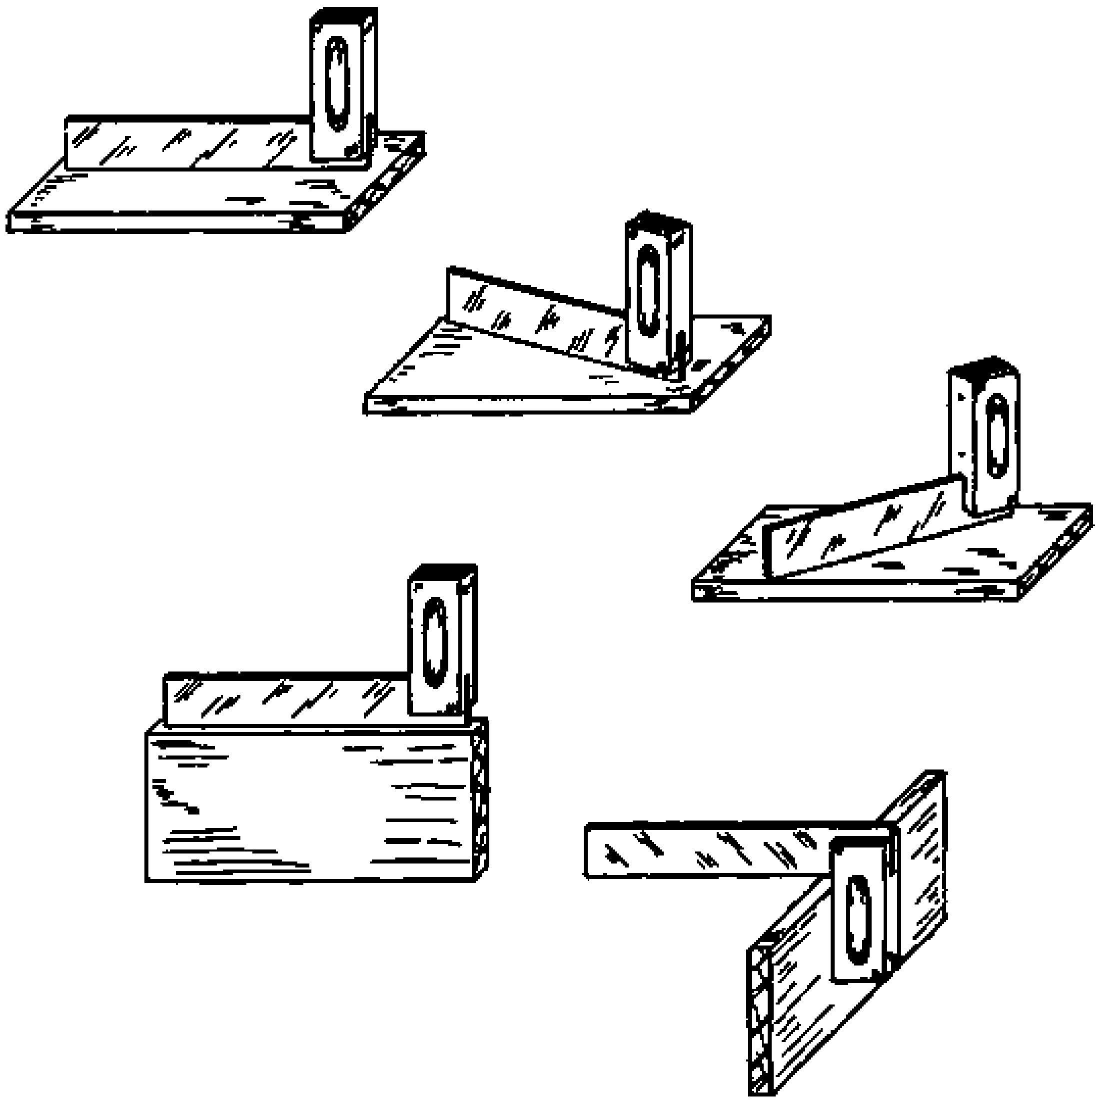

Fig. 3

NOTES:

How to test long work pieces

Test for winding (twisting) using the winding strips; one at each end of the board, across the grain. Go to the end of the board and look along the board, with your eye just at the same level as the strips (Fig. 1). When the top edges of the strips do not appear parallel (Fig. 1a), the board is not flat. Check with the winding strips at different spots, making sure that the strips are parallel (Fig. 1b).

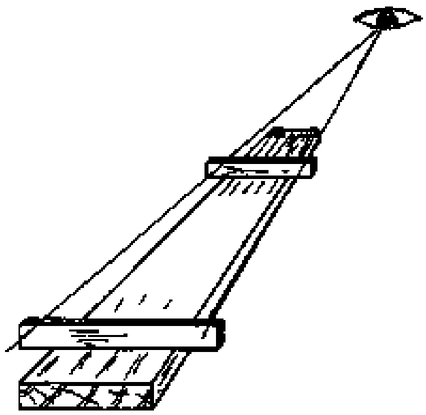

Fig. 1

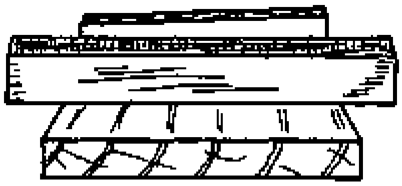

Fig. 1a

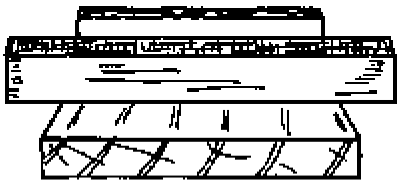

Fig. 1b

Test for cupping by putting a try square across the grain at different spots along the board. If you check this against the light, you will see all of the uneven places (Fig. 2).

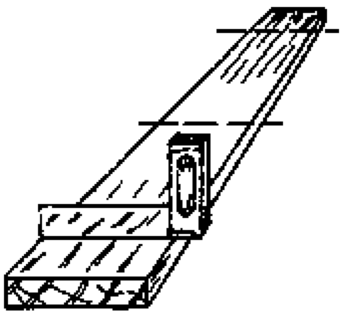

Fig. 2

To check for bowing you can do the same test, using a straight edge along the grain (Fig. 3).

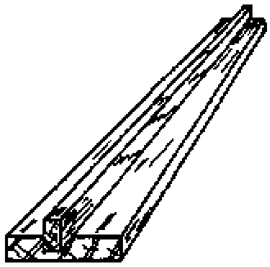

Fig. 3

For long boards you can sight along the boards with one eye closed, to see the places which are uneven (Fig. 3a).

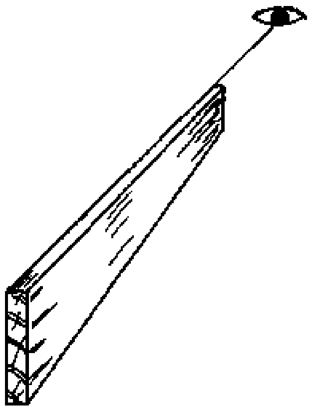

Fig. 3a

Using a try square, check whether the angle between the face side and the edge is exactly 90 degrees. Make this test at several places (Fig. 4).

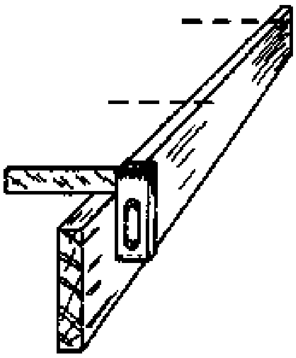

Fig. 4

When all these tests have been performed with satisfactory results, the board will be straight and true in all directions and it is ready to be used in a project.

NOTES:

MEASURING AND MARKING OUT TIMBER

Accurate measuring and marking out are the first requirements for success in the building trade. Common measuring and marking tools are the folding rule and zig-zag rule (Reference Book, page 11).

Measuring with a rule

To measure between two points, place the rule on one point and read the mark nearest to the other point (Fig. 1).

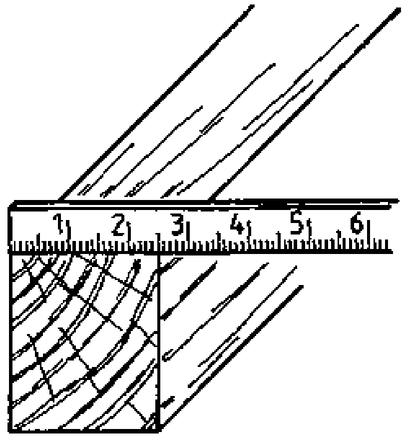

Fig. 1

When the end of the rule has become worn and inexact, you can still get an exact measurement. Place the 1 cm mark of the ruler at the first point and read at the second point. The true measurement is that reading minus 1 cm. For example, the measurement in Fig. 2 is: 3,5 cm minus 1 cm equals 2,5 cm.

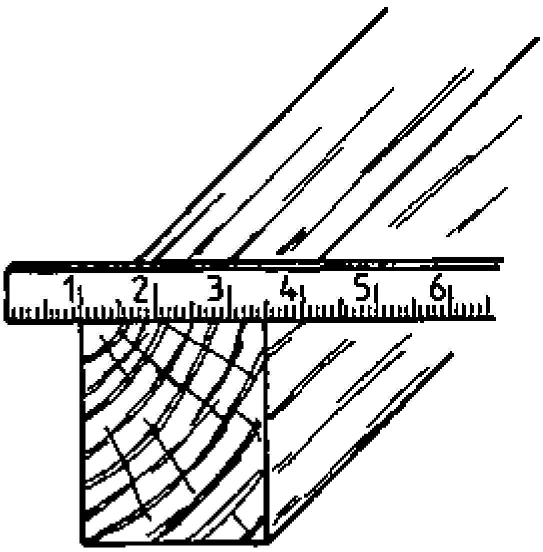

Fig. 2

Marking out with a rule

To mark out measurements with a rule, place the end of the rule (or the 1 cm mark) carefully at the start of the measurement and then make a fine mark with a pencil exactly even with the marking on the rule at the correct distance.

For very accurate marking and measuring, lay the rule on its edge so that the marks on the rule touch the work (Fig. 3).

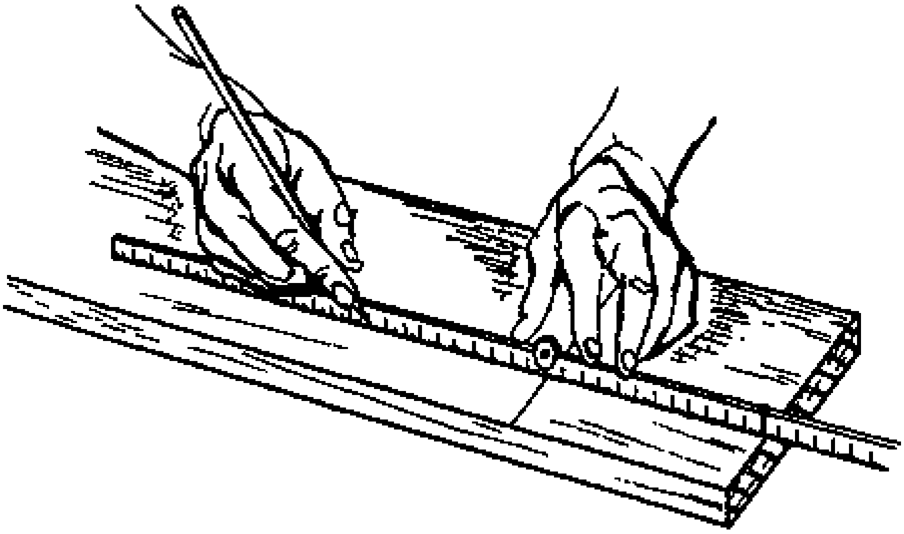

Fig. 3

To mark out several measurements on a line, it is best to mark all of the measurements without raising the rule or moving it. If the rule is moved and each measurement is made separately, there is a much greater possibility of error.

NOTES:

Marking with a pencil

When a marking gauge (Reference Book, Tools, page 39) is not available, straight lines can be gauged along timber by one of the following methods.

- Grasp the pencil lightly in your closed fist with the point protruding the desired distance. For example, to make a line 1 cm from the edge of the timber, the point of the pencil should stick out exactly 1 cm from your fist. Now pull the pencil along the board keeping your thumbnail pressed firmly to the edge of the board (Fig. 1).

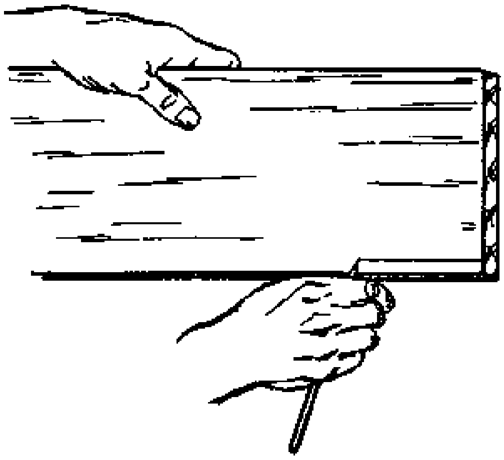

Fig. 1

- To gauge lines further from the edge of the board, use a rule and a pencil. Grasp the rule in one hand with your thumbnail at the desired marking. Then draw the rule along while keeping your thumbnail against the edge of the board. With your other hand hold a pencil at the end of the rule to make the line (Fig. 2).

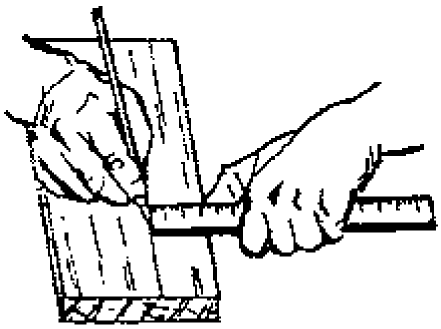

Fig. 2

With these methods you should be careful not to get splinters in your fingers.

- Another method of drawing lines parallel to an edge is with a small pencil gauge. This is simply a small, rebated wooden block which is pressed against the edge of the timber and used to guide the pencil, as shown in Fig. 3. The pencil gauge is often used to mark out the position of chamfers.

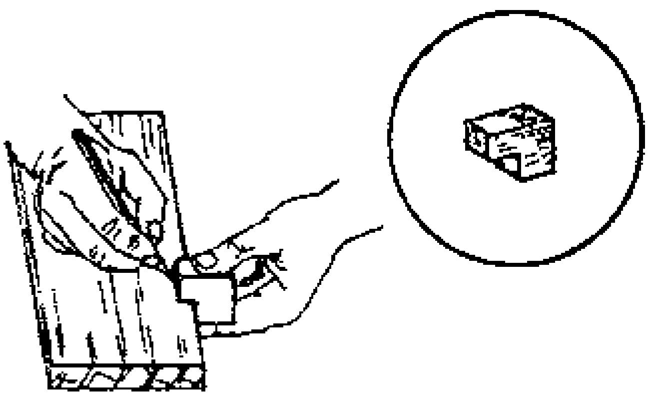

Fig. 3

- A straight edge can also be used in marking out longer lines.

Marking with a chalk line

A quick and simple way of marking out a straight line on any surface is with a chalk line. This is simply a piece of string that has been rubbed with chalk until it is coated in chalk dust (charcoal may also be used for this purpose).

To use the chalk line, stretch the line between two points which are the ends of the line you want to mark. Hold it in place by tying the ends to nails, or have a helper hold it for you.

Lift the line up in the middle and allow it to snap back (Fig. 4), making a straight chalk line on the surface.

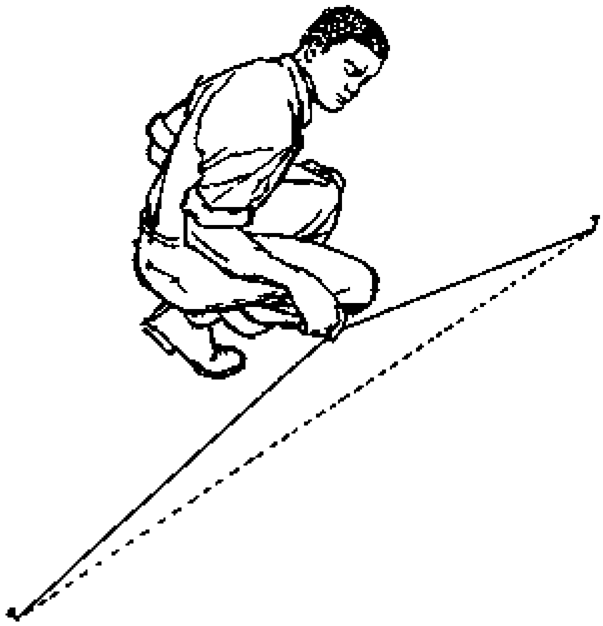

Fig. 4

NOTES:

TIMBER CONSTRUCTIONS

The last few lessons were about the very basic things you will need to know before you can actually make any construction of wood. Therefore we started with some technical terms which are important because you will see them again and again in the lessons and will use them in practical work.

The next sections include all the information you will need to prepare for a project: how to get the wood pieces to the right size and shape; how to mark the timber; and how to plan a project using a cutting list. Included here is a section on nailing and one on driving screws. Before you study those sections, look up nails and screws in the Reference Book, Products, pages 207 to 211, so that you are familiar with the parts of nails and screws and how they look.

Each section starts with a list of tools. Refer to the Reference Book, Tools section, and learn about each of these tools before you study the rest of the section.

NOTES:

PREPARATION OF TIMBER

In order to carry out the construction of any practical exercise or project, it is essential to have the wood pieces for the project prepared so that they have the correct size, true and flat surfaces, and square corners and angles.

There is of course a correct procedure to be followed for this preparation. It is important to carry out the following steps in their correct order on every piece of timber, whether large or small.

An easy way to remember the steps in their correct order is to keep the following word in mind: FEWTEL.

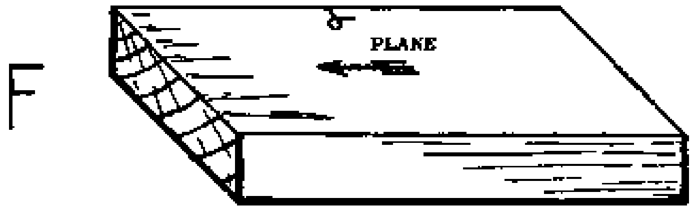
Face	Edge	Width	Thickness	End	Length
F	E	W	T	E	L

The tools which are required for this preparation are the bench, jack plane, straight edge, winding strips, pencil, try square, marking gauge, charcoal line, back saw, ruler and crosscut saw. Look these up in the Reference Book and make sure that you understand what they are and how they are used.

NOTES:

Sequence of operations for preparing timber

Step 1. Plane the face side (F)



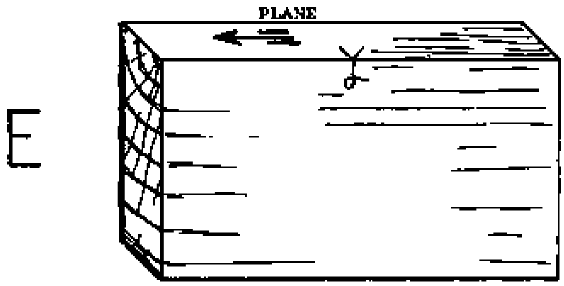
- Put your work on the bench with the better side up. If the board is not flat, put the hollow side down to keep it from rocking or moving around. In the case of very long or thin boards or twisted or deformed boards, put thin wedges of wood underneath where needed, to keep the work steady and keep it from bending in the middle during planing.

- Plane this side perfectly true.

- Test for flatness with the straight edge, winding strips and try square.

- Mark this side as the face side; the face mark should point to the edge which will be the face edge. The face edge will be the best edge of the board.

Step 2. Plane the face edge (E)



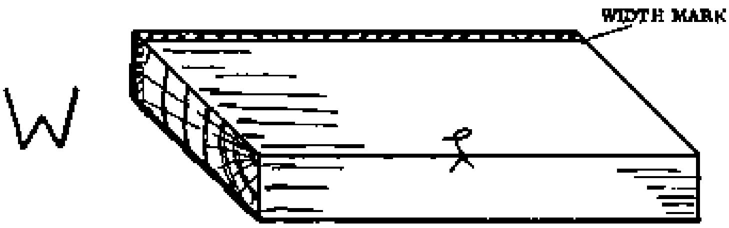
- Fasten your board to the side of the bench, with the face mark up. The planed side must be towards you and not against the bench, unless this would mean you would have to plane against the grain. In that case, you should turn the board so the other edge is up, keeping the face side towards you because the try square has to be set against the face side.

- Plane the face edge perfectly straight and square to the face side.

- Test for straightness with the straight edge and for squareness with the try square.

- Mark it with a face edge mark pointing to the face side.

Step 3. Plane the width (W)



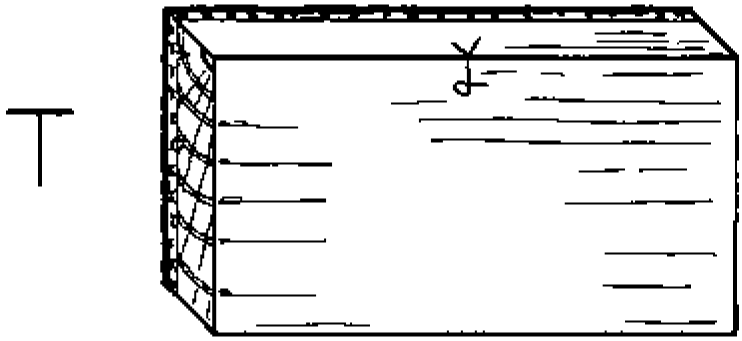
- With a marking gauge, mark the width of the board. Press the gauge against the face edge and mark on the face side.

- Plane down to the middle of the gauge line and be careful to get a square, straight edge when you reach the mark.

- Test for flatness with a straight edge and try square.

NOTES:

Step 4. Plane the thickness (T)



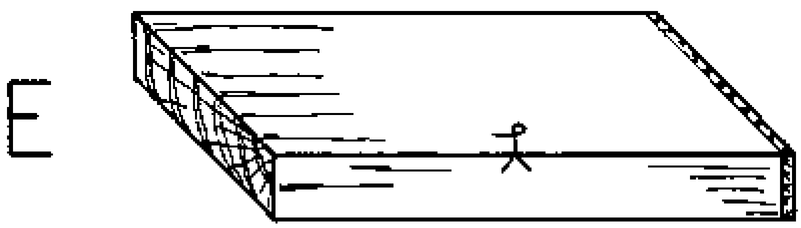
- Use a marking gauge to mark the thickness of your board. Press the gauge against the planed side and mark both edges.

- Plane down to the middle of the gauge lines.

- Test for flatness as you get near the two marked lines. Be sure to check for flatness across the board at several points. Check for winding with the winding strips.

Generally timber is not prepared to the exact length. Waste is left on each end to protect the corners from damage. If it is necessary to prepare it to the exact length, the procedure is as follows:

Step 5. Cut one end (E)



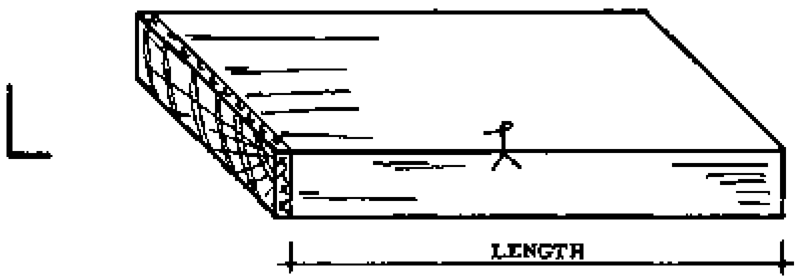
- With a try square, square the best end; with as little waste as possible.

- Cut that end perfectly square to the face side and face edge. Saw on the waste side of the line.

- Test for squareness in all directions.

- Mark the end with a cross, so that you know which is the prepared and tested end.

Step 6. Cut the length (L)



- Measure the required length from the prepared end and square with the try square.

- Cut that end perfectly square in all directions.

- Test it with a try square.

NOTES:

Timber marks

The purpose of face marks, as they are shown under preparation of timber, is to show clearly the prepared and tested sides and the edges which are square.

During all further marking, squaring and gauging we should try to work from these sides and edges.

Marking of frames

Making frames is an important part of Rural Building. We have to mark the members of a frame in a standard way so that we do not confuse their positions.

- Select and prepare the timber according to the sequence given in the section on preparation of timber. Lay out the various members as they will be when they are finally assembled into a frame (Fig. 1).

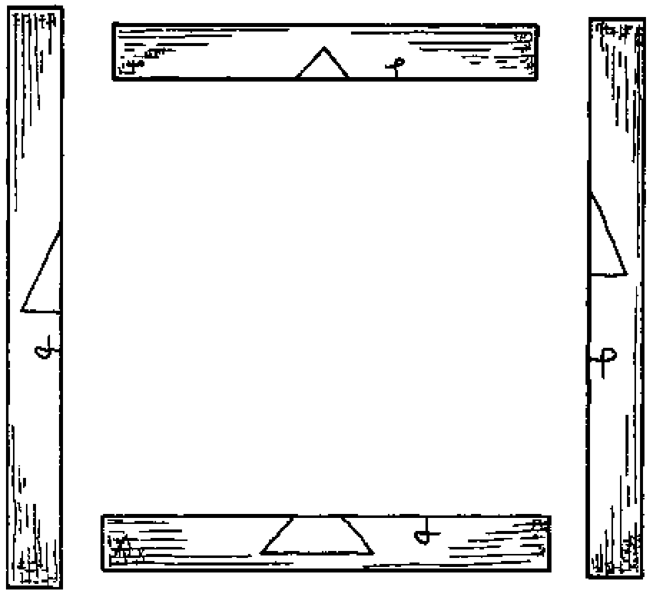


Fig. 1

- Take care that all surfaces which will be visible in the finished product are of good timber and without defects. Usually these will be the face sides and face edges. Always try to keep the face sides on one side, and the face edges all on the inside or all on the outside.

- Now put the inside edges of the horizontal members together, mark the length of the members and put the triangular mark as shown in Fig. 2. The triangle always should point up.

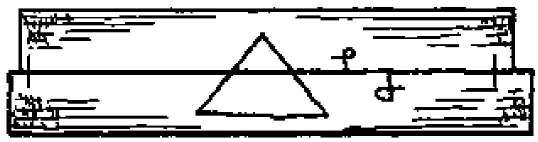

Fig. 2

- Now do the same thing for the vertical members. Put the inside edges together, mark the lengths and put the triangular sign, again pointing upwards (Fig. 3).

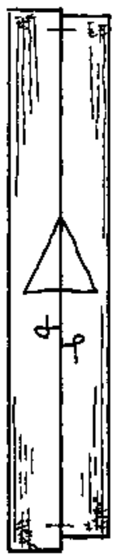

Fig. 3

- All further marking should be done using these sides as a reference.

NOTES:

Cutting list

After you design and make the drawing for a piece of work, you need to make a cutting list showing the length, width and thickness of all the parts. These will be the finished sizes. So that each part will be straight, true and smooth, we must begin with slightly bigger pieces to have an allowance for planing the sawn timber true.

The planing allowance for a board is:

3 mm extra in thickness
6 mm extra in width
12 mm extra in length

For square pieces the allowance is:

3 mm extra on each side
12 mm extra in length

An example is shown below of a cutting list for a simple box (Fig. 1). The list shows the parts of the box, the kind of wood, the number required of each part and the finished size of the part. In the last column we find the size of the timber that will be required when the planing allowance has been added.

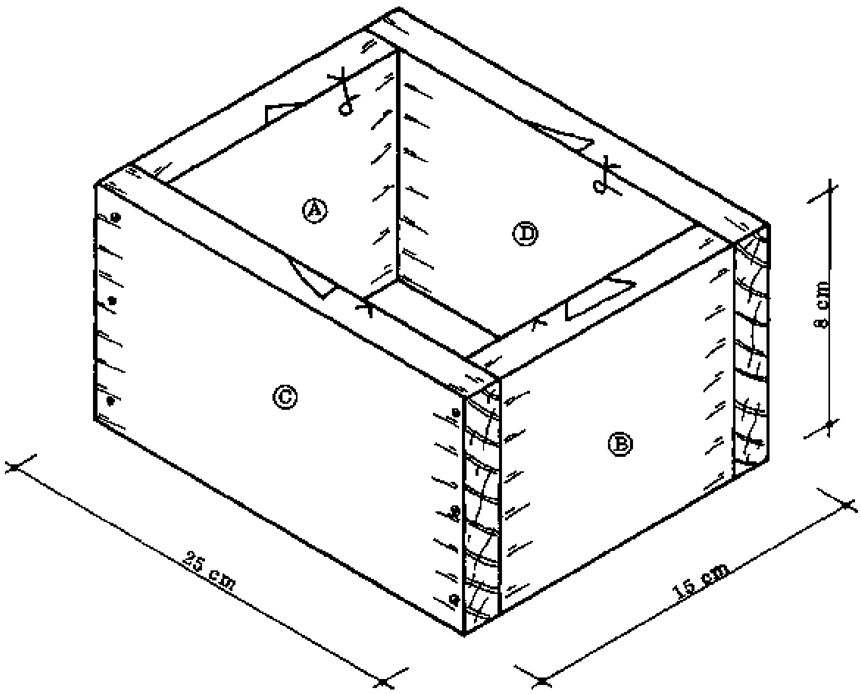

Fig. 1

NOTES:

Usually it is best to plan a project according to the sizes of timber you have available, subtracting the planing allowances first in order to prevent waste.

Cutting list:

			finished size (cm)			timber size (cm)		
part	wood	no.	L	W	T	L	W	T
A	Odum	1	10,6	8	2,2	11,8	8,6	2,5
B	Odum	1	10,6	8	2,2	11,8	8,6	2,5
C	Odum	1	25	8	2,2	26,2	8,6	2,5
D	Odum	1	25	8	2,2	26,2	8,6	2,5

When you are choosing timber for a piece, choose the best, straight boards for the long pieces. The crooked or defective boards can be used for the shorter pieces.

NOTES:

FASTENING WITH NAILS

Before you read this section, look up Nails in the Reference Book, Products section, page 207.

Driving nails

To start a nail, hold it steady between your thumb and fingers with one hand and strike one or two light blows with the hammer (Fig. 1).

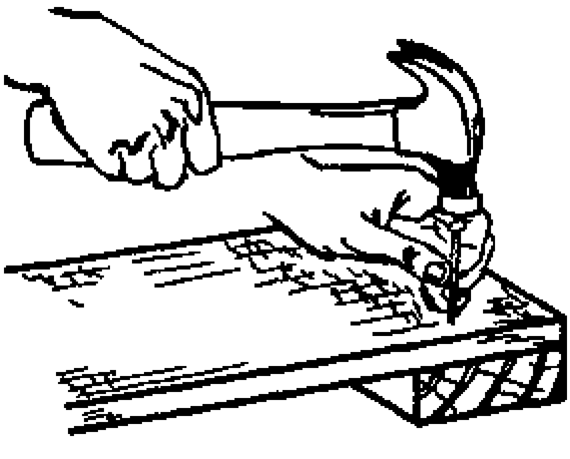

Fig. 1

After the nail is well started, drive it in with firm blows. Hold the handle of the hammer near the end and strike the nailhead straight.

When you drive a nail all the way in, be careful on the last blows not to hit the wood and leave a hammer mark on it.

Holding power

The holding power of the nail depends on the pressure of the wood fibres against the shank of the nail and also on the size of the nailhead (Fig. 2).

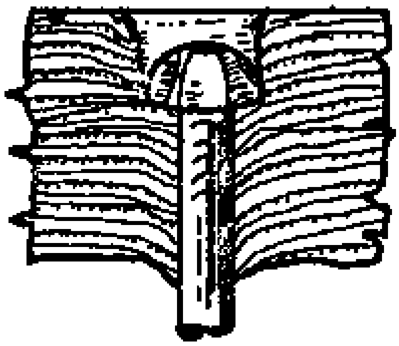

Fig. 2

Hard dry wood holds better than soft or wet wood. End grain doesn't hold nails very well. If the nail is driven across the fibres, the nail's length should be 2 1/2 times the thickness of the top piece (Fig. 3). If it is driven into end grain, the length should be 3 times the thickness of the top piece (Fig. 4).

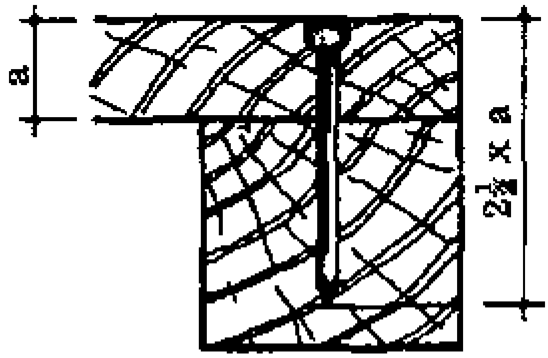

Fig. 3

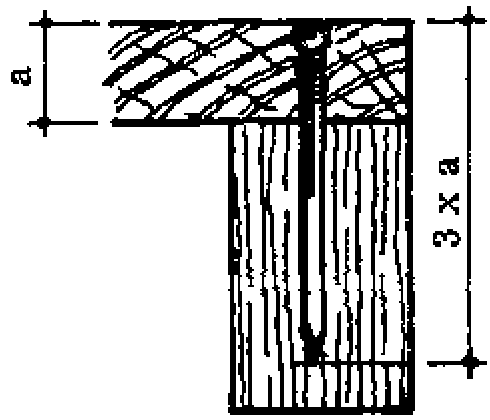

Fig. 4

The holding power of nails in end grain can be improved by dovetail nailing, which means the nails are inserted at slight angles (Fig. 5) instead of straight in (Fig. 6) which is the usual way.

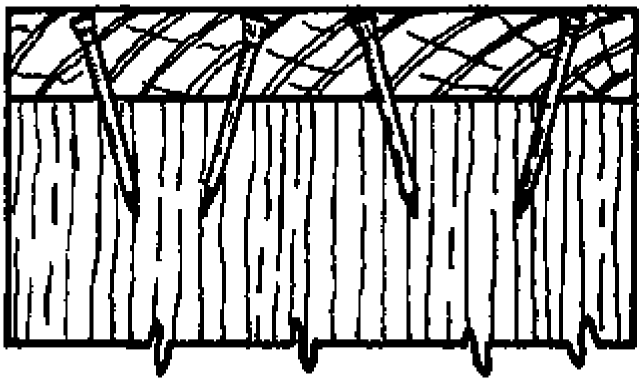

Fig. 5

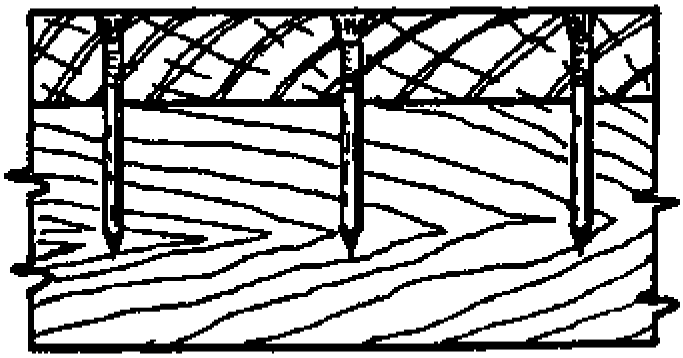

Fig. 6

If possible the nails should be inserted at right angles to the force that will be applied to the piece; so that any force tends to shear off the nail rather than pull it out.

The correct placing of the nails is important with respect to the strength of the finished piece.

NOTES:

__How to prevent splitting during nailing__

Nails can be staggered (inserted out of line) to prevent splitting along the fibres of the wood (Fig. 1).

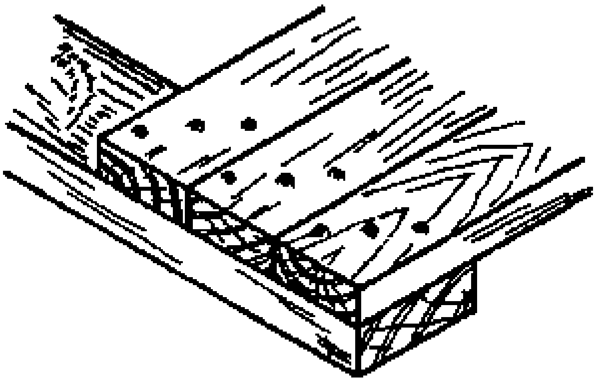

Fig. 1

Blunting the nail with one or two hammer blows on the tip also helps to prevent the nail from splitting the wood (Fig. 2).

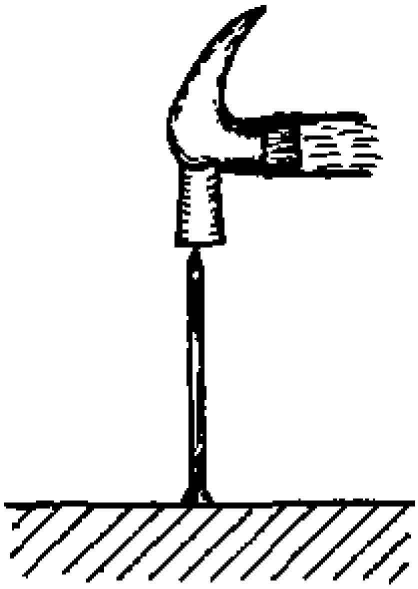

Fig. 2

If large nails are to be fixed, drill holes first to keep them from splitting the timber. The holes should be slightly smaller in diameter than the nails.

Finishing off

Lost head nails are punched (knocked below the surface of the wood) with a nail punch or a large blunt nail. The remaining hole can be filled with putty (Fig. 3).

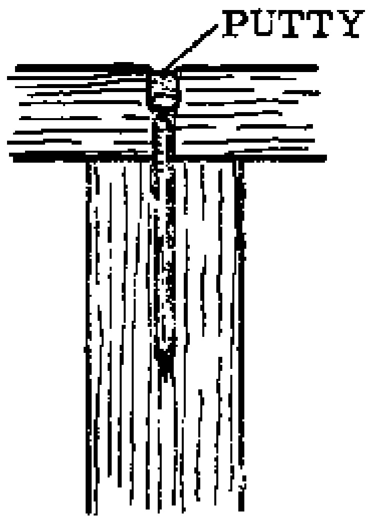

Fig. 3

When the sharp points of nails come all the way through the timber and out on the other side, they are clenched; that is the tips are bent over and flattened against the wood, out of the way. There are two ways of doing this:

- Knock the tip flat and punch it into the wood with a nail punch (Fig. 4).

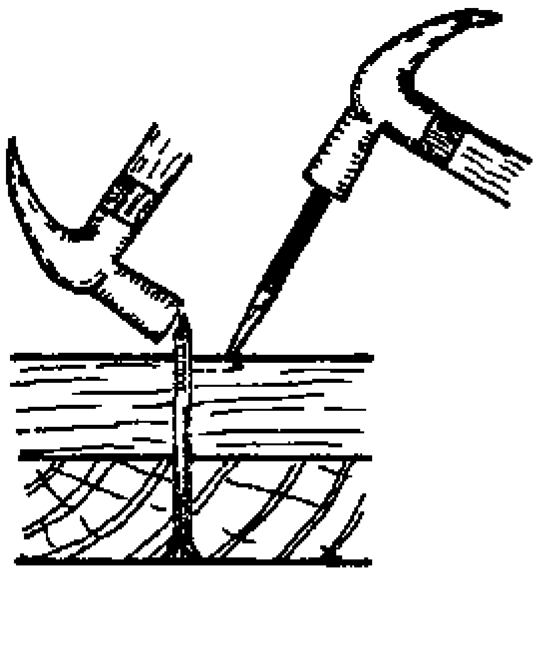

Fig. 4

- Bend the point at a right angle first, and then knock it back into the wood (Fig. 5; a, b, & c). This is done where the nail projects more than 1 cm.

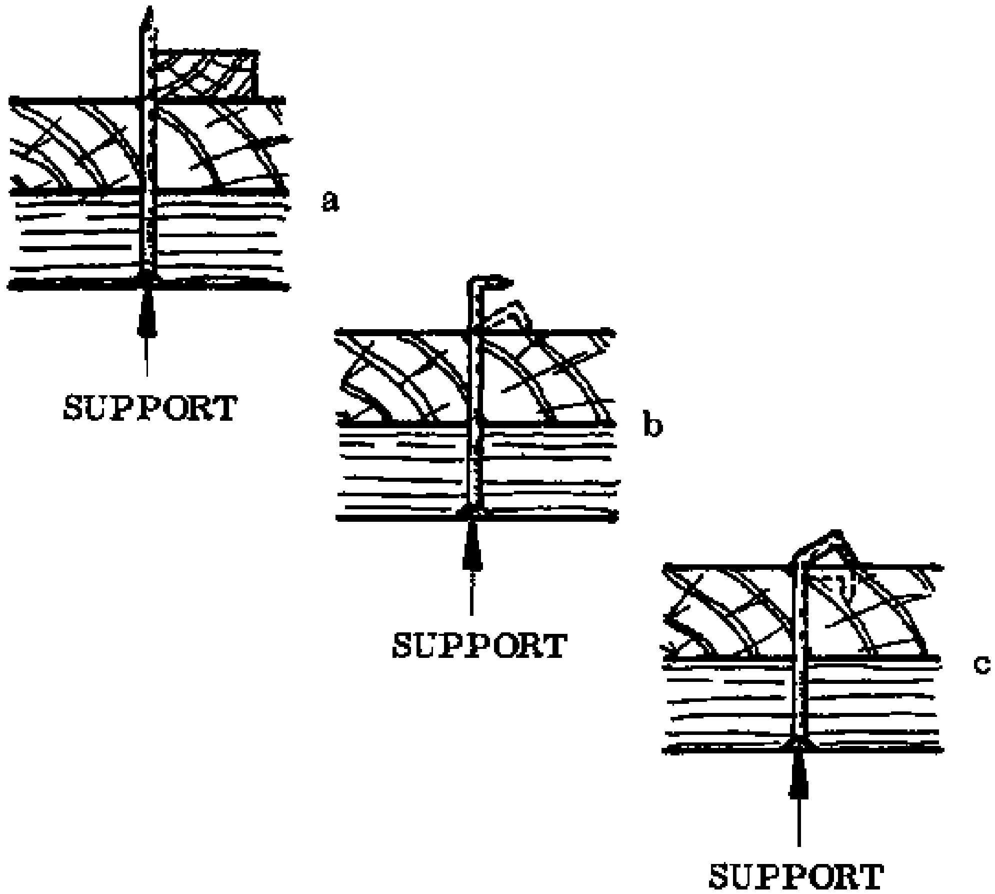

Fig. 5

The head of the nail should be supported during clenching to keep it from being pushed out again.

Bent nails can be straightened if you tighten one end in a vice and support the other end with a hammer while knocking out the bent part with another hammer (Fig. 6).

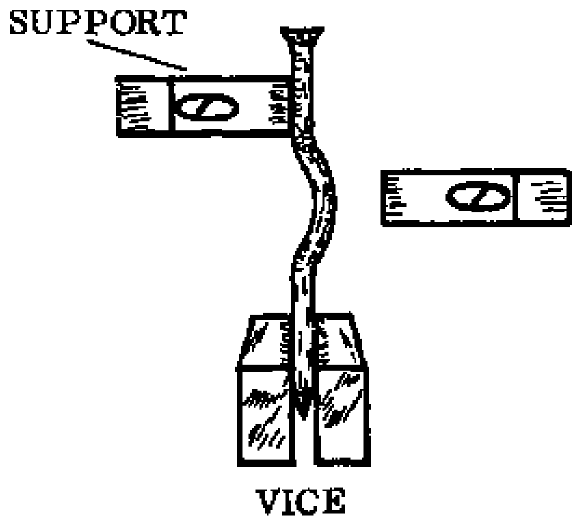

Fig. 6

NOTES:

FASTENING WITH SCREWS

Before you read this section, look up screws in the Reference Book, page 209; screwdrivers on page 77; and maintenance of screwdrivers on page 103.

Holding power

The holding power of a screw depends on how the thread embeds in the fibres, the length of the screw and the strength of the head which holds the top piece.

When a screw is driven across the grain, the screw's length should be about twice the thickness of the top piece (Fig. 1).

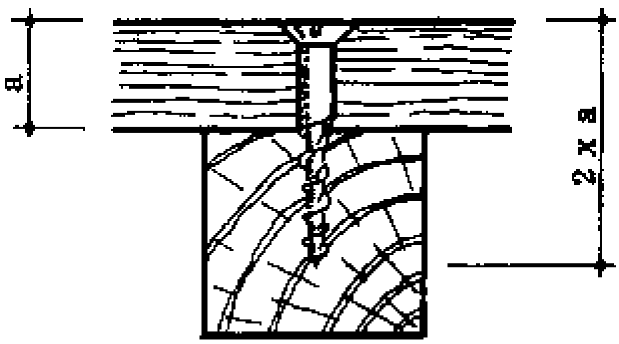

Fig. 1

Screws driven into the end grain should be longer, about 3 times the thickness of the top piece (Fig. 2).

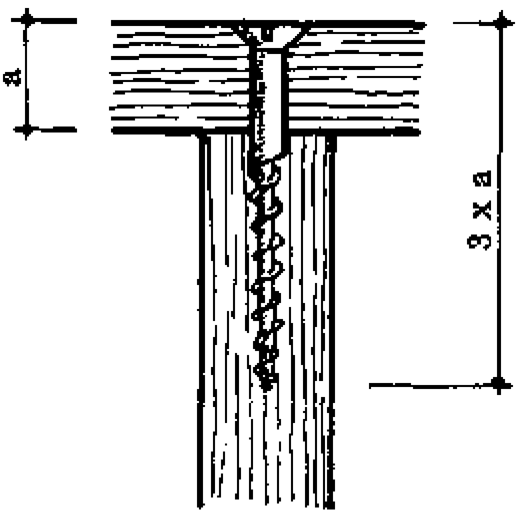

Fig. 2

Driving screws in soft wood

- Bore a hole in the top piece with the same diameter as the shank of the screw (Fig. 3a). The bottom piece may be punched with a large nail or awl (Reference Book, page 73).

- Countersink if necessary (Fig. 3b).

- Drive the screw (Fig. 3c).

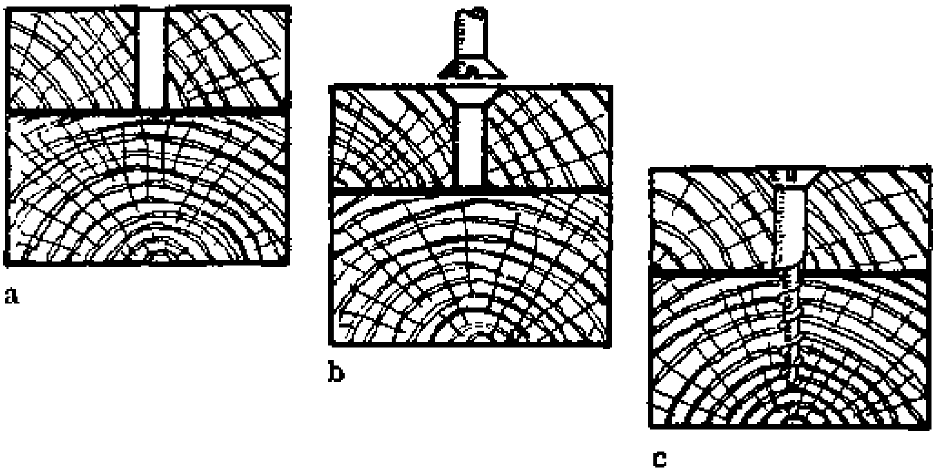

Fig. 3

Driving screws in hard wood

- Bore a hole in the top piece with the same diameter as the shank of the screw (Fig. 4a).

- Bore a hole in the bottom piece with the same diameter as the core of the screw (Fig. 4b).

- Countersink if necessary and drive the screw (Figs. 4c & 4d).

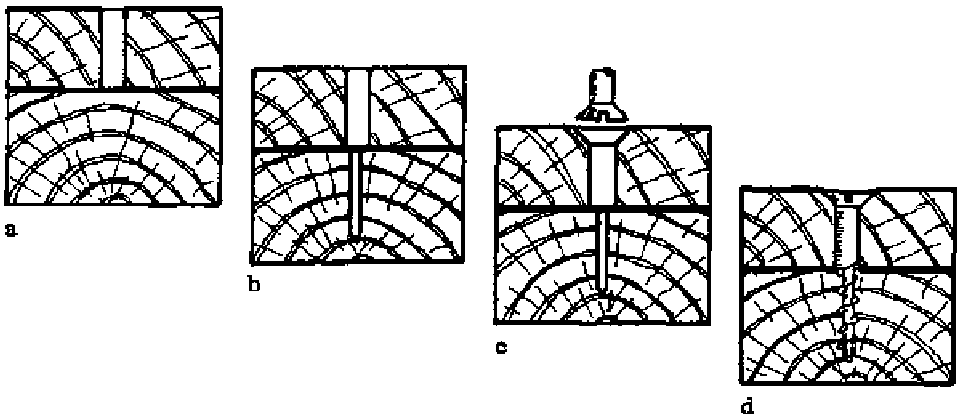

Fig. 4

Use a screwdriver with the correct tip only. If the screw turns too hard, the hole may be too small or not deep enough. Remove the screw and find out what the problem is so it can be corrected, otherwise the screw may break or split the board.

- Turn the screw down until the head is just seated. Overturning weakens the holding power and may break the screw.

- To make driving easier and to protect against rust, a bit of soap or oil may be put on the tip of the screw.

ANGLE JOINTS

Angle joints are joints where the sides of the pieces (the wide surfaces) meet at right angles to each other. Angle joints are used for box-like constructions such as small boxes, tool boxes etc. For an example of a box using angle joints, see the illustration for the Cutting List lesson, on page 89. In this chapter we will consider the most common types of angle joints and their construction.

Nailed butt joint

The simplest angle joint is the nailed butt joint. The end of one piece of wood is cut square, then butted against the face of the other piece. It is held in place with nails, or both nails and glue (Fig. 1).

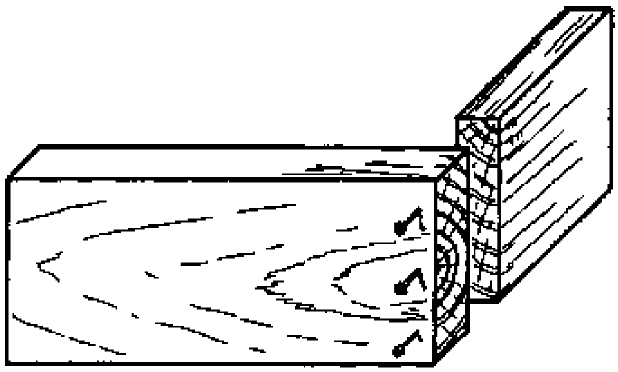

Fig. 1

Plain mitred joint

The ends of the pieces are mitred (cut at 45 degrees) across the thickness. The mitred ends are butted together and held in place with glue and nails (Fig. 2). This is a weak type of joint although it is stronger than the butt joint because it is nailed from two sides. Its advantage is that the end grain is not exposed to damage from water or insects, and it has a neater appearance.

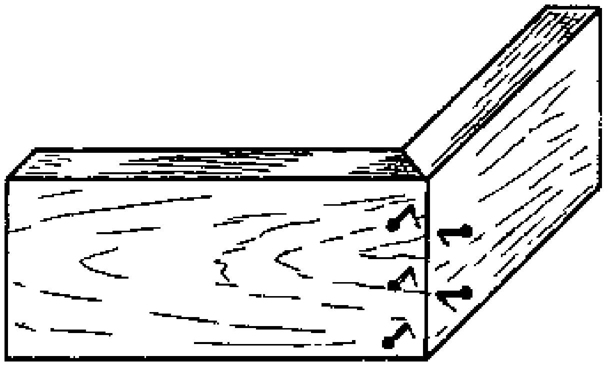

Fig. 2

Rebated butt joint

The end of one piece fits into a rebate at the end of the other piece. This joint is strong because two surfaces are available for nailing, and because the shoulder of the rebate supports and helps to hold the other piece (Fig. 3).

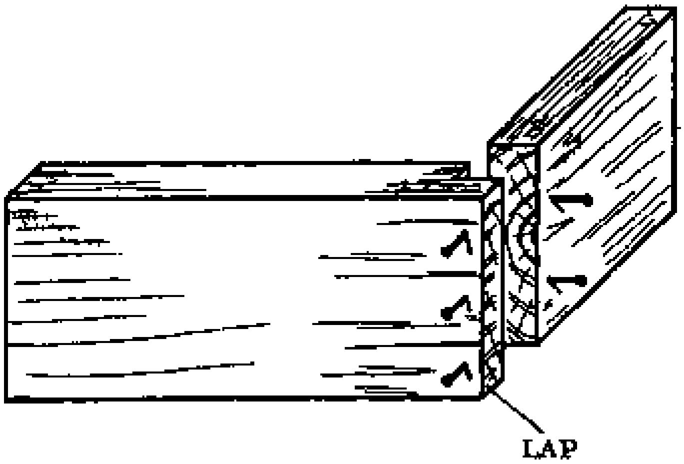

Fig. 3

The lap is the section of wood which is left projecting after the rebate is cut (Fig. 3). The lap is usually one-half of the thickness of the board. This lap will be important later when we are figuring out the length of our pieces for making a box.

The rebated butt joint is simple to construct. In the following sequence of operations we will describe how to make a simple box with this joint while also practising some techniques discussed earlier, like making a cutting list and preparing timber to size.

The tools required here will be the same ones we used for the preparation of timber; with the additions of a firmer chisel, a smoothing plane, and a backsaw. Make sure you know what these tools are and how to use them before you go on.

Sequence of operations for constructing a box with this joint

Step 1. Preparation of timber

- Make a cutting list. The end pieces can be cut to the required length, that is the outside width of the box minus the width of the two laps. Allow 3 mm extra at each end of the side pieces, for planing off after assembly (Fig. 2).

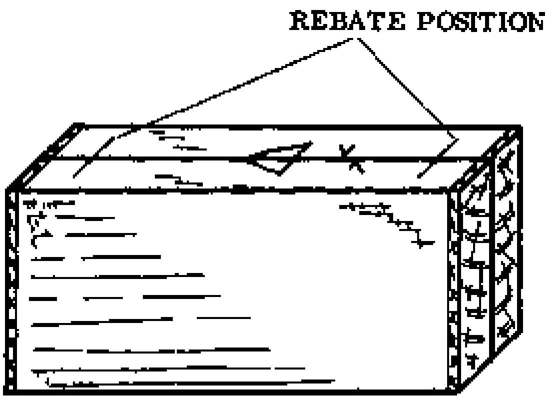

Fig. 2

- Prepare the pieces (see Preparation of Timber section, pages 84 to 86).

Step 2. Marking out

- Mark the sides and ends as shown in Fig. 1, on the face edges (Marking of frames, page 88). All further marking will be done from the sides with these marks.

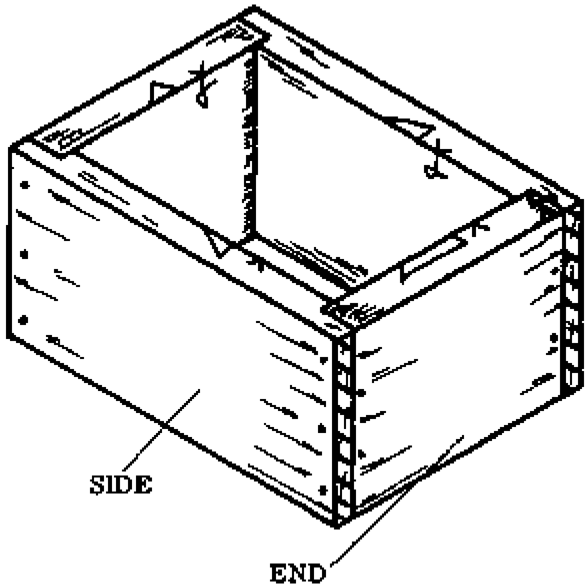

Fig. 1

- Place the two sides together and mark the position of the rebates, squaring with the try square (Fig. 2).

- Mark the shoulder lines of the rebate on the inside face of the piece, using the try square (Fig. 3).

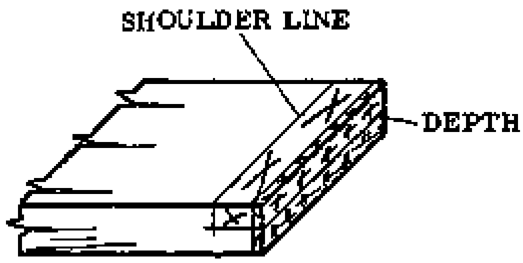

Fig. 3

- Mark the depth of the rebate on the end grain and the edge, using a marking gauge (Fig. 3). Show the waste with crosses.

Step 3. Cutting the rebate

- Saw the shoulders down to the gauge line. Cut on the waste side of the line. If the piece is very wide, nail or clamp a guide over the line to guide the saw. Use a backsaw (Fig. 4).

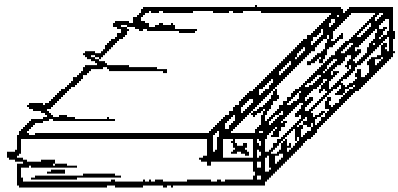

Fig. 4

- Remove the waste carefully to the gauge line with a firmer chisel (Fig. 5). Find out the direction of the grain by chiselling out small pieces first, so that you don't accidentally chisel too deep.

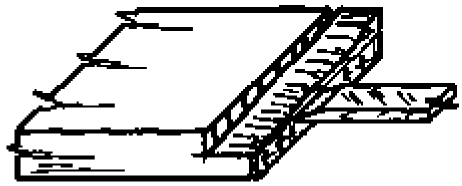

Fig. 5

Step 4. Assembling

- Clean up the inside faces with a smoothing plane (Fig. 6).

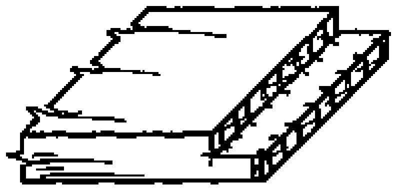

Fig. 6

- Assemble the box with glue and nails.

- Measure the diagonals to check for squareness.

- Clean up the face and bottom edges with a smoothing plane.

- Plane off the waste from the sides with the smoothing plane. Prevent splintering by working inwards from the ends (Fig. 7).

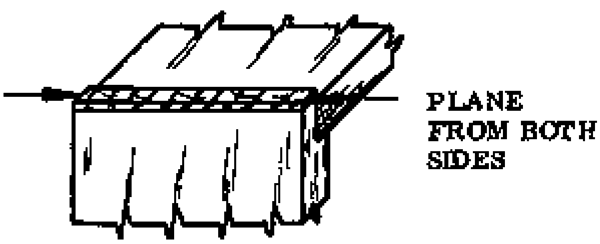

Fig. 7

NOTES:

Housed joint

These joints are another type of angle joint, also used in box-like constructions.

Housing consists of sinking the end of one piece into a trench which is cut into the face of another piece (Fig. 1).

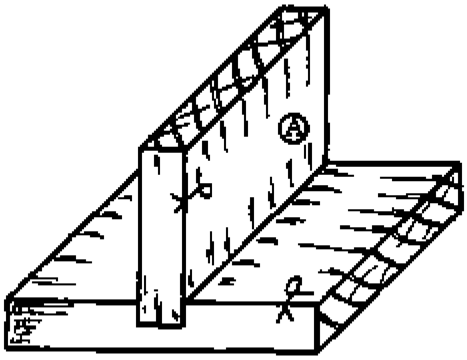

Fig. 1

The tools required for making this type of joint are the same ones used to make the rebated butt joint.

Sequence of operations for constructing the joint

Step 1. Preparation of the timber

- Make a cutting list.

- Prepare the timber (see Preparation of Timber section).

Step 2. Marking out

- Mark one edge of the trench with a try square and the other edge by using piece A as a guide (Fig. 2). (Smooth piece A before using it to mark the trench).

- Gauge the depth of the trench at each edge (Fig. 3).

- Show the waste with small crosses (Fig. 3).

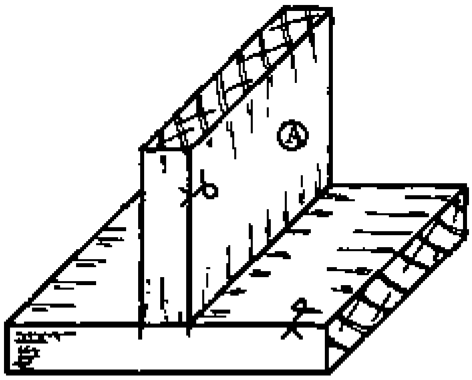

Fig. 2

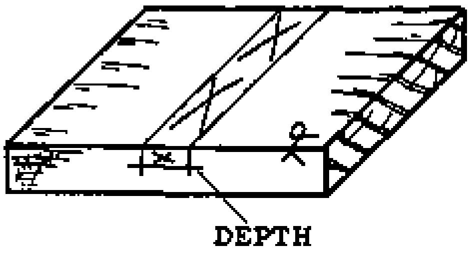

Fig. 3

Step 3. Cutting the trench

- Saw the sides of the trench (on the waste side of the lines) down to the gauge lines (Fig. 4).

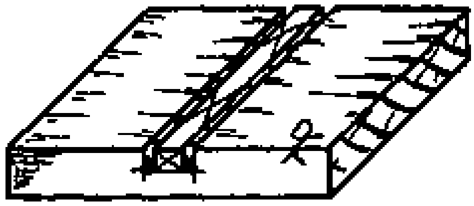

Fig. 4

- Chisel out the waste from the trench (Fig. 5).

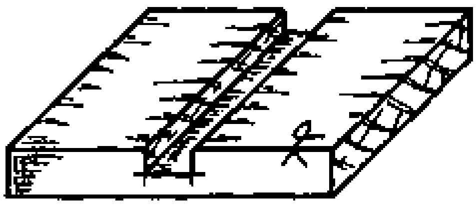

Fig. 5

Step 5. Assembling

- Assemble the two parts with nails and glue.

- Clean up the edges with a smoothing plane.

NOTES:

Common mortice and tenon joint for box-like constructions

This is one of the commonest and strongest joints. The two parts are (Fig. 1): the tenon (B) which is a projection on the end of one part and the mortice (A), the hole in the other part into which the tenon fits. The tenon is usually 1/3rd of the width of the board.

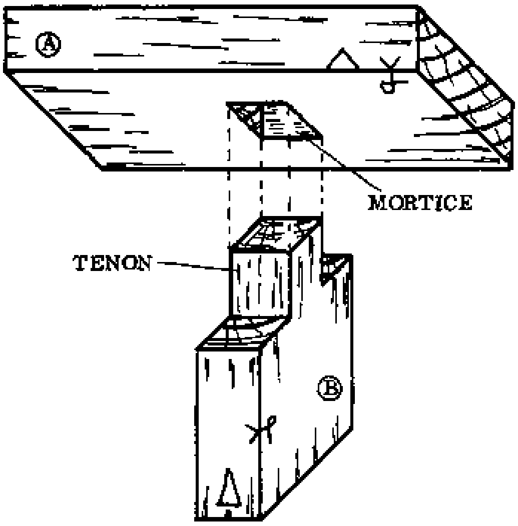

Fig. 1

The tools we need are ones we have discussed before, plus a mortice chisel, a brace and drilling bits.

Sequence of operations for constructing the joint

Step 1. Preparation of timber

- Make a cutting list.

- Prepare the timber to the required sizes. (In the following steps, the piece with the mortice is “piece A” and the one with the tenon is “piece B”.)

Step 2. Marking out

- Mark out the length of the tenon on piece B. Allow 3 mm waste in the length and make square lines all around with a try square and pencil (Fig. 2).

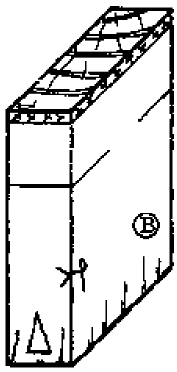

Fig. 2

- Take piece A and mark out the position of the mortice on the face edge and make square lines on the edges on both sides with the try square (Fig. 3).

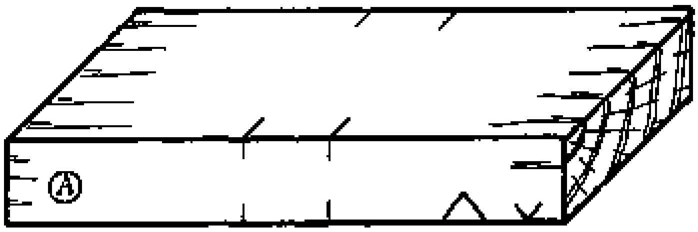

Fig. 3

- Set the marking gauge to the width of the tenon and mark the lines around piece B at the width. Mark the waste with small crosses (Fig. 4).

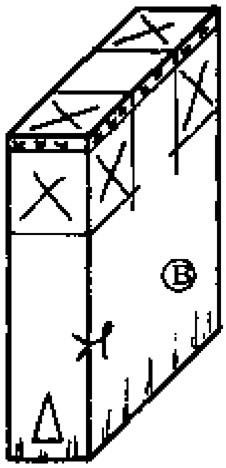

Fig. 4

- Use the same setting to mark both faces of piece A and use a try square and (already smoothed) piece B to mark the remaining two lines for the width of the mortice (Fig. 5). Mark the waste with a small cross.

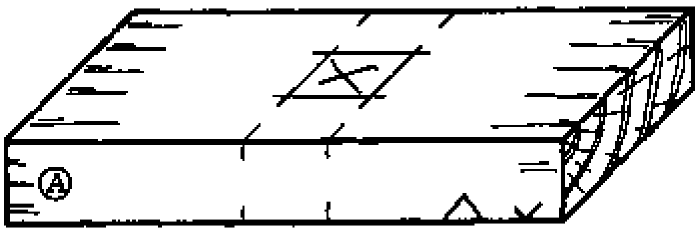

Fig. 5

If the marking gauge has two pins, set each at its correct measurement and mark both lines at once. If not, mark with the first setting on all the members, then change the setting and mark the other measurement on all the members.

- Always mark from the face edge. Check the marking by setting piece B against the marks on piece A to see if they fit. Piece B must be smoothed first.

NOTES:

Step 3. Cutting the mortice

- Bore out most of the waste, using a brace and bit (Fig. 6). Clamp a piece of wood to the underside to prevent splintering and damage to the bench.

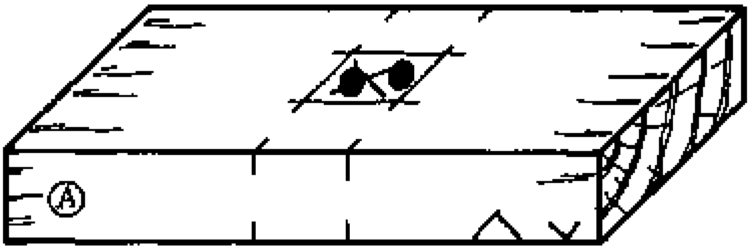

Fig. 6

- Chop out the remaining waste with a mortice chisel, chiselling halfway through from both sides. Leave about 2 mm extra waste on all sides to prevent damage to the sides. Keep the cutting edge of the chisel across the grain.

- Carefully chop out the rest of the mortice up to the lines (Fig. 7). Keep the bevel of the chisel towards the inside of the mortice. Do not use the mallet.

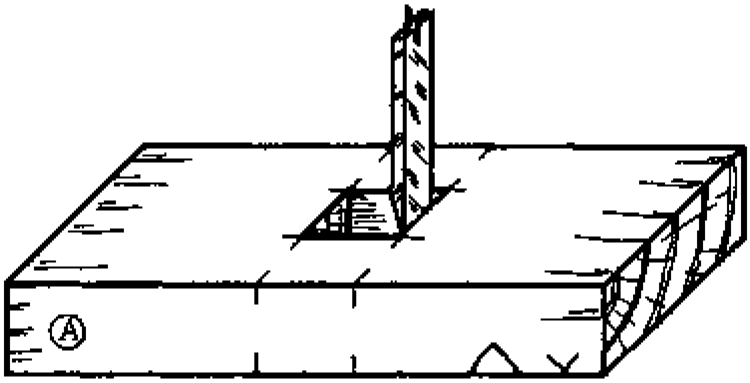

Fig. 7

Step 4. Cutting the tenon

- Rip the sides of the tenon, sawing on the waste side of the line (Fig. 8). Cut in stages as shown in (Fig. 11, a, b, c, & d).

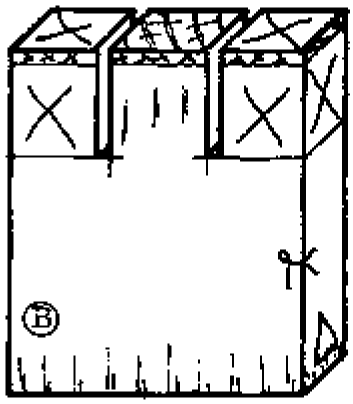

Fig. 8

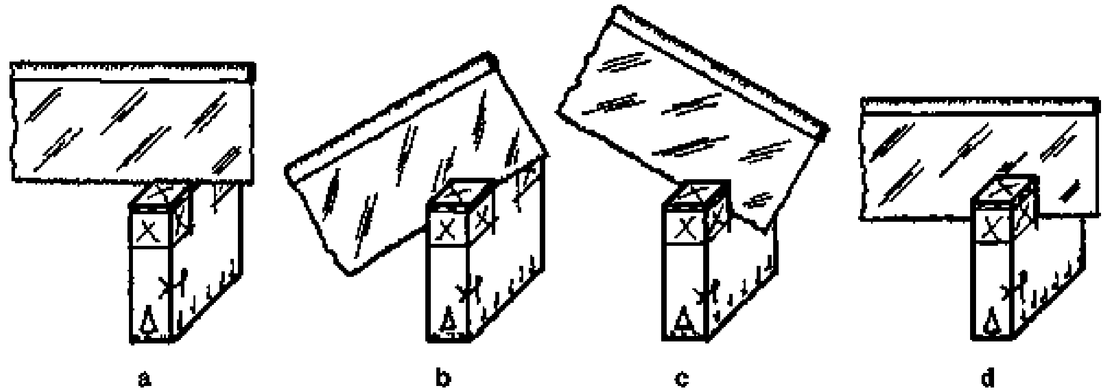

Fig. 11

- Carefully saw the shoulders, making sure to hold the saw straight. Keep on the waste side of the line (Figs. 9 & 10).

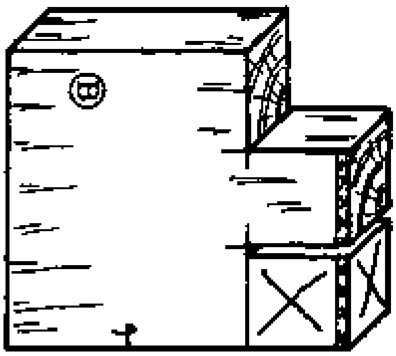

Fig. 9

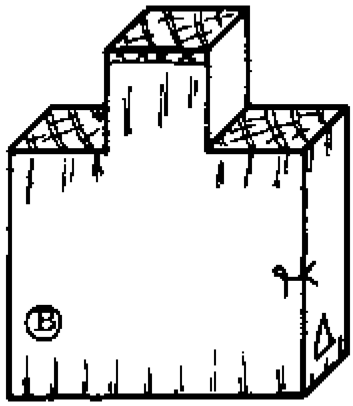

Fig. 10

Step 5. Assembling the joint

- Check the fit of the members. The tenon should fit tightly into the mortice without splitting the morticed piece. There should be no gap between the shoulders of the tenon and the morticed member. Don’t force the members together. If they don’t fit, find the problem and correct it.

- Clean up the inside of the joint where it can’t be reached after assembly with a smoothing plane. (Remember that the tenon should be smoothed before using it to mark out.)

- Assemble the joint.

- Plane off the waste end of the tenon, clean up all sides and edges with the smoothing plane.

NOTES:

__Cornerlocked joint__

The cornerlocked joint is similar to the mortice and tenon joint. It is an angle joint with a series of tenons on one member which correspond to slots on the other member (Fig. 1). The resulting joint is strong because it can be nailed from two sides, and the interlocking tenons and slots also help hold the pieces together.

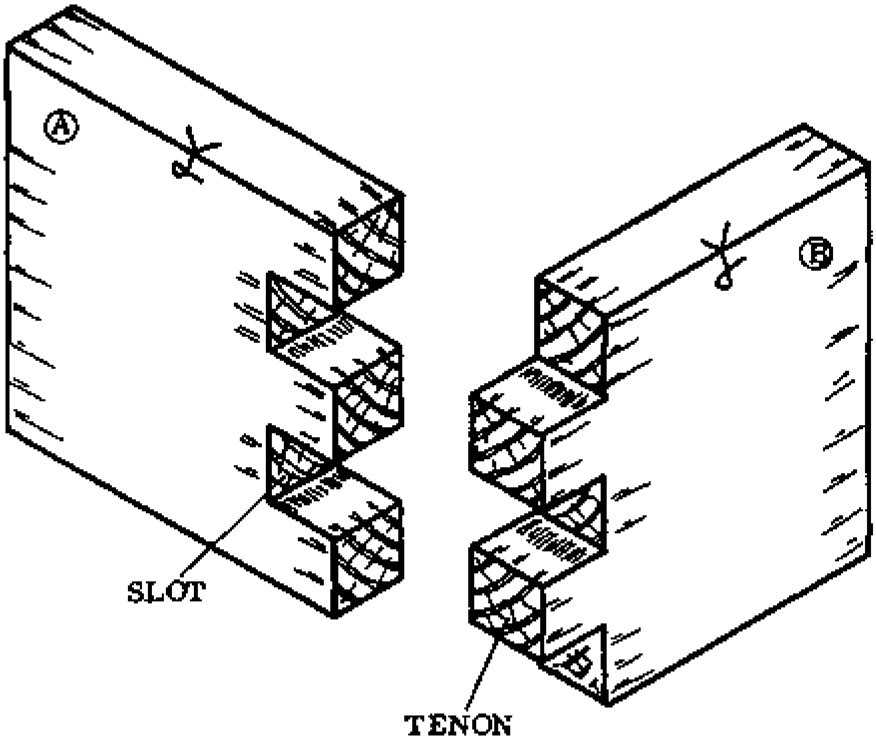

Fig. 1

The tools required to make this joint are the same ones used for the mortice and tenon joint.

__Sequence of operations for constructing the joint__

Step 1. Preparation of the timber

- Make a cutting list.

- Prepare the timber to the required sizes. (In the following steps, the member with the slots is piece “A” and the one which has the tenons is piece “B”.)

- If the members are to be used for a box where the external appearance is important, the face sides should be outside.

- In most cases the face edges are kept upwards.

Step 2. Marking out

- Mark out the position of the tenons and slots by gauging or squaring lines at the corners on the ends of the pieces: on piece A the depth should be equal to the thickness of piece B (Fig. 2); while on piece B the depth should be equal to the thickness of piece A (Fig. 3). Allow 2 mm waste for cleaning up after assembly.

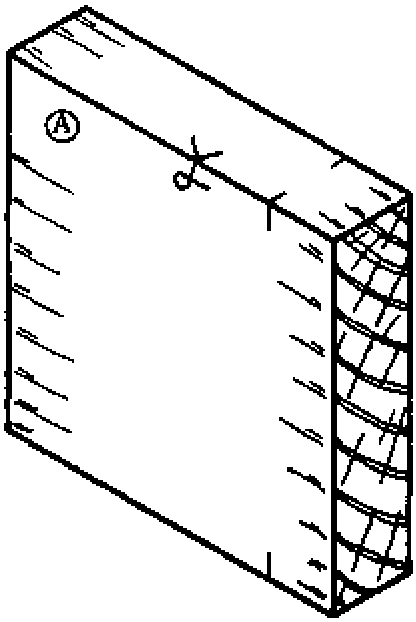

Fig. 2

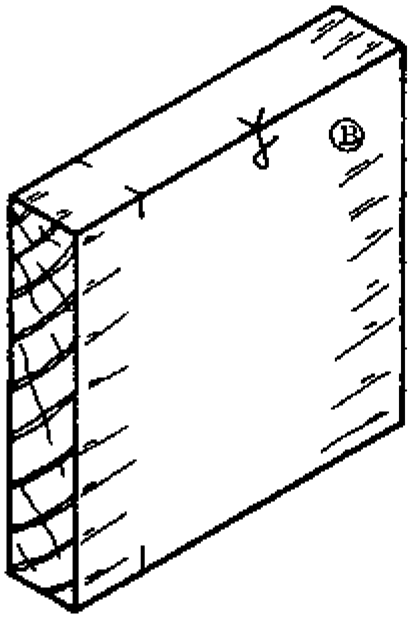

Fig. 3

- Mark out the shape of the tenons on piece B. Keep all tenons the same size (Fig. 4).

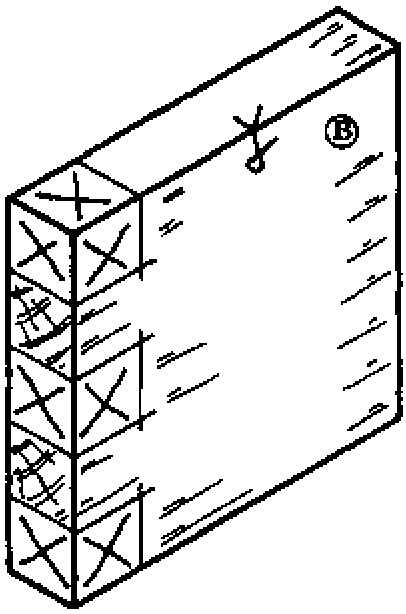

Fig. 4

- Immediately mark the waste between the tenons with crosses (Fig. 4).

NOTES:

Step 3. Cutting the tenons

- Rip the sides of the tenons down to the gauge line (Fig. 5). Saw on the waste side of the line.

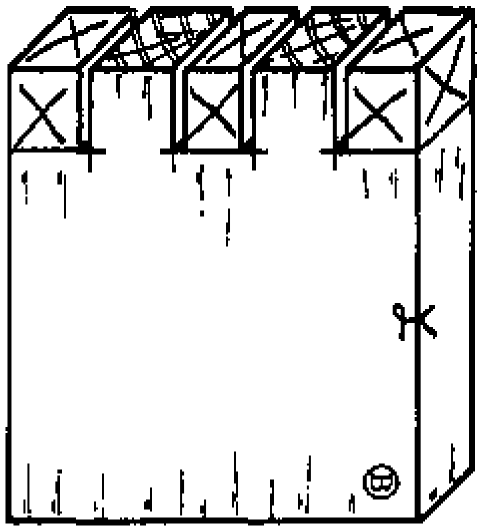

Fig. 5

- Chop out the waste by chiselling alternately vertically and then at an angle, making “V” cuts halfway through from each side (Figs. 6, 7, & 8).

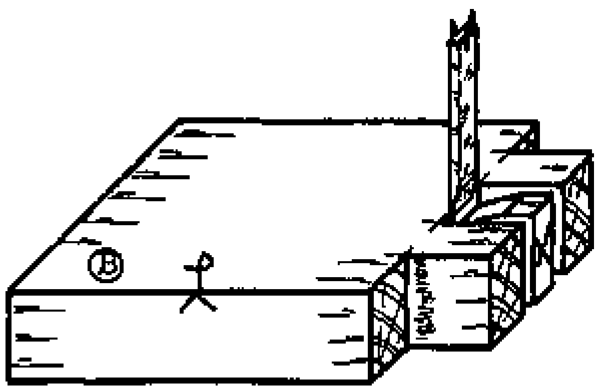

Fig. 6

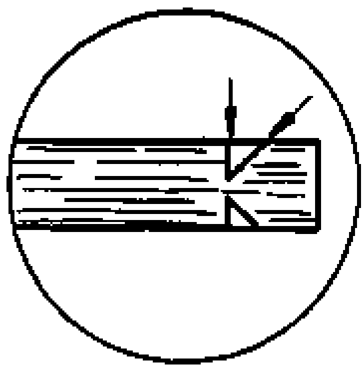

Fig. 7

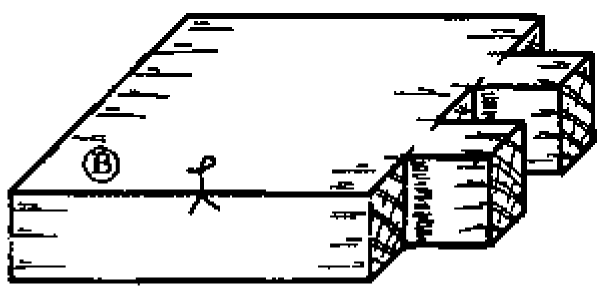

Fig. 8

Step 4. Cutting the slots

- Place piece B (with the tenons) over the end of piece A, with the face side to wards the outside as indicated in Fig. 9.

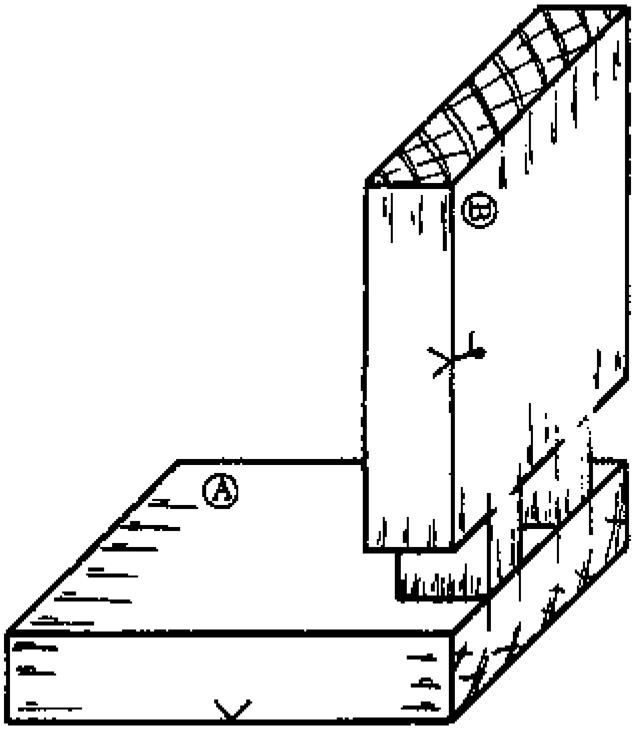

Fig. 9

- Mark the shape of the tenons onto piece A with a pencil (Fig. 9).

- Square the sides of the slots down both sides (Fig. 10).

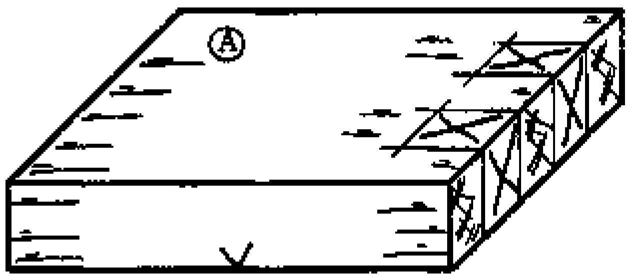

Fig. 10

- Mark the waste with small crosses (Fig. 10).

- Rip the sides of the slots, sawing on the waste side of the line.

- Chop out the waste from the slots, chiselling from both sides as explained in the previous step (Fig. 11).

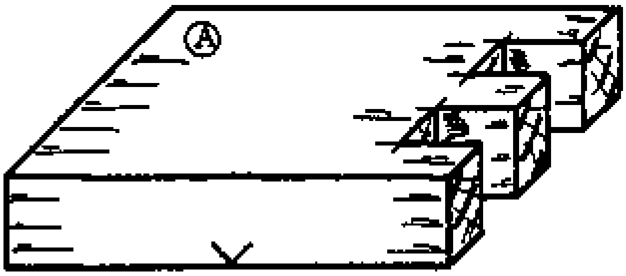

Fig. 11

Step 5. Assembling the joint

- Clean up the inside faces of the joint.

- Assemble the joint with glue and nails.

- When the glue is dry, clean up the waste of the tenons and slots with a smoothing plane. Make sure the nails are punched well below the surface to prevent damage to the sole of the plane.

- Clean up the outside faces and edges with a smoothing plane.

NOTES:

FRAMING JOINTS

Framing joints are those used in frame-like constructions. The members are usually constructed with their edges at right angles to each other; in contrast to the angle joints used in box-like constructions, where it is the sides which form the right angle (previous pages).

Halved joints

Halved joints are one type of framing joint. The name is applied to joints where the pieces of timber which meet or cross each other are halved; that is, at the place where they cross, each piece is 1/2 the thickness of the rest of the piece. The result is that in the assembled joint, the surfaces of both pieces are flush.

Halved joints are used for constructing simple frames.

In Rural Building, we deal with four different kinds of halved joints. Here we will cover the description and construction of the "tee-halved joint", since the construction of the other joints follows much the same procedures.

The tee-halved joint consists of a pin (a) on the end of one piece which fits into a socket (b) in the other piece (Fig. 1).

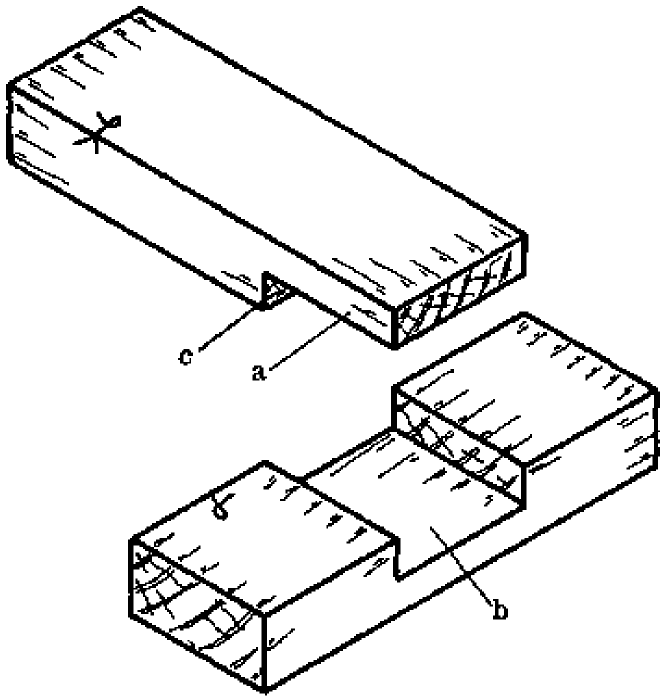

Fig. 1

The pin is half the thickness of the timber, and the depth of the socket equals the thickness of the pin. The shoulder of the pin (c) fits against the face edge of the socket (Fig. 1).

The tools required to make this joint are the same ones we used to make the mortice and tenon joint in the last chapter.

Sequence of operations for constructing the joint

Step 1. Preparation of timber

- Make a cutting list.

- Prepare the pieces to the required size.

Step 2. Marking out

- Mark the length of the pin by placing the socket piece on top of it and marking at the width. A small amount of waste can be left on the end of the pin, to be planed off after the joint is assembled.

- Make lines square at the shoulder of the pin, drawing them across the side and halfway down the edges, with a try square and pencil (Fig. 2). Mark the waste.

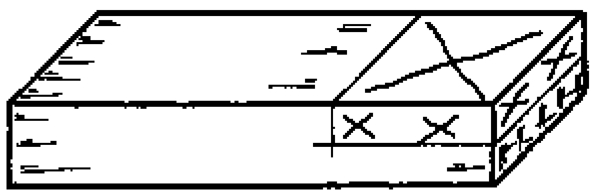

Fig. 2

- Mark the position of the socket, using the piece with the pin as a guide. Smooth the pin before using it to mark the socket.

- Square the lines across the side and halfway down the edges with a try square. Mark the waste (Fig. 3, previous page).

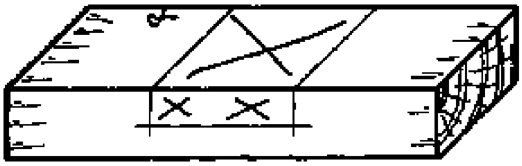

Fig. 3

- Gauge the thickness of the pin around its edges and mark the waste (Fig. 2, previous page).

- With the same setting, gauge the depth of the socket on both edges and mark the waste (Fig. 3, previous page).

- Both pin and socket should be gauged from the face side.

- Place the pin over the position of the socket and check the fitting (Fig. 4, previous page).

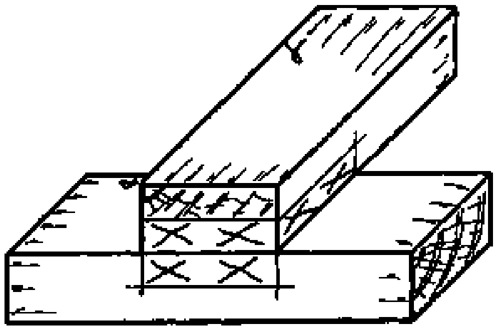

Fig. 4

Step 3. Cutting the pin

- Rip the thickness of the pin. Cut in stages as shown in Fig. 5, a through d. Take care to keep on the waste side of the line.

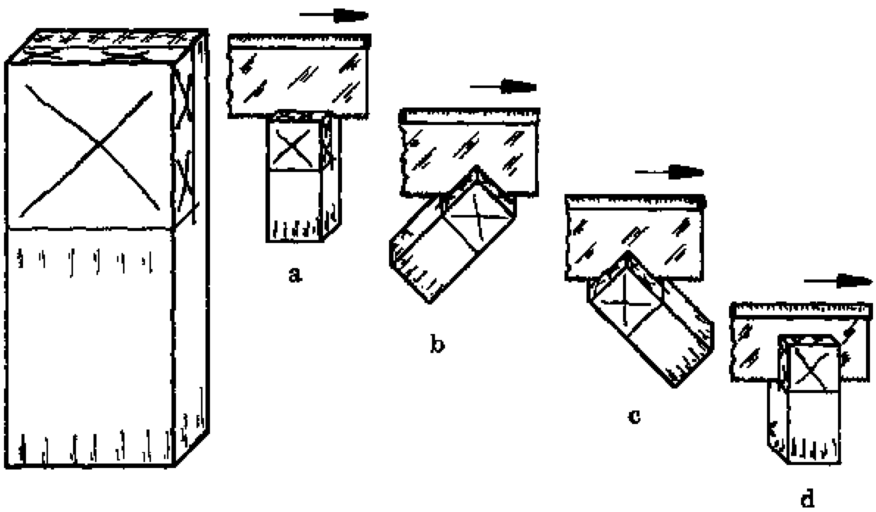

Fig. 5

- Saw the shoulder of the pin, keeping on the waste side of the line (Fig. 6).

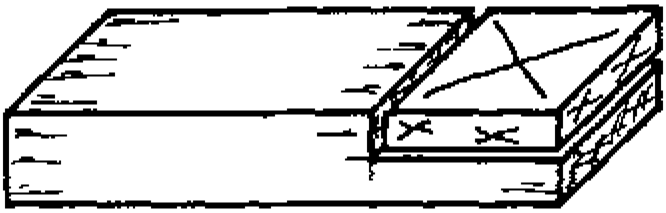

Fig. 6

Step 4. Cutting the socket

- Saw down to the gauge lines of the socket, keeping on the waste side of the lines (Fig. 7).

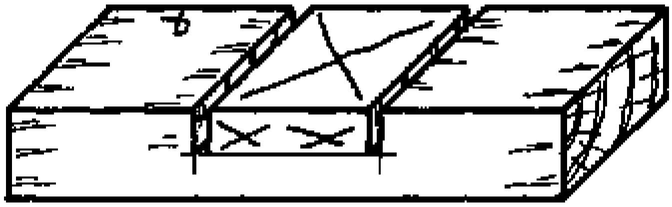

Fig. 7

- Chisel out the waste, chiselling halfway through from both edges (Figs. 8 & 9).

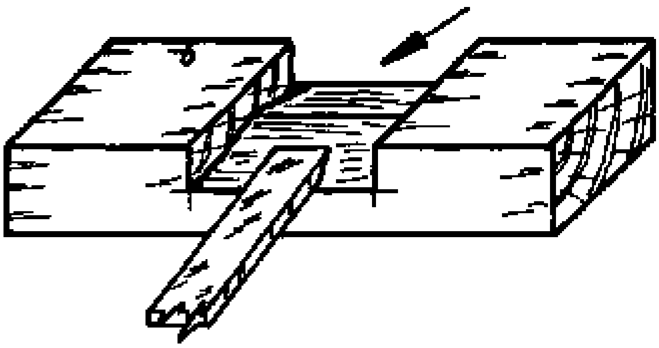

Fig. 8

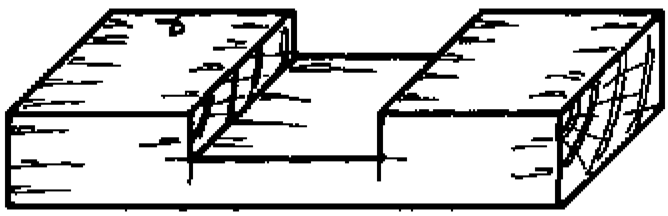

Fig. 9

- Test the flatness of the socket with the blade of the try square.

Step 5. Assembling the joint

- Clean up the inside edges with a smoothing plane.

- Assemble the joint with glue and nails.

- When the joint is dry, plane off the waste of the pin.

- Clean up all sides and edges with the smoothing plane.

NOTES:

Corner-halved joint

Another halved joint is the corner-halved joint (Fig. 1). It is used where the pieces meet at their ends to form a corner.

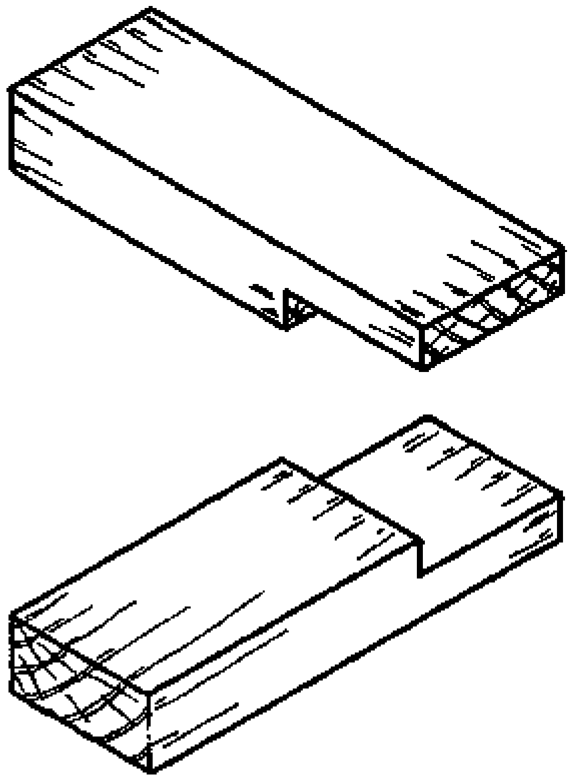

Fig. 1

The sequence of operations to construct this joint is similar to the one for the tee-halved joint, except that instead of a pin and a socket, two pins have to be marked and cut.

Cross-halved joint

The third halved joint we deal with is the cross-halved joint (Fig. 2). It is used where two members cross each other.

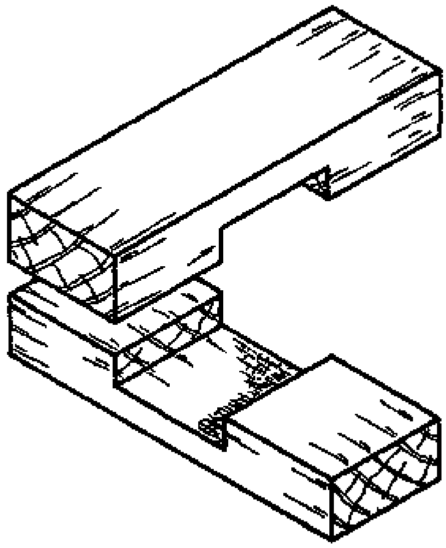

Fig. 2

The sequence of operations to construct this joint is similar to the tee-halved joint, but instead of a pin and a socket, two sockets have to be marked and cut.

Stopped tee-halved joint

In this joint the socket is stopped away from the edge and the pin is cut short, so that in the assembled joint the end grain of the piece is not seen (Fig. 3).

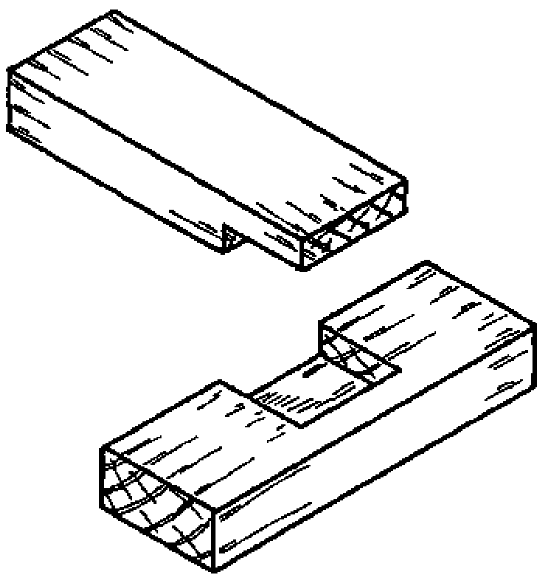

Fig. 3

Otherwise, the same sequence is followed as for the tee-halved joint.

NOTES:

__Common mortice and tenon joint for frame-like constructions__

One of the most common and strongest forms of framing joint is the mortice and tenon joint (Fig. 1).

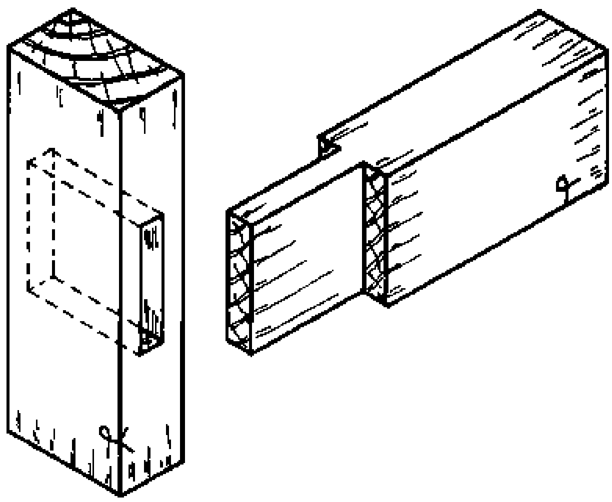

Fig. 1

The sequence of operations to construct a mortice and tenon joint for frame-like constructions is almost the same as for box-like constructions. Of the four types of mortice and tenon joints mentioned in this chapter, we will only go into detail about the construction of one of them, the common mortice and tenon. No new tools will be needed.

__Sequence of operations for constructing the joint__

Step 1. Preparation of timber

- Make a cutting list.

- Prepare the timber.

Step 2. Marking out

- Mark out the position of the mortice and square the lines across the face side and edges, using a try square and pencil (Fig. 2).

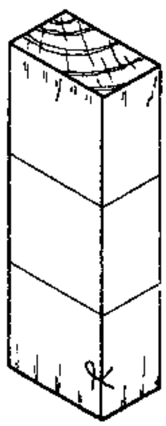

Fig. 2

- Mark out the length of the tenon on the other member. Allow 3 mm waste on the end.

- Square lines all around (Fig. 3).

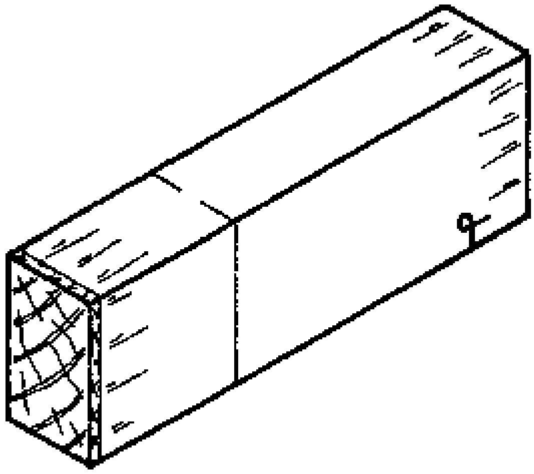

Fig. 3

- Set a marking gauge to the size of the tenon (one-third of the width of the piece) and mark around the end of the tenon (Fig. 5). Mark the waste.

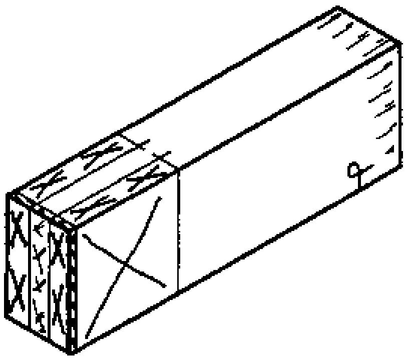

Fig. 5

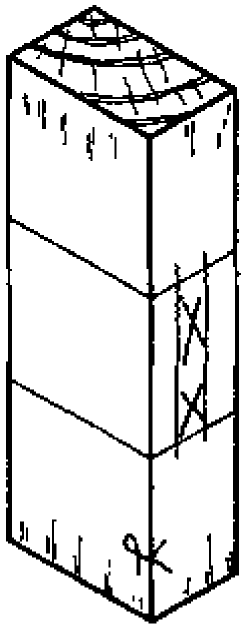

Fig. 4

- Use the same setting to mark both edges of the mortice and mark the waste (Fig. 4).

- Do all marking from the face side.

- Check the marking, using the pieces as a guide by placing them over the marks (compare this sequence to the mortice and tenon for box-like constructions, page 104).

NOTES:

Step 3. Cutting the mortice

- Most of the waste may be bored out (Fig. 6). Bore halfway through from both edges. Make sure you keep the brace at a 90 degree angle to the edge.

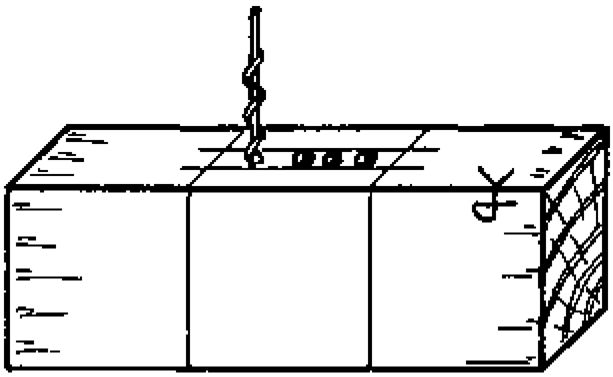

Fig. 6

- Chop out the remaining waste, chiselling halfway through from both edges. Leave about 2 mm extra to prevent damage to the sides of the mortice during chiselling (Fig. 7).

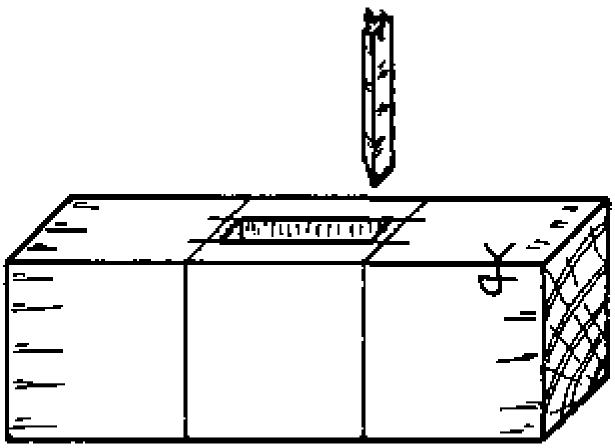

Fig. 7

- When most of the waste is out, chisel out the remainder to the line (Fig. 8).

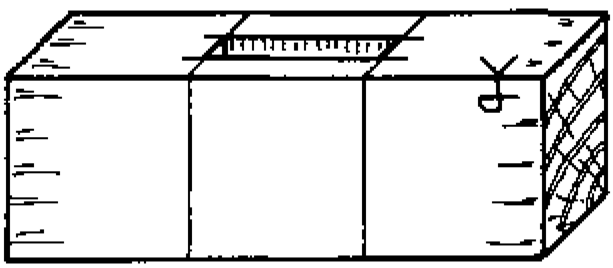

Fig. 8

- Keep the cutting edge of the chisel across the grain.

Step 4. Cutting the tenon

- Rip the sides of the tenon, sawing on the waste side of the lines (Fig. 9).

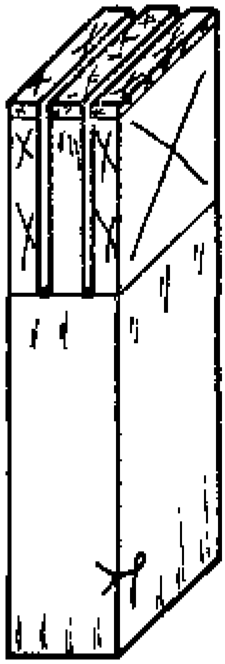

Fig. 9

- Saw in steps (see tee-halved joint).

- Carefully saw the shoulders, keeping the saw vertical and on the waste side of the line (Fig. 10 & 11).

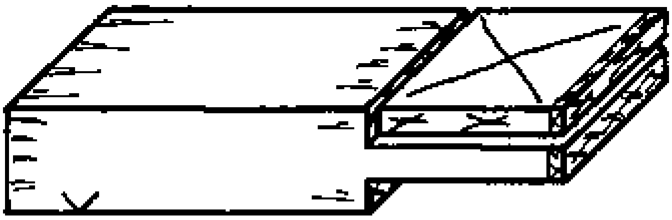

Fig. 10

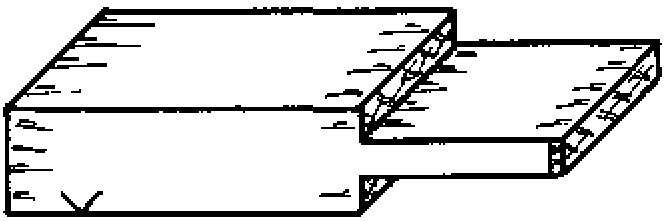

Fig. 11

Step 5. Assembling the joint

- Check whether the members fit together (see Assembly section for the mortice and tenon joint for box-like constructions).

- Clean up inside the joint where it cannot be reached after assembly.

- Assemble the joint with glue.

- When it is dry, plane off the waste of the tenon.

- Clean up the edges and sides with a smoothing plane.

Note the importance of marking the waste as you mark out the pieces. This cannot be over-emphasized. Most construction mistakes are made by cutting on the wrong side of the line, due to improper marking.

NOTES:

Haunched mortice and tenon joint

Another type of mortice and tenon for frame-like constructions is the haunched mortice and tenon (Fig. 1). This joint is used where one member meets another at a corner.

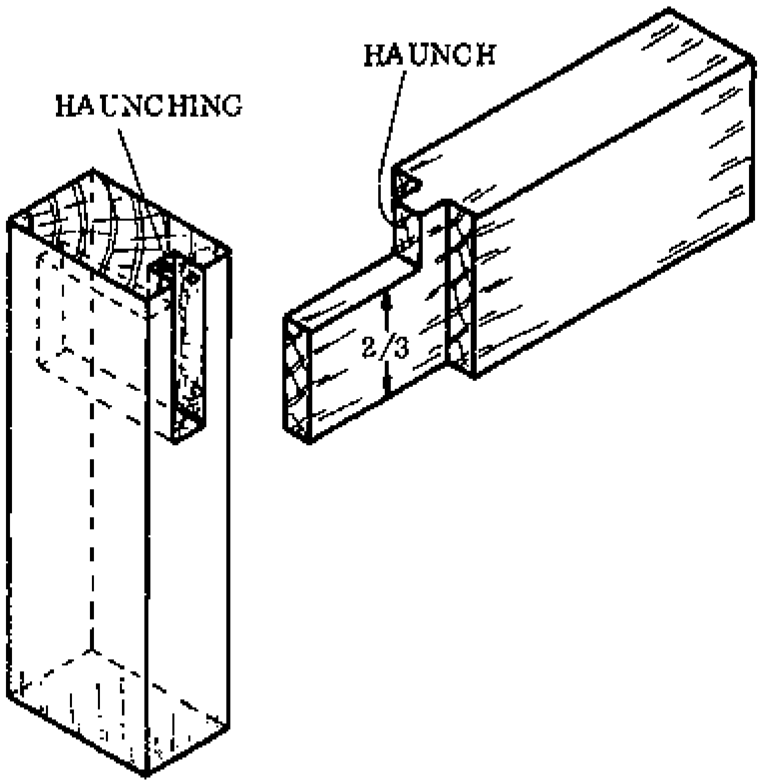

Fig. 1

The width of the tenon is reduced to 2/3rd of the width of the board and the mortice size is reduced to suit (Fig. 1).

A haunch is left on the tenon to prevent it from twisting in the mortice. The length of the haunch is equal to the thickness of the tenon and it fits into a recess above the mortice, called the haunching.

Otherwise, the sequence of operations for construction of this kind of joint is the same as for the common mortice and tenon joint.

When you make the cutting list for this type of joint, the allowance in length for the member with the mortice should be 25 mm instead of 12 mm to help prevent splitting of the haunching (see Cutting List, page 90).

Stub tenon joint

Where the end grain of the tenon and the opening of the mortice must be hidden, the stub tenon joint is chosen (Fig. 2). In this joint the tenon does not pass through the morticed member, but is stopped inside. The sequence of operations for constructing this joint is the same as for the common mortice and tenon joint. Stub tenons are also used for box-like constructions.

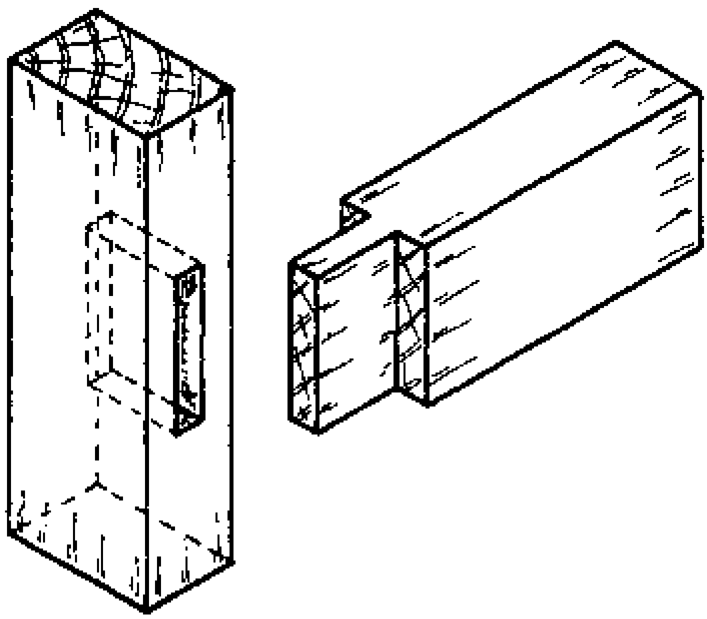

Fig. 2

At times a combination of the haunched and stub tenons is required. This is called a haunched stub mortice and tenon joint.

Twin tenon joint

Where the members to be joined are very thick, twin tenons are used (Fig. 3). Each tenon is then not 1/3rd, but 1/5th of the thickness of the members.

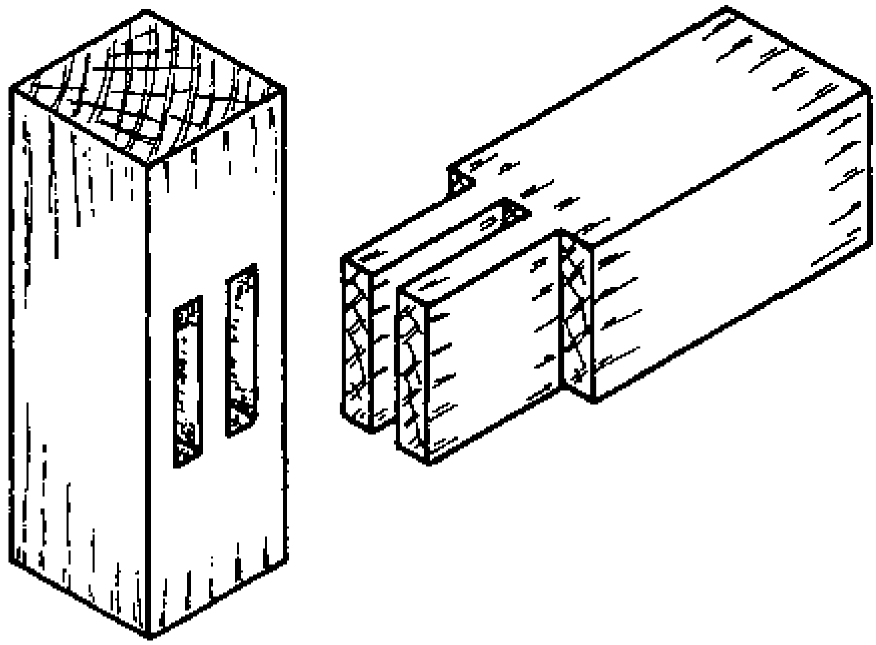

Fig. 3

The sequence of operations is almost the same as for the common mortice and tenon joint, with the only difference being that two mortices and tenons have to be marked and cut instead of only one.

This joint can be used for both frame-like and box-like constructions.

NOTES:

Securing the joints

Instead of nails to secure mortice and tenon joints, either pegs or wedges can be used.

One or two holes are drilled through the assembled joint and wooden dowels, or pegs, as they are called in this case, are inserted with glue to securely fix the joint (Fig. 1).

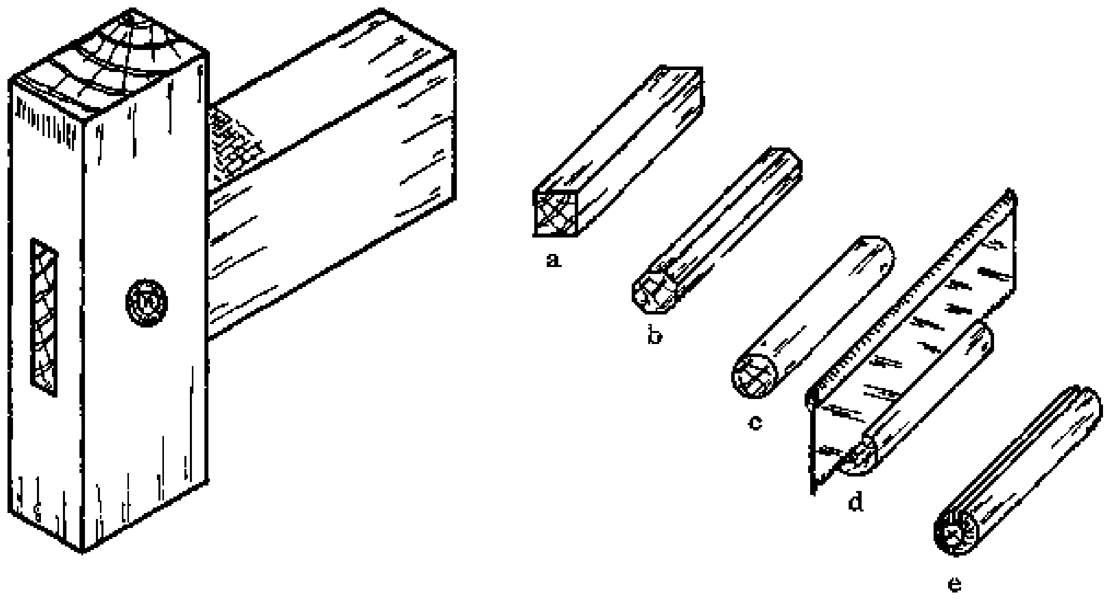

Fig. 1

- To make the dowels, plane off the corners of a square piece of hard wood, until the piece is round. When the dowel is cut to length, chamfer the ends and cut a groove along the length to permit air and excess glue to escape (Fig. 1, a - e).

Follow the steps below to secure a joint by means of wedges.

- Cut the mortice with an allowance of 2 mm in width, tapering from the outside edge to about 2/3rd of its depth (Fig. 2).

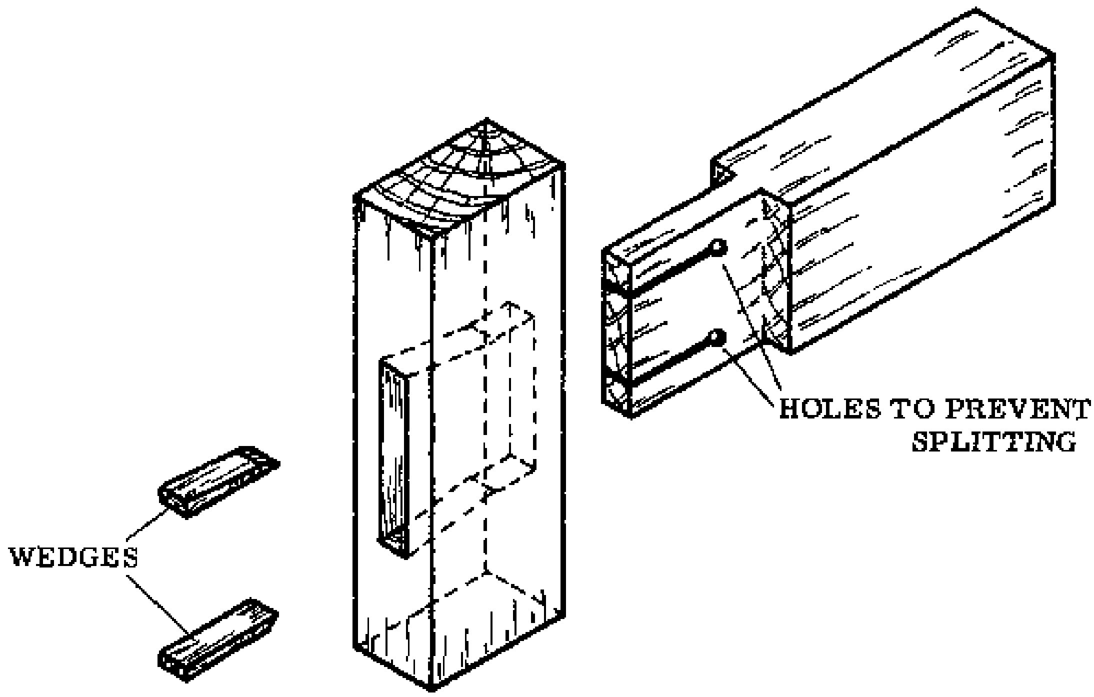

Fig. 2

- Make cuts in the tenon to receive the wedges.

- To prevent splitting of the tenon, drill small holes at the end of each cut.

- Cut the wedges from small pieces of waste wood; they should have the same length as the tenon.

Haunched mortice and tenon joints in frame-like constructions should not be wedged, because of the danger of breaking off the small haunch at the corner of the joint.

Both wedges and pegs can be used for securing mortice and tenon joints in box-like constructions.

NOTES:

Bridle joint

Bridle joints are similar to mortice and tenon joints. They consist of a pin and a socket (Fig. 1). The thickness of the pin is 1/3rd of the thickness of the member.

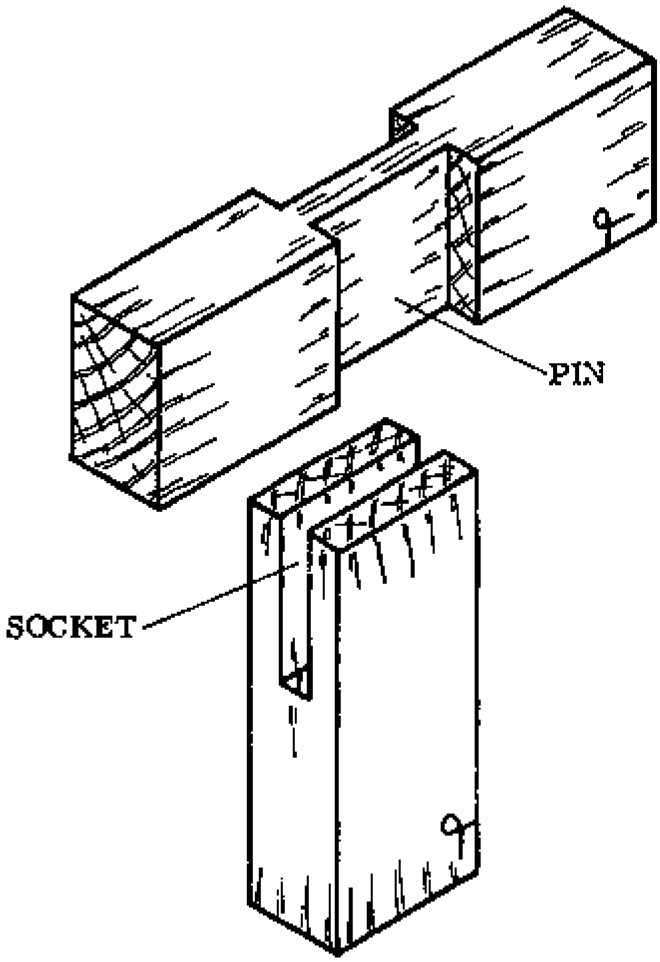

Fig. 1

The two types of bridle joint are the tee bridle (Fig. 1) and the corner bridle.

Here we will only go into detail about the tee bridle, since the construction of the corner bridle joint follows much the same procedure. .

Sequence of operations for constructing the joint

Step 1. Preparation of the timber

- Make a cutting list.

- Prepare the timber.

Step 2. Marking out

- Mark the position of the pin on one member, making the distance between the shoulders equal to the width of the other piece. Square the lines all around the piece with a try square and pencil (Fig. 2).

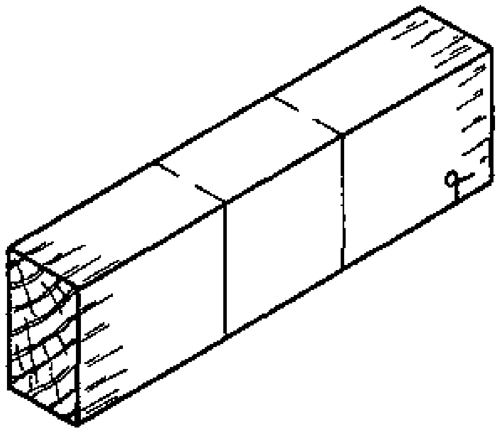

Fig. 2

- Mark the length of the socket (plus 2 mm waste) on the end of the other member, making the length equal to the width of the pin. Square the lines across the face side and on both edges (Fig. 3). Remember to smooth the pieces before using them to mark.

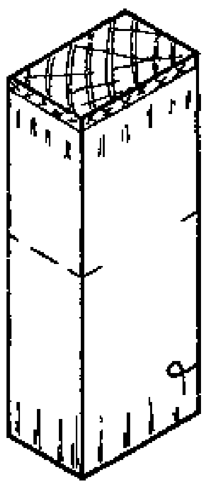

Fig. 3

- Set a marking gauge to 1/3rd of the thickness of the member and gauge along both edges of the pin. Use the gauge from the face side only. Mark the waste with small crosses (Fig. 4).

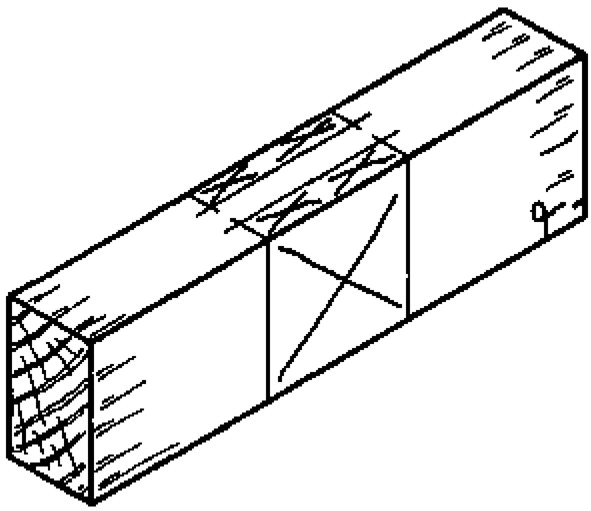

Fig. 4

- With the same setting on the gauge, mark around the end of the socket. Mark the waste (Fig. 5).

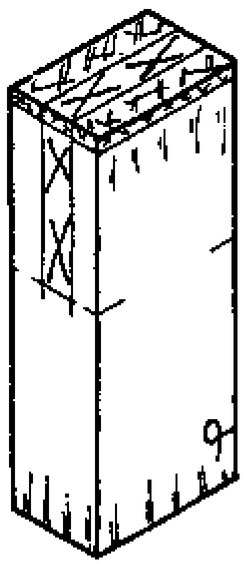

Fig. 5

- Mark the other side of the socket in the same manner, from the face side, with the gauge set at 2/3rds of the thickness of the piece. If you have a gauge with 2 pins, mark both lines at once.

- Check the fitting.

NOTES:

Step 3. Cutting the pin

- Carefully saw the shoulders down to the gauge line, sawing on the waste side of the line (Fig. 6).

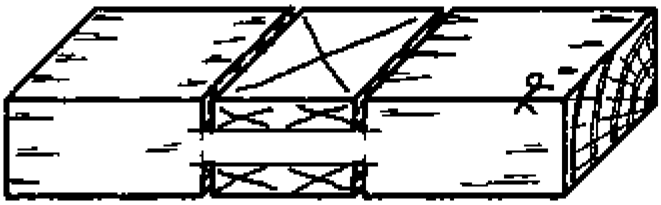

Fig. 6

- Chisel away the waste, chiselling halfway through from both edges (Fig. 7).

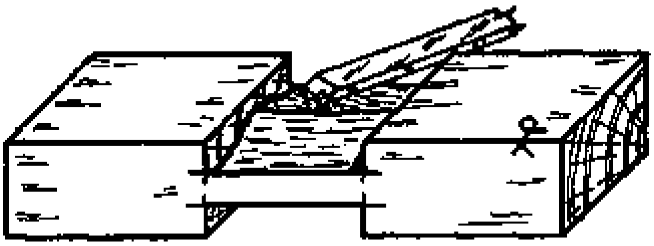

Fig. 7

Step 4. Cutting the socket

- Rip the sides of the socket down to the required depth, sawing on the waste side of the lines (Fig. 9). Saw in steps (see Tee-halved joint, Cutting the pin, page 114).

Fig. 8

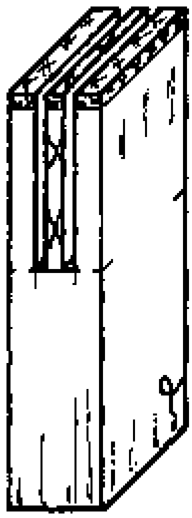

Fig. 9

- Chop out the waste with a mortice chisel, chiselling halfway through from both edges (Figs. 10 & 11).

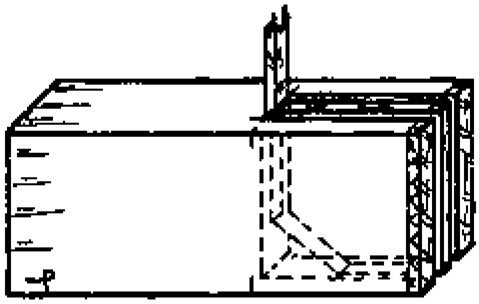

Fig. 10

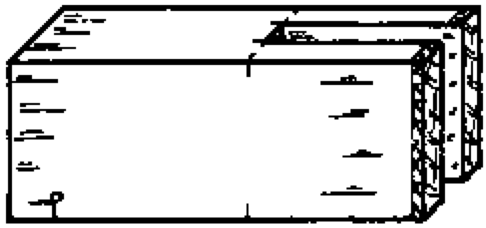

Fig. 11

Step 5. Assembling the joint

- Clean up the inside edges which cannot be reached after the joint is assembled.

- Assemble the joint with glue and nails.

- When the glue is dry, plane off the waste of the socket.

- Clean up the sides and edges with a smoothing plane.

Corner bridle joint

The corner bridle joint is used where members meet to form the corner of a frame. Like the tee bridle, it consists of a pin and a socket (Fig. 12).

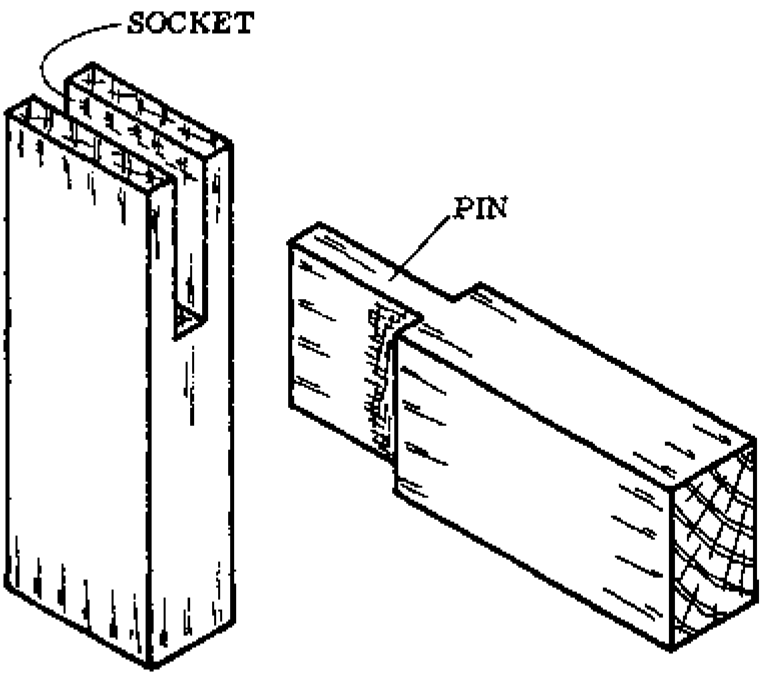

Fig. 12

The pin is constructed like the tenon in the sequence of operations for the mortice and tenon joint for frame-like constructions, pages 118 to 120.

The socket is constructed in the same way as the socket for the tee bridle joint, above.

NOTES:

WIDENING JOINTS

Widening joints are joints used to make a single, wide board by joining two or more narrow boards along their length, edge to edge (Fig. 1).

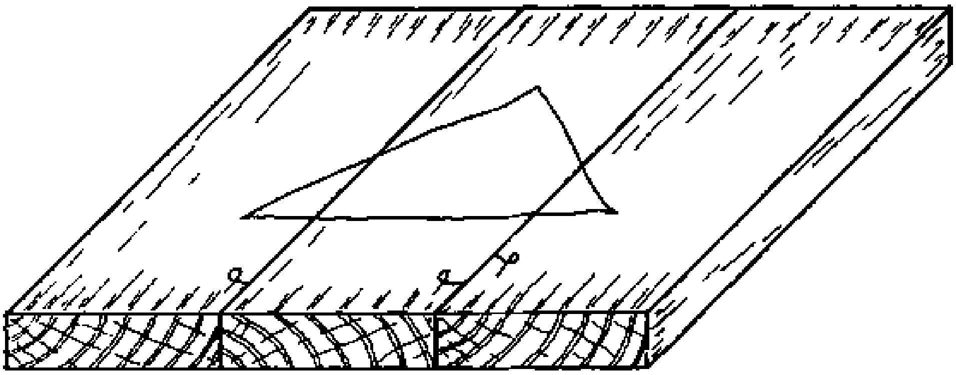

Fig. 1

The boards that will be joined must first be marked. Lay the boards out in the desired position and mark them with a triangular mark over all the boards (Fig. 1). The triangle should point upwards. This mark will help us to keep in mind the position of each board during the steps that follow.

Plain glued butt joint

This is the simplest widening joint (Fig. 2). The edges of the boards are planed perfectly straight and square, and then butted together. The joint is glued and clamped tightly to force out the surplus glue. For narrow pieces this is done with G-clamps. For wider pieces, wooden or metal sash clamps are used.

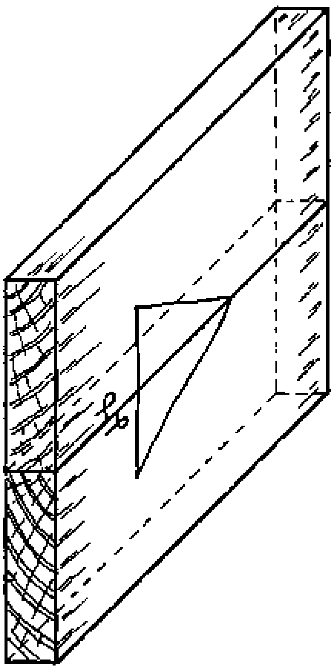

Fig. 2

Dowelled widening joint

This joint is similar to the plain glued butt joint, but strength is added by means of cylindrical wooden pins, called dowels. Dowels are made as explained in the section on securing joints. The dowels are then glued into holes in the edge of each board (Fig. 3). The diameter of the dowels should be about one-third of the thickness of the pieces that are being joined.

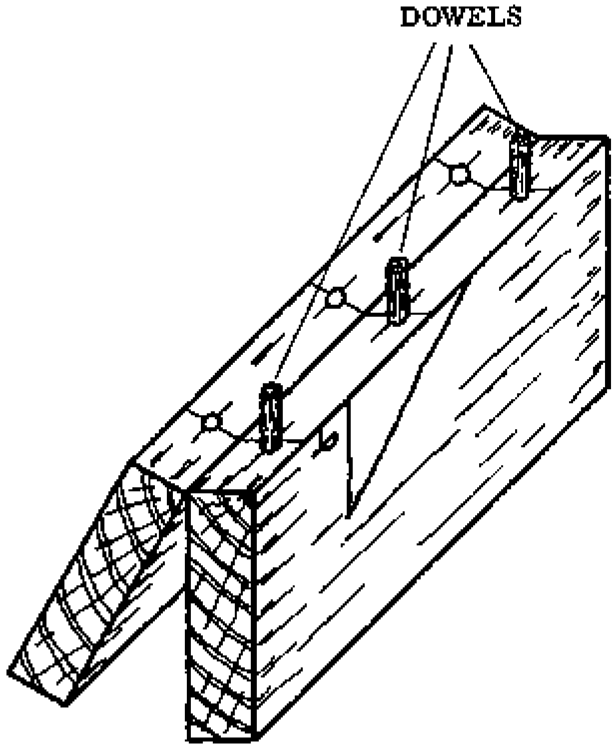

Fig. 3

The holes should be about as deep as the boards are thick, and they should be slightly countersunk (see Fastening with Screws, page 96).

Mark out the position of the dowels by putting the boards on top of each other, sides together and marking both edges at the same time. The centre can be marked with a marking gauge, marking from the face side.

Metal or wooden sash clamps are used to press the boards together during glueing.

NOTES:

Rebated joint

In this widening joint, the edges of the boards are rebated to match each other (Fig. 1). The rebating is done with either an ordinary rebate plane or an adjustable one. This joint is stronger than the plain glued butt joint.

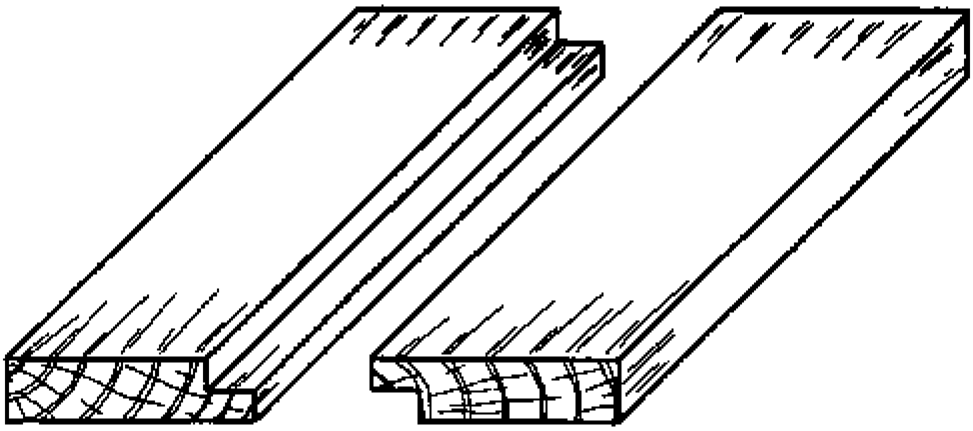

Fig. 1

How to plane a rebate with an ordinary rebate plane

Step 1.

- Mark the depth and width of the rebate with a marking gauge (Fig. 2).

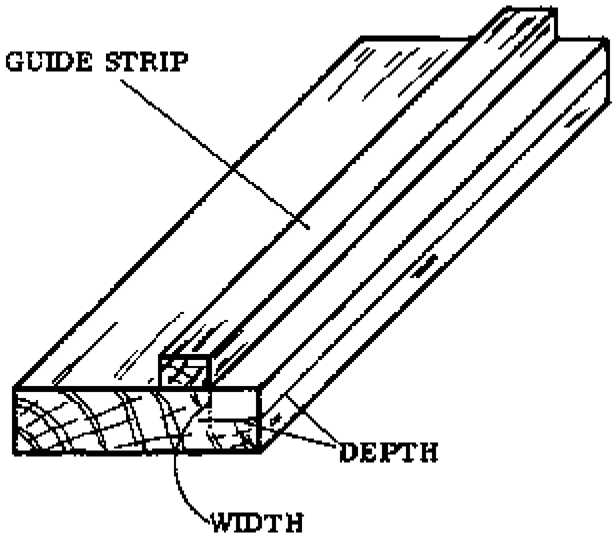

Fig. 2

Step 2.

- Fix a wooden guide strip along the line that marks the width of the rebate (Fig. 2).

The guide strip must be perfectly square and it should lie flat.

Step 3.

- Plane until you reach the line marking the depth of the rebate. Take care that the side of the plane is always against the guide strip, so that the width of the rebate is the same along the whole length.

- If you notice that you are planing against the grain, stop just before you reach the required depth and plane from the other direction. This will ensure that the surface of the rebate is smooth.

An important point in planing rebates is setting the plane correctly. The side of the cutting iron that faces the rebate must be set so it is exactly flush with or only slightly coming out at the side of the plane. If it projects too far it will damage the guide strip, and if it is set in from the side it will not plane true (Fig. 3).

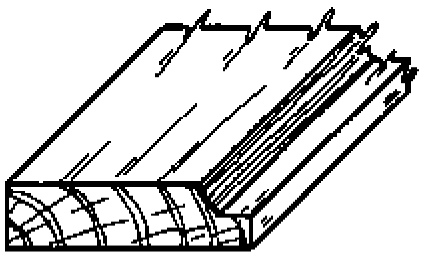

Fig. 3

When you set the cutting iron, do not knock on it with a steel hammer. This will damage the iron. Rather, loosen the wedge slightly and knock it with a mallet or a piece of wood.

When the rebate plane is not set well, it will tend to slip off the rebate and will not produce a good surface.

NOTES:

How to plane a rebate with an adjustable rebate plane

To make work simpler, we can fix guides onto the rebate plane itself. Thus, fixing guide strips on the boards is unnecessary (Fig. 1).

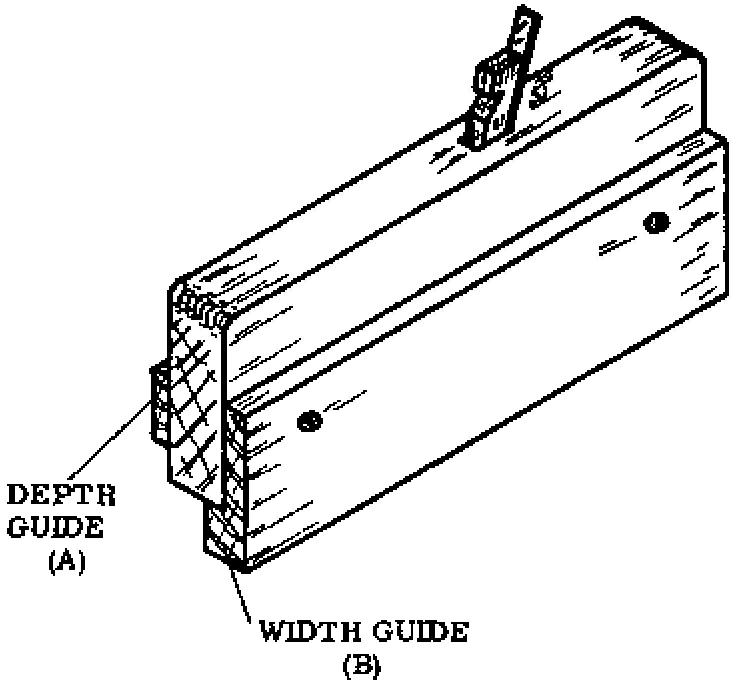

Fig. 1

One wooden piece is fixed on the sole of the plane (B) at the standard width for rebates and another piece is fixed on the side of the plane (A) and can be moved up or down to adjust the depth of the rebate. The width can also be adjusted, by using a wider or narrower wood guide (Fig. 2).

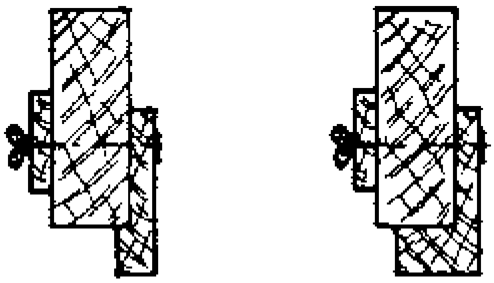

Fig. 2

The guides should not be nailed to the plane, since that would damage it. They should be fixed by bolts and nuts, so that they can be easily removed.

Plane until the depth guide just touches the work. Take care that the width guide is always firmly pressed to the side of the timber. If you notice that you are planing against the grain, stop just before you reach the required depth and finish planing with the guide strips removed, which enables you to plane in the other direction. This gives a good surface to the rebate.

See the section on the ordinary rebate plane for tips on how to set the cutting iron.

Loose tongued joint

This joint is used where a joint stronger than the plain glued or rebated joint is needed. The boards to be joined must be at least 2 cm thick (Fig. 3).

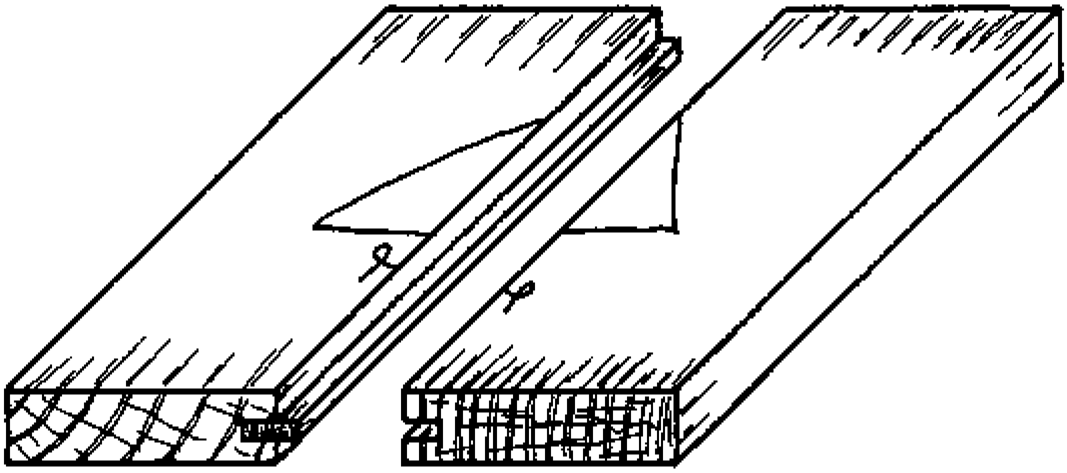

Fig. 3

The joining edges are grooved and a tongue is glued into the grooves. The depth of the groove is about 2/3rd of the thickness of the board. The width of the groove is equal to the thickness of the tongue. The groove should be slightly deeper than the projection of the tongue, to allow for expansion (Fig. 4).

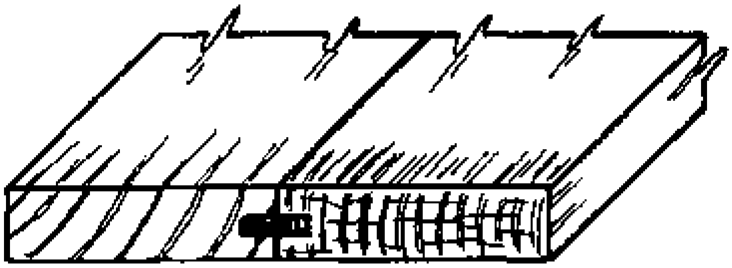

Fig. 4

Plywood makes a very strong tongue and it is frequently used for this purpose.

If solid wood is used as a tongue, care must be taken that it is always cut across the grain. A tongue cut with the grain will make a weak joint.

NOTES:

How to plane a groove for a loose tongued joint

Usually special planes called plough planes are used to plane grooves for this kind of joint. If a plough plane is not available, we can adapt our rebate plane for this purpose and make an improvised plough plane (Fig. 1).

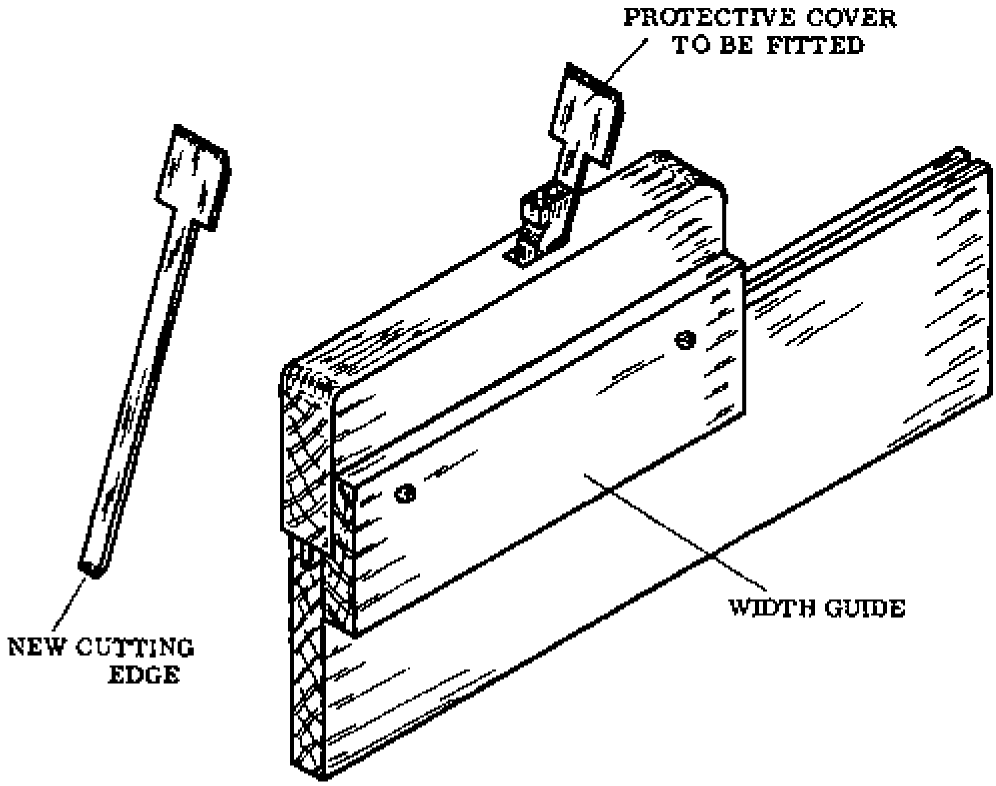

Fig. 1

To do this, grind and sharpen the narrow end of the rebate plane cutting iron to make a cutting edge. Grind the sides of the iron to the size of the most commonly used tongue, which is 6 mm plywood. The sides should be slightly bevelled to ensure free movement in the groove.

When the iron is fitted into the plane it is adjusted so that the cutting edge projects out of the sole by exactly the required depth of the groove.

A guide, similar to the one used for the adjustable rebate plane, is now fitted to the side of the plane. This guide keeps the cutting iron at the right distance from the face side of the boards. It should be adjusted according to the most common thickness of the boards, in this case it is about 22 mm for a planed board. For a tongue size of 6 mm then, the distance between the edge of the guide and the edge of the cutting iron will be 8 mm.

When planing press the guide firmly against the side of the wood and hold the plane exactly at a right angle to the edge of the board.

The most difficult part will be to start the groove, since the cutting iron will tend to slip off the edge and it requires some experience to keep it steady. Go slowly at first.

Work from the face side at all times.

To prevent injuries cover the cutting edge where it sticks out of the top of the plane.

NOTES:

MISCELLANEOUS CARPENTRY TECHNIQUES

Marking a board to fit an irregular surface

To mark the edge of a board which you want to fit against an irregular surface such as an unplastered wall, hold the board firmly and level to the wall and mark it with a compass or a similar device as shown in Fig. 1.

Fig. 1

As one leg of the compass moves along the wall, the other leg will mark on the board an exact copy of the irregularities of the wall surface. The legs of the compass have to be set apart by a distance a little greater than the width of the biggest gap between the wall and the board.

If no compass is available, a small wooden block can be used instead (Fig. 1a). The pencil is held in the notch at one end and the other end is moved along the surface of the wall.

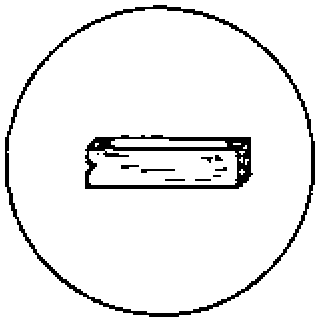

Fig. 1a

Measuring the width of openings

A convenient way to measure the width of openings such as doors and windows is to use two sticks as shown in the illustration (Fig. 2) to just span the opening. Then transfer the measurement to a single board by marking and measure it with a rule.

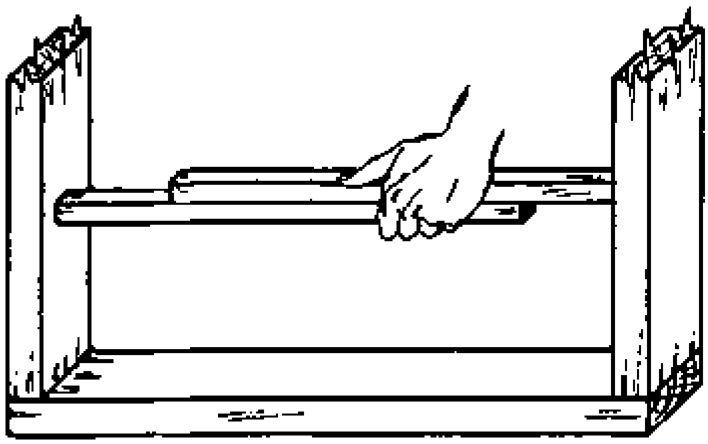

Fig. 2

Marking out irregular designs with templates

When you want to mark out several pieces with the same irregular shape, you can save time and ensure more accurate work by marking from a template (Fig. 3). Templates are thin pieces of cardboard or plywood onto which the required pattern is drawn and then cut out.

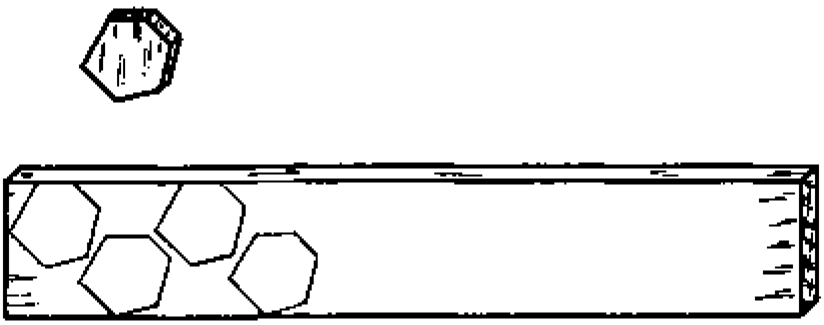

Fig. 3

The template is used by placing it on the material to be marked and holding it firmly in place while drawing around it.

NOTES:

PART 3: PREPARATION FOR ON-THE-JOB TRAINING

BUILDING PRELIMINARIES

Before anyone can actually start to erect a building, a number of preliminary steps must be completed. The very first step is the preparation of the plan.

Plan

The plan, also called the drawing, is a layout of a building drawn on paper. It contains all the information necessary to erect the house (see Drawing Book, page 55). The data and measurements given in the plan are essential for the builder to be able to construct the building so that it satisfies the customer's demands (Figs. 1 & 2).

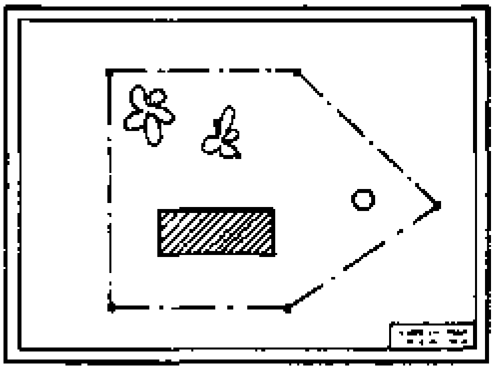

Fig. 1 LOCATION PLAN

Plot and site clearing

A plot is an area of land containing one or more sites. It is determined and limited by boundaries (Fig. 1).

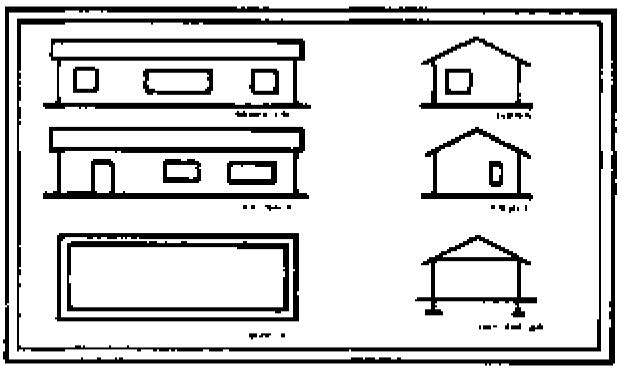

Fig. 2 BUILDING PLAN

The site is that area of land within the plot which is actually used for construction.

With the location plan in hand, the builder can prepare both plot and site for the construction of the building. The location plan tells him exactly where the trees and bushes have to be removed so that they don't interfere with the work. This preparation includes making a drive, cutting the grass, and levelling the surface of the ground.

The builder must pay special attention to the roots of trees which are on the site or very close to it. These must be completely removed. If some roots, such as those of the neem tree, remain in the ground, they can grow again and damage the structure.

Site organization

When the land clearing is completed, the building materials can be brought in to the building site.

Temporary work-sheds and stores may be erected in suitable places (Fig. 3).

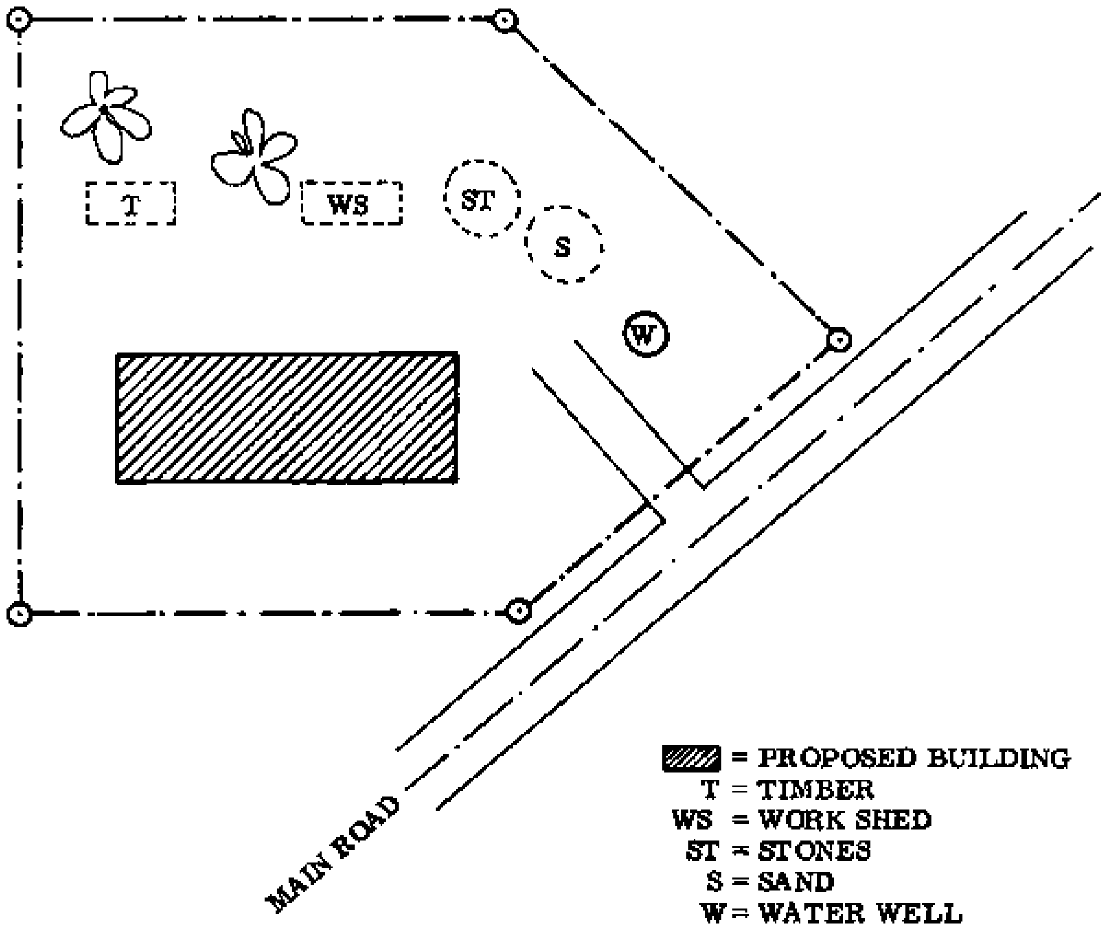

Fig. 3 SITE ORGANIZATION

The builder must ensure that there is an adequate supply of clean water. Without water no building can be constructed.

SETTING OUT

At the beginning of any construction activity the work must be carefully set out. This is also known as pegging out or lining out.

Setting out means to put pegs in the ground to mark out an excavation; or to mark on the floors to locate walls.

3-4-5 Method

The first line to be set out is the front line of the carcass (Fig. 1). A “carcass” is the building when it is structurally complete but otherwise unfinished. In this case we mean that the front line marks the position of the outside face of the (future) unplastered wall. The lines of all the other walls are measured from this front line. If the building is rectangular, right angles are set off from the front line by using the 3-4-5 method.

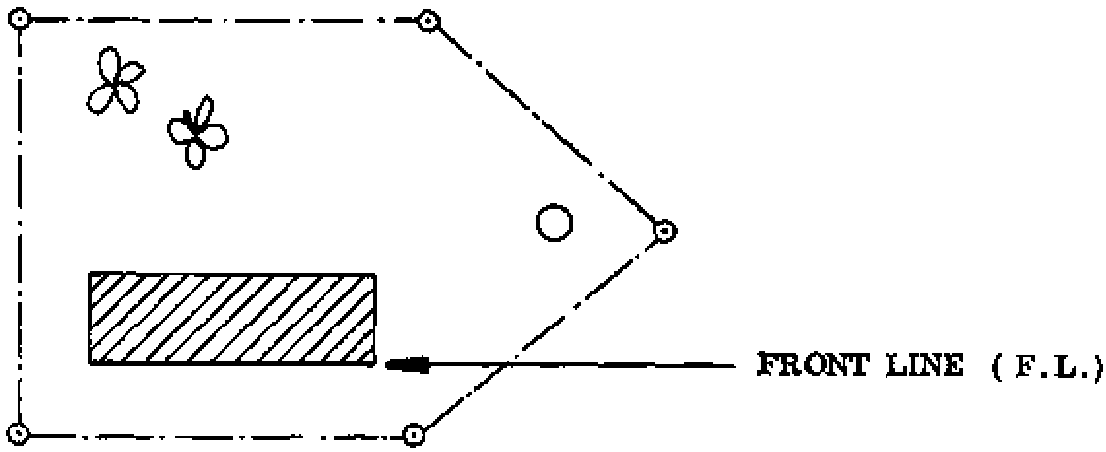

Fig. 1 LOCATION PLAN

The second line to be set out is the line of one of the side walls of the carcass. This line intersects the front line at the corner of the future building. To make sure that this corner is a right angle, we use the 3-4-5 method.

- Measure a distance of 4 m along the front line starting from point A, and mark this on the line (point B) (Fig. 2).

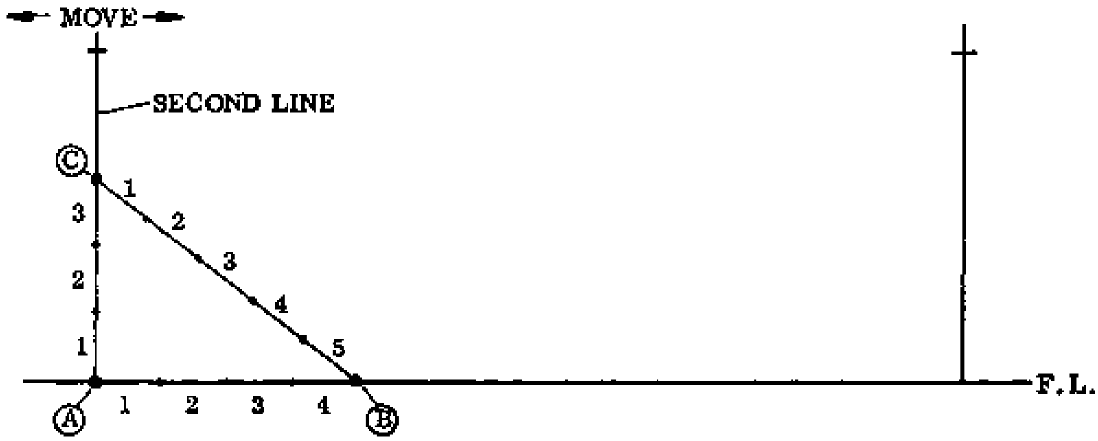

Fig. 2 3-4-5 METHOD

- Measure a distance of 3 m along the second line, starting from the corner (point A) and mark this distance (point C).

- Now take a line which is marked with a distance of 5 m, and stretch it taut from point B towards the line with point C. Keeping the end points of both lines steady (points A & B) and the lines taut; move the free ends of the side line and the 5 m line until the 5 m mark and the mark at point C meet each other. This is best done with two men, one at the end of each line.

- The corner angle must now be a right angle.

- Measure the required length of the side line and insert a peg at the end. Set out the opposite side line in the same way.

If the setting out has been done accurately, the length of the back line between the two pegs should be equal to that of the front line. Make a further check by measuring the diagonals, which must be equal (Fig. 3).

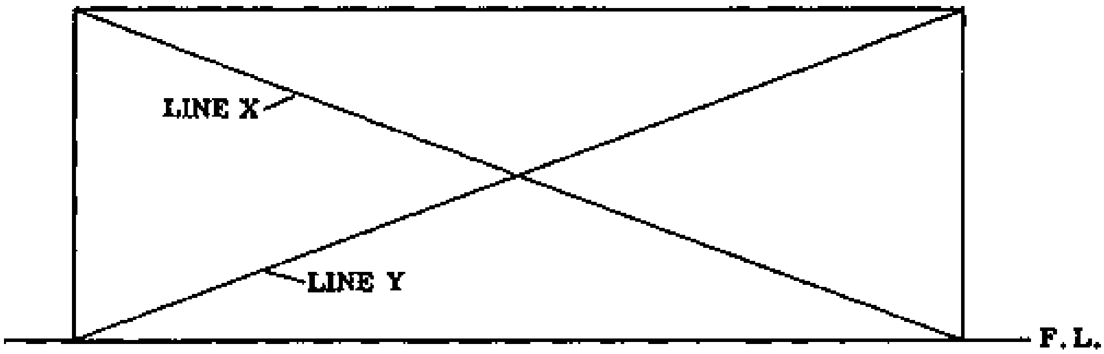

Fig. 3 LINES X AND Y ARE EQUAL IN LENGTH

NOTES:

Lining out

Once the positions of the corners and the distances between them are determined, the positions of the foundations, footings and walls as well as their thickness must be marked. A simple example of setting out and marking a foundation is shown in Fig. 1. The more complicated and permanent methods will be treated later.

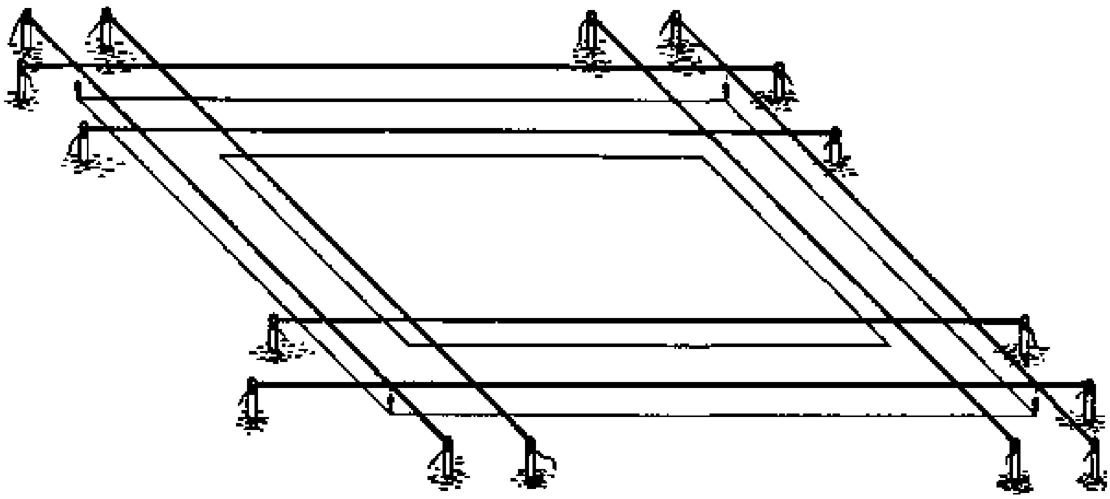

Fig. 1 SETTING OUT THE LINES & MARKING THE GROUND

These marks will be needed until the plinth course is completed, so they must be relatively durable, so that they remain accurate for a longer period and are not destroyed by rain or other influences.

Direct marking

Small buildings or small extensions of houses may be marked directly on the flat ground, provided that the excavation work can proceed immediately and can be quickly completed, so that the marking need not be repeated (Fig. 1).

In this procedure, the setting out must be done in stages.

- Mark the position and width of the foundation directly on the ground, and dig the trenches immediately.

- The next step is to level the bottom of the trenches and to peg off the foundation depth (Fig. 2).

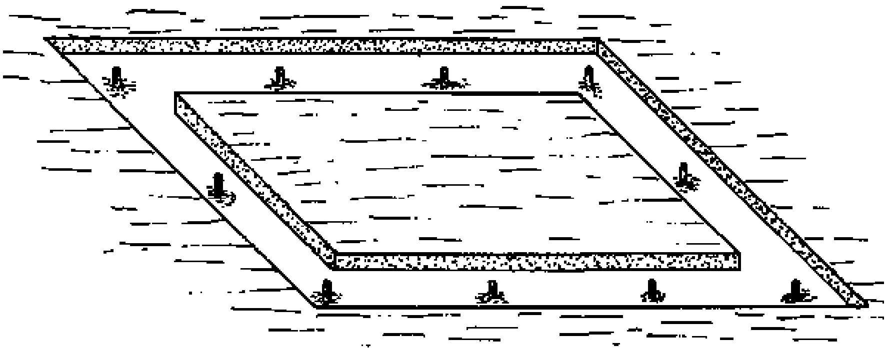

Fig. 2 PEGGING OFF THE FOUNDATION DEPTH

- After the foundation concrete is cast and set hard, set out the footings directly on the surface of the foundation (Fig. 3) and build them to the required height.

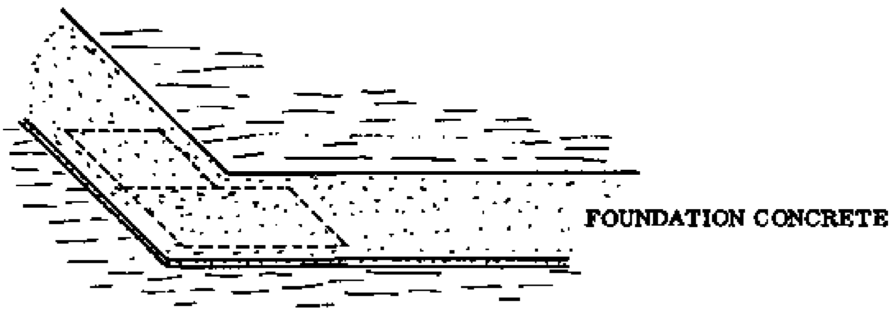

Fig. 3 SETTING OUT THE FOOTINGS (ENLARGED DETAIL)

- When the footings and hardcore filling are complete, set out the plinth course on the footings.

- NOTE: The information given in this section and in most of the following sections is not intended to be a detailed explanation. It is simply meant to give you, the trainee, an idea of the operations you can expect to encounter in your on-the-job training. Lining out, marking, etc. will be covered in detail in the Construction Book.

NOTES:

Using the plumb bob to mark the foundations

Hold the plumb bob with one hand by the suspending line so that the tip of the cylinder is just off the ground. Move it slowly until the suspending line just touches the intersection of the lines stretched between the pegs (see A & B, Fig. 1). When the swinging movement of the plumb bob has stopped, mark the point directly below the tip of the cylinder by inserting a peg.

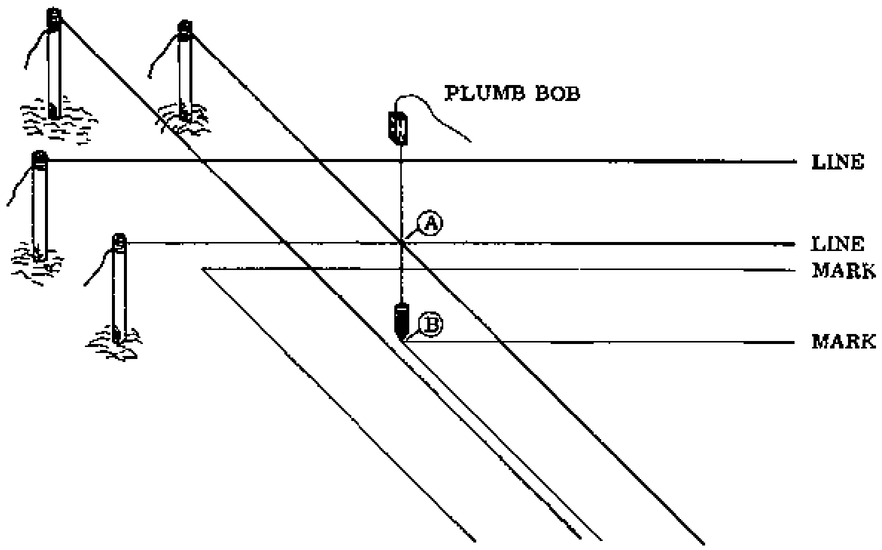

Fig. 1 USING THE PLUMB BOB

The peg is directly in line with the intersection of the lines above.

This procedure is repeated at all inside corners and outside corners, so that the edges of the foundation trenches can be marked on the ground.

Using the large square

The large square, described in the Reference Book, Tools, page 12, may be used to set out and mark off the positions of inside walls. This is less time-consuming than using the 3-4-5 method.

Place the large square on the ground with one side along an already determined line, and mark off the corner on the other side (Fig. 2).

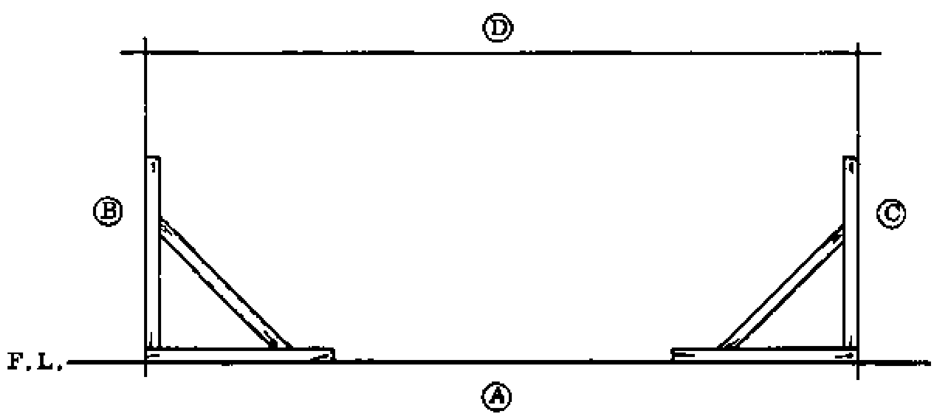

Fig. 2 USING THE LARGE SQUARE

PROCEDURE:

1 - FIX THE FRONT LINE; LINE A.
2 - MARK POINTS 1 AND 2.
3 - SET OUT LINE B SQUARE TO LINE A.
4 - SET OUT LINE C SQUARE TO LINE A.
5 - LINE D SHOULD BE THE SAME LENGTH AS LINE A.

Not only the whole building, but also each room in the building must be checked for squareness by comparing the diagonals, which have to be equal.

Using the mason square

Although it is less accurate than the large square because of its smaller size, the mason square can be used to mark off the corners of short set-backs such as niches designed to receive built-in wardrobes, etc. Follow the same procedure as with the large square (Fig. 2).

- NOTE: A niche, also called a blocked doorway, is a small recess in a wall, usually not extending to the ceiling. A set-back or return is the part which goes back, away from the front or direct line of the structure.

NOTES:

FOUNDATIONS

A foundation is the strong base of a building. It is the lowest part of the structure, the part which is in direct contact with the ground.

The purpose of the foundation is to receive the loads from the structure above and to spread them over a larger area of supporting soil or rock.

Excavating the foundation trenches

Once the setting out is completed and the position of the foundation is marked on the ground, the next step is to dig the trenches for the foundation concrete.

Remove the loose, soft topsoil to uncover the firm subsoil, preferably rocky soil. Dig the trenches to the required depth.

The soil which is taken out should be piled within or near to the area of the future building, so it can be used later for the hardcore filling. Take care to make the sides of the trenches vertical, and the bottom level. The corners should be sharp, not rounded (Figs. 1 & 2).

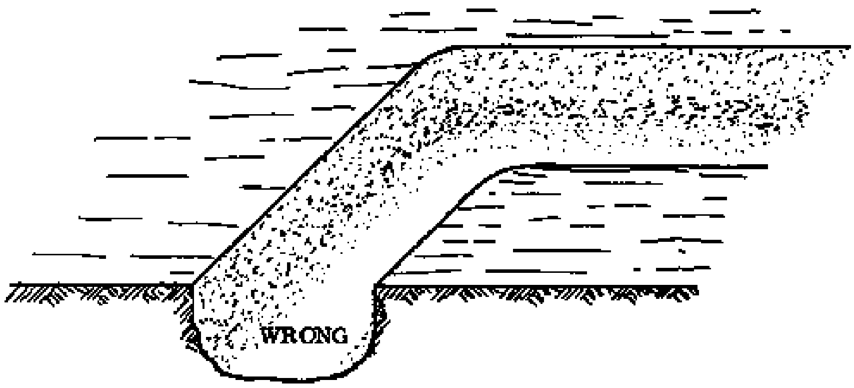

Fig. 1 CORNERS ARE NOT SHARP

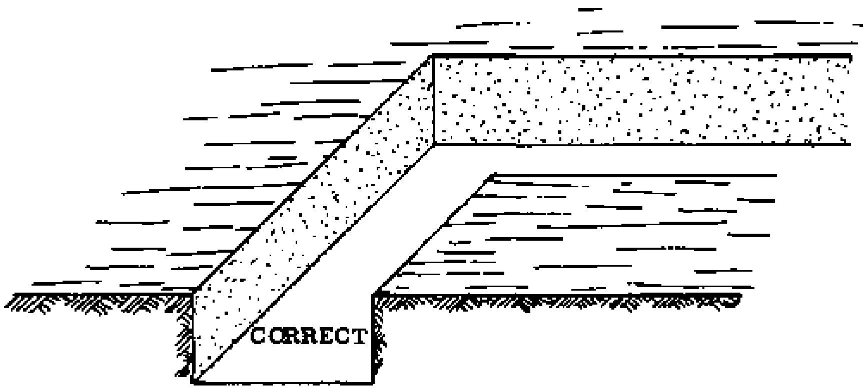

Fig. 2 CORNERS ARE SHARP

Marking the depth of the concrete and levelling the trench

When the trenches have been dug, the next step is to mark the depth of the foundation concrete. This is done by driving pegs in the bottom of the trench. The pegs are levelled across their tops, and their height above the trench bottom should be equal to the planned depth of the concrete bed (Fig. 3).

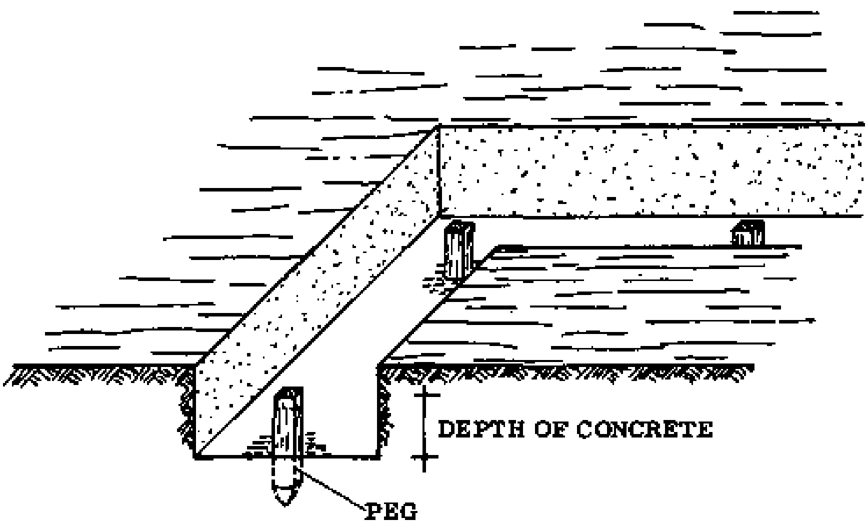

Fig. 3 HARKING THE DEPTH OF THE CONCRETE

If the exposed heights of the levelled pegs are not equal, that means the bottom of the trench is not level. The uneven spots have to be levelled by taking out some soil, until all the pegs project equally.

- NOTE: Never level the bottom of a trench by adding loose soil, as this might lead to uneven settlement which causes cracks in the structure. Trenches are always levelled by removing soil. If this means that the trench is deeper than planned, then either the foundation concrete has to be deeper or the height of the footings must be increased.

NOTES:

Foundation concrete

When the trenches are dug and the thickness of the concrete has been marked, the next step is to mix the foundation concrete. The proportions for the mix can be from 1:10 to 1: 15 (Reference Book, pages 166 to 170; and Tables of Figures, page 234).

Casting - Compacting - Levelling

If the work is done during the dry season, the sides and bottom of the trenches must be watered down before the ready-mixed concrete is cast. This keeps the soil from absorbing too much moisture from the concrete before it has set. The concrete is carefully poured into the trenches and compacted by tamping.

Rammers are used to compact the concrete (Reference Book, page 18). The heavy rammer is repeatedly lifted and dropped, compacting (packing together) the comparatively stiff concrete.

A strike-board (Reference Book, page 25) is used to level the concrete to the height of the pegs. A straight edge can also be used instead of the strike board.

If wooden trench pegs were used, remove them now and fill in the holes.

If iron pegs were used, they can be left in the concrete unless they are needed for another job.

Curing

Cover the top of the freshly cast foundation with empty cement bags or straw. This keeps it from drying out in the sun and air, and keeps the surface clean.

Once the concrete starts to harden, the top of the foundation should be kept wet.

NOTES:

FOOTINGS

The term footing is given to the courses of brickwork, stone or blockwork at the foot of a wall. The footing courses start immediately above the foundation and are laid flatwise. The rising wall is erected in the middle of the footing courses, so the footings, which are wider than the rising wall, project equally on both sides of the rising wall.

Purpose of footings

Two main functions must be fulfilled by the footings:

- They are the connecting link between walls and the foundation and act as an intermediate foundation for the walls, spreading the loads over a wider area of the concrete below.

- They raise the floor level high enough above ground level to keep water out during the wet season.

Height of footings

In Rural Building, the top of the foundations is usually at ground level, although they can be either above or below ground level depending on the subsoil.

When three footing courses are laid on top of the foundations, the soffit of the future floors will be 51 cm above ground level. This will meet the requirements of most situations.

If the building is in a valley, or in a place where the rain-water cannot run off quickly, the height of the footing courses must be increased.

NOTES:

HARDCORE FILLING

Hardcore filling is the compacted sub-base of floors; it consists of stones, broken sandcrete blocks or coarse gravel. It fills up the space between the subsoil and the soffit of the concrete floor.

Function of the hardcore filling

The hardcore filling has to carry most of the mass of the concrete floor, except for a small portion supported by the projecting inside edges of the footings. The filling must be well compacted to be firm enough to withstand the weight of the floors.

In addition, the hardcore filling must be built up in such a way that it prevents moisture from rising through it to penetrate the concrete floor.

Methods of filling and compaction

The topsoil is removed first (Figs. 1 & 2), then the hardcore filling is added in layers no more than 15 cm deep. Each layer is compacted very well before the next is added.

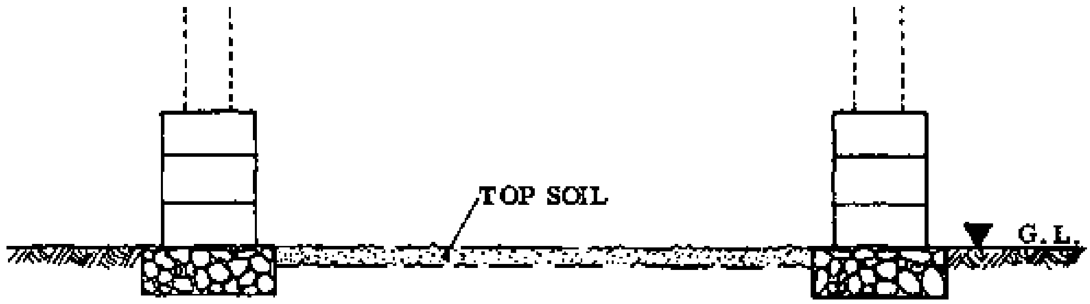

Fig. 1 FOOTING COMPLETED

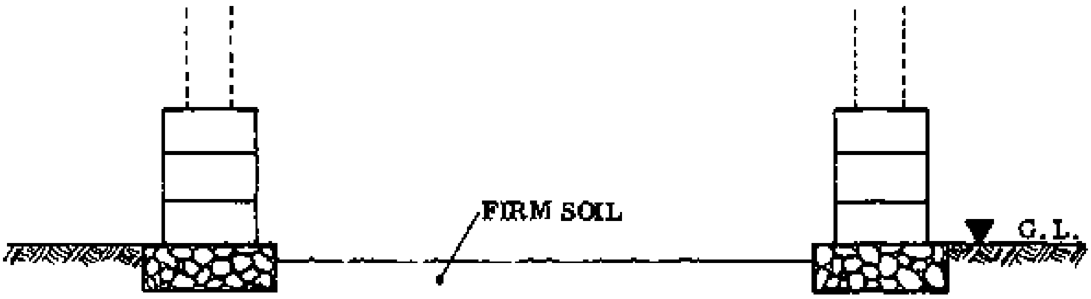

Fig. 2 TOP SOIL REMOVED

The bottom layer consists of small rocks, stones or broken sandcrete blocks. The second layer consists of smaller stones. Coarse gravel is used for all the remaining layers, up to about 6 cm below the tops of the footings. The last 6 cm or so is filled with fine sand, which seals off the surface so that no cement is wasted during the floor construction.

As can be seen in Fig. 3, the structure of the hardcore filling becomes denser and finer with each layer, starting from the bottom to the top. This is the correct way to protect the floor from the penetration of moisture.

Fig. 3 HARDCORE FILLING

All layers are compacted with rammers. The coarse gravel can be watered down to ensure proper compaction and to ease the work. If there is a tractor available, it may be used to move the fillings and to speed up the heavy work.

NOTES:

PLINTH COURSE

The plinth is a slightly thicker course at the base of a wall or a column; often made of a more durable material than the rest of the wall or column.

In Rural Building, the plinth commonly consists of only one sandcrete course. The plinth course forms the first course of the rising wall immediately above the footings, and it is 1 cm wider than the landcrete blocks (Fig. 1). This 1 cm difference is evident from the inside face of the wall, but it is covered when the wall is plastered.

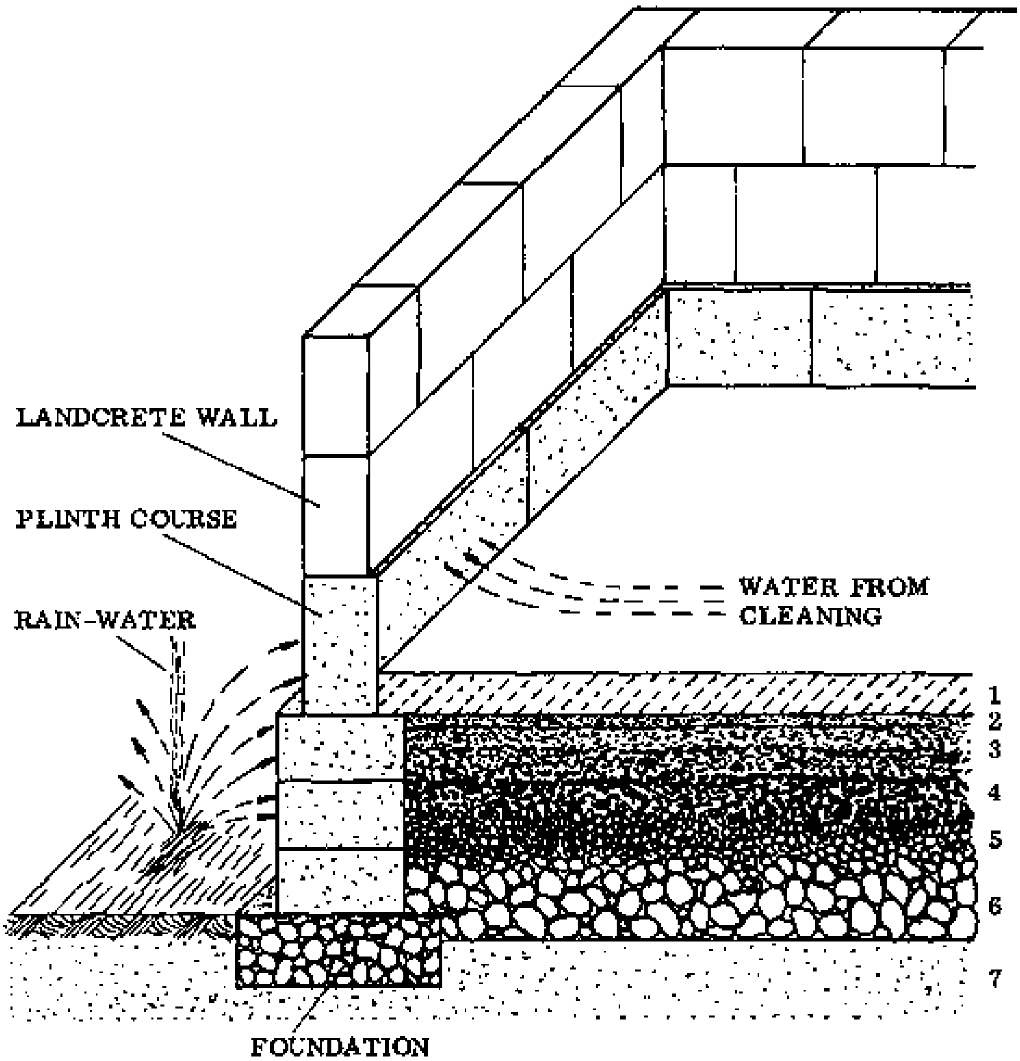

Fig. 1

1 - CONCRETE FLOOR
2 - FINE SAND
3 - FINE GRAVEL
4 - COARSE GRAVEL
5 - SMALL STONES
6 - ROCKS & STONES
7 - FIRM SOIL

Function of the plinth course

The plinth course raises the landcrete blocks above the finished floor level so that they cannot be penetrated by moisture (from outside by rain, from inside by water used for cleaning, etc.).

Although the landcrete blocks can withstand a skin-deep penetration of water for a short time, they must be protected against the long-lasting influences of the rainy season.

The most affected part of a building is always at the foot of the walls. Rain-water coming from the roof splashes up against the wall and creates a dirty strip about 60 cm in height, which is seen all along the footings. This area is more exposed to penetration by water than the rest of the wall, but the landcrete blocks are raised by the plinth course well above the endangered zone.

The illustration on the opposite page shows the possible paths which the water can take when penetrating the structure.

NOTES:

OPENINGS

An opening is a space in a wall left open for a door or a window. The first openings to be made in walls are the door openings.

Door openings

Before the plinth course is built, the door openings are marked in their correct positions on the footings.

In Rural Building, the door frames are usually made and set into place on the footings before the plinth course is built against the frames (Fig. 1).

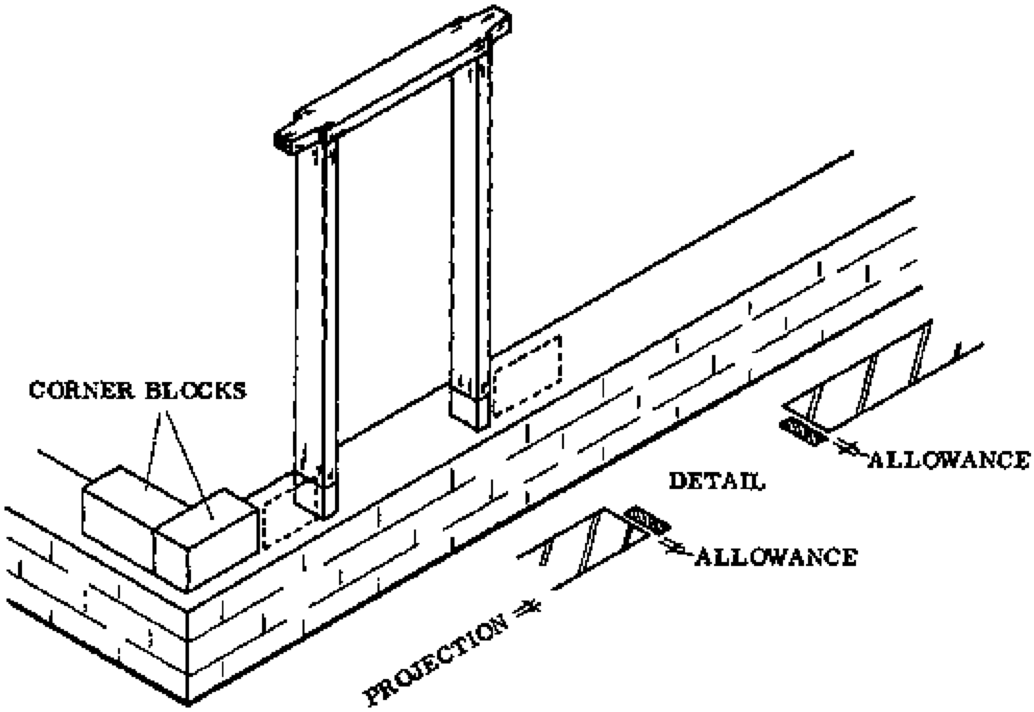

Fig. 1

If for some reason the door frames are to be installed later, the jambs of the openings (Fig. 2) are built up as described in the chapter on stopped ends, page 22.

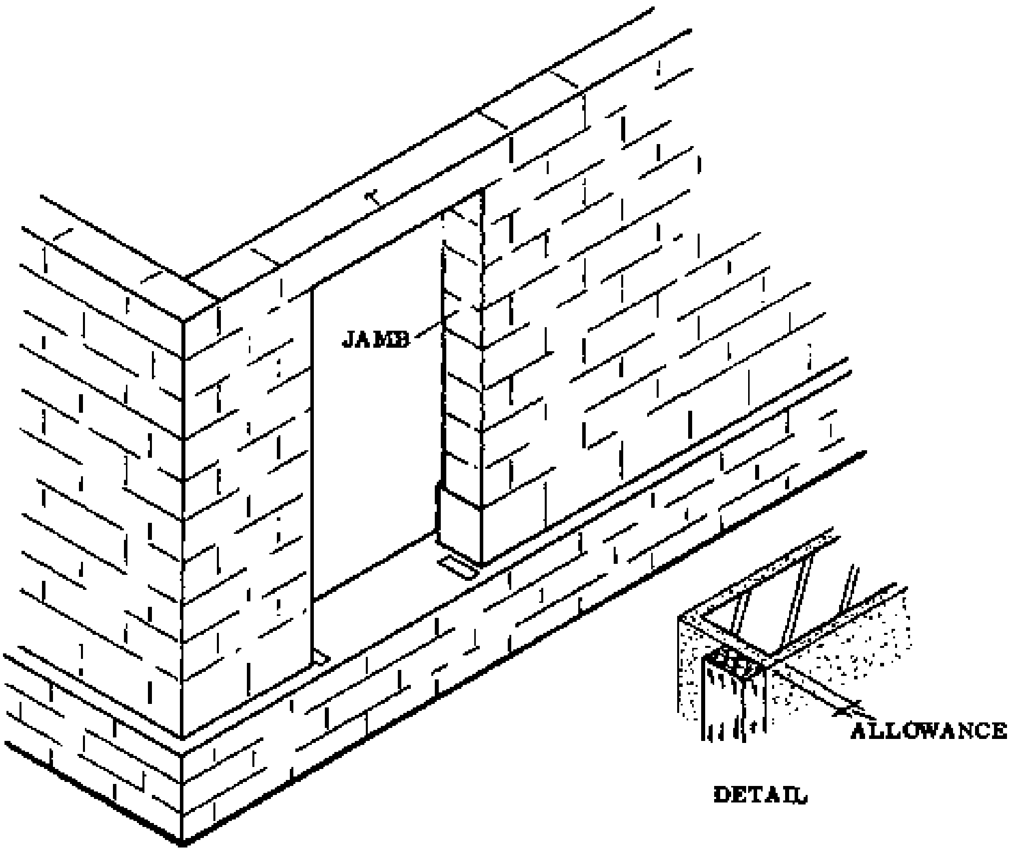

Fig. 2

A jamb is the portion of wall, or wall face, at the side of an opening. The jambs are built a little wider than the outside measurement of the frame (Fig. 2) so that the frame can fit into the wall opening.

Walling then continues until the window cill level is reached. This is the height where the window openings are set.

Window openings

The window frames are set and braced before the walling between them is completed. If the frames are to be set later, the window openings must also be built a little wider than the frames, so that the frames can be fitted in later.

In case the opening is to be filled with a decorative grille (Reference Book, page 193) or ventilation blocks (Reference Book, page 195), it is advisable to complete course by course including the special blocks.

This is done because it is easier than putting the decorative blocks into an opening later, and it provides the openwork screen blocks with more stability within the wall during construction.

NOTES:

SCAFFOLDING

A scaffold is a temporary structure which supports workers and materials during building and other work. It can be made of steel, aluminium, timber or bamboo.

According to their functions, there are three main types of scaffolds:

- Working scaffolds
- Protecting scaffolds
- Supporting scaffolds

Each type may be erected separately and serve only one purpose. Some situations however, require a combination of two or even all three types.

Working scaffolds

As the name indicates, the working scaffold is used for working from. It holds the worker at a height which enables him to comfortably complete walls etc. when the construction has proceeded to a level that makes it difficult to work from the ground. The following is a description of two simple scaffolds used to complete walling between door and window frames. Protecting scaffolds, supporting scaffolds and a number of more complicated scaffolds and their construction will be treated in the Construction Books.

- BLOCK SCAFFOLD: This is the lowest and simplest working scaffold. It is used to raise the worker a bit higher to make it easier to build the wall up to the actual scaffold height of 1,5 m. Set the sandcrete blocks on solid, level ground and lay one or two boards across them (Fig. 1).

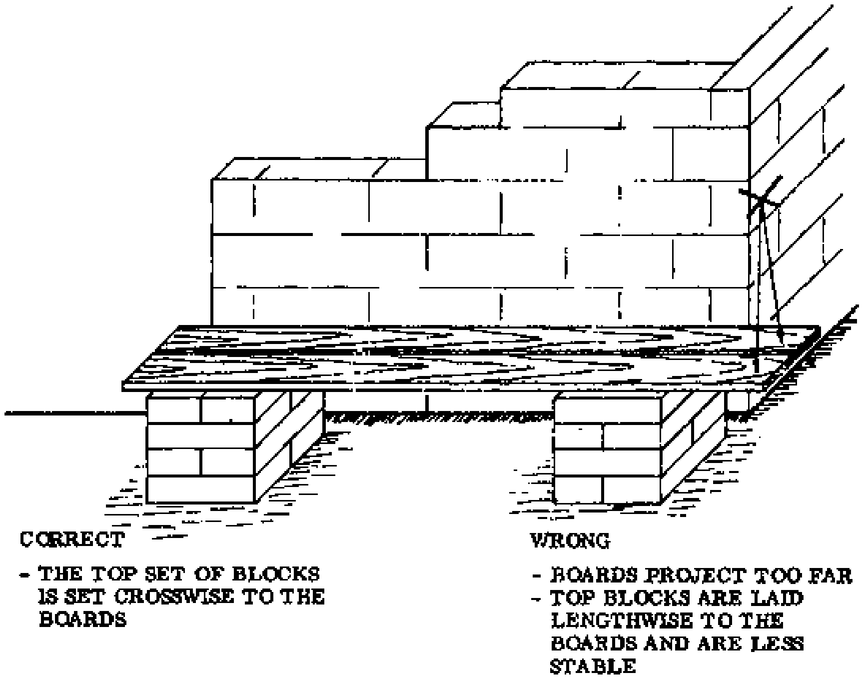

Fig. 1

- TRESTLE SCAFFOLD: This is a low-level scaffold, consisting of wooden trestles covered by two or three boards (Fig. 2). A trestle is a horizontal beam of wood with two legs on each end. Two or more of them are used to support the boards. Set them on firm, level ground, no further than 1,5 m apart. The height of the trestles can be from 75 to 100 cm. Small quantities of blocks and mortar can be kept on the platform. This scaffold enables the worker to continue walling up to lintel height, and to erect the formwork of the lintels.

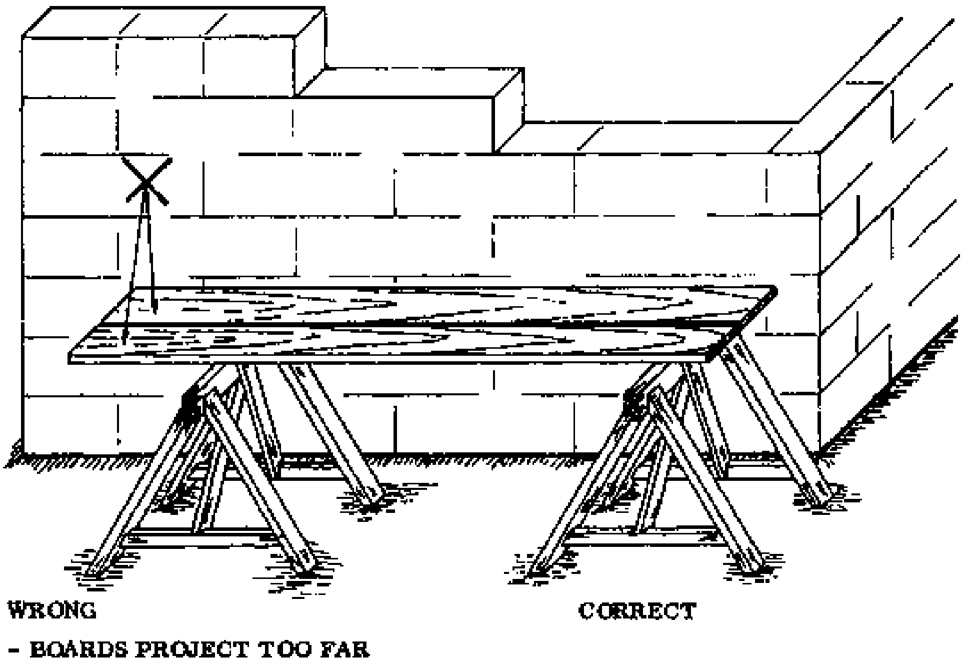

Fig. 2

NOTES:

Ladders

A ladder consists of two lengths of wood, metal or rope, called rails; which are connected at a certain distance from each other by rungs (Fig. 1).

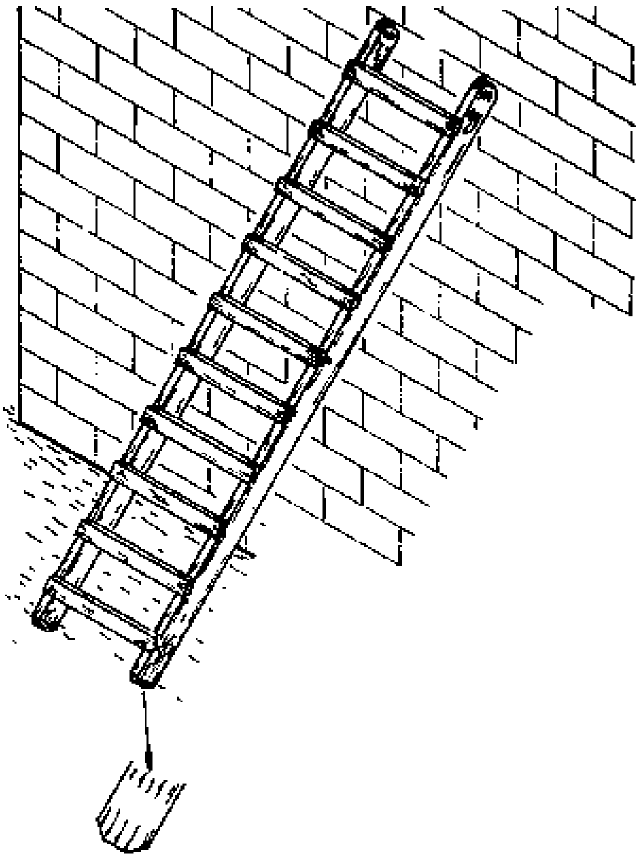

Fig. 1

Ladders are used to climb and descend scaffolds, walls, etc. during the construction of a building, and to do light maintenance work from later. Since such a piece of equipment is needed not only during the construction but also later in and around the house, it should be made from sound timber in a proper way so it can be used as a permanent ladder.

- CONSTRUCTING THE LADDER: Both the rails and rungs are made out of Odum. The dimensions of the two rails are 5 × 7,5 × 325 cm, while the ten rungs are 2,5 × 5 × 75 cm. The wood should be straight grained and planed to the above sizes.

Round the top ends of the rails where they touch the wall and cut off the foot ends as shown in Fig. 1, with a 45 degree bevel from each side. To prevent splinters and help the hands to move safely up and down the rails, round off all the edges. Incidentally, when climbing or descending ladders, keep your hands off the rungs. Grip the rear edge of the rails.

The over-all width of 75 cm gives an inside width of 65 cm which is wide enough to hold two scaffold boards on the rung. Later we will discuss making a ladder scaffold, in the Construction Book.

The distance of 30 cm between the rungs must not be exceeded, as a wider spacing would make it difficult to climb the ladder.

The rungs are inserted in notches cut in the rails, and fastened by using 75 cm nails as shown in Fig. 2.

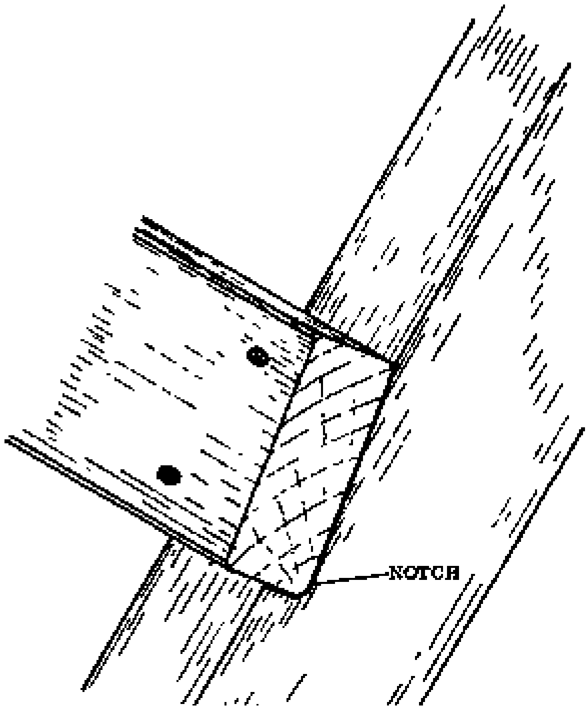

Fig. 2 ENLARGED DETAIL

Sometimes ladders are reinforced by fastening iron rods, threaded at both ends, through both rails behind the first, centre, and last rungs. The rods are held in place by nuts on the threaded ends.

- NOTE: A good ladder should be treated with oil or another preservative. Dried-out wood is the greatest threat to the safeness of the ladder. Always keep ladders in the shade when they are not in use.

NOTES:

BRIDGING OPENINGS

To bridge something means to connect the two sides or parts. This can be done in building with a structure of wood, stone, block work, steel or concrete. The essential thing is that the door and window openings must be safely bridged so that the walls above or other members of the structure cannot collapse and damage the house or the people inside.

Methods of bridging

There are various ways of bridging an opening. Which one of these is used depends on the distance to be bridged, the shape of the opening and the materials available.

One method which was common in former times was to make the openings so small that a single stone could be laid across them (Fig. 1). Openings which are low enough can also be bridged by inserting supporting blocks arranged like a “V” (Figs. 2, 3, & 4). This method is still common in the dry areas of Africa.

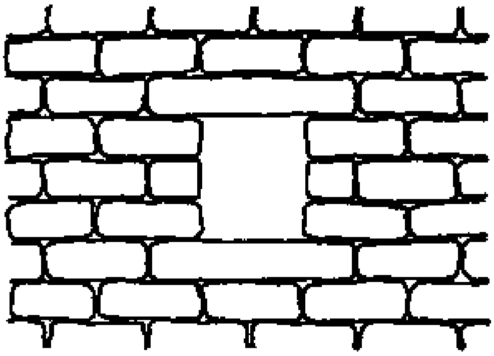

Fig. 1

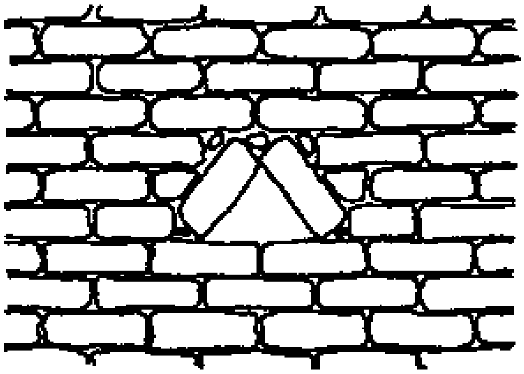

Fig. 2

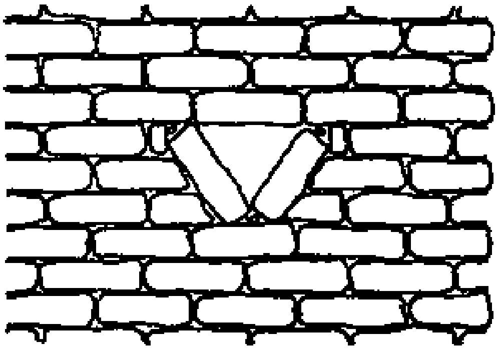

Fig. 3

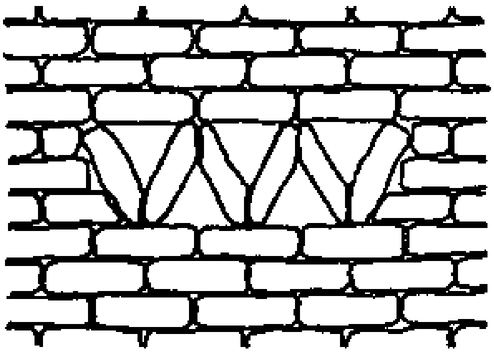

Fig. 4

The wider an opening becomes, the more difficult it is to bridge. Builders from many parts of the world eventually learned that if the blockwork remains closed above an opening, both sides of the wall will support each other, maintaining stability. This knowledge was often applied not only to bridge openings but also to construct roofs. The technique was to let each course overlap the one below until the blockwork met at the top and the two sides bonded into each other (Fig. 5).

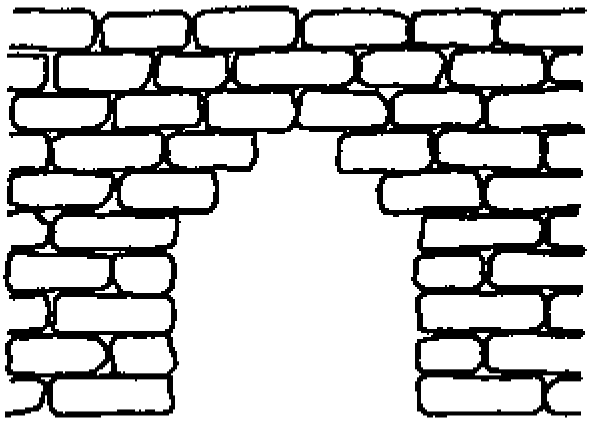

Fig. 5

From this simple method, arches were the next development. They are much stronger and have a more attractive appearance (Fig. 6).

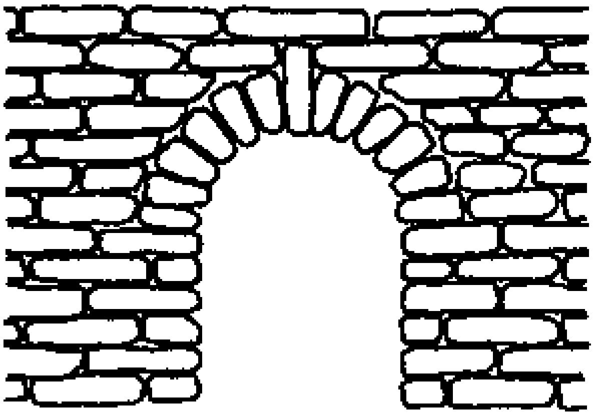

Fig. 6

Lintels were introduced in order to produce a square opening into which a frame could be fitted.

NOTES:

LINTELS

Built-up wooden lintel

A lintel, whatever material it is made from, is a horizontal member of the structure which bridges an opening (Fig. 1).

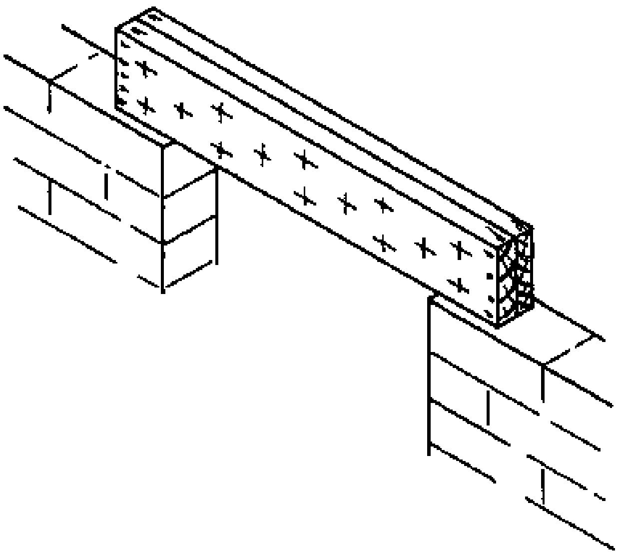

Fig. 1 BUILT-UP WOODEN LINTEL

Its function is to distribute the weight of the blockwork above and any other loads to the supporting walls. With a lintel the opening of the door or window can be lower than with an arch, and it is also easier to fit a frame into the opening.

For short-span openings such as doors and smaller windows which have no additional loads above, the wooden built-up lintel can be employed.

This lintel consists of two or more hardwood boards which are nailed, bolted or screwed together (Fig. 1). In order to save materials when a wider lintel is required, the boards are sometimes connected with spacers between them (Fig. 2).

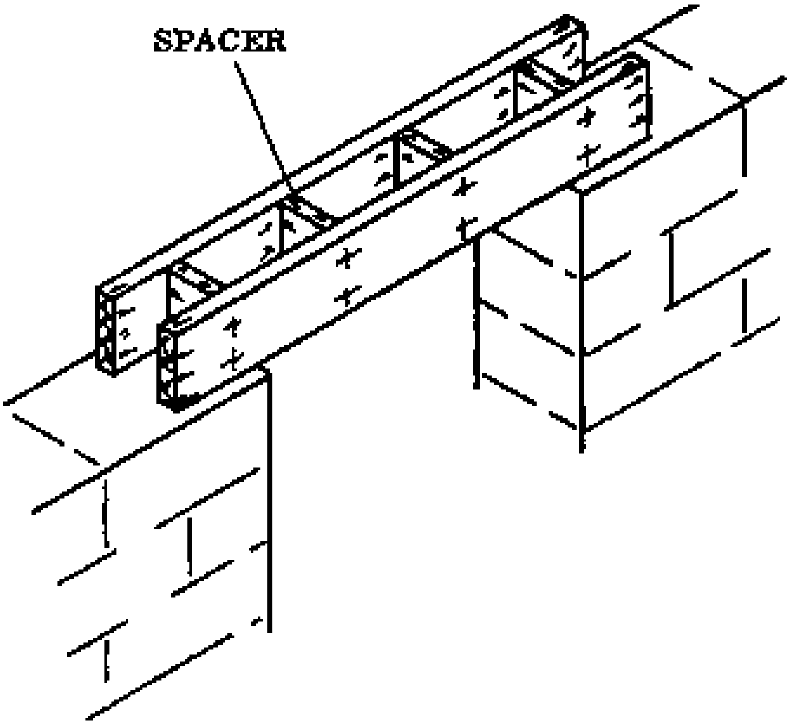

Fig. 2 WIDE BUILT-UP WOODEN LINTEL

For long-span openings and in situations where additional loads are present, arches or reinforced lintels are used.

Reinforced concrete lintel

Like the human body which is strengthened by bones, reinforced concrete is made stronger by the steel bars or metal netting embedded in it.

It is known that concrete alone can withstand enormous pressures, but if it is exposed to tensile stresses it will break (Reference Book, pages 168 & 169). Fig. 3 shows that a long board supported only on its ends will bend if weight is set on it. Similarly, a pure concrete lintel will try to bend under a heavy weight, but because the concrete is not flexible this will result in cracks forming across the soffit face, or even in collapse (Fig. 3).

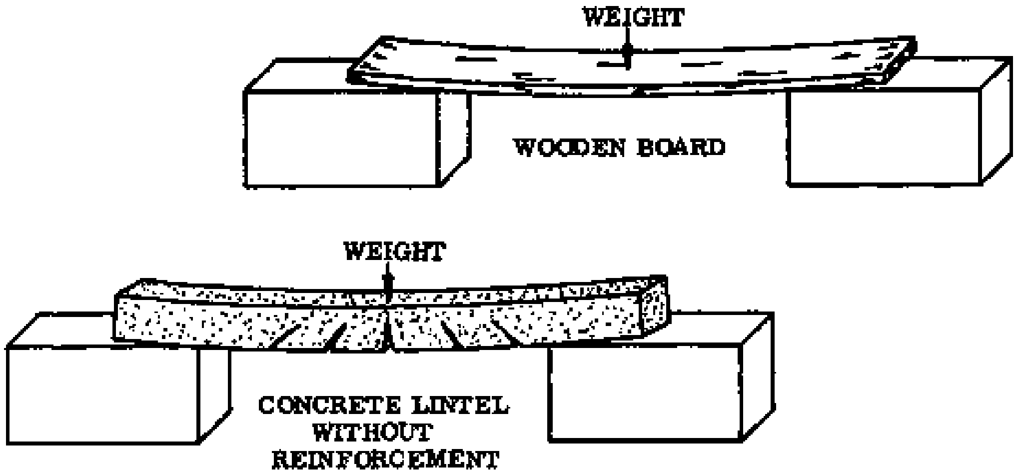

Fig. 3

To prevent this, reinforcement bars are embedded in the concrete if the lintel is expected to receive tensile stresses. The combination of concrete and steel does the job where one of them alone would not work: the concrete resists all pressure while the embedded steel resists all stresses.

The reinforcement for a lintel consists of several members with different diameters, shapes and functions. The members are often assembled beforehand in the form of so-called cages (see Fig. 1).

NOTES:

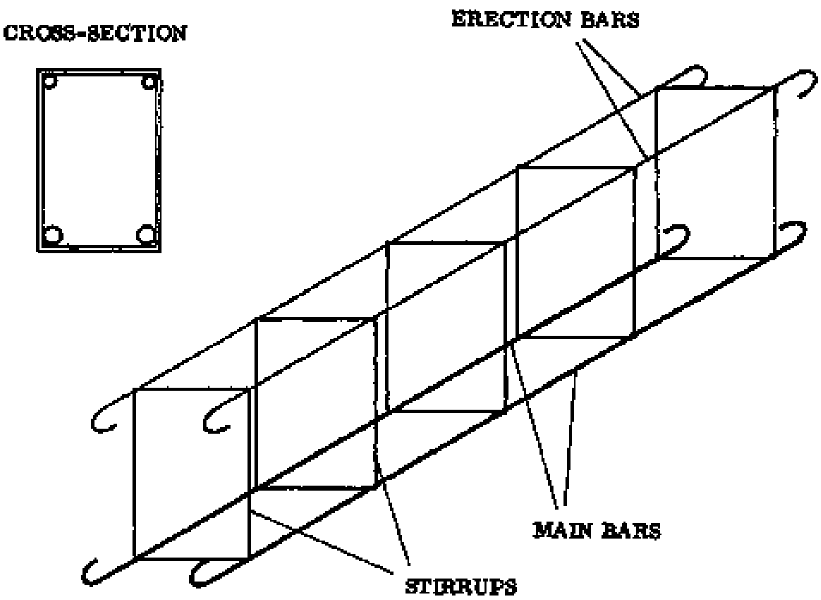

Fig. 1 REINFORCEMENT CAGE

- REINFORCEMENT CAGE: A typical reinforcement cage is shown in Fig. 1. The lower bars are the main bars. They are normally 12 mm in diameter be cause they do the actual strengthening of the lintel. The upper bars are thinner and are called erection bars. Since their main function is to hold the cage together, their diameter is only 6 mm. The square-shaped pieces are called the stirrups. They hold the main bars and the erection bars in position. All the different members are bound together with binding wire.

- CUTTING: All reinforcement bars have to be carefully measured and marked off before they are cut. A well equipped building site will have two different sized bolt cutters available. One is to cut the bars ranging from 4 to 10 mm in diameter and one is for bars up to 19 mm. If bolt cutters are not available, a hacksaw or a chisel may be used instead (Reference Book, page 19).

- BENDING: The bars are bent with the aid of the bending plate which is fixed on the work bench; and the bending bars (Reference Book, page 23). Each diameter of bar has to be bent with a specific size of bending bar.

- The bending is done according to a certain radius (this refers to the sharpness of the bend) in order to prevent overstraining and cracking of the bar (this will be explained in more detail later). The stirrups for the cages may be bent around a peg that has the same diameter as the main bars.

- BINDING: The members must be bound together in order to ensure that the bars remain in the correct positions while the concrete is being poured. Binding wire is bound around pieces at the connections (Figs. 2a & 2b). The wire should be stretched taut and then twisted tight with the pincers.

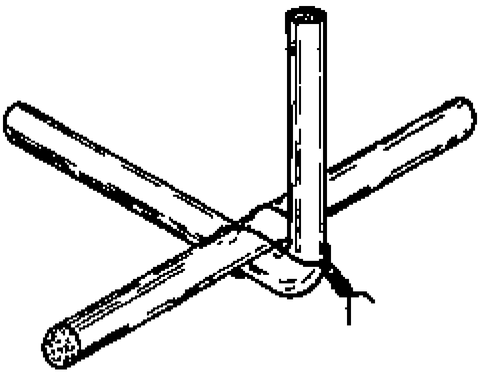

Fig. 2a STIRRUP TO MAIN BAR

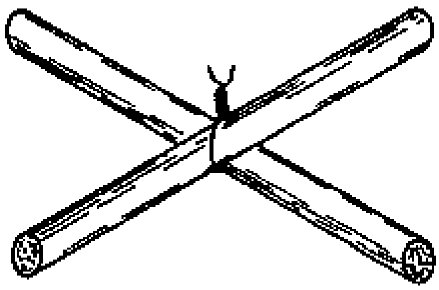

Fig. 2b BINDING OF CROSSING BARS

- NOTE: Examine the bars before you use them to make sure that they are free from paint, grease, loose scale or mud. Slight rusting will do no harm, but any loose rust should be removed.

For additional information on concrete and reinforcement steel, see the Reference Book, Materials and Products sections.

NOTES:

Formwork for a reinforced concrete lintel

The form is simply a temporary box into which the freshly mixed concrete is cast and kept until it has hardened. The inside shape of the box will be the outside shape of the concrete member.

All parts and members of a formwork used for casting reinforced concrete lintels are shown in Fig. 1 on the opposite page. The parts are nailed together in such a way that they can easily be taken apart after the concrete has hardened.

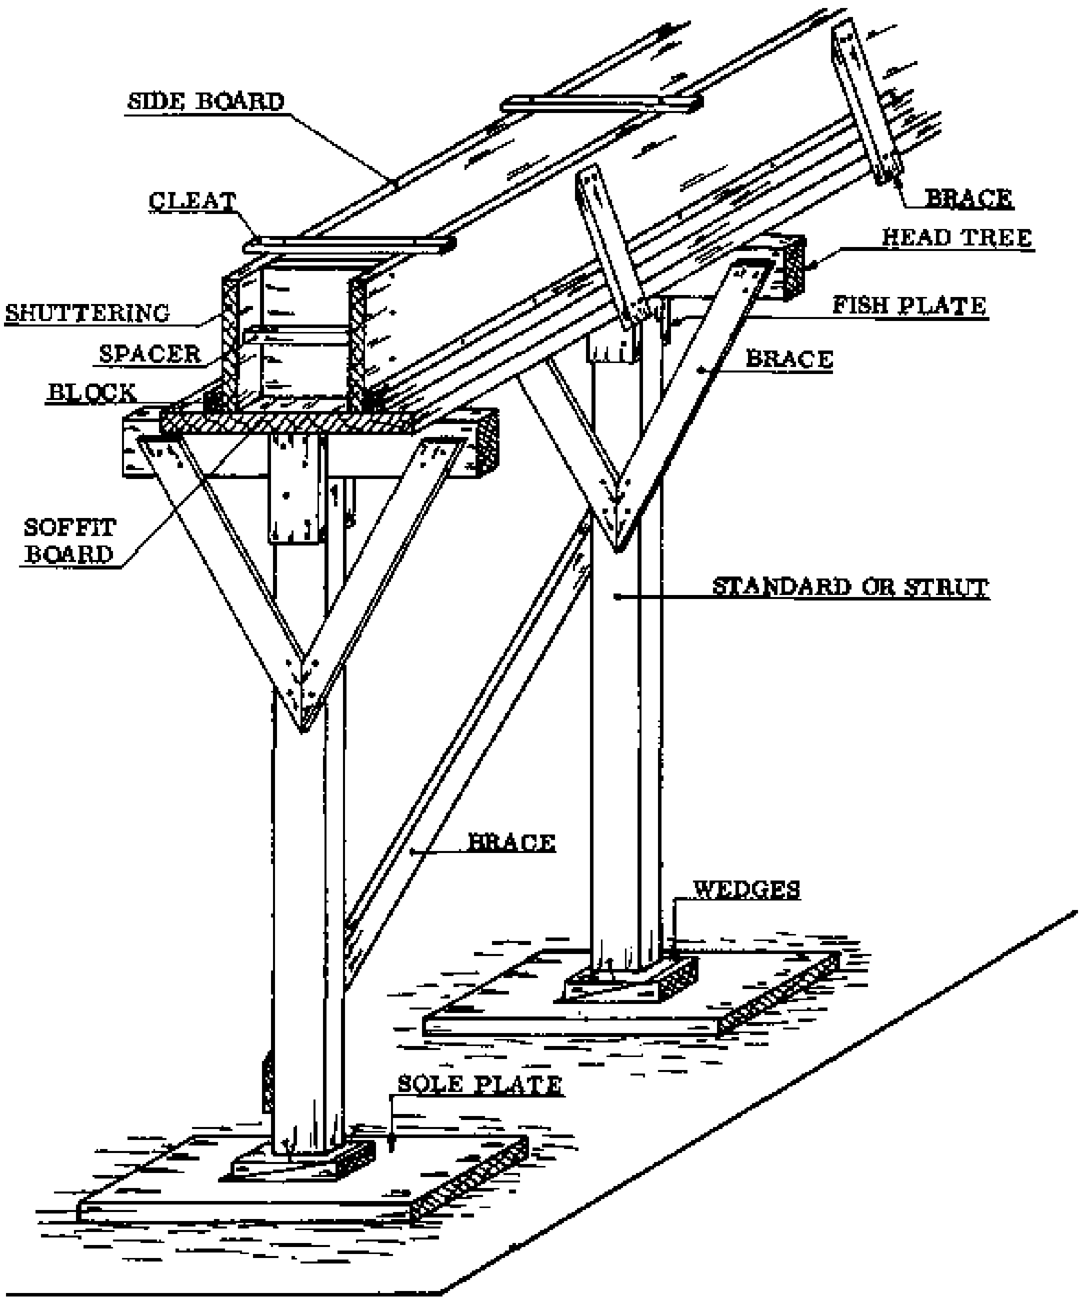

Fig. 1

Formwork is made of wood or metal and consists of two structural parts: the shuttering and the strutting.

- SHUTTERING: The shuttering is the actual shaping part of the formwork which is in direct contact with the concrete. Usually Wawa boards are used for shuttering because they are soft and light-weight, thus easy to work with.

- STRUTTING: The strutting is the supporting and bracing part of the formwork. It keeps the shuttering in position and supports both the shuttering and the concrete inside it until the concrete has set hard. Odum boards are usually used for the strutting because they are harder and stronger than the Wawa.

- CONCRETE COVER: Concrete cover, also called clear cover, is the thickness of concrete between the surface of the concrete and the nearest reinforcement bar enclosed in the concrete (Fig. 2).

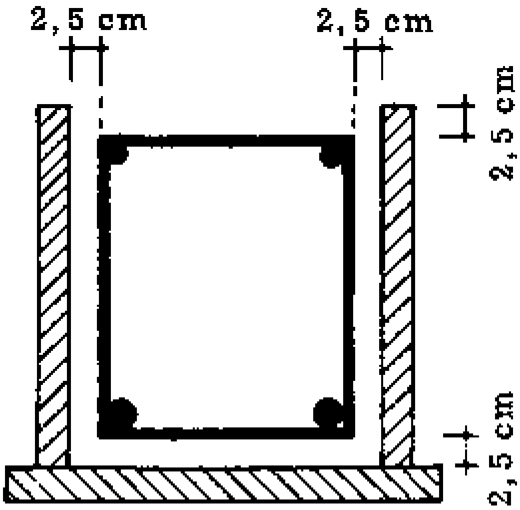

Fig. 2 CLEAR COVER

When the formwork is ready, the reinforcement cage is set into it. Spacers are attached to the bottom side of the stirrups (Fig. 3). These ensure that the reinforcement bars are correctly positioned within the concrete. The spacers are made beforehand out of cement mortar to the dimensions specified for the concrete cover thickness. A short piece of binding wire should be pressed into the fresh mortar of the spacer, so that it can be fixed properly on the rod.

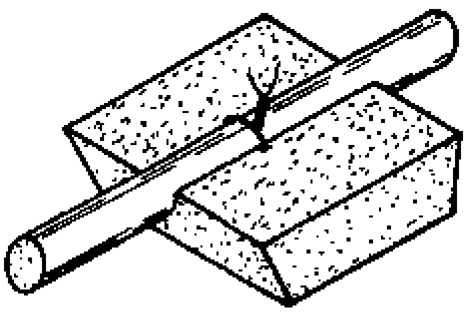

Fig. 3 DOVETAILED SPACER

There must also be spacers on the sides of the cage, to hold the stirrups away from the side boards of the shuttering.

- NOTE: When casting concrete, take care that the cage remains in position and that the concrete is well compacted around the reinforcement bars.

NOTES:

Casting reinforced concrete lintels

Concrete lintels are made in two ways. They are either cast-in-situ or they are precast.

- CAST-IN-SITU: This method is the most common one in Rural Building. The lintel is cast in situation; in the place where it is needed (Fig. 1). The advantage of this method is that no soffit board is needed for the form, because the head of the door frame acts as the bottom of the form, provided that the frame has been installed already. A further advantage is that any roof anchorage, if needed here, can easily be inserted into the reinforcement cage at the correct position.

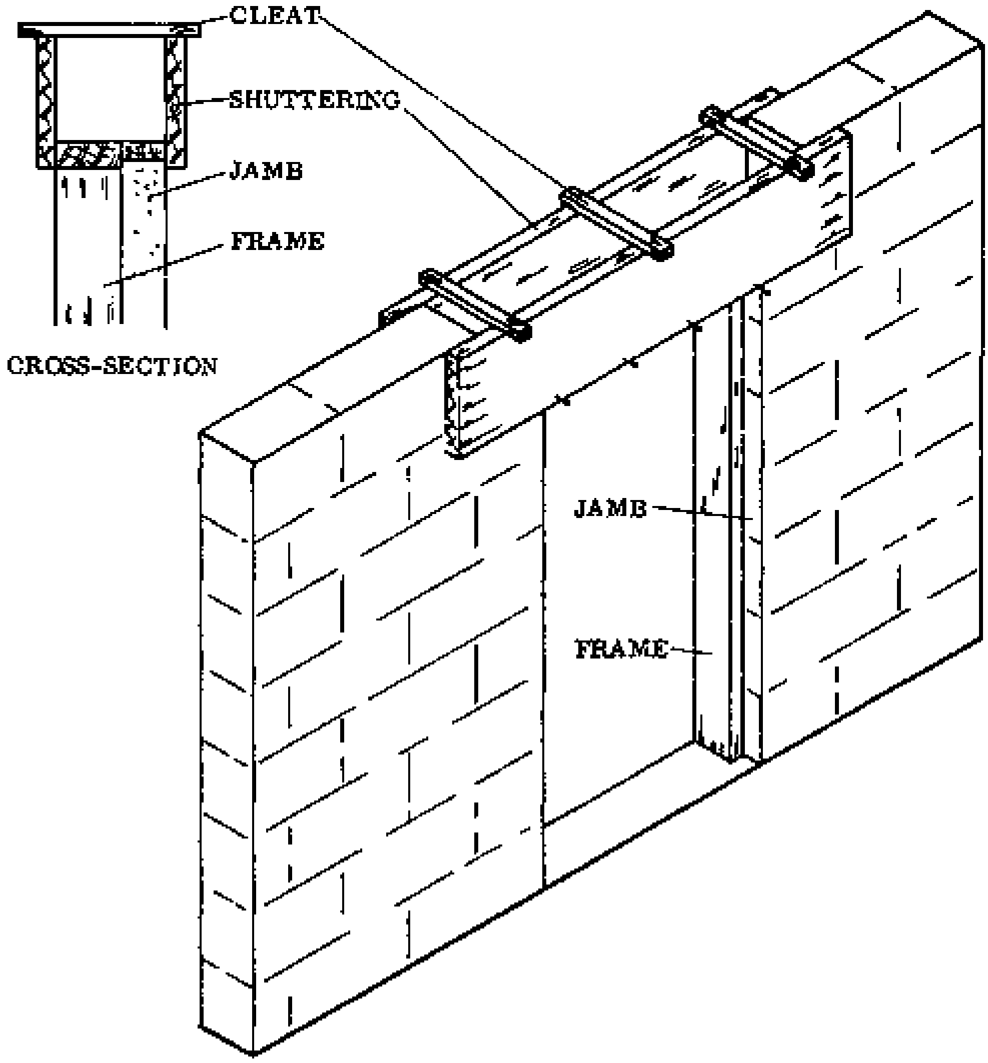

Fig. 1 CAST-IN-SITU

- PRECAST: A precast concrete lintel is a lintel which is made in advance. The formwork is on the ground and the concrete is cast there. When the construction reaches lintel height, the concrete lintel has set hard and can be set into position. The advantage of this method is that it saves time, since the wall above can be completed immediately after the lintel has been laid (Reference Book, page 137).

If several lintels have to be made, a form like the one shown in Fig. 2 can be used.

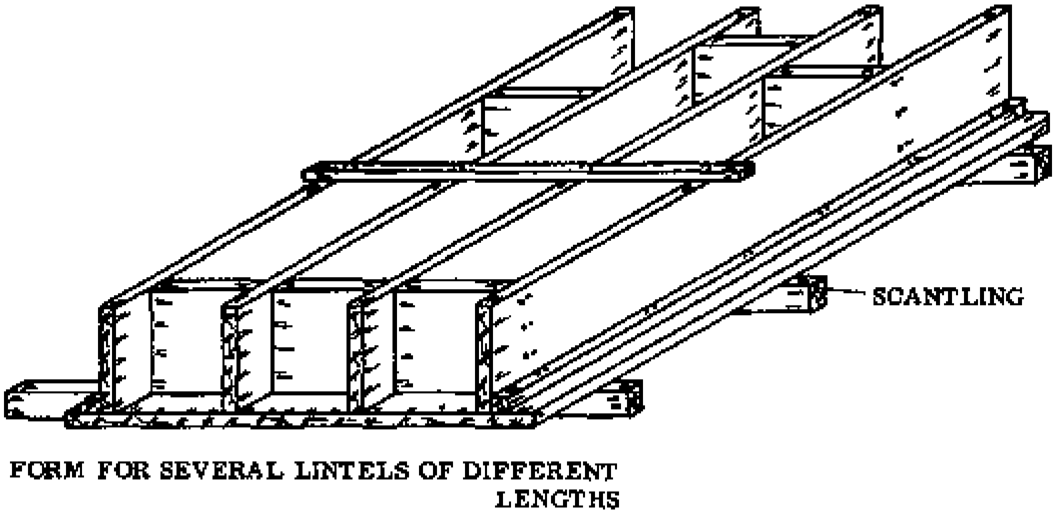

Fig. 2 PRECAST

- NOTE: Precast concrete lintels must be marked on their top face with the letter “T” to ensure that they are placed in the correct position and not upside-down.

- PREPARATION OF THE FORMWORK: No matter which of the above methods is used, the formwork has to be prepared before the concrete is cast. This involves cleaning dirt and dust from the surfaces which will be in contact with the concrete, and watering or oiling them.

The formwork must be completely sealed so that no gaps remain for the cement paste to escape. This would result in voids and weak concrete.

- COMPACTION: The concrete is filled into the formwork in layers, and compacted by tamping with an iron rod or the trowel. Tapping lightly on the formwork with a hammer also helps to consolidate the concrete.

- CURING: When the concrete is starting to get hard, the lintel must be kept wet and covered. This process is called curing and must be continued until the concrete is completely set and the formwork can be removed.

NOTES:

- STRIPPING: Stripping refers to the removal of the formwork; this has to be done carefully to avoid causing shocks or vibrations.

After the formwork is removed, clean all the parts of it and remove the nails. Stack the different parts neatly to keep them from getting bent or warped.

- STRIPPING TIME: This is the period between the casting of the concrete and the time the formwork can be stripped off. During this time the formwork containing the fresh concrete must not be disturbed, so that the concrete can set hard without any cracks forming in it.

Depending on the size, shape and position of the concrete member, the stripping time varies from 4 to 28 days.

NOTES:

ROOFS

Anchor beam

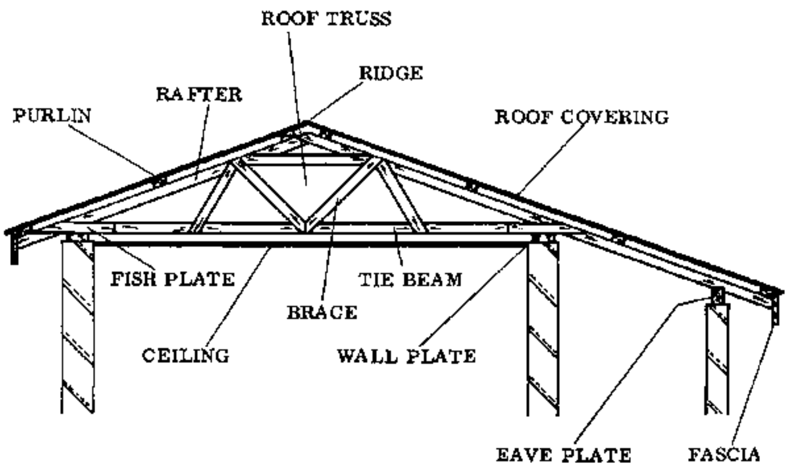
When the walling above the lintels is completed, the top of the wall may be covered with a strip of reinforced concrete, all around the outside walls of the house. This is the anchor beam, where the roof construction is anchored. It is also known as the ring beam or concrete belt.

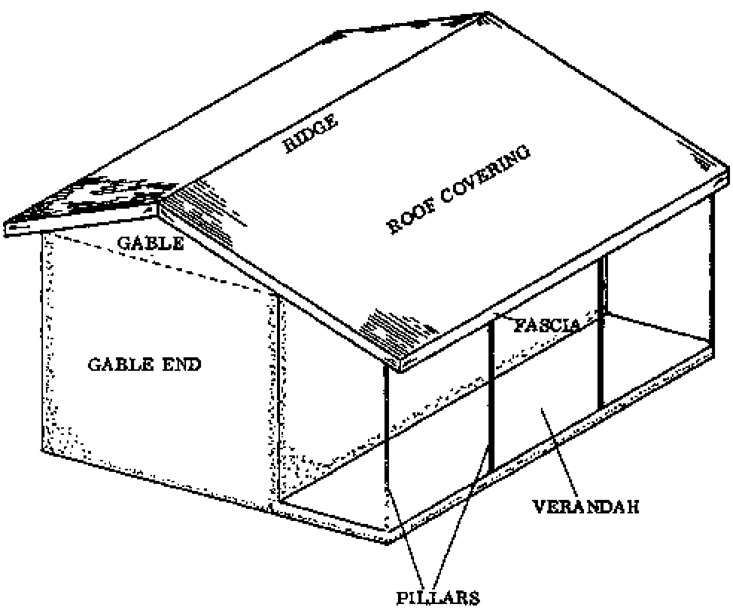
Wall plate

For smaller spans, the Rural Builder can install a wooden wall plate instead of an anchor beam. Both of these are explained further in the section on roofs in the Construction Book.

Terms

On this page and the next page, most of the parts and members of the roof construction are mentioned. The details of roof construction are dealt with in the Construction Book.





NOTES:

PLASTER - RENDER

Plaster and render are mortars with different mix proportions; they are applied to walls to protect the blocks from weather etc.

Internal surfaces are plastered; the mortar used is called plaster. External surfaces are rendered; the mortar is called render.

Functions of plaster and render

Since most of the wall consists of landcrete blocks, it has to be rendered to make it weatherproof, and to protect the blocks against rain which otherwise quickly damages them. The ideal rendering will prevent water from penetrating, will be free from cracks and will stick tightly to the wall. At the same time, the appearance of the building is improved.

The function of plaster is to give the inside walls a smooth, plain finish so that the rooms both look nice and are easily cleaned. No gaps or holes should remain for insects, spiders, etc. to find shelter in. Wet areas such as bathrooms, showers, kitchens and toilets, are plastered to protect the landcrete blocks from moisture penetration. In addition, the plaster serves as a protection against fire in buildings which are made out of a wood skeleton covered with mud (a common construction in southern Ghana).

Application

The application of the plaster can be done with one coat or two coats. Generally one coat work is done, but two coats may sometimes be required, for example when the wall is very uneven and a thick plaster coat is needed to cover the irregularities.

Sometimes a spatterdash coat is applied to the wall before the plaster, to give a good grip to the plaster. This is discussed on page 176; see also the Reference Book, page 29.

NOTES:

Plastering or rendering

Before the plaster or render is applied, the wall should be thoroughly checked to make sure that it is plumb and its surface flat. Holes and hollow parts should be filled in, and single projecting blocks must be chiselled off. The latter problem can often occur on the inside of walls due to irregularly made blocks.

The face of the wall should be free from loose dirt and dust, and it must be well dampened to reduce the absorption of moisture from the mortar.

On outside corners, so-called edge boards are fixed so that they project past the edge by a distance equal to the thickness of the coat to be applied (Fig. 1).

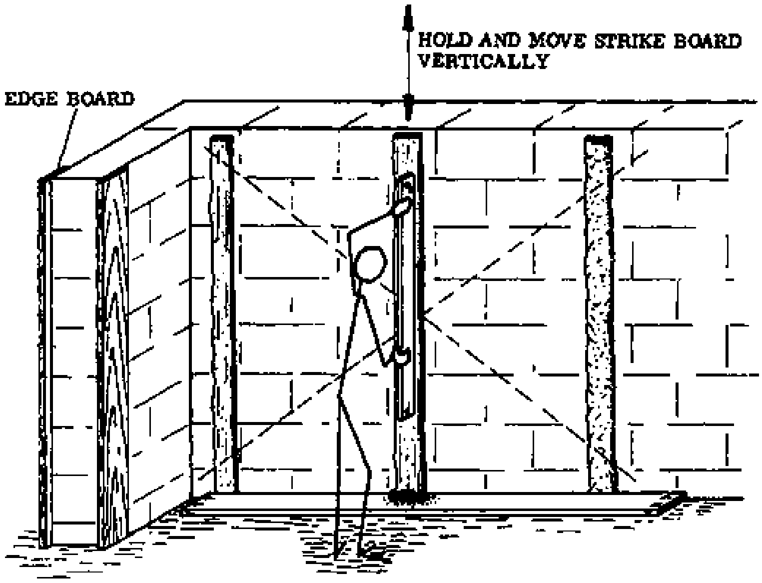


Fig. 1 PREPARATION OF SCREEDS

On inside walls and between edge boards, screeds are prepared according to the required thickness; they are situated as wide apart as the strike board (Reference Book, page 25) can readily bridge.

A screed is a strip of plaster or render which is carefully applied to the correct thickness to act as a guide for the strike board. In making the screeds, hold the strike board vertically and give it an up and down motion as you move it across, smoothing the screed (Fig. 1). The screeds will be flush with the finished surface and must be carefully plumbed and lined out (Fig. 1).

A board can be laid close along the bottom of the wall so that any mortar which is dropped can be picked up again, to avoid wasting material.

When the screeds are ready, the plaster can be applied as shown in Fig. 2. For this step the strike board is held horizontally and moved from side to side as it is pushed up the wall, smoothing the plaster.

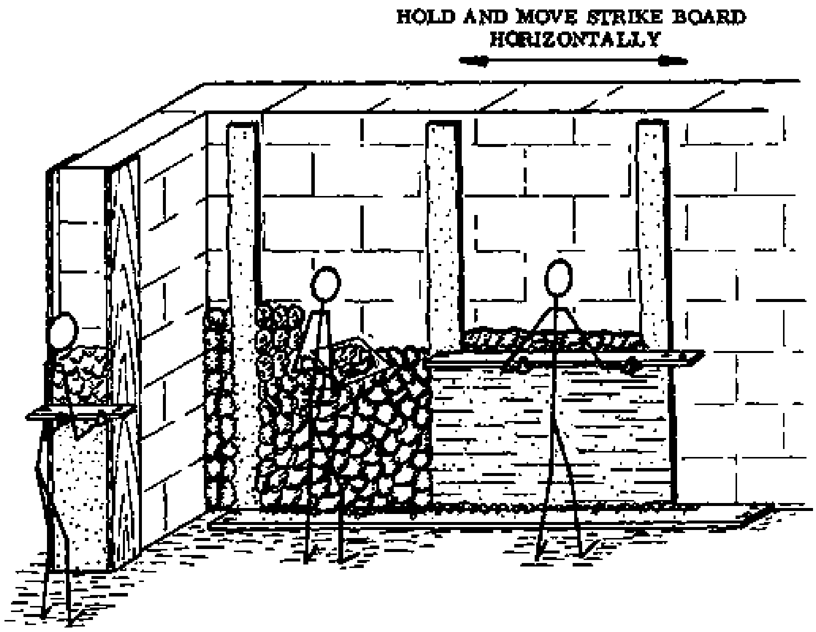

Fig. 2 APPLYING PLASTER

The aggregates

Regardless of where the sand for the plaster or render comes from, it must be clean and suitably graded (Reference Book, page 159, and pages 147 to 151).

Sand for rendering should be sharp and well graded, from fine to very coarse. The mortar may be difficult to apply, but nevertheless this is the best way to get a rendering that will not crack and let water in.

Sand for plastering should be well graded, from fine to fairly coarse; and for a finishing coat from fine to medium. Well graded sand reduces the drying shrinkage and cuts down the danger of cracking and crazing. Crazing means the formation of hairline cracks on the surface of concrete, plaster or render; usually it is caused by too much water in the mix, or by a too rich mix.

Mix proportions

In Rural Building, most of the mortars used for plaster and render are cement mortars, because lime is not always available.

The mix proportion for plaster ranges from 1:8 to 1:12, depending on the condition and grading of the sand. Both coats should have the same strength as far as possible if two coats are applied.

The mix proportion for render can vary from 1:6 to 1:10. It is generally agreed that the sides of the house which are exposed to rain should have a better mix. However, the mix proportion should never be better than 1:6, and should be adapted if possible to the strength of the background (Reference Book, pages 158 to 165).

Additional protective measures

When the plaster or render has set hard and has dried, it is advisable to paint the whole surface with emulsion paint (Reference Book, page 201).

If lime is available (Reference Book, page 152 and page 200) the walls are first white-washed to fill up the tiny holes in the surface. After this the emulsion paint is applied in two coats. The paint prevents water from penetrating into the plaster or render; reflects light and thus keeps the walls cooler, and gives the house an attractive appearance.

When emulsion paint has dried, it will not dissolve in water, so it can easily be cleaned with water and a soft brush.

- REMEMBER: Sand for plaster and render should be clean, properly graded and as coarse as is appropriate for the particular application.

Joints should be carefully raked out while the mortar is still fresh, so that the plaster or render can grip well. Another method is to apply a spatterdash to the wall to give a good grip to the plaster or render.

No coat should be richer than the coat underneath it. If you have to make two of different strengths, then the undercoat should be stronger than the finishing coat. Try to avoid making two coats of plaster or render, because it is difficult to get a good connection between the two coats. The spatterdash is not a coat, it is a background for the plaster or render.

NOTES:

__Spatterdash__

Spatterdash can be used to produce an attractive appearance, or it can be applied before plastering in order to make a good surface for the plaster or render.

Spatterdash is a wet, rich mix of cement and sand, called a slurry. This sand and cement is mixed to a proportion of 1:1,5 or 1:3. This slurry is thrown hard, or spattered, against the smooth block or concrete surface, and then allowed to harden (Fig. 1).

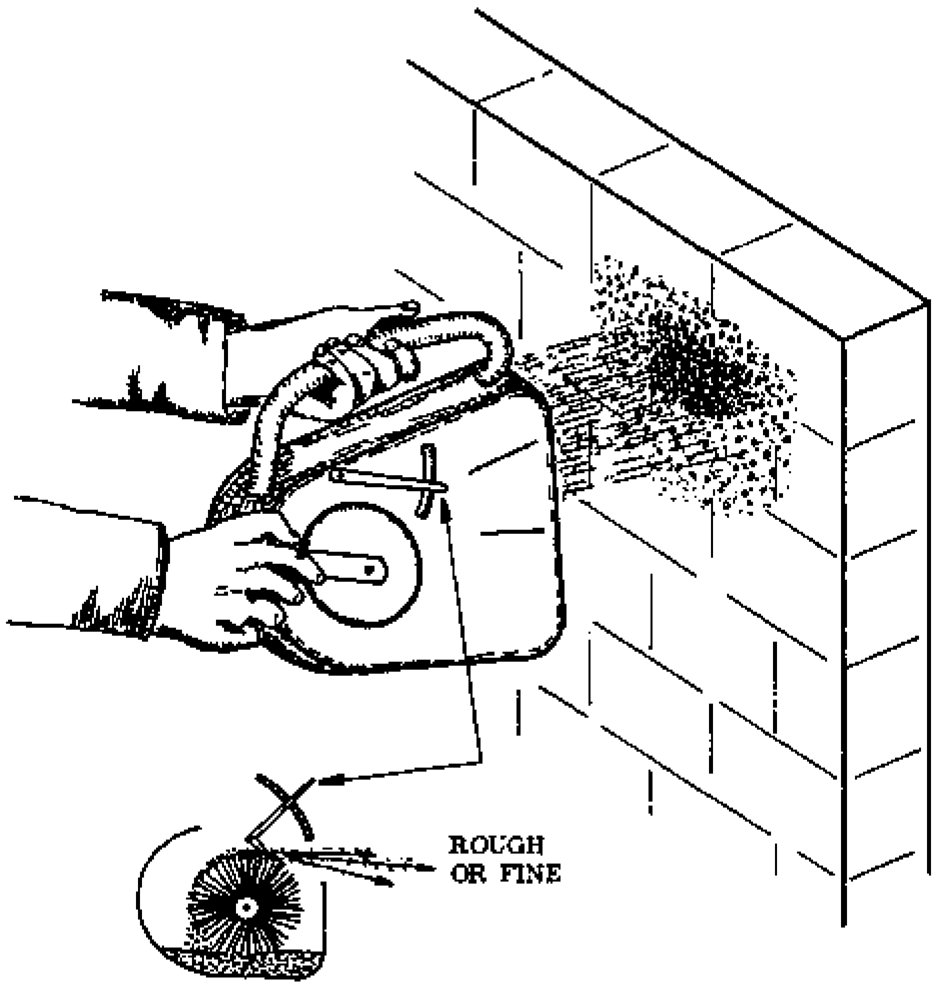

Fig. 1 & Fig. 2 FLICKER BAR

When you work with this hand operated machine (Reference Book, page 29), do not overload the machine with material. It is better to use small quantities at frequent intervals. All of the slurry must be used within 1 hour of the time it is mixed.

Do not set the flicker bar adjuster beyond the second notch when the machine is new. Only when the bar wears out should it be set to a lower notch (Fig. 2).

FLOOR CONSTRUCTION

The dry climate in the north of Ghana makes it advisable to construct the floor after the roof covering has been completed. This makes it easier to cure the concrete, and to make sure that the floor sets hard without cracking due to excessive drying. There are various methods to construct floors. In Rural Building the main ones are: one-course work, and two-course work.

One - course work

This means that the final surface finish is completed before the base layer has set hard. The result is a monolithic floor construction; which means that the floor throughout can be considered as one solid mass (Fig. 1). The advantage of this method is the short construction time, using a minimum of materials, and no separation between the top layer (screed layer) and the base layer.

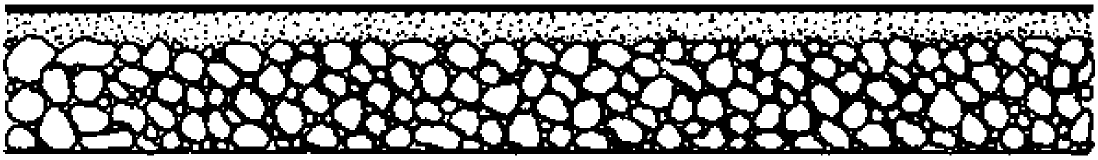

Fig. 1 ONE - COURSE WORK

Two - course work

This means that the base layer and the finish layer are constructed separately. After the base layer has set hard, a floor screed is applied. This is a fine-grained mortar layer, about 2 cm thick, laid to finish the floor surface (Fig. 2).

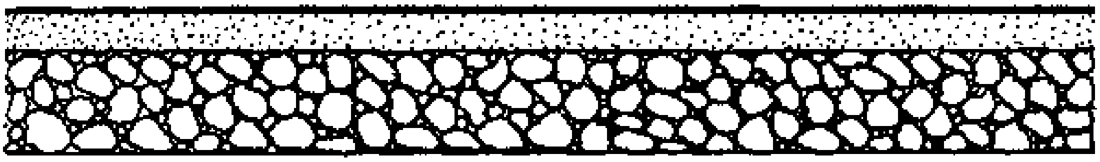

Fig. 2 TWO - COURSE WORK

The advantage of this method is that any faults in the base layer, such as cracks, can be covered. However, it takes longer to construct and requires more cement. Another disadvantage is that it can be difficult to get a good connection between the base layer and the floor screed. The base layer should be carefully treated with cement and water to form a good connection between the floor screed and the base layer.

Casting methods

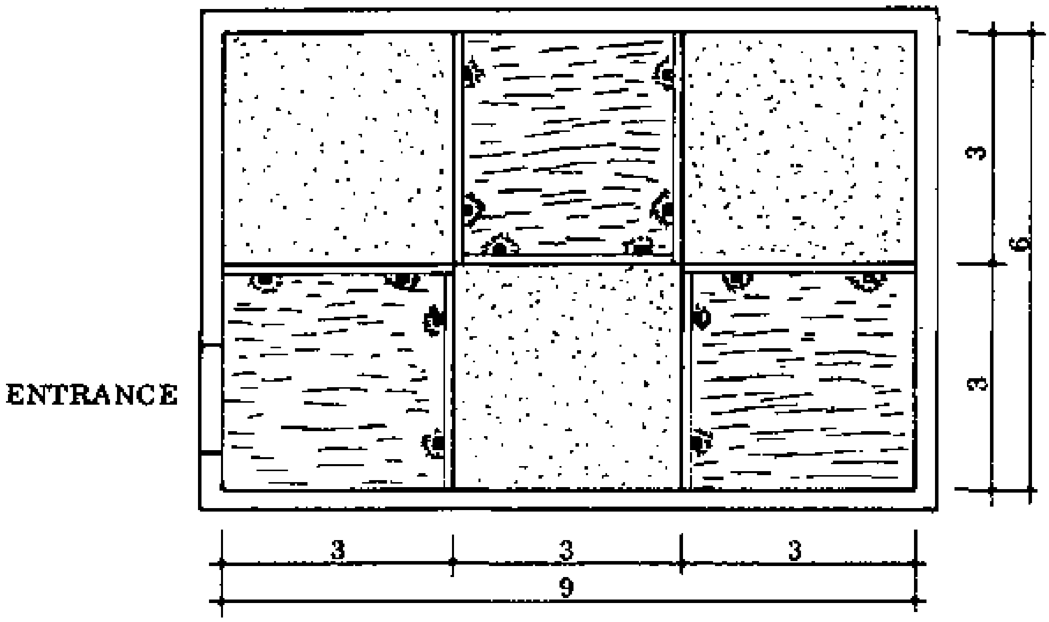
If a floor area is larger than approximately 10 square meters, the area should be divided into bays for concreting. A bay is one of several uniform divisions of a concrete floor which are cast at any one time.

The bays are separated by edge boards, which are laid and levelled to the required floor thickness. The edge boards act as a guide for the strikeboard to level off the concrete surface, therefore they must be laid and levelled with great care.

On the drawing below you can see the positions of the edge boards when the floor is divided into six bays. The boards should be arranged as shown so that the corners of the concrete bays will match each other when the floor is complete.

The division of the floor into bays helps to prevent the development of cracks due to shrinkage during the hardening process. The smaller the area, the less the shrinkage, and the fewer cracks will appear. Square-shaped bays are the best because all the sides will shrink by the same amount.

Bays also make the construction process easier. The bays are small enough to be cast, levelled and finished within a manageable time. The work can be interrupted to allow the already completed bays to harden. Then the edge boards are removed and the empty bays are cast, using the completed ones as a guide. Once you start casting a bay, it must be completed. Never interrupt a concreting process, as this can result in a faulty bond and the joint will always be visible. For the sequence of operations for casting a floor see Figs. 1 to 8 on the following two pages.



DIVISION INTO BAYS

- MAKE A BEVEL ALONG THE EDGES FOR THE SHRINKAGE JOINTS (ARROW)

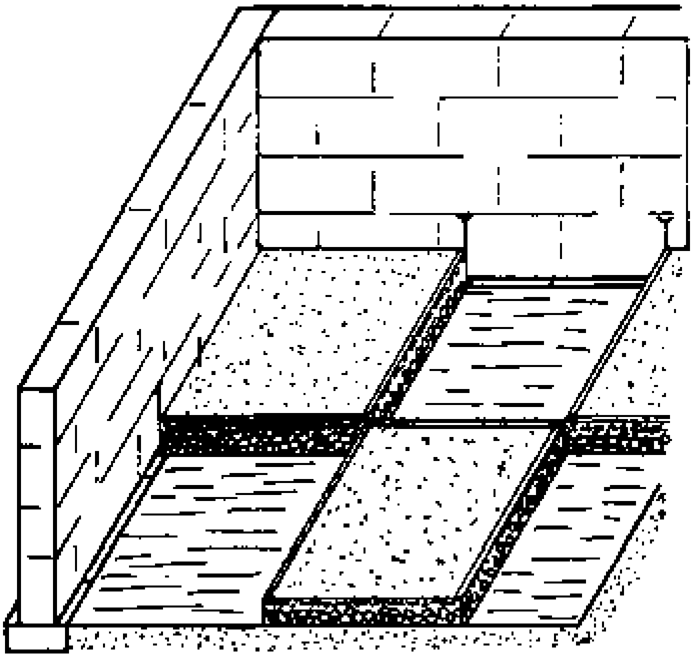

Fig. 8

- TAKE AWAY THE EDGE BOARDS AND PUT SAND ON TOP OF THE FLOOR

- WATER THE FLOOR REGULARLY

Shrinkage gaps

When one set of bays has hardened, the edge boards are carefully removed and the remaining bays can be cast. Shrinkage gaps are made between the adjoining bays. This is done by placing plastic or paper between the bays when the second set of bays is cast, so that the bays are kept separate from each other.

The shrinkage gaps allow the concrete bays to shrink a bit as they harden without cracking. This type of gap is used where the floor is not exposed to the sun or to great temperature changes; usually only for inside floors. Shrinkage gaps can be made in either one-course work or two-course work. A “V” is made along the top edges of the gap to improve the appearance of the floor (Fig. 1).

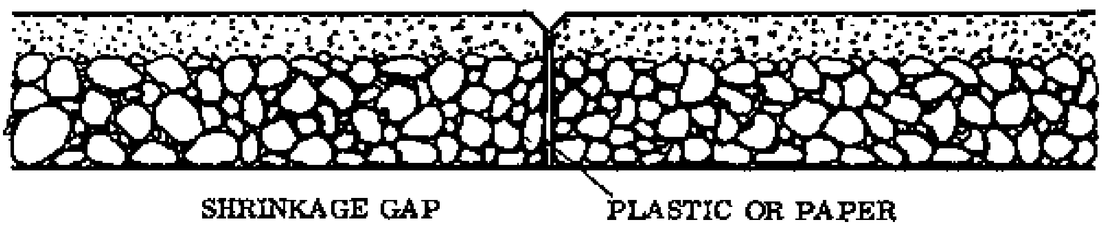

Fig. 1 SHRINKAGE GAP

Expansion gaps

Where the floor is exposed to the sun, as in a verandah floor or any concreted area outside the house itself, expansion gaps have to be made. In this case the edge boards are not removed until all the bays have been cast and hardened. The boards are then removed and the gap between the bays is filled with wet sand, and the floor screed is applied over the top

(Fig. 2). Expansion gaps can only be made in two-course work.

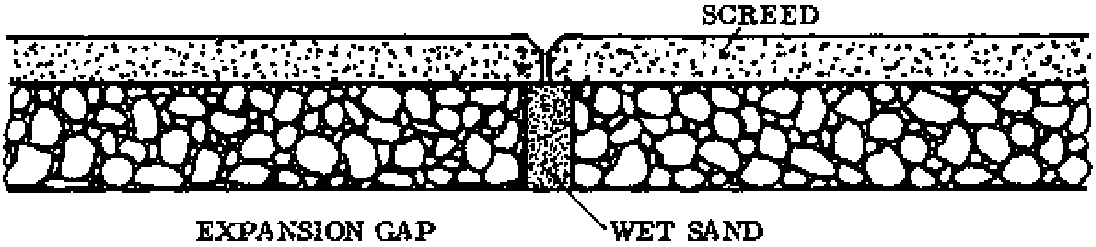

Fig. 2 EXPANSION GAP

The expansion gap allows the floor to expand and contract with the temperature changes without forming cracks. Expansion occurs when the floor is heated by the sun during the day, and shrinkage occurs at night when it cools down. Floors exposed to the sun should be divided into bays of no more than 5 square metres, and expansion gaps should be made in them. The floor screed must also be provided with a shrinkage gap; this should be located directly above the expansion gap in the base layer (Fig. 2).

A WORD FOR THE TRAINEE BEFORE ON-THE-JOB TRAINING

With the basic knowledge you have gained in this part of the course, you should now be prepared to go to a building site for on-the-job training.

Remember that so far you have covered only the first part of the course. You will still need to acquire much more knowledge and many more skills before you can be called a Rural Builder.

While you are working at the building site, remember that this time is also supposed to be a learning experience. If you want to learn, you have to ask questions about how and why certain things are done. If you can’t get your questions answered at the time, write them down and bring them to your instructors for explanation. It is a good idea to keep a notebook; writing down in it the methods you applied at the building site, the time that a certain operation required, the materials used and how much was needed, and any ideas you have about how it could have been done differently.

You should occasionally review the information in this book, especially as it comes up on the job. Don’t be afraid to use the book and to write notes in it; the notes which you make at this time can be very helpful to you later on, when you have finished the course and are working as a builder.

NPVC

RURAL BUILDING

REFERENCE BOOK

PREFACE

This official text book is designed purposely to meet the needs of trainees who are pursuing rural building courses in various training centres administered by the National Vocational Training Institute.

The main aim of this book is to provide much needed trade information in simple language and with illustrations suited to the understanding of the average trainee.

It is the outcome of many years of experiment conducted by the Catholic F. I. C. brothers of the Netherlands, and the German Volunteer Service instructors, in simple building techniques required for a rural community.

The National Vocational Training Centre is very grateful to Brothers John v. Winden and Marcel de Keijzer of F.I.C. and Messrs. Fritz Hohnerlein and Wolfram Pforte for their devoted service in preparing the necessary materials for the book; we are also grateful to the German Volunteer Service and the German Foundation For International Development (DSE) - AUT, who sponsored the publication of this book.

We are confident that the book will be of immense value to the instructors and trainees in our training centres.

DIRECTOR: National Vocational Training
Institute, Accra

INTRODUCTION TO A RURAL BUILDING COURSE

Vocational training in Rural Building started in the Nandom Practical Vocational Centre in 1970. Since then this training has developed into an official four year course with a programme emphasis on realistic vocational training.

At the end of 1972 the Rural Building Course was officially recognised by the National Vocational Training Institute. This institute guides and controls all the vocational training in Ghana, supervises the development of crafts, and sets the examinations that are taken at the end of the training periods.

The Rural Building programme combines carpentry and masonry, especially the techniques required for constructing housing and building sanitary and washing facilities, and storage facilities. The course is adapted to suit conditions in the rural areas and will be useful to those interested in rural development, and to farmers and agricultural workers.

While following this course, the instructor should try to foster in the trainee a sense of pride in his traditional way of building and design which is influenced by customs, climate and belief. The trainee should also be aware of the requirements of modern society, the links between the old and new techniques, between traditional and modern designs - and how best to strike a happy medium between the two with regard to considerations like health protection, storage space, sewage and the water supply. The trainee should be encouraged to judge situations in the light of his own knowledge gained from the course, and to find his own solutions to problems; that is why this course does not provide fixed solutions but rather gives basic technical information. The instructor can adapt the course to the particular situation with which he and the trainee are faced.

This course is the result of many years of work and experimentation with different techniques. The text has been frequently revised to serve all those interested in Rural Development, and it is hoped that this course will be used in many vocational centres and communities. It is also the sincere wish of the founders of this course that the trainees should feel at the completion of their training that they are able to contribute personally to the development of the rural areas, which is of such vital importance to any other general development.

We are grateful to the Brothers F.I.C., the National Vocational Training Institute and the German Volunteer Service for their assistance and support during the preparation of this course.

Bro. John v. Winden (F.I.C.)
Wolfram Pforte (G. V. S.)
Fritz Hohnerlein (G.V.S.)

LAY-OUT OF THE RURAL BUILDING COURSE

The Rural Building Course is a block-release-system course, which means that the trainee will be trained in turn at the vocational centre and at the building site. The period of training at the centre is called "off-the-job" training, and the period on the building site is called "on-the-job" training. Each will last for two years, so that the whole course will take four years and will end with the final test for the National Craftsmanship Certificate.

<u>BLOCK RELEASE SYSTEM</u>

YEAR	TERM 1	TERM 2	TERM 3
1	X	X	X
2	O	O	O
3	O	X	O
4	X	O	X

X = OFF-THE-JOB TRAINING
O = ON-THE-JOB TRAINING

The total "off-the-job" training period is approximately 76 weeks, each week 35 hours. During this training about 80% of the time is spent on practical training in the workshop. The remaining 20% of the time is devoted to theoretical instruction.

The total "on-the-job" training period is approximately 95 weeks, each week 40 hours. During this period the trainee does full-time practical work related to his course work. In addition some "homework" is assigned by the centre and checked by the instructors.

A set of books has been prepared as an aid to the theoretical training:

A - Rural Building, Basic Knowledge (Form 1)
B - Rural Building, Construction (Forms 2, 3, 4)
C - Rural Building, Drawing Book (Forms 1, 2, 3, 4)
D - Rural Building, Reference Book

All these books are related to each other and should be used together. The whole set covers the syllabus for Rural Building and will be used in the preparation for the Grade EL, Grade I, and the National Craftsmanship Certificate in Rural Building.

CONTENTS

BOOK INTRODUCTION

Rural Building Tools, Maintenance of Tools, Materials and Products is a reference book. This means that you should not read it through at once like a textbook, but use it when you need to look up information about certain tools, about the maintenance of a tool, or about a kind of building material or building product.

This book is divided into 4 parts:

PART 1: RURAL BUILDING TOOLS

This part of the book covers the basic tools needed in Rural Building and how to use them. It also treats a variety of site tools, site equipment and some optional tools.

PART 2: MAINTENANCE OF TOOLS

This section is about how to maintain the tools, so that they work better and last longer,

PART 3: RURAL BUILDING MATERIALS

This part deals with building materials; both the traditional ones and modern ones, that are used in Rural Building.

PART 4: RURAL BUILDING PRODUCTS

This part of the book covers the products such as reinforcement steel, blocks, paint, sheet materials, roofing sheets etc. used in Rural Building.

It is very important that you know all the technical terms, so if you come across a word or term that you don't understand you should look it up in the glossary at the end of this book, where most of the technical terms are explained. If you can't find the word in the glossary, write it down and ask your instructor to explain it.

The Tables of Figures in Appendix I are intended to help you to figure out the amounts of building materials that will be required for the planned building.

GENERAL RULES FOR SAFETY

1. Give all your attention to the job and don't distract others.

2. Be sensible in your behavior, don't play with tools or run about the building site or workshed.

3. Be alert, watch out for any dangerous situations, warn your colleagues, and report it to the person in charge.

4. If you are not sure of the correct way to use a tool, ask your instructor.

5. Make sure that your workpiece is safe and securely fastened in place before you start cutting or any work.

6. When cutting wood, guide the cutting tool in the correct way and keep your hands away from the cutting edge. Always cut away from yourself.

7. Wear safety goggles when cutting blocks, breaking concrete or grinding tools.

8. Carry tools with the pointed ends down.

9. When you finish working with a tool, clean it and return it to the toolbox.

10. Never throw or drop tools.

11. Keep the place tidy. A workplace scattered with tools is dangerous.

12. Maintain your tools, work only with clean and sharp tools.

13. A good quality, well maintained tool can do half the work for you.......

NOTES:

PART 1: RURAL BUILDING TOOLS

During thousands of years of development, people became aware that making certain things and doing certain jobs requires the use of special tools. Technical tasks could not be done with bare hands alone.

To make the things that they wanted, people were forced to design and make different tools for different jobs. For example, without tools like the plough, the farmer would not be able to feed his family. The plough was invented to make his work easier and to make sure that he could harvest a surplus of food for the benefit of the whole society. The plough was invented step by step and adapted to serve under different conditions.

In the same way, tools are very important in building. They enable people to shape all kinds of materials into useful articles and to make improved shelters to protect them from the weather and from enemies.

Early tools were the axe and the cutlass, which allowed men to cut wood for building instead of breaking it, and to make things like ladders, wheels and stools.

Now the Rural Builder uses more advanced tools and it is necessary for him to learn how to use and treat these tools well, because they are valuable. Even the most skilled craftsman can do little or nothing without the proper tools.

Since the Rural Building trade combines the crafts of carpentry and masonry, the Rural Builder's set of tools must also be a combination of masonry and carpentry tools.

This combined set of tools is limited and adapted for building in rural areas. It will enable the Rural Builder to construct perfectly well the kind of living quarters that are needed in the Northern and Upper regions of Ghana, starting from the foundation to the last nail of the roof construction.

Due to the structure of this course it is convenient to introduce the masonry tools first.

NOTES:

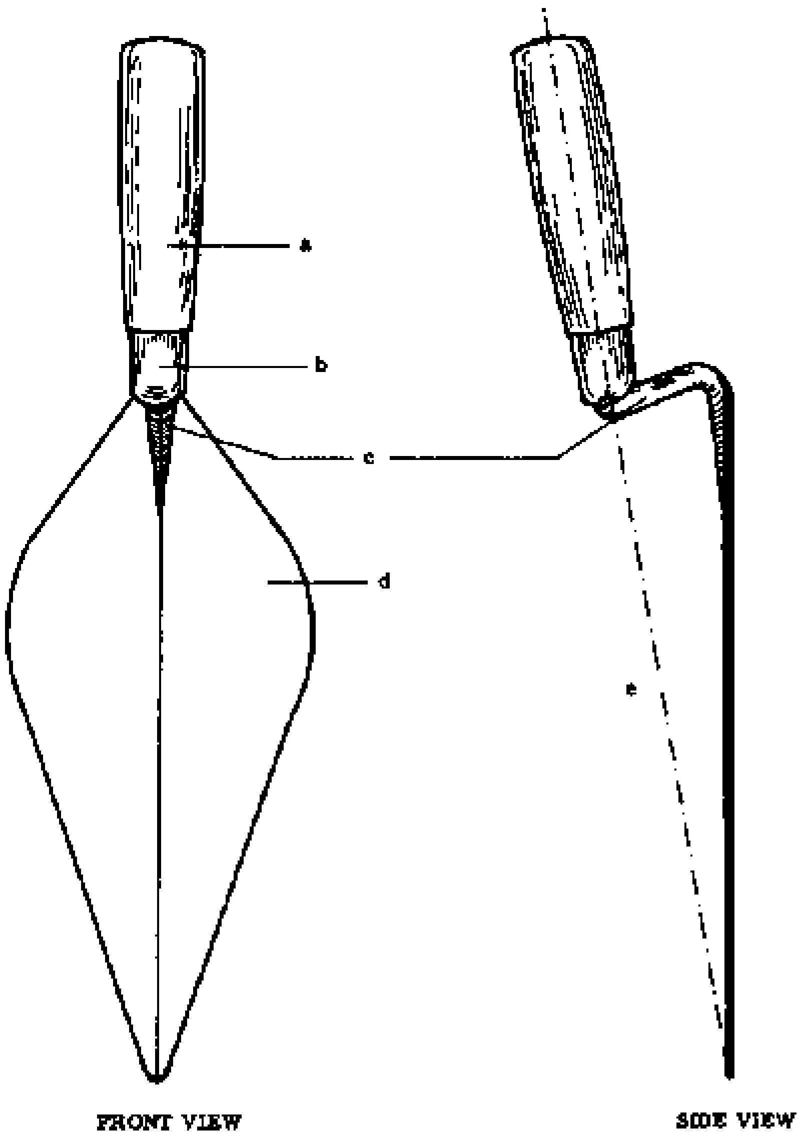

Fig. 1

NEVER CUT SANDCRETE BLOCKS WITH A TROWEL, AS THIS WILL DENT THE EDGE OF THE BLADE.

LAYING TOOLS

THE TROWEL

Of all the tools that a blocklayer uses, the brick trowel is by far the most important one, for it is almost continuously needed during the building construction.

Its main function is to pick up the mortar and to spread it to an even thickness in preparation for laying the blocks. Apart from its use in the trimming of landcrete blocks, the trowel is needed for any work where mortar or concrete is worked up.

NOTE: Never cut sandcrete blocks with a trowel, as this will dent the edge of the blade.

The long narrow-bladed trowel shown in Fig. 1 is very popular in this country and it is most frequently used for laying blocks and trowelling floorscreeds.

This trowel consists of a wooden handle (a) connected by a ferrule (b) to the shank (c) which joins the steel blade (d). The size of the blade ranges from 23 to 36 cm in length; this dimension being measured from the back of the shank to the tip of the blade, while the width varies from 9 to 13 cm.

The extended axle line of the handle (e) should line up with the tip of the blade in order to provide the best handling. This applies to all types of brick trowels.

When you buy a trowel, make sure that the blade is of a good quality steel. You can judge this quality by knocking your fingernail on the blade. The higher the sound the harder the steel.

The blade should also be able to bend slightly and return to its original position. If not, the blade is too soft.

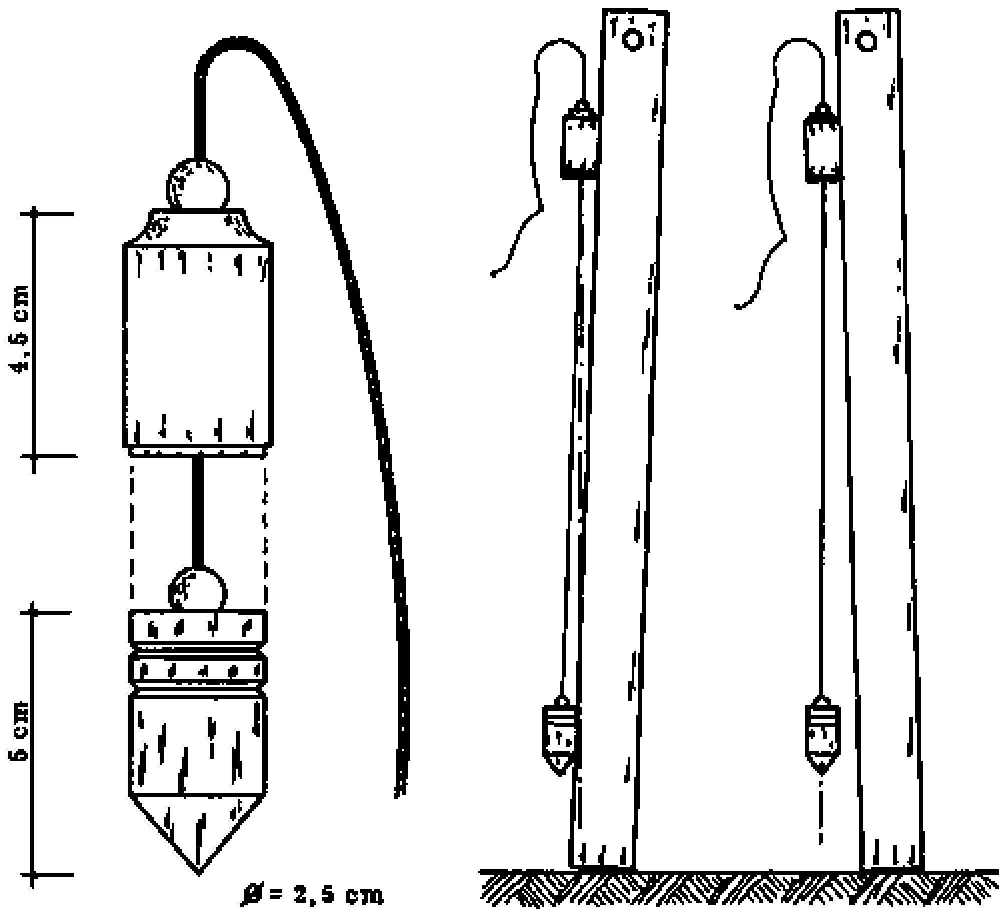
NOTES:

WOODEN SPIRIT LEVEL

Fig. 1

METAL SPIRIT LEVEL

Fig. 2



PLUMB BOB TOUCHING FLYING

STRAIGHTENING TOOLS

There are four main straightening tools.

SPIRIT LEVEL

These are wooden or metal straight edges specially fitted with plastic tubes containing spirit and a bubble of air.

These tubes are set into the straight edge so that when it is placed across two points which are level to each other, the air bubble will be exactly in the centre of the tube. This position is clearly marked with lines inside the tube (Figs. 1 & 2).

In a similar way, a tube is set in the straight edge to read with the level held vertically, which enables you to plumb members over short distances. If the level is used in conjunction with a straight edge you can plumb or level over a longer distance.

To level a longer horizontal distance you cannot use a straight edge with a level. Instead you have to use a water level which will be explained later. To level a vertical distance which is longer than your straight edge you can use your plumb bob.

PLUMB BOB

This tool consists of a solid brass or metal cylinder with a pointed end, which is attached to a suspending line so that its tip is always pointing vertically down. Its upper part is a small wooden block with a hole drilled in its centre so that the line with the cylinder on it can be pulled up or lowered down through the hole.

The diameter of the wooden block is slightly greater than the diameter of the cylinder, so that the cylinder can move freely up and down without touching the workpiece. The dimensions of the plumb bob are shown in Fig. 3.

The main use of the plumb bob is as a more accurate replacement for the vertical spirit level and also to transfer points down vertically in marking. Both methods will be described later.

NOTES:

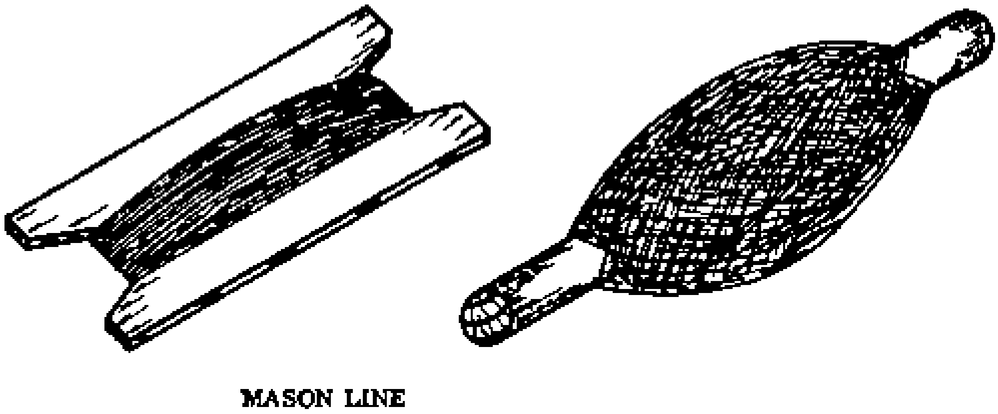


Fig. 1

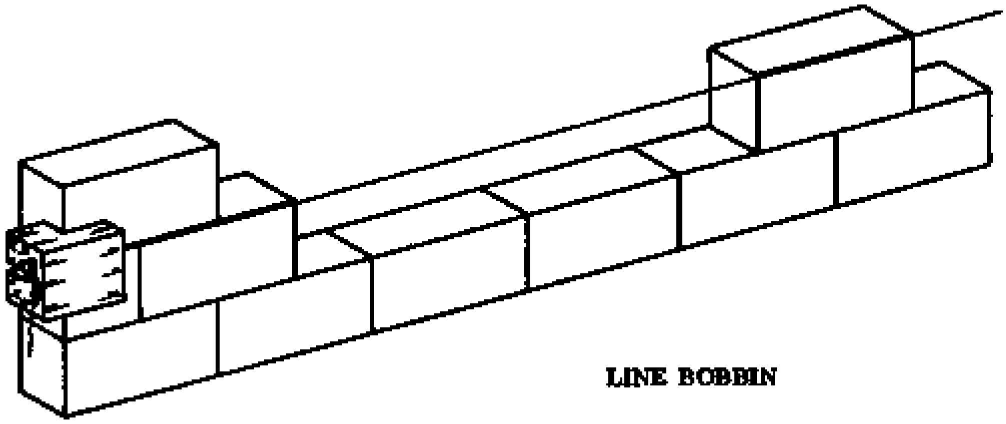

Fig. 2

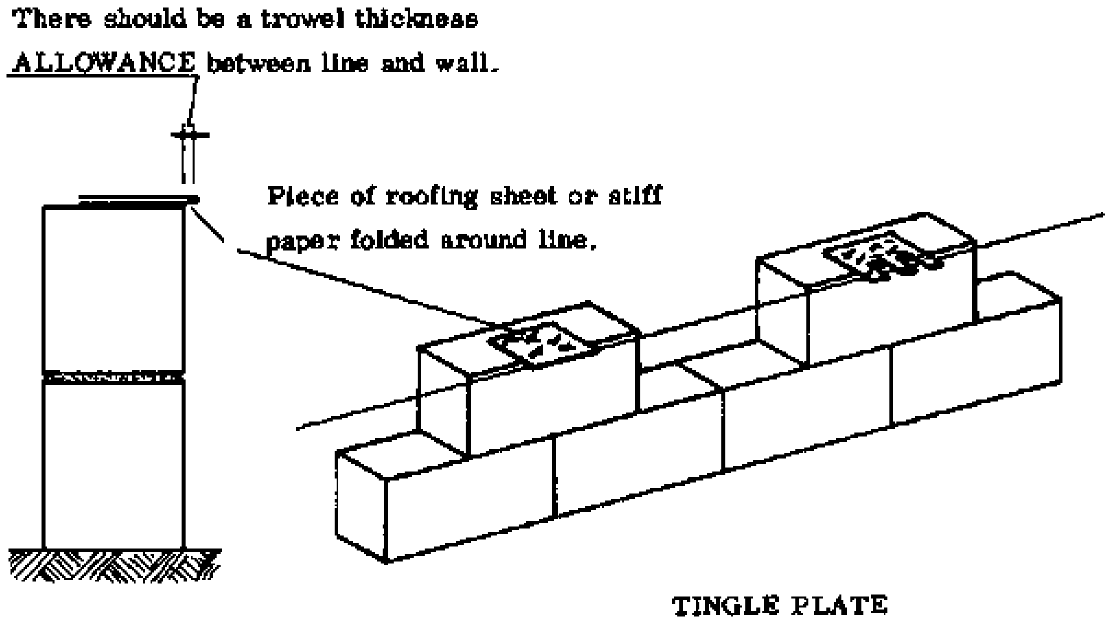

Fig. 3

MASON LINE

When building up walls between two quoins we employ the mason line, which is approximately 30 metres long, to ensure that the courses are straight and at the correct height (Fig. 1).

The line is tightened between two nails driven into the bed joints.

Mason lines are also used for setting out buildings, lining out frames for doors and windows and many other purposes where a straight line is needed for a guide over longer distances.

Instead of nails, so-called line bobbins may be used. These are hard wood blocks made to the size and shape indicated in Fig. 2. The line is stretched between opposite quoins, passed through the sawcut of each bobbin and wrapped around the projecting screws. Their uses will be explained later.

Line bobbins are preferred to nails, as they are easily adjusted to the required level and no holes need to be made in the bed joints.

In addition to the mason line, a tingle plate must be used if the distance between the quoins becomes too great and the line starts to sag. A tingle plate is made from thin metal and it is used to support the line in the middle to prevent sagging. The tingle plate must of course be set at the correct height (Fig. 3).

A tingle plate can easily be made from a piece of roofing sheet or any other sheet metal. Sometimes a piece of stiff paper is used for the purpose.

If the line breaks, it should be spliced and not tied with a knot, because a line full of knots will not be straight.

NOTES:

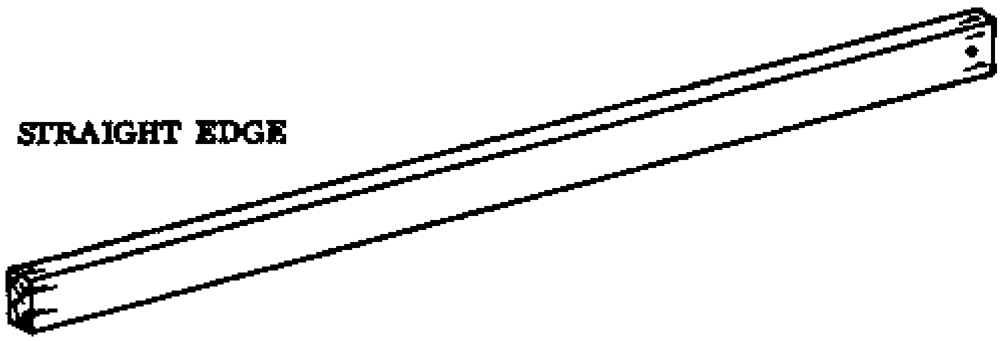

Fig. 1

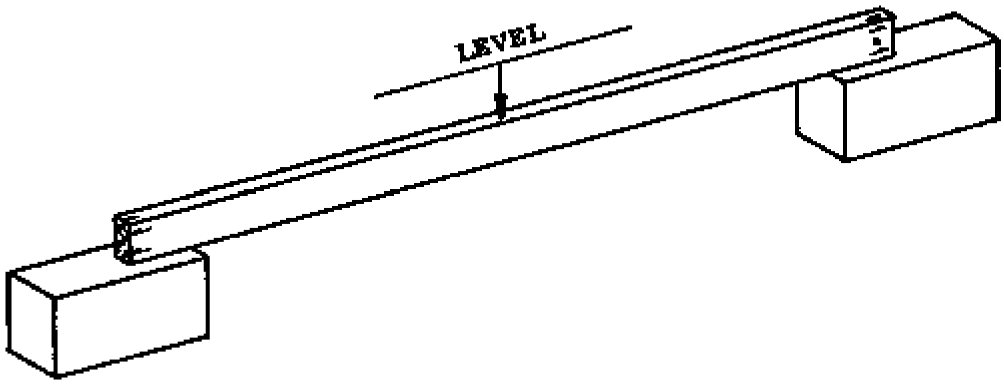

Fig. 2

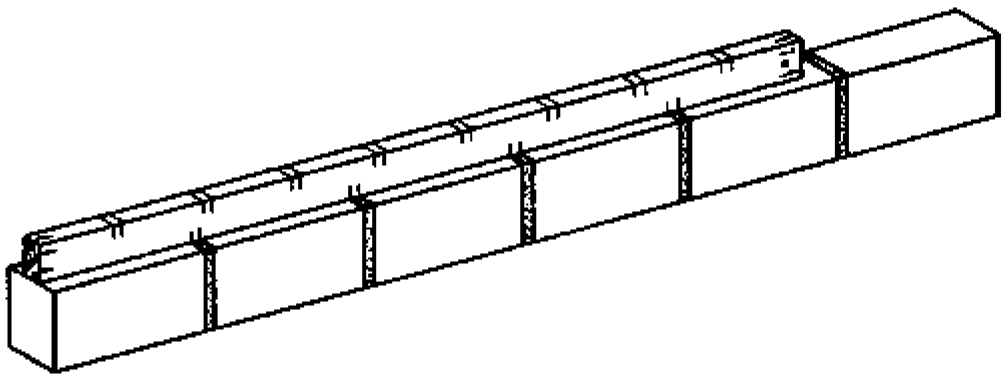

Fig. 3

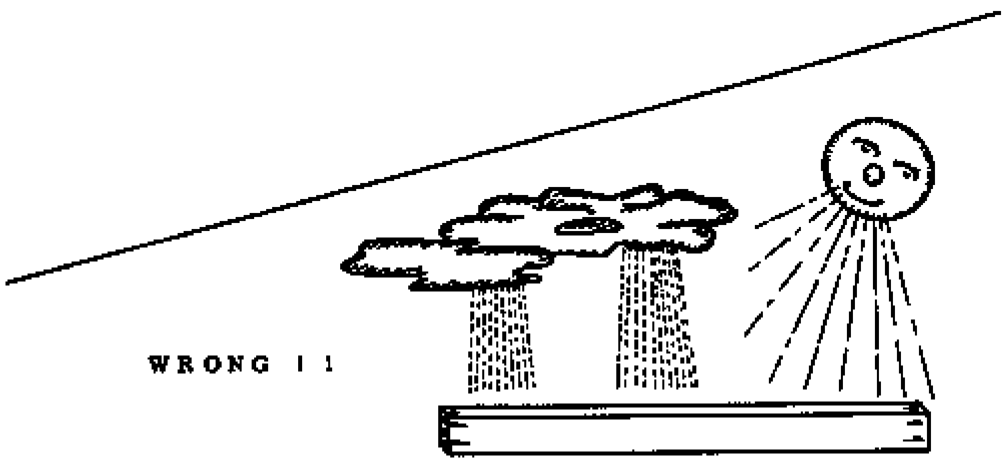


STRAIGHT EDGE

This is a planed piece of wood which should be well seasoned and dry to prevent it from bending and twisting. The dimensions of a straight edge are usually 2 to 2,50 m long, 7,5 cm wide and 2,5 cm thick; both edges must be perfectly straight and parallel (Fig. 1).

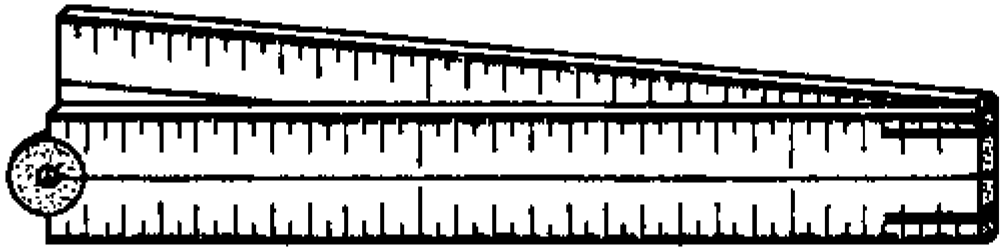
The straight edge is employed for testing masonry work either alone or in conjunction with the spirit level (Fig. 2).

Some straight edges are marked off with saw cuts to the required gauge; that is, one division is equal to the height of a block plus the joint; and, on the other edge, the length of a block plus the joint (Fig. 3).

Its wide range of further applications will be described as it is needed for certain constructions.

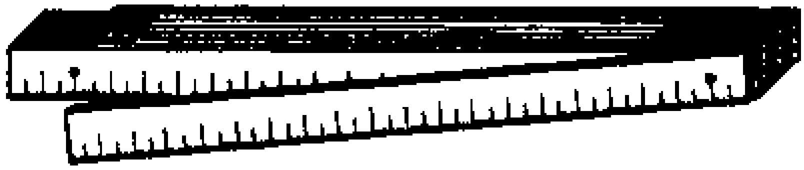
Do not allow a straight edge to dry out in the sun or to be soaked in water as this may cause it to bend or twist (Fig. 4). When you are finished using it, hang the straight edge in a protected place to keep it straight.

NOTES:



FOLDING RULE

Fig. 1



ZIG-ZAG RULE

Fig. 2

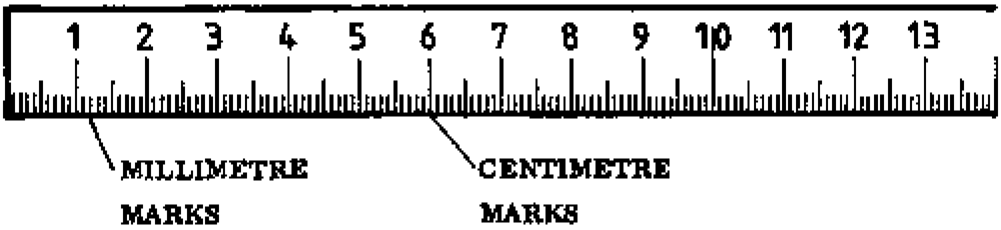


Fig. 3

Fig. 4

PENCIL

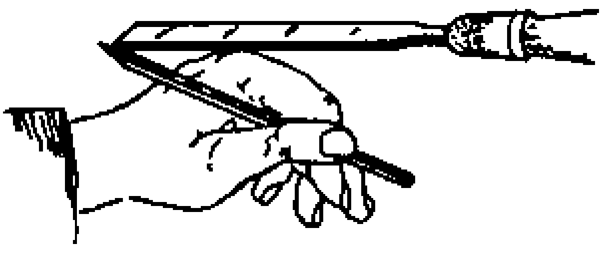

Fig. 5

MEASURING AND MARKING TOOLS

FOLDING RULE

The four-fold rule shown in Fig. 1 is made of four wooden, plastic or metal pieces which are held together by special hinges. It is one metre long and divided on both sides into millimetres and centimetres. It is used to find and check measurements as well as to mark out the work.

To make the rule operate more smoothly and last longer, put a drop of machine oil in the joints.

ZIG-ZAG RULE

A zig-zag rule is similar to a folding rule (Fig. 2). It is made out of the same materials but from pieces which are 20 cm long. As the hinges are different from those of the folding rule, be careful not to break it when opening and closing it. They come in lengths of 100 and 200 cm.

HOW TO READ RULES

The marks on a rule are of different lengths to make it easier to read accurately (look at the rule you use in class). The marks at each centimetre are the longest, the marks for 5 mm (1/2 cm) are medium long, while the millimetre marks are shortest (Fig. 3).

When measuring with the folding rule or the zig-zag rule, one must make sure that the rule is completely opened and straight. It is then held parallel to an edge, or at right angles to a face. If this is not done, the measurements you get will always be a little different from the correct ones.

PENCILS

For marking on wood, a hard lead pencil (H or 2H) is best (Fig. 4). The point should always be kept sharp, because using a blunt pencil can result in an inaccuracy of up to 2 mm.

Fig. 5 shows how to hold a pencil while sharpening it.

NOTES:

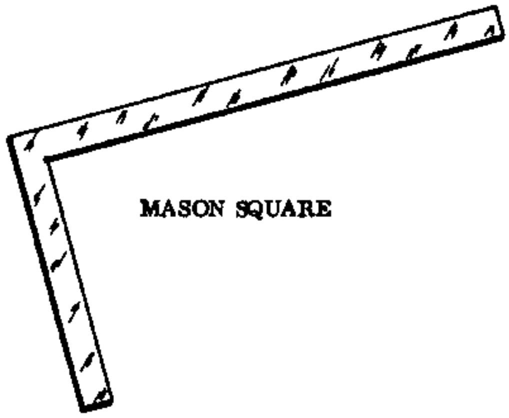

Fig. 1

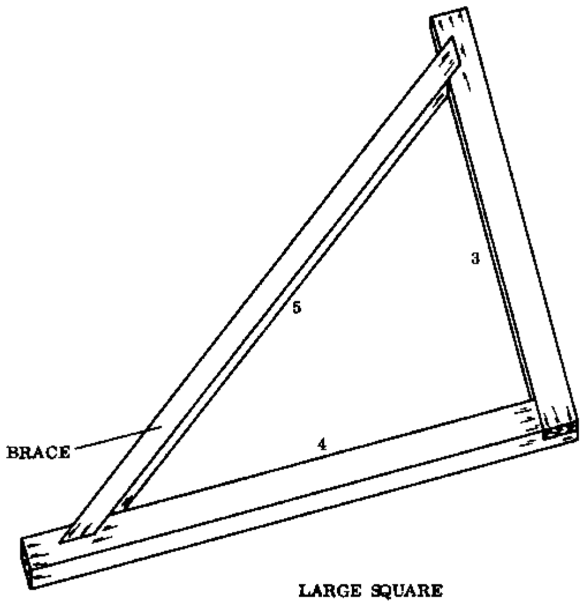

Fig. 2

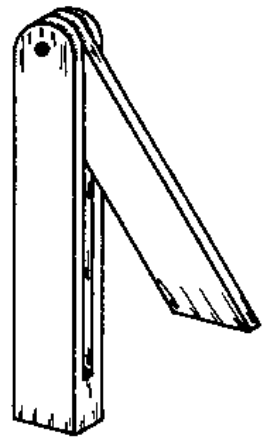

Fig. 3

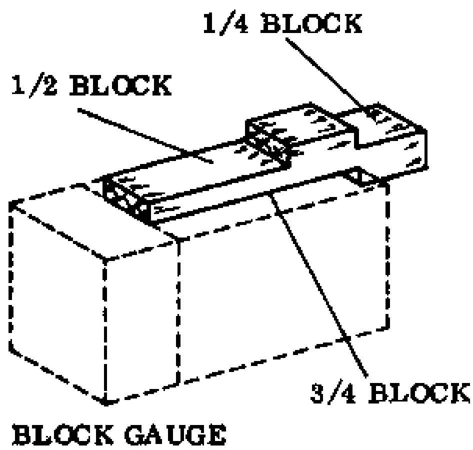

Fig. 4

THE MASON SQUARE

The mason square is made from steel (Fig. 1). Measured along the outer edge, the short blade is 33 cm long and the long blade is 60 cm long. The blades are sometimes marked with millimetres, centimetres, and decimetres.

The mason square is used for setting out right angles as at quoins, and for testing corners during plastering.

When using the square, hold it either horizontally or vertically (not at an angle) to be sure of getting the correct angles.

THE LARGE SQUARE

This square is made entirely from wood (Fig. 2). To construct this large square which is made at the building site, use the 3-4-5 method and nail the boards together securely. A brace over the two legs ensures that the square remains at the correct angle. The square is used to test larger right angles.

THE SLIDING BEVEL

A sliding bevel (Fig. 3) can be made out of wood by the Rural Builder. The two legs are adjustable and held together by a small bolt with a wingnut to make it easy to adjust the bevel. It is used when you have to mark many blocks at a certain angle (also see page 78).

BLOCK GAUGES

These are pieces of wood cut to the size and shape indicated in Fig. 4. Block gauges may be used to mark off the sizes of 1/4, 1/2, or 3/4 blocks. Since the dimensions of landcrete blocks are different from sandcrete blocks, the trainee will make two different block gauges.

The gauges help the Rural Builder to work more efficiently when he is measuring blocks for cutting.

- NOTE: More tools for measuring and marking are included in the following sections with the carpentry tools.

NOTES:

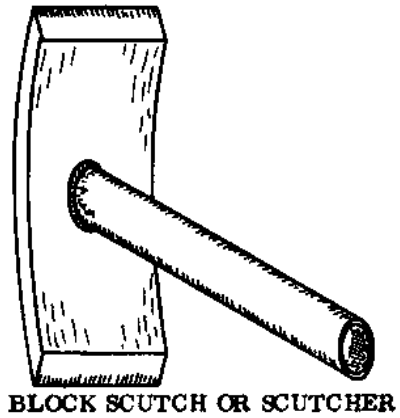

Fig. 1

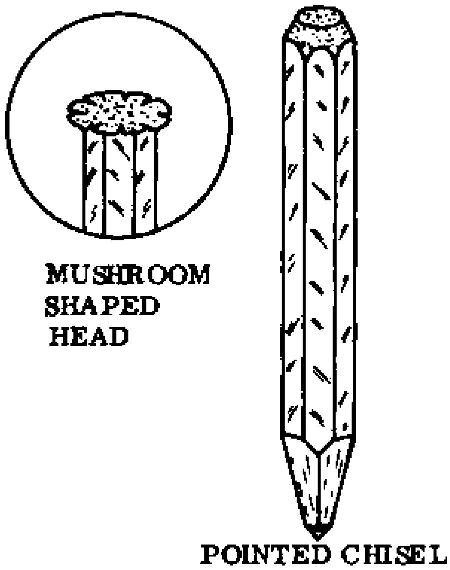

Fig. 2

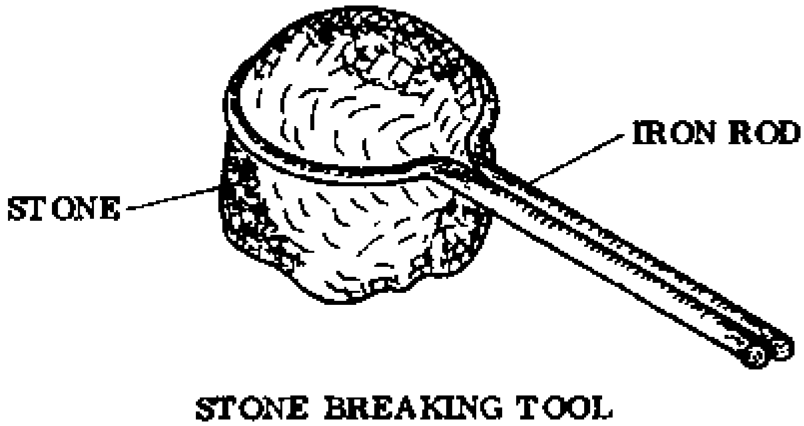

Fig. 3

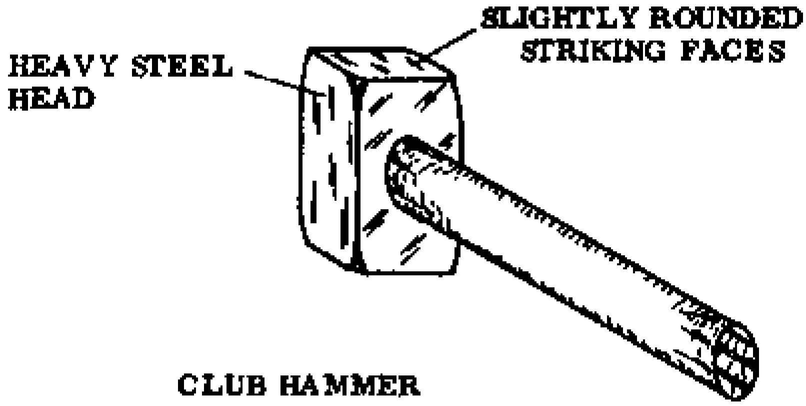

Fig. 4

CUTTING TOOLS

THE BLOCK SCUTCH

This tool consists of a hard steel blade with two cutting edges, welded to the handle which is made of iron pipe (Fig. 1). It is used for cutting all sorts of blocks and dressing cut surfaces. The angle between the blade and handle should be 75 to 80 degrees, which increases the effectiveness of the blow. The handle is oval shaped to provide a better grip.

THE POINTED CHISEL (COLD CHISEL)

This is a forged steel rod with a hardened cutting tip and striking end. It is octagonally shaped to provide a better grip for the hand (Fig. 2). Cold chisels are available in different sizes and are used together with a club hammer.

The head of the cold chisel should never be allowed to become mushroom shaped, as this may result in badly cut hands or in a piece of steel breaking off and piercing someone's eye. Always wear your safety goggles when you use the chisel.

THE STONE BREAKING TOOL

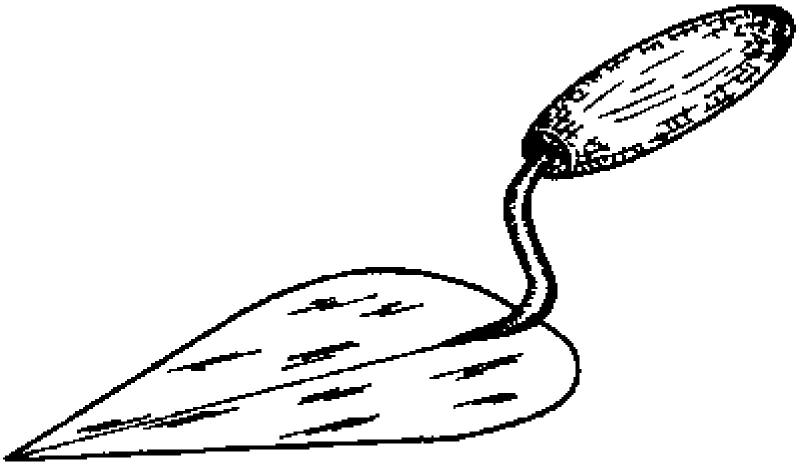
A device like the one in Fig. 3 is a useful tool on the building site. It can be made locally and is used to break stones into smaller pieces needed for concrete work. Place the device on top of the piece of stone and press it down during the hammer blow.

THE CLUB HAMMER

This hammer has a heavy steel head with slightly rounded striking faces and it can weigh from 1 to 2 kg.

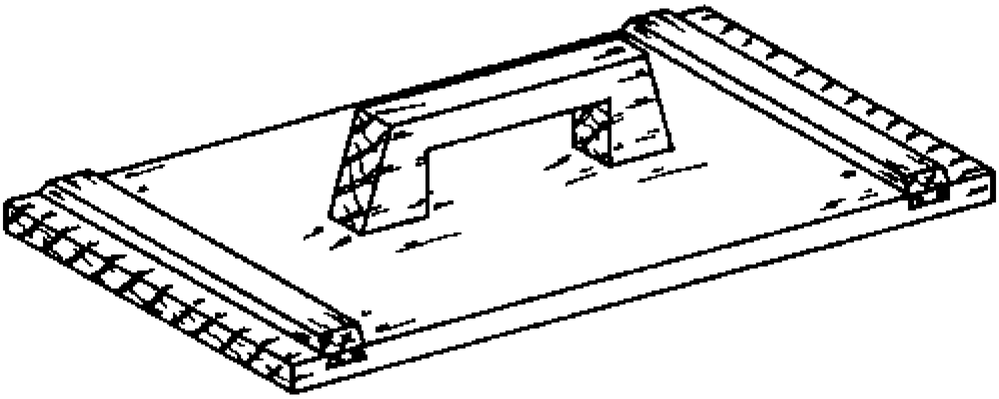
The head is fixed on a wooden handle which is 15 to 20 cm in length. The hammer is used to strike cold chisels and to break stones into smaller sizes. When using the hammer, make sure that the wedge that holds the handle in the head is firmly in position (Fig. 4).

NOTES:



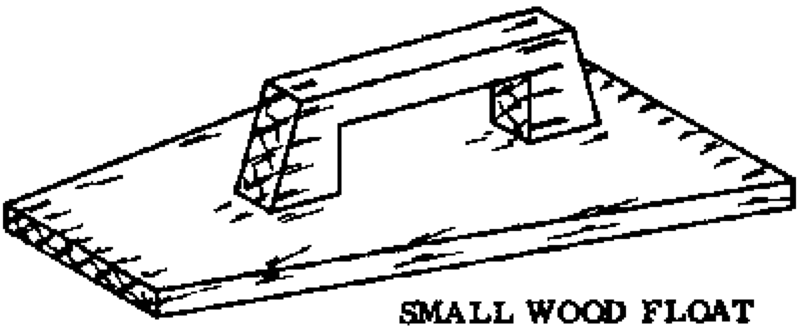
POINTING TROWEL

Fig. 1



BIG WOOD FLOAT

Fig. 2



SMALL WOOD FLOAT

Fig. 3

FINISHING TOOLS

THE POINTING TROWEL

Fig. 1 shows a trowel of almost the same shape as the brick trowel mentioned earlier, but smaller in its dimensions.

This pointing trowel is chiefly used for precision work such as finishing in general and the dressing of corners and edges in particular.

THE BIG WOOD FLOAT

This tool has a blade made of a soft wood like Wawa. It measures approximately 40 cm long and 25 cm wide. A handle made from hard wood is fixed to it with screws so that the blade can be replaced when necessary (Fig. 2).

Its main uses are to distribute an even thickness of mortar during plastering and to flatten concrete surfaces during floor construction.

THE SMALL WOOD FLOAT

The small wood float is constructed in the same way as the big one but with smaller dimensions, being approximately 25 cm in length and 15 cm in width.

As it is used mainly to give the plaster and floor surfaces a smoother finish, its blade may be made from hard wood (Fig. 3).

Because the wood float is made from wood it absorbs water from the wet mortar or cement during use, and it tends to warp. To prevent it from warping, keep the float under water when it is not in use so that all the sides are wet and the wood swells evenly.

NOTES:

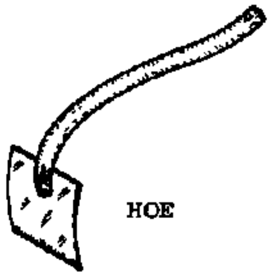

Fig. 2

Fig. 3

Fig. 4

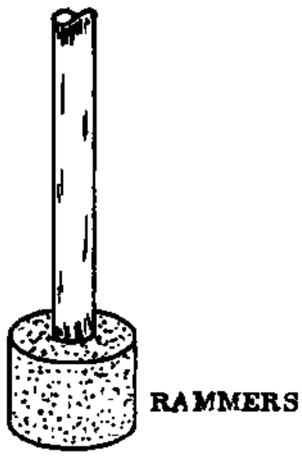

Fig. 5

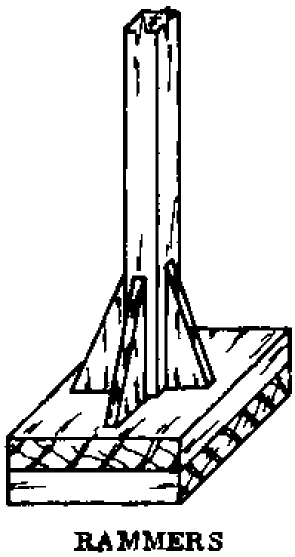

Fig. 6

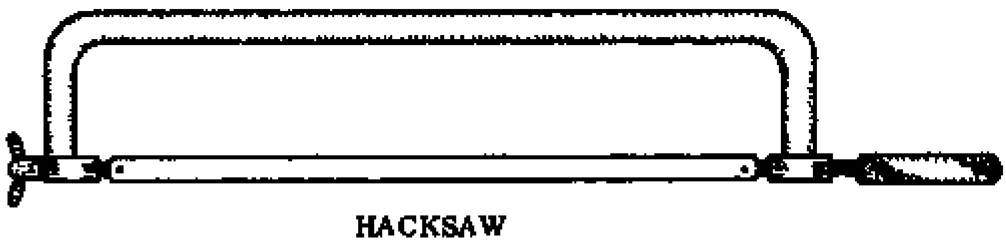

Fig. 7

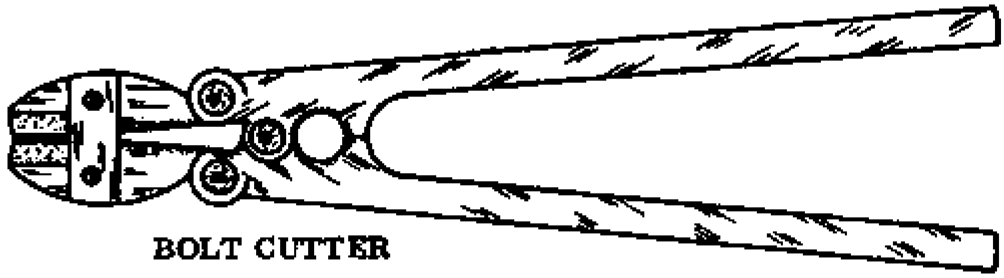

Fig. 8

SITE TOOLS

CUTLASS

The cutlass (Fig. 1) is used for clearing the site and other general cutting work.

HOE

This farming tool is often used in Rural Building to excavate top soil (Fig. 2).

SHOVEL

There are various types of shovel-like tools. The most common type is the one with a round-nosed steel blade of about 25 by 30 cm, connected to a short wooden shaft that has a "D" or "Y" shaped handle at the end (Fig. 3).

Whether the shovel has a short or a long handle is a matter of personal preference or local custom. It has been observed that the short-handled one is more suitable for filling purposes and for moving light soil, while the long-handled shovel with a square steel blade is better for loading sand and for mixing.

PICK-AXE

This digging tool consists of a heavy steel head with one pointed end and one end with a chisel edge. The head is connected to a wooden shaft (Fig. 4). The pickaxe is used during excavation to break up hard rocky soils or loosen laterite etc.

RAMMER

Rammers are either made entirely out of wood or they have a wooden handle attached to a metal or concrete head (Figs. 5 & 6). They are used to compact soil or concrete.

HACKSAW

A hacksaw is a handsaw used for cutting metal. It consists of a steel blade tightly stretched in a metal frame. The blade is removable and other blades can be fixed in the frame for cutting asbestos-cement or other materials (Fig. 7).

BOLT CUTTER

The bolt cutter is a tool which is used to cut steel reinforcing rods up to 19 mm in diameter (Fig. 8).

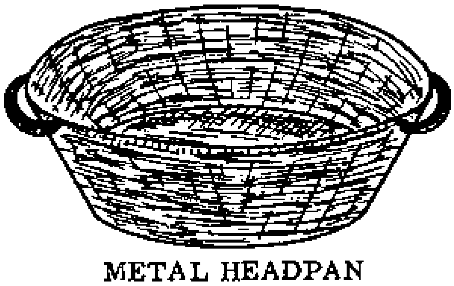

Fig. 1

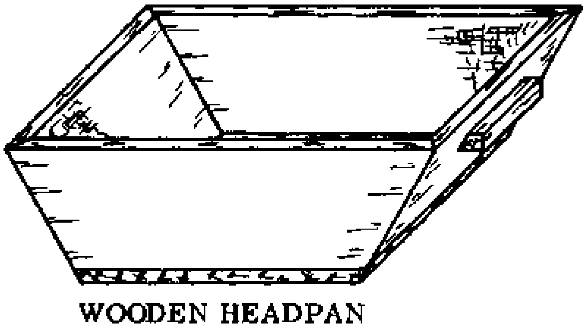

Fig. 2

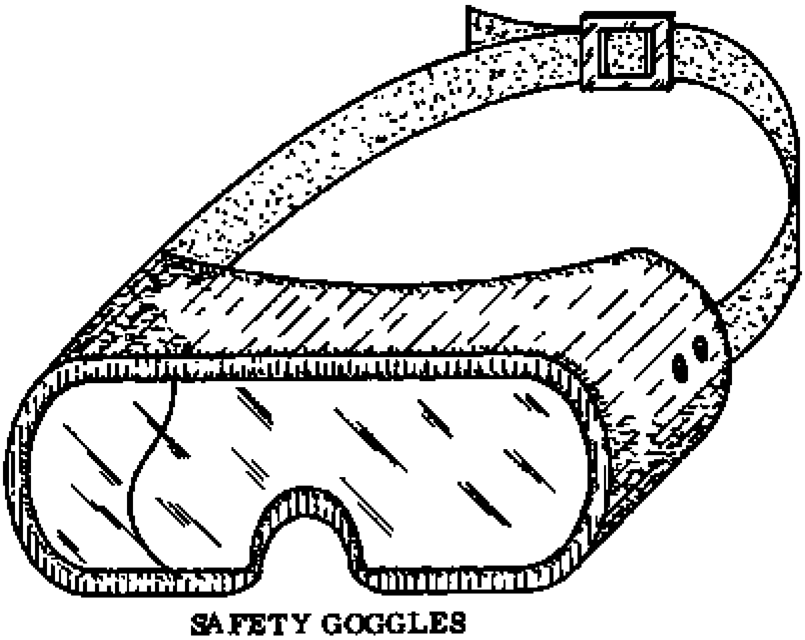

Fig. 3

HEADPAN

Smaller quantities of mortar and concrete are kept and transported in headpans. These are round containers shaped like bowls and made from mild steel or sheet metal (Fig. 1).

If made locally from wood, the headpan will be square with slanting sides (Fig. 2).

The common headpan has a holding capacity of about 15 litres for liquids, or half a bag of cement (slightly heaped up). These figures indicate that the headpan can also be used as a measure.

If you make your own headpan from wood or metal, be sure that it has the same capacity as other headpans so that you can measure accurately with it.

SAFETY GEAR

SAFETY GOGGLES

These are made from plastic and are designed to protect the eyes during all kinds of cutting or grinding operations and where there is a lot of dust in the air (Fig. 3).

NOTES:

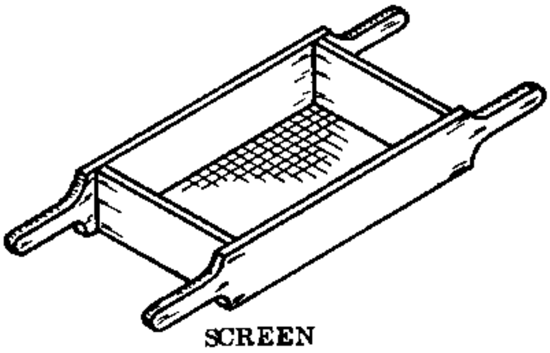

Fig. 1

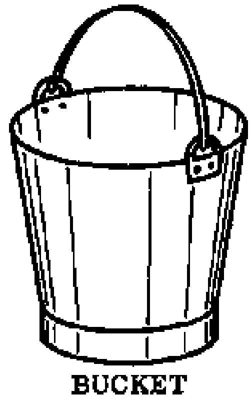

Fig. 2

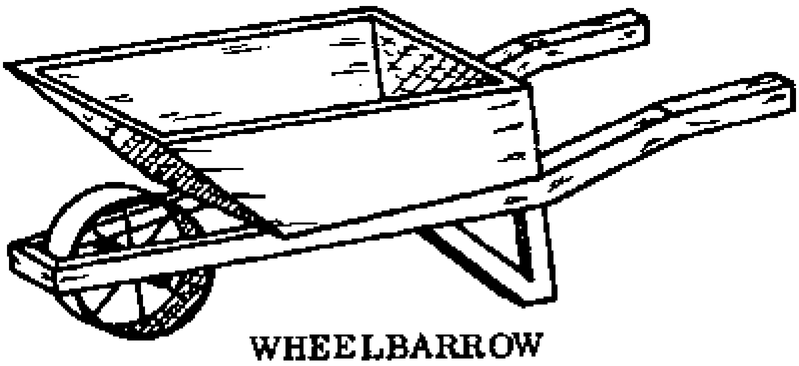

Fig. 3

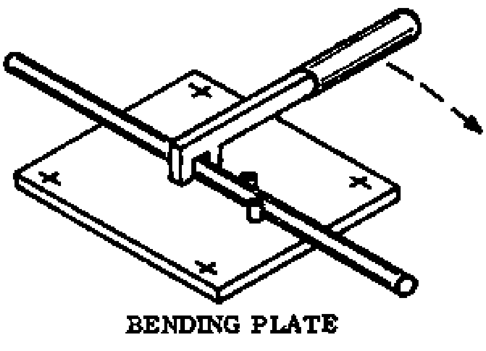

Fig. 4

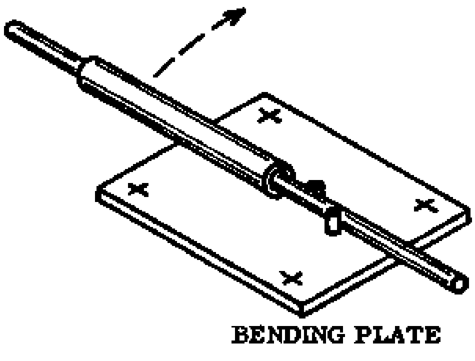

Fig. 5

SITE EQUIPMENT

SCREEN

A screen is a rectangular frame with a wire mesh built into it for separating impurities or stones from sand (Fig. 1). A well-equipped building site will have two different screens: a larger mesh to separate out stones of a convenient size; and a smaller one to sieve sand that will be used for plastering.

BUCKET

Buckets are open containers that can be made from different materials like rubber, plastic, or galvanized iron (Fig. 2). The average bucket (size no. 28) has a volume of 10 litres and is used mainly for carrying water.

ROPE

Ropes used on the building site are usually made from hemp or nylon. Nylon ropes have a tendency to stretch when they are under strain, and this must be taken into consideration when you use this kind of rope during construction work.

WHEELBARROW

The wheelbarrow is a steel or wooden container with a single steel or rubber-tyred wheel in front. It is lifted and pushed forward by means of two hand-holds attached to the frame (Fig. 3).

BENDING PLATE

Our Rural Building equipment for bending iron rods simply consists of a base-plate with two steel pegs which are spaced according to the diameter of the rod to be bent, and a bending bar (Fig. 4). The bending bar is used to do the actual bending. This is a key-shaped tool with a slot in one side into which the rod fits. Each different diameter of rod needs its own bending bar. If a suitable bending bar is not available, a pipe can be used to do the job (Fig. 5).

WATERING CAN

The watering can (not illustrated here) is a container with a pouring spout, used for watering plants. On the building site it is often used to wet down newly poured concrete or freshly made sandcrete blocks.

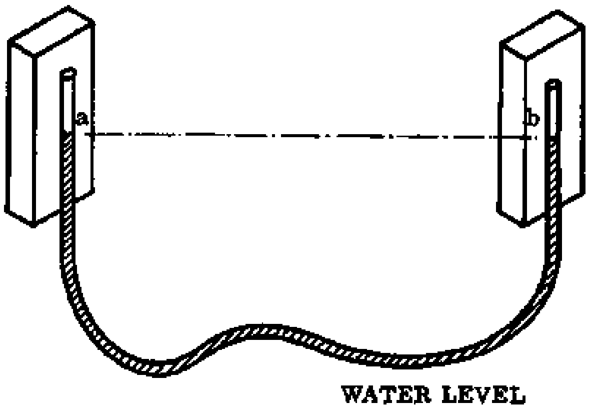

Fig. 1

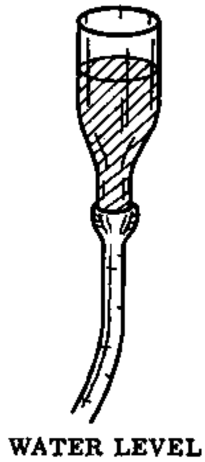

Fig. 2

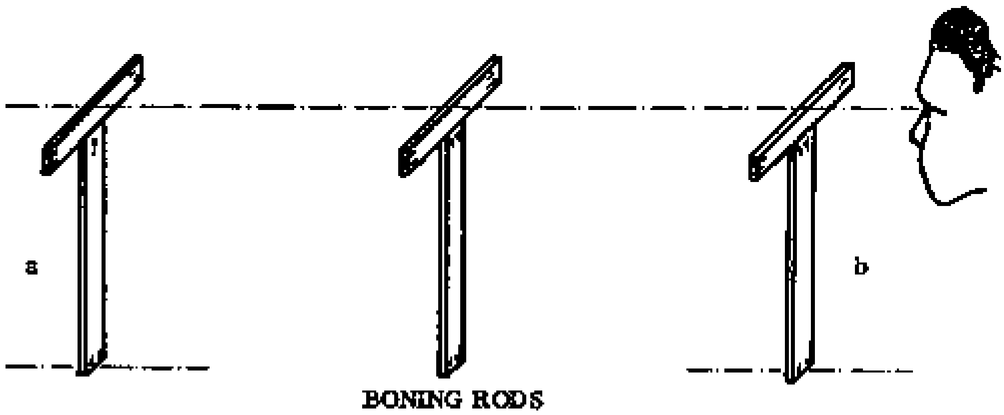

Fig. 3

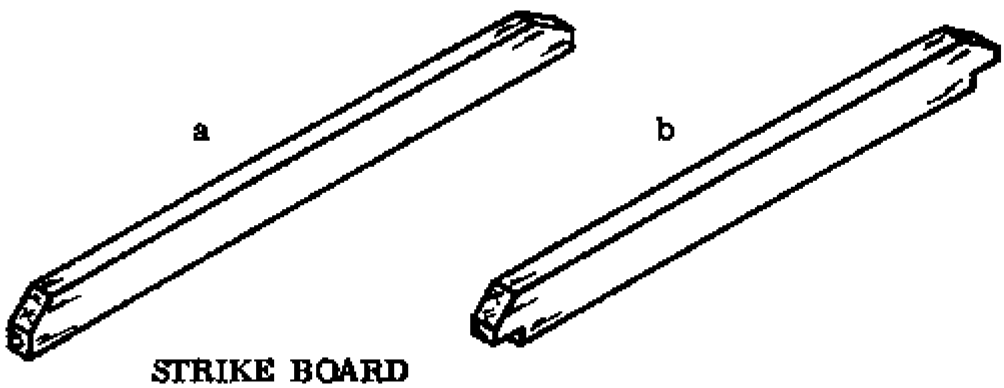

Fig. 4

WATER LEVEL

This instrument is used for setting out levels on the site as well as to transfer and control levels over large distances. It consists of a transparent plastic tube filled with water (Fig. 1). The level of the water at one end of the tube (a) will be at exactly the same height as the level at the other end (b), provided that there is no air bubble in the tube and it is not buckled.

The water level enables us to level over large distances with a high degree of accuracy.

If there is no transparent plastic tube available and some rubber hose can be found, the Rural Builder can take two glass bottles, knock out the bottoms and fit the bottle necks to each end of the hose. This apparatus is then filled with water until the water is seen in the bottles. Levels can be read as easily with this device as with any other water level (Fig. 2).

BONING RODS

Boning rods are T-shaped wooden tools, usually 120 cm high and 20 cm wide at the top. They are used in sets of three to help the Rural Builder to level between two given points (Fig. 3).

Points a and b are marked with the water level and any point in between them can be obtained by using the third boning rod and sighting along the rods (Fig. 3).

STRIKE BOARD

Strike boards are made from well seasoned wood. They are similar to straight edges except that they are usually longer (Fig. 4).

Strike boards (a) are used to level off the screed on floors, or in the case of notched strike boards (b) to level off concrete before the screed is layed.

NOTES:

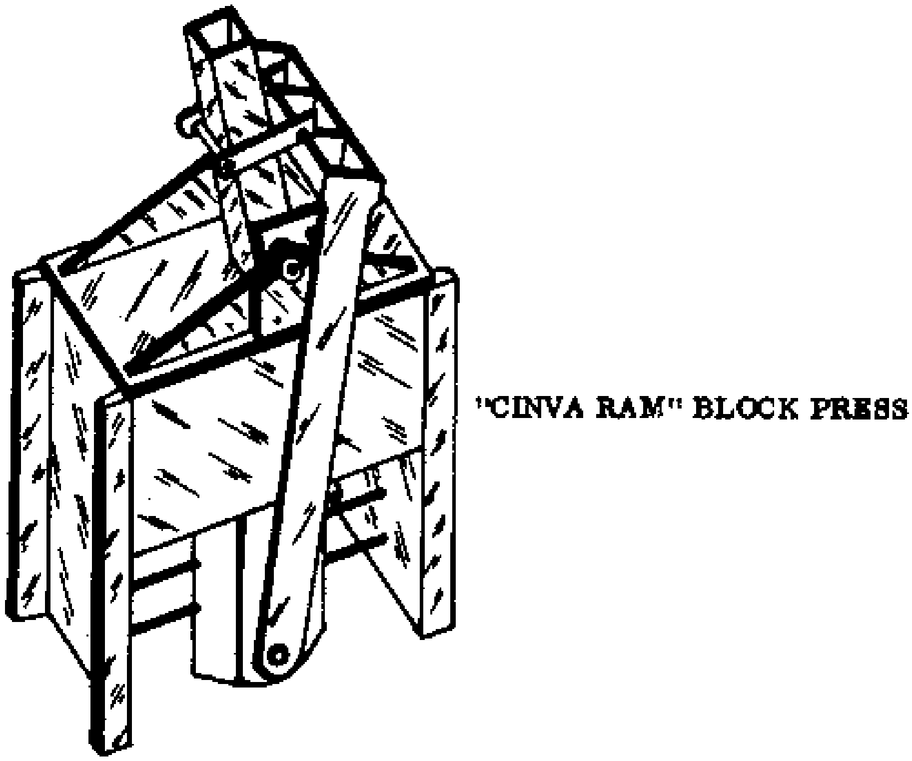

Fig. 1

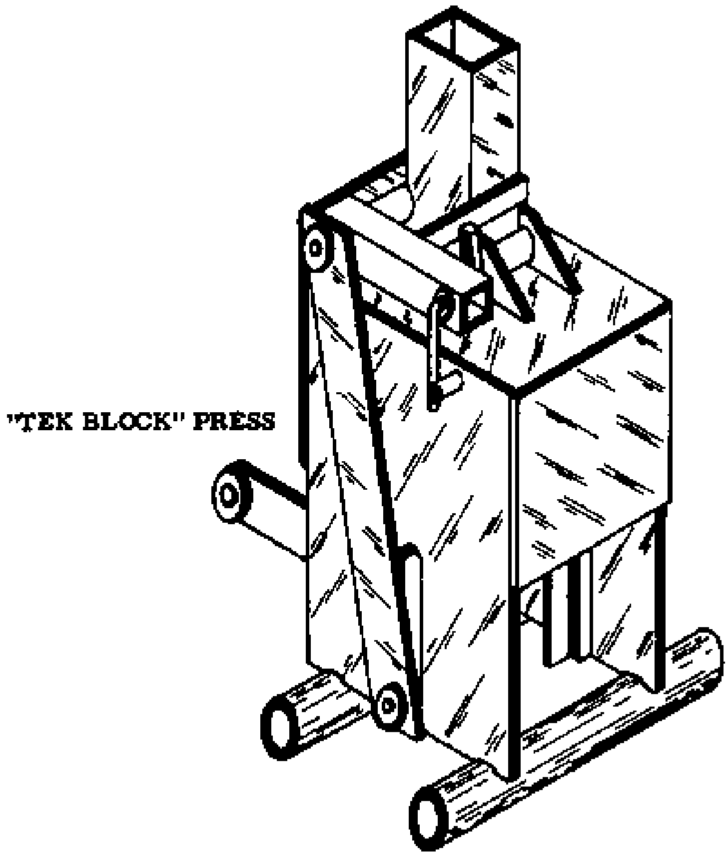

Fig. 2

"CINVA RAM" BLOCK PRESS

The Cinva Ram block press is a simple low-cost machine which produces building blocks from common laterite. It consists of a mould in which a slightly moist soil/cement mixture is compressed (packed down) by a hand operated piston and lever system (Fig. 1).

Unlike sand-cement blocks made with a similar press, these blocks can be removed immediately from the press and stacked for curing without the use of a pallet underneath.

The machine is made from steel and it is tough, durable and will stand up to long and hard use. Little maintenance is needed except for oiling.

- SPECIFICATIONS:	Size of blocks	--	10 × 15 × 30 cm
	Building unit	--	12 × 17 × 32 cm (2 cm joints).

"TEK" BLOCK PRESS

The Tek block press is similar to the Cinva Ram, except that this press produces blocks of larger dimensions (Fig. 2).

The Tek block press was designed at U. S.T. Kumasi and has been used successfully in the field for many years. The Tek block press can make blocks in any area where good laterite is available.

A moist soil/cement mixture is put into the steel mould box, pressed into a block and ejected (pushed out).

With the wooden handle, one man can put a lot of pressure on the block, so the blocks are very hard and long-lasting.

- SPECIFICATIONS:	Size of blocks	--	14 × 22 × 29 cm
	Building unit	--	16 × 24 × 31 cm (2 cm joints).

- MAINTENANCE: Oiling the machine will make it work better and last longer. Oil or grease the moving parts at least twice a day when the machine is in use.

Wipe the inside of the mould box with oil about every 10 blocks. This will make it easier to remove the blocks.

If more than one man presses on the handle of the machine, the handle should break. If the handle is too big and strong, the machine will break instead of the handle. A broken machine is far more difficult to repair than a broken handle, therefore do not use any handle which is longer than 2,5 m.

When the machine is not in use, paint it with oil to prevent rust.

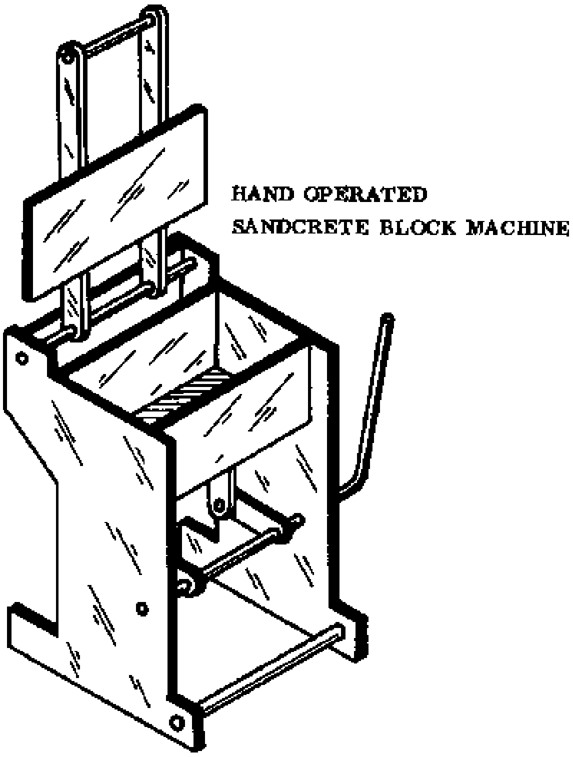

Fig. 1

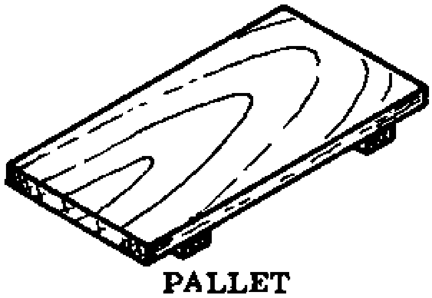

Fig. 2

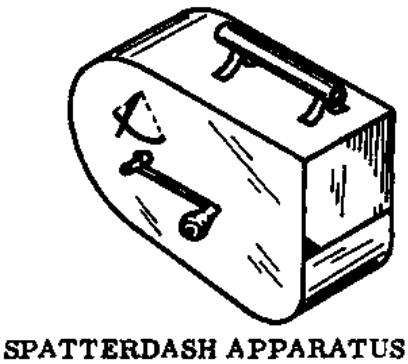

Fig. 3

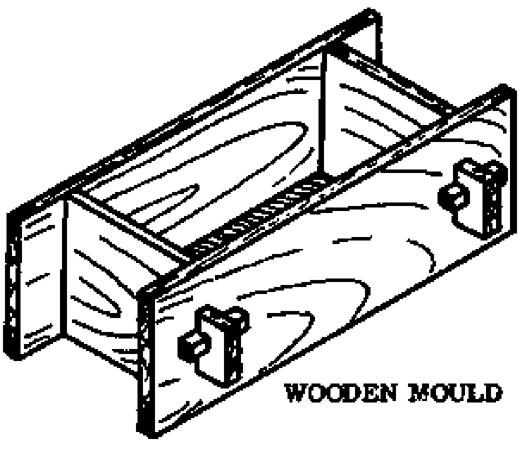

Fig. 4

HAND OPERATED SANDCRETE BLOCK MACHINE

This type of block machine consists mainly of a mould box with a movable bottom plate mounted into a supporting frame. The bottom plate is connected to a handle so that it can be raised (Fig. 1).

The lid is made of heavy material so that it presses down to compact the sandcrete. Sometimes additional weights are attached to the top of the lid to make it press harder.

After it is compacted, the block is pushed out by means of the handle at the side of the machine.

Unlike landcrete blocks, sandcrete blocks must be made on pallets, as they are too soft to be carried when they are freshly made (Fig. 2).

The inside measurements of the mould box are approximately: 46 cm in the length, 23 cm in the width, and 28 cm deep. Blocks of various shapes can be made with this machine by changing the height of the pallet or by using inserts.

SPATTERDASH APPARATUS

The spatterdash apparatus is used to give plaster or concrete an attractive appearance without the use of paint.

A slurry of sand and cement is placed in the apparatus (Fig. 3); when the handle is turned, the mixture is thrown against the wall, giving the surface a textured effect. Another handle adjusts the texture of the spatterdash from rough to fine.

WOODEN MOULD

A specially made wooden mould can be used when unusual blocks such as arch-blocks are needed or when there is no block-making machine available.

To make work easier and more accurate, the wooden mould should be made so that the sides of the mould can be removed easily and fixed back together by using wedges through tenons (Fig. 4).

NOTES:

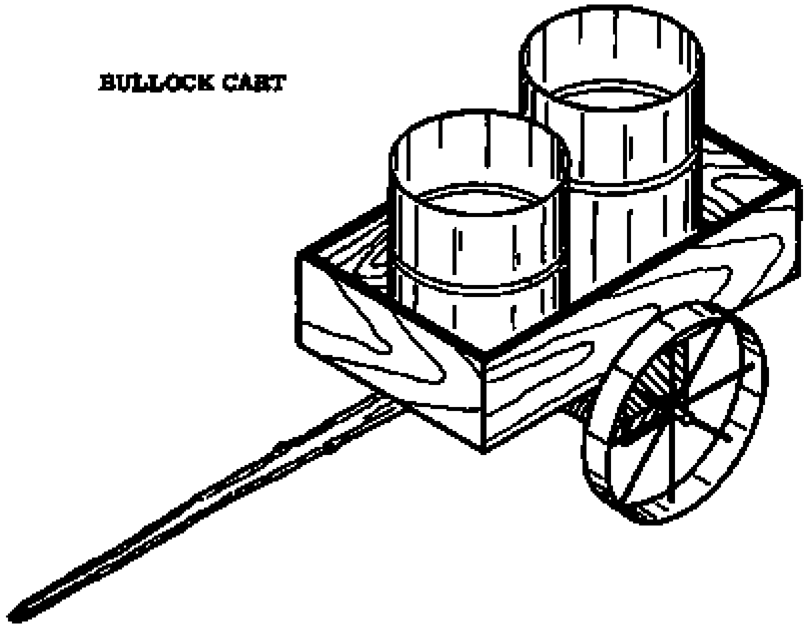

Fig. 1

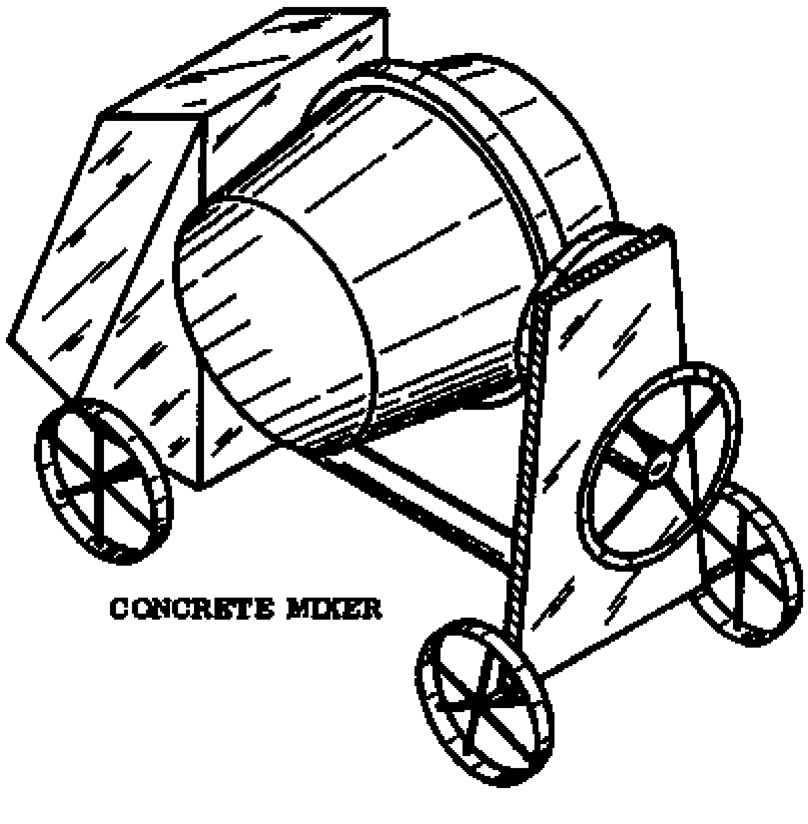

Fig. 2

BULLOCK CART

A bullock cart can transport water and limited quantities of building materials and it is therefore particularly useful at a Rural Building site. Bullock carts are made locally from wood and have steel rimmed wheels. The steel axles turn In wooden bearings which are soaked in oil. These bearings should be inspected and oiled regularly (Fig. 1).

CONCRETE MIXER

If there are few labourers and it is necessary to mix large amounts of concrete, a concrete mixer can be hired to do some of the work (Fig. 2).

The Rural Builder should know how to load the machine, in the right sequence and make sure that the concrete is well mixed and has the correct content of water.

After the job is done the machine should be cleaned thoroughly with water and all sand and cement should be washed off from the drum and the frame of the machine.

A maintenance card will tell you how to maintain the machine and how often this needs to be done.

The engine needs special care and the Rural Builder should learn as much as he can about caring for it.

NOTES:

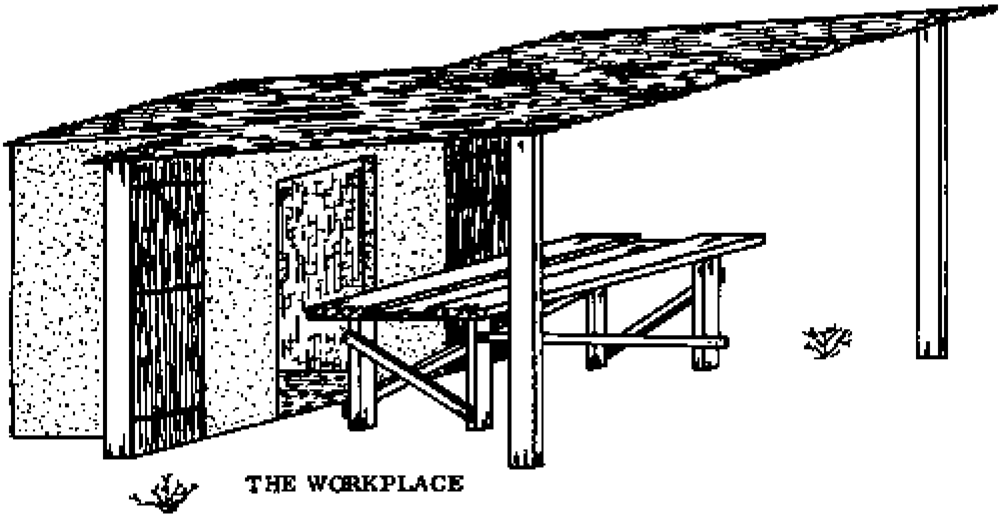

Fig. 1

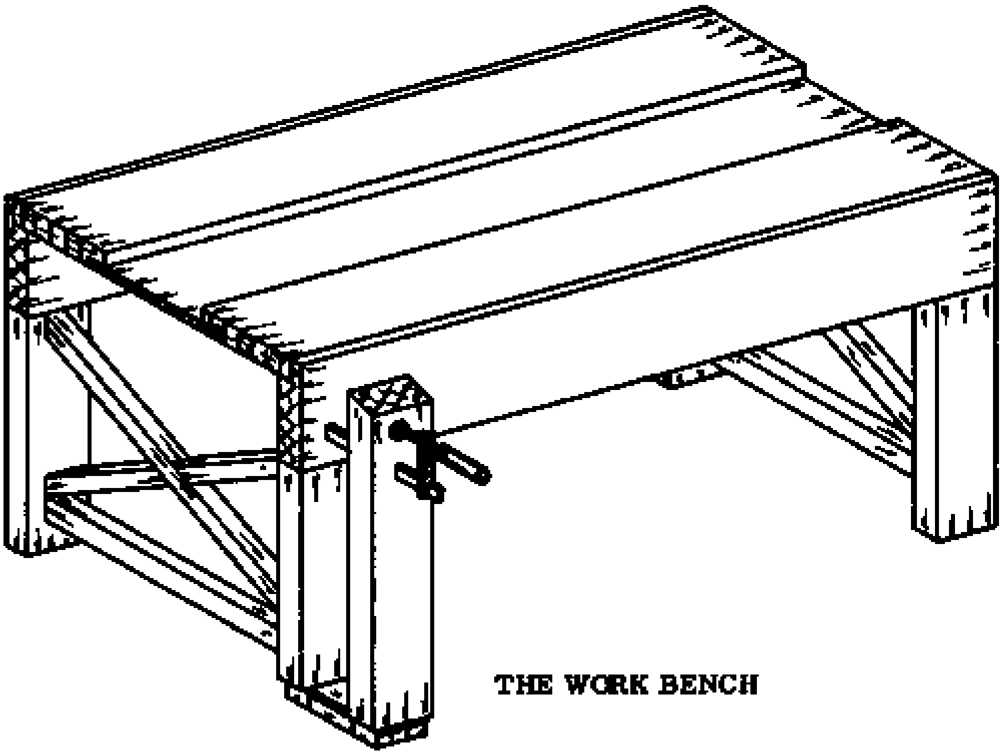

Fig. 2

THE WORKPLACE

The ideal workplace (Fig. 1) will have a waterproof shed which is open on three sides. The fourth side should be arranged for laying out the tools and toolboxes. If possible there should be a lockable store for tools and materials next to the workshed. The workshed should be close to the timber pile.

THE WORK BENCH

The bench is used for supporting the workpiece while it is being marked and during the various operations of its construction. Therefore, the bench must be strong, rigid and made from good wood.

The top must be flat and it is constructed out of planks which are 5 cm thick and 30 cm wide. The length of the bench can be from 2 to 4 metres. The height of the bench can vary between 80 and 90 cm. The legs should be well braced.

There are single and double width work benches. The last type is commonly used at the building site. It must be wide enough to handle door and window frames and long enough (a full board length of 4 metres) to be used for bending concrete iron.

If the bench is built on the building site, it is not necessary to use extra timber. The timber used in the bench can be reused for some other workpiece after the carpentry work is finished.

Permanent work benches (Fig. 2) used in a workshop will be constructed slightly different from the types used at a construction site (Fig. 1). A wooden vice is used to hold the timber, with the help of a G-clamp (Fig. 2).

NOTES:

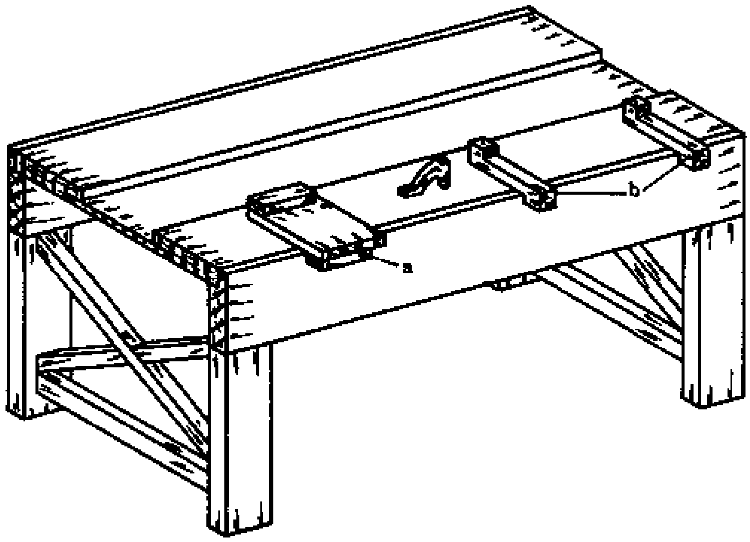

Fig. 1

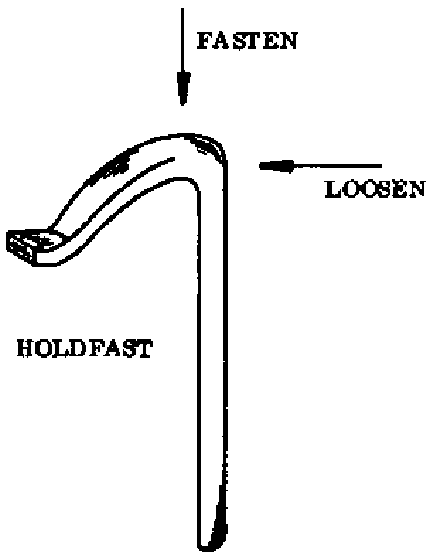

Fig. 2

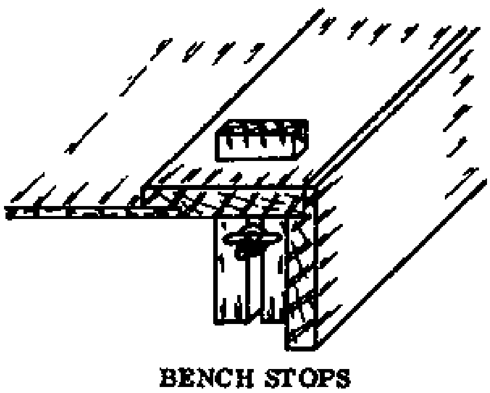

Fig. 3

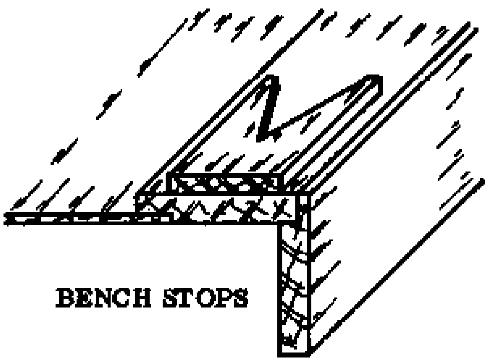

Fig. 4

BENCH HOOKS

When we have to cut a short piece of timber across the grain, we use a wide bench hook to support it. The bottom batten of the hook is held against the side of the bench and the work is pressed against the upper batten (Fig. la).

For long pieces of timber, we use small bench hooks for support (Fig. 1b).

Wide bench hooks measure approximately 15 × 25 cm; small ones about 5 × 25 cm.

THE HOLDFAST

A holdfast can be used to fasten wood firmly to the top of the bench. It is made tight or loosened by knocking it with a hammer (Fig. 2).

Holdfasts can be made locally from a piece of concrete iron, 2,5 cm in diameter, with a piece of a car spring welded to the top.

THE BENCH STOP

On the left side of the bench there is a bench stop made from hard wood, to support the timber during planing.

Some bench stops can be moved up or down. These are called adjustable bench stops (Fig. 3). Other bench stops are stationary (Fig. 4).

NOTES:

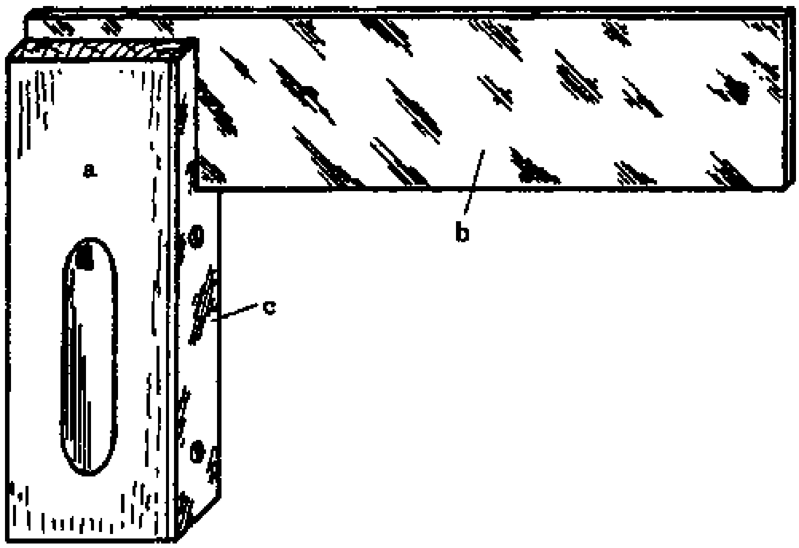

Fig. 1

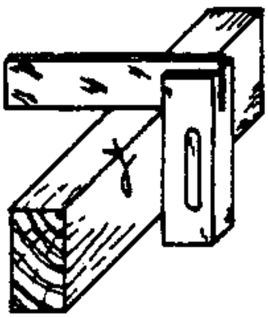

Fig. 2

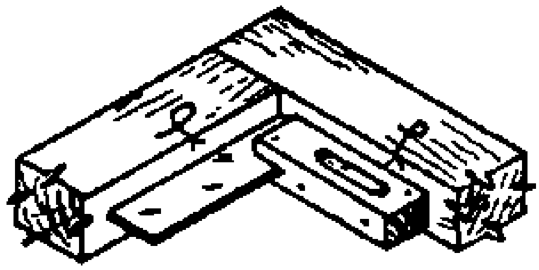

Fig. 3

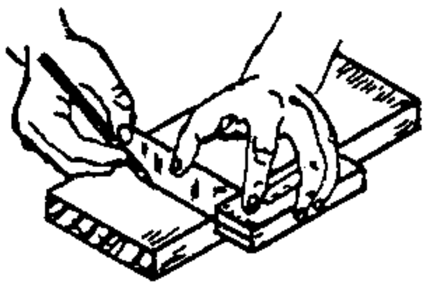

Fig. 4

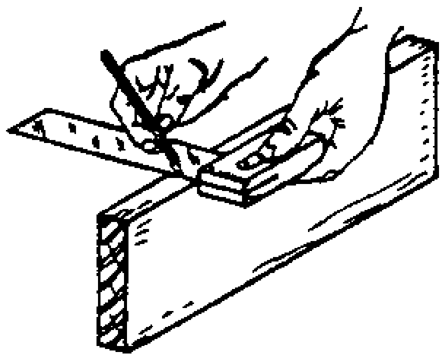

Fig. 5

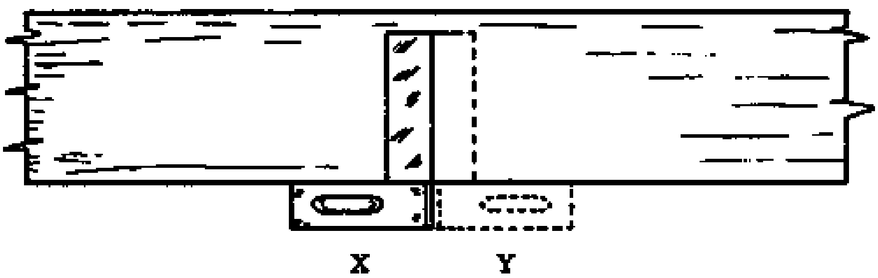

Fig. 6

THE TRY SQUARE

The try square is used for marking timber, and for testing right angles to make sure that they are correct.

Its parts are (Fig. 1): the stock (a), the blade (b) and the stockface (c). The stock can be all metal or it can be made of hard wood with a brass stockface. The blade is made of steel. The angle between the stockface and blade is exactly 90 degrees.

HOW TO USE THE TRY SQUARE

- To test the angles of workpieces and boards, place it as shown in the figures on the left (Figs. 2 & 3). Always use the try square with the stock against the face edge or the face side of the workpiece when you are squaring or testing angles.

- For marking timber, press the stockface against one edge or side of the work-piece and use the blade to guide your pencil (Figs. 4 & 5).

- Keep the pencil pressed to the blade, to avoid making double lines.

- Be careful not to drop the try square or use it carelessly. Any small movement of the blade will make it inaccurate.

HOW TO TEST THE TRY SQUARE

1. Select a board with a true edge.

2. Lay the blade in position "X" and draw a line along the blade (Fig. 6).

3. Turn the square over as shown by the dotted lines (position "Y"). If the line and the blade come together exactly, the angle of 90 degrees is true.

NOTES:

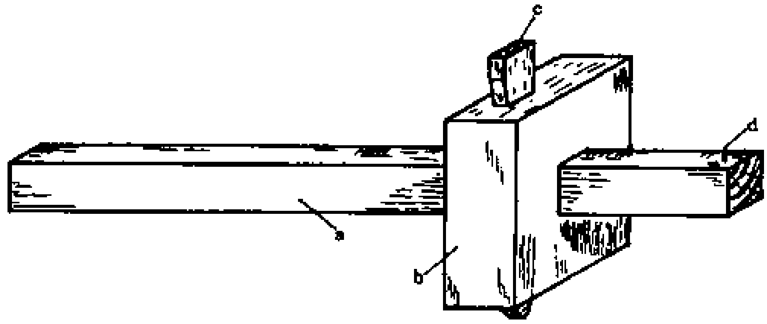

Fig. 1

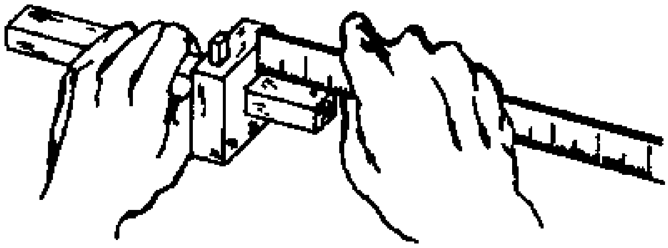

Fig. 2

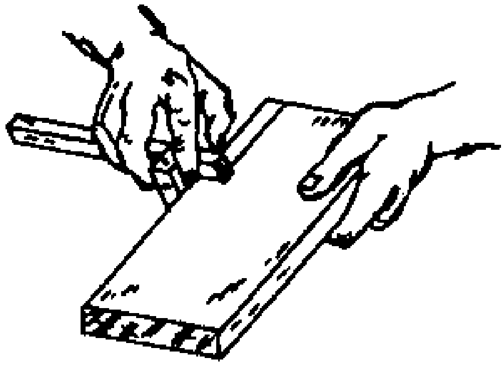

Fig. 3

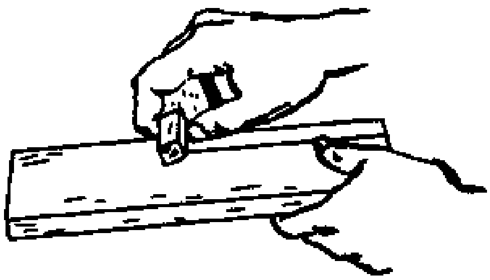

Fig. 4

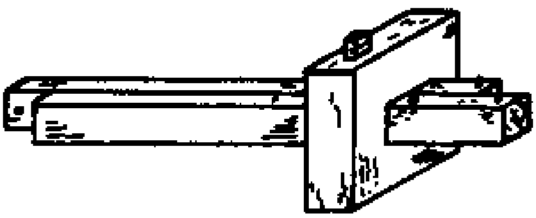

Fig. 5

THE MARKING GAUGE

The marking gauge (Fig. 1) is used to make lines on timber, parallel to the edge of the timber; that is, the lines always continue at the same distance from the edge.

The parts of the marking gauge are: the stem (a), the stock(b), the wedge (c) and the spur or pin (d). Sometimes a screw is used instead of a wedge.

HOW TO SET THE GAUGE

1. Use a rule to measure and slide the stock along the stem until the stockface is at the required distance from the pin (Fig. 2).

2. Slightly tighten the wedge or screw.

3. Check the size once more and make any necessary adjustments by tapping the end of the stem on the work bench.

4. Finally, properly tighten the wedge or screw.

HOW TO USE THE GAUGE

- Hold it in your right hand, with the face side of the stock pressed against the edge of the wood (Fig. 3).

- Keep it tilted slightly forward, so that the pin drags lightly along the wood. Don't try to make a deep mark with the pin (Fig. 4).

- Push it away from you. The pin will trace a line on the wood (Fig. 4) parallel to the edge of the wood. The stock must be held firmly against the timber edge as you move the gauge along.

- The pin may be forced out of line by grooves in the wood structure; if that occurs, mark from the other direction.

- If the gauge is hard to use at first, steady it by holding one end of the wood against the bench stop or hook.

Sometimes, marking gauges with two stems are used for marking out mortices. They are called Mortice gauges (Fig. 5).

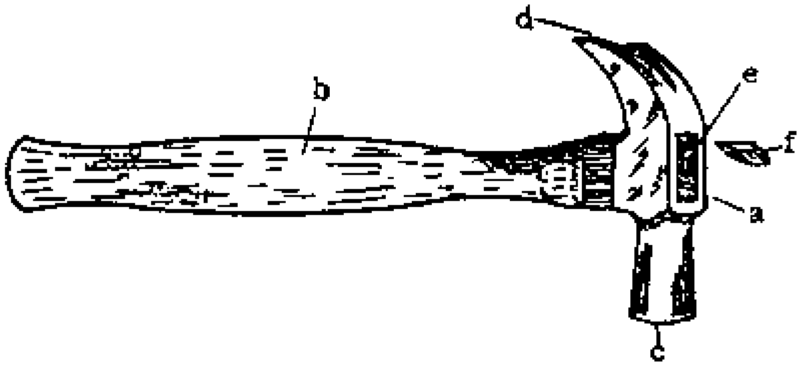

Fig. 1

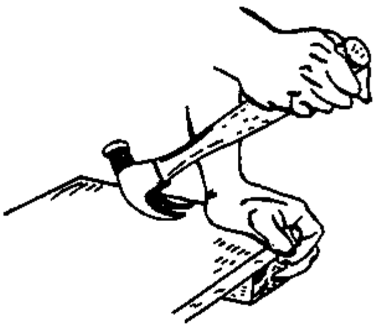

Fig. 2

Fig. 3

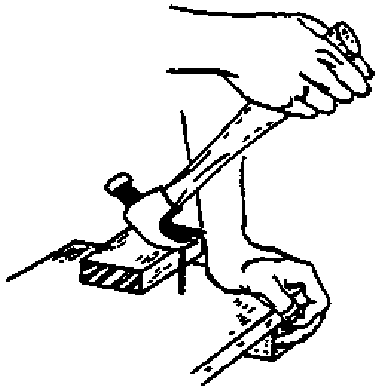

Fig. 4

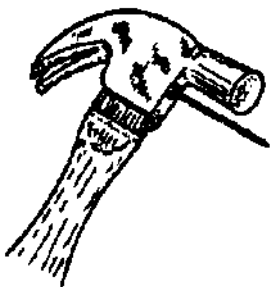

Fig. 5

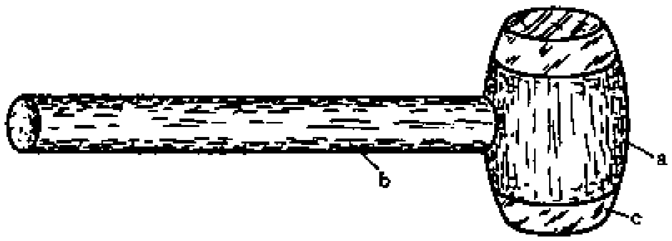

Fig. 6

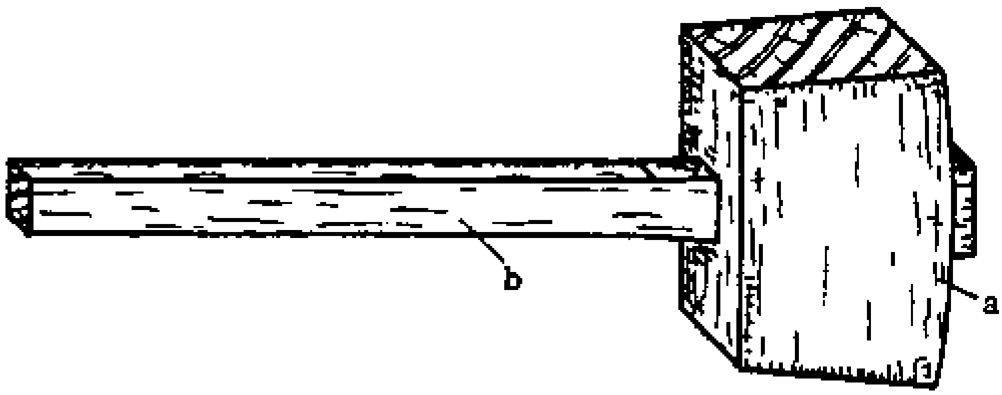

Fig. 7

THE CLAWHAMMER

The clawhammer (Fig. 1) is used in light or heavy carpentry work, for driving and extracting nails. Its size, determined by the weight of the head, can be from 350 to 650 gr.

A hammer has two main parts: the head (a) and the handle (b). The head is made of steel, with a hardened face (c) and a claw (d) for extracting nails. The wooden handle is held in the eye (e) by metal wedges (f). The handle is usually made of hard wood, which absorbs shock better than metal and keeps the arm from getting tired so quickly.

HOW TO PULL NAILS

To pull a nail, slip the claws under the nailhead and pull up and back on the hammer handle (Figs. 2 & 3). When the handle reaches the vertical position and the nail is not yet all the way out, use a block of wood under the hammer (Fig. 4) to help. Pulling the handle back too far may overstrain or possibly break it.

HOW TO DRIVE NAILS

Nailing is covered in detail in the Basic Knowledge book, pages 92 to 94.

- To drive nails when you have only one hand free, hold the nail on the hammer as shown in Fig. 5 and start it in the wood with one sharp blow.

THE MALLET

The mallet is used for driving chisels, assembling joints and knocking together pieces where the hammer would damage the wood or the chisel handle. The mallet (Figs. 6 & 7) has two parts: the head (a) and the handle (b), which passes through a tapered mortice in the head.

The head can be square or round in shape. The round type can be strengthened with a metal collar (c) to prevent it from splitting. This can be made from an old shock absorber mantle.

NOTES:

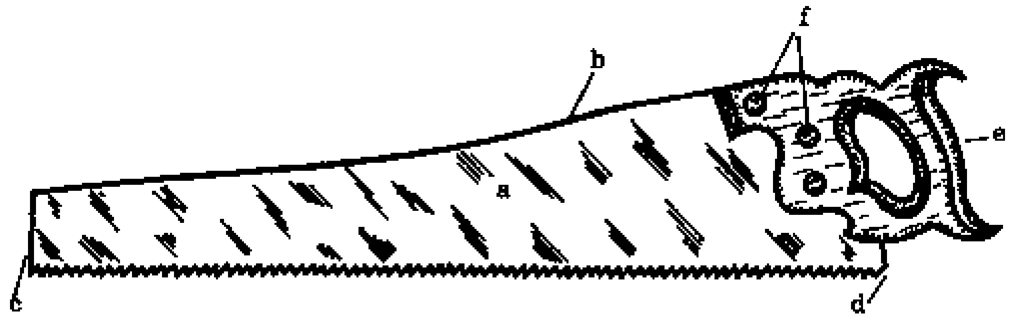

Fig. 1

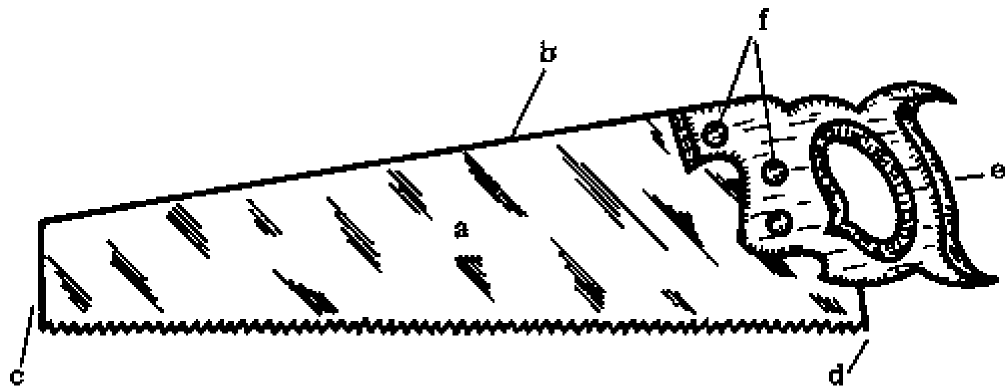

Fig. 2

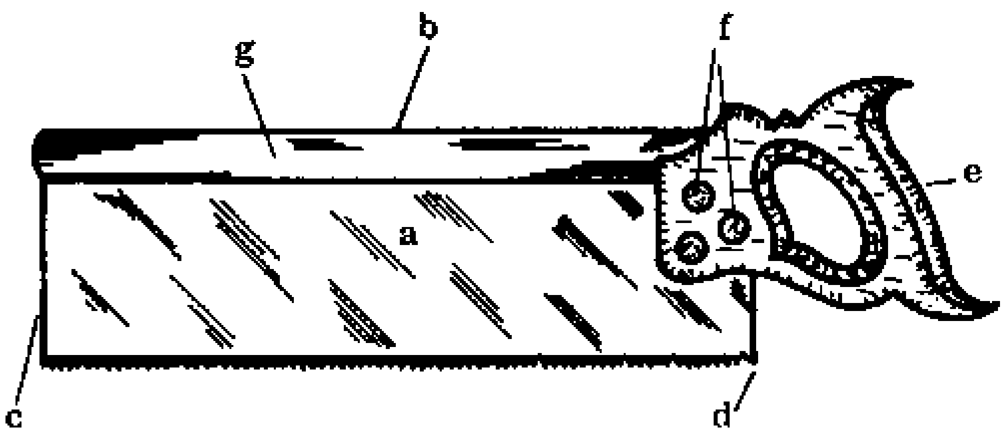

Fig. 3

HANDSAWS

Saws are used for cutting timber to the required size and shape with a minimum of waste in materials and labour. The principal types used in Rural Building are handsaws.

The parts of the saw are (Fig. 1): the blade (a) which has a back (b), toe (c) and heel (d), the handle (e) and the sawscrews (f) which hold the handle to the blade.

Better quality saws are taper ground, that is, they are thinner towards the back of the blade than at the cutting edge. Such saws can run (move) more freely in the kerf (the saw cut).

A good sawblade makes a clear sound when it is slightly bent and struck on the back with a fingernail. The handle should be made of good hard wood and have a comfortable grip.

Manufacturers make saws in various grades, of hard or soft steel, regular or light weight to suit any need. Depending on the kind of work we want to do, we use one of three types of handsaw: a ripsaw, a crosscut saw or a backsaw.

THE RIPSAW

The ripsaw (Fig. 1), because of the special shape of its teeth, is used only to cut with the grain of the wood. The length of the saw can vary from 66 to 71 cm. A long saw can cut faster, but it is harder to control.

THE CROSSCUT SAW

The crosscut saw (Fig. 2) is designed for cutting across the grain. Its length can vary from 51 to 66 cm.

THE BACKSAW

The backsaw (Fig. 3) is used to make fine and finished cuts. In general, the blade of the backsaw is thinner than that of a ripsaw or crosscut saw. The fold of steel that sits on the back of the blade (g) makes it stiff and it can be removed if necessary to make deep cuts.

NOTES:

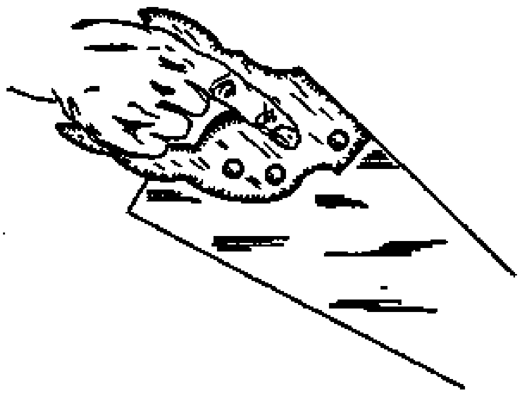

Fig. 1

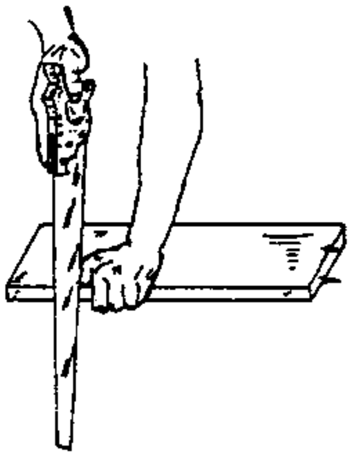

Fig. 2

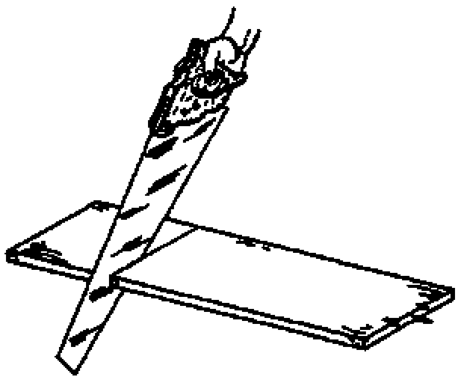

Fig. 3

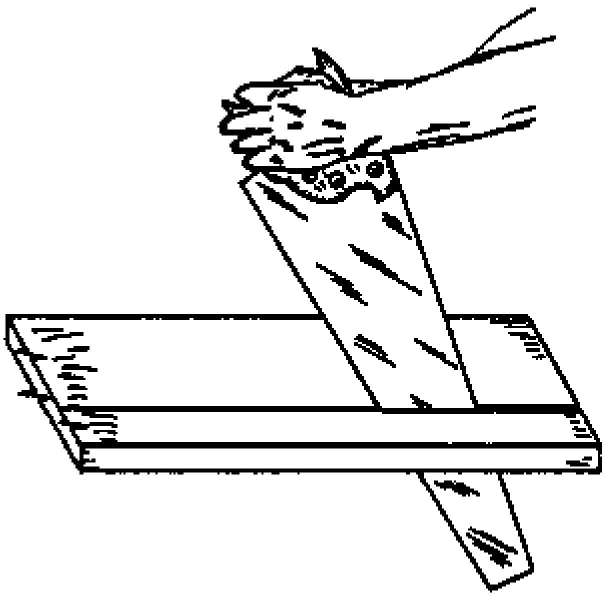

Fig. 4

HOW TO USE A HANDSAW

- Grasp the handle of the saw firmly. Your index finger should point along the blade (Fig. 1). This gives maximum control of the saw and it is the rule for holding all the different kinds of handsaws.

- To start a sawcut, grasp the far edge of the wood with your left hand, using the thumb to guide the saw while starting the cut (Fig. 2). Make two or three backstrokes, lifting the saw on the forward strokes. Draw the saw slowly and carefully, exactly along the cutting line (Fig. 3).

- After the saw is started, push it forward and pull it back, using Long, easy strokes and light pressure.

- Hold the saw at an angle of about 30 degrees to the board for rough work and almost flat to the board for fine cuts.

- If the saw tends to go to one side of the line, twist the handle slightly and gently to make it come back to the line gradually, as the sawing proceeds.

HOW TO RIP BOARDS

For ripping boards (cutting with the grain), you can use different methods. The most common method used in Ghana is known as overhand ripping.

- To do overhand ripping, hold the saw in both hands as shown in Fig. 4.

When cutting timber take care that you always watch the edge of the work bench, to avoid sawing into it.

NOTES:

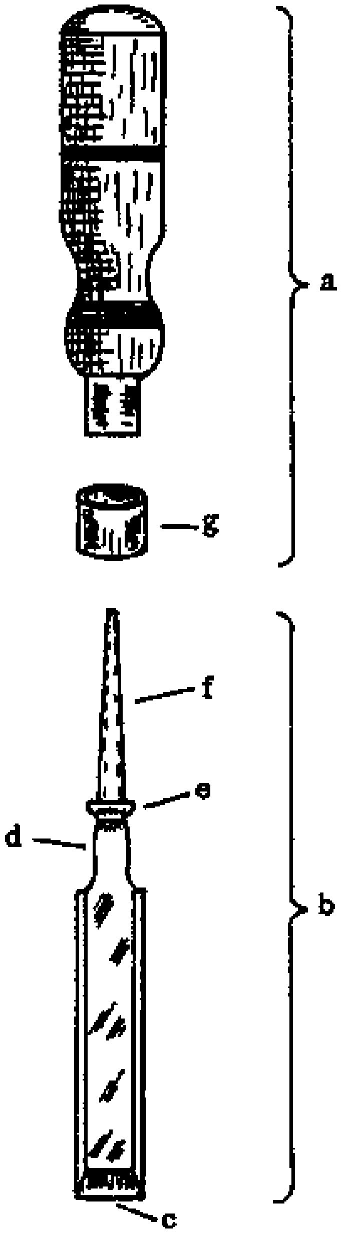

Fig. 1

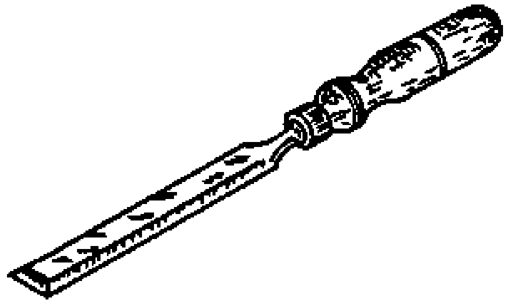

Fig. 2

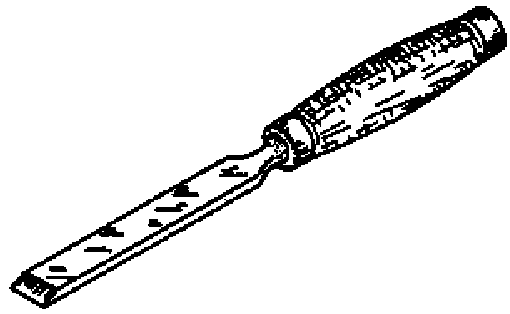

Fig. 3

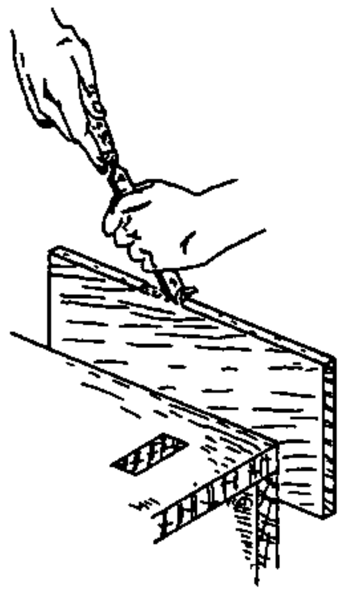

Fig. 4

THE CHISEL

Chisels are used for shaping wood in places where the plane cannot be used.

They have two main parts (Fig. 1): the blade (a) and the handle (b). The blade is made of steel, with a cutting edge (c) which is 3 to 32 mm wide and ground at an angle of 25 degrees. The neck (d) is the narrow part at the top of the blade. The shoulder above the neck (e) is to prevent the blade from being driven too far into the handle and splitting it. The tang (f) is the end of the blade which fits into the. handle and holds the two parts together.

The ferrule (g) at the bottom of the handle keeps the wood from splitting where the blade enters the handle. The handle itself is made from hard wood or plastic and it is slightly rounded on top to prevent splitting.

For the various tasks of carpentry work in Rural Building, there are different kinds of chisels. The two most common ones are the firmer chisel and the mortice chisel.

THE FIRMER CHISEL

Most of the firmer chisels (Fig. 2) are the type with a bevelled edge. The firmer chisel is normally driven into the wood by hand and is used only for light cutting and shaping work.

THE MORTICE CHISEL

The blade of the mortice chisel (Fig. 3) is thicker and stronger than that of the firmer chisel, as it is used for heavy work. This chisel is driven into the wood with a mallet (never with a steel hammer), so it is usually fitted with two ferrules, at the top and bottom of the handle, to prevent splitting.

NOTES:

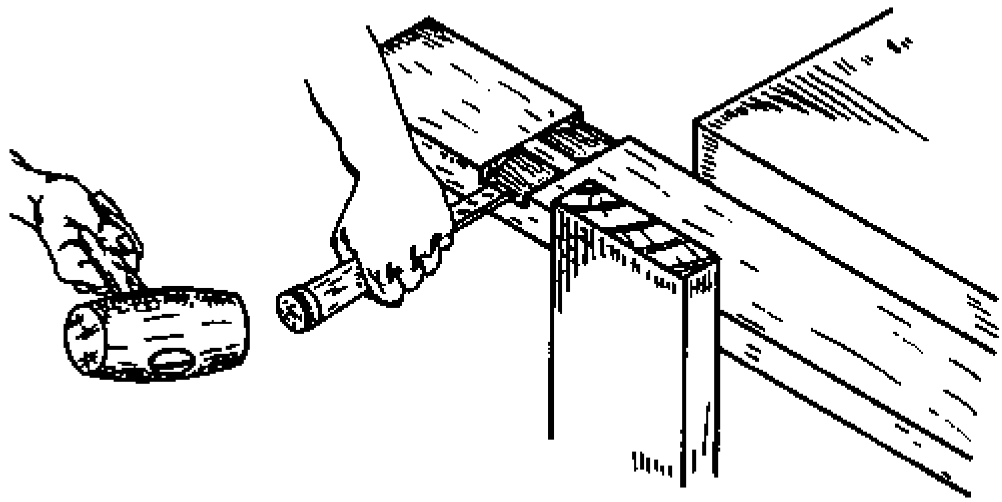

Fig. 1

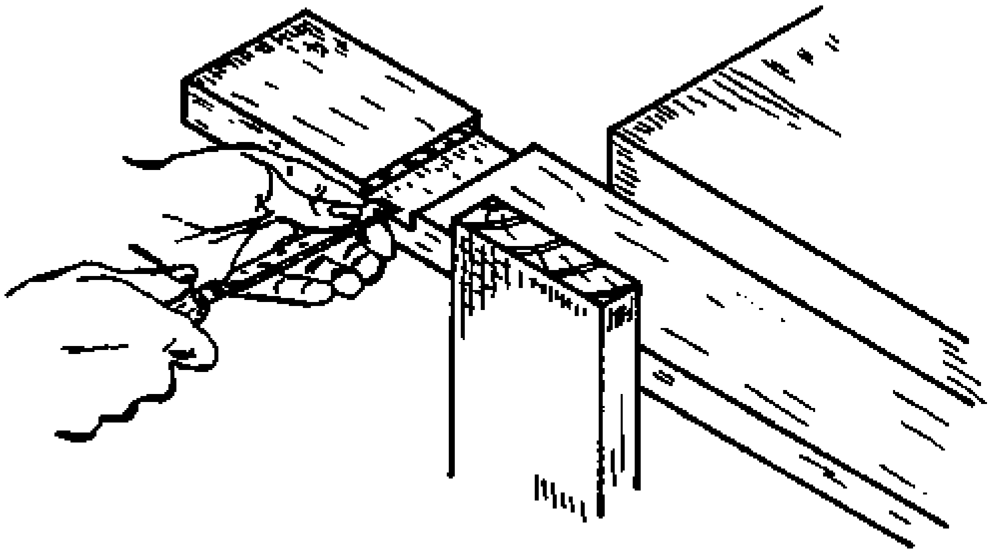

Fig. 2

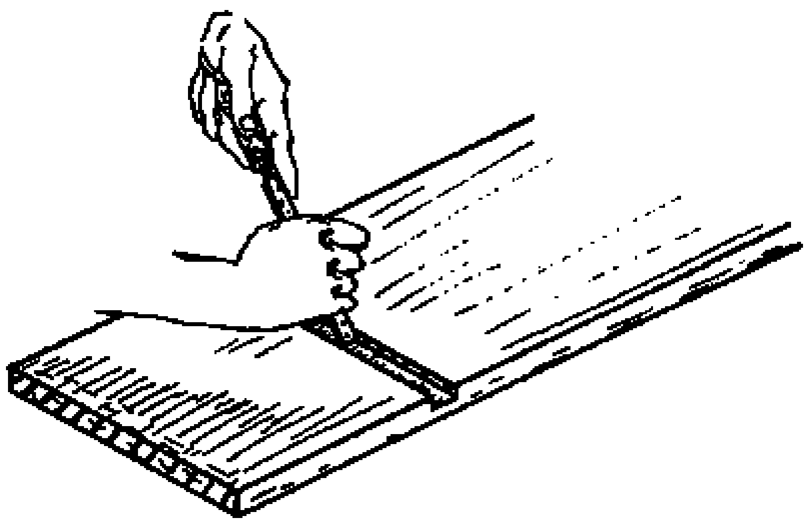

Fig. 3

HOW TO USE THE CHISEL

To do good work, you need a sharp chisel. A dull chisel is hard to force through the wood and it is also hard to guide and control, making the resulting work rough and inaccurate. The time you use to stop and sharpen a dull chisel will soon be regained by better and faster work.

To prevent dulling the chisel, do not allow the cutting edge to touch other tools or the bench top. Always lay the chisel on the bench with the bevel side down.

CHISELLING WITH THE GRAIN

When chiselling with the grain, observe the following points (see Fig. 4 on the previous page):

- Always work with the grain, to avoid splintering or splitting the wood.

- Fasten the work securely so your hands are both free for the chisel.

- Always push the chisel away from yourself, keeping both hands behind the cutting edge.

- Use your left hand to guide the chisel, and your right hand to push on the handle.

CHISELLING ACROSS A BOARD

When chiselling across the grain, observe the following:

- Grasp the blade of the chisel between the thumb and forefinger of your left hand, to guide it and act as a brake, while the pushing is done with your right hand (Fig. 2).

- Cut with the bevel side up, raising the handle just enough to make the chisel cut. For heavier chiselling and for rough cuts, the mallet may be used as is shown in Fig. 1.

- When chiselling across wide boards, where the chisel cannot reach to the center of the board, work with the bevel side down (Fig. 3).

NOTES:

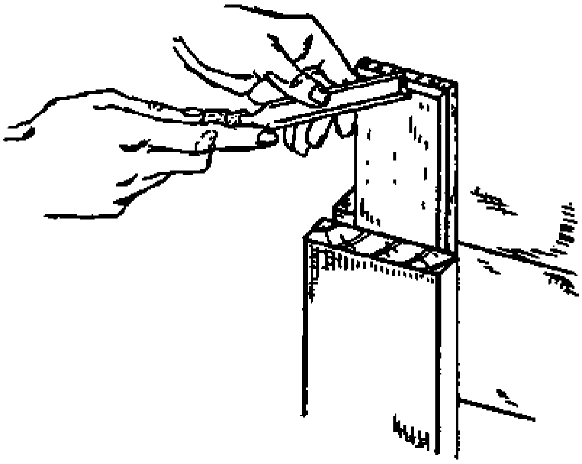

Fig. 1

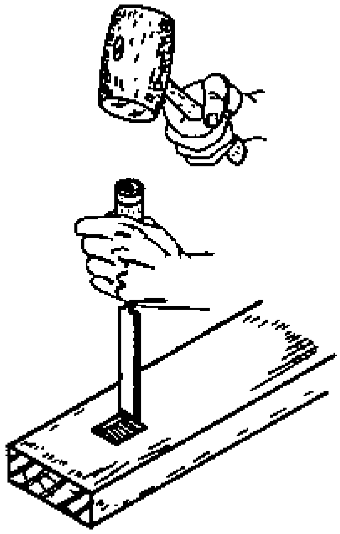

Fig. 2

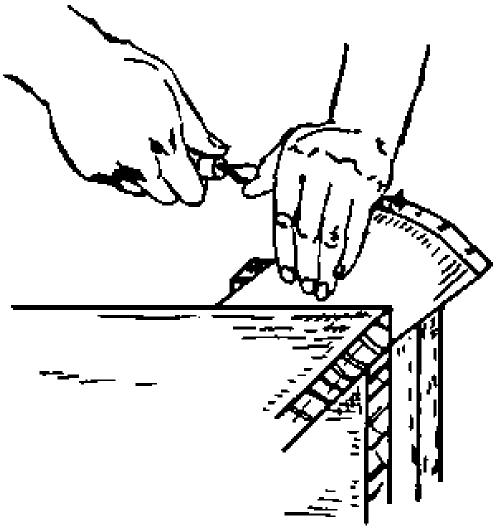

Fig. 3

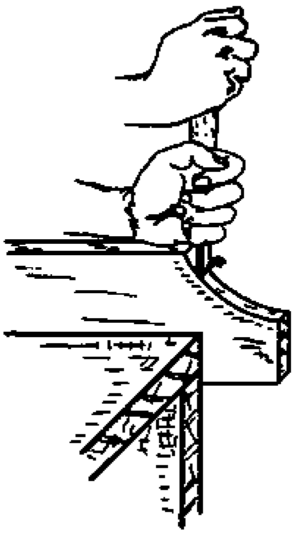

Fig. 4

USING THE MALLET

Use a mallet to drive the chisel when force is required to make deep, rough cuts. Never use a steel hammer, it will soon damage the chisel handle.

- Make a series of light taps with the mallet instead of heavy blows, as light taps will give you better control.

CHAMFERING

The chisel may be used to make chamfers or bevels, with or across the grain.

- Keep the bevel up. As you push the chisel forward, move the handle slightly from side to side, so that the cutting edge works obliquely (at an angle) (Fig. 1).

- Prevent splintering in cutting end chamfers or bevels by working part way from one edge and part way from the other.

MORTICING

Morticing is done as shown in Fig. 2 on the left page.

CUTTING CURVES WITH THE CHISEL

Convex curves can be shaped with the chisel as shown in Fig. 3.

- Use the chisel with the bevel side up. Hold and guide it with your left hand while you push it forward with your right hand.

Concave or inside curves may also be finished with the chisel, as in Fig. 4.

- Use the chisel with the bevel side down.

- Guide it with your left hand, while your right hand pushes down and pulls backward at the same time.

NOTES:

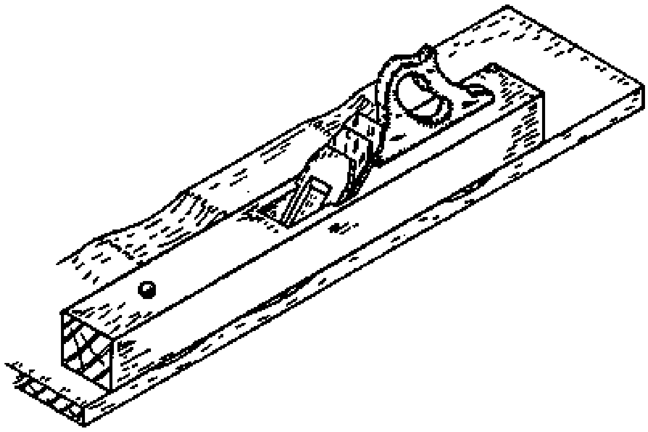

Fig. 1

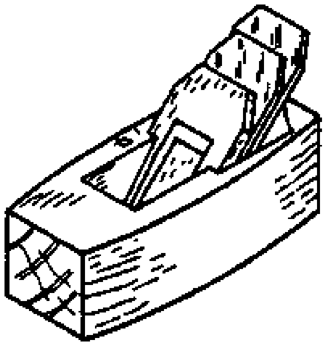

Fig. 2

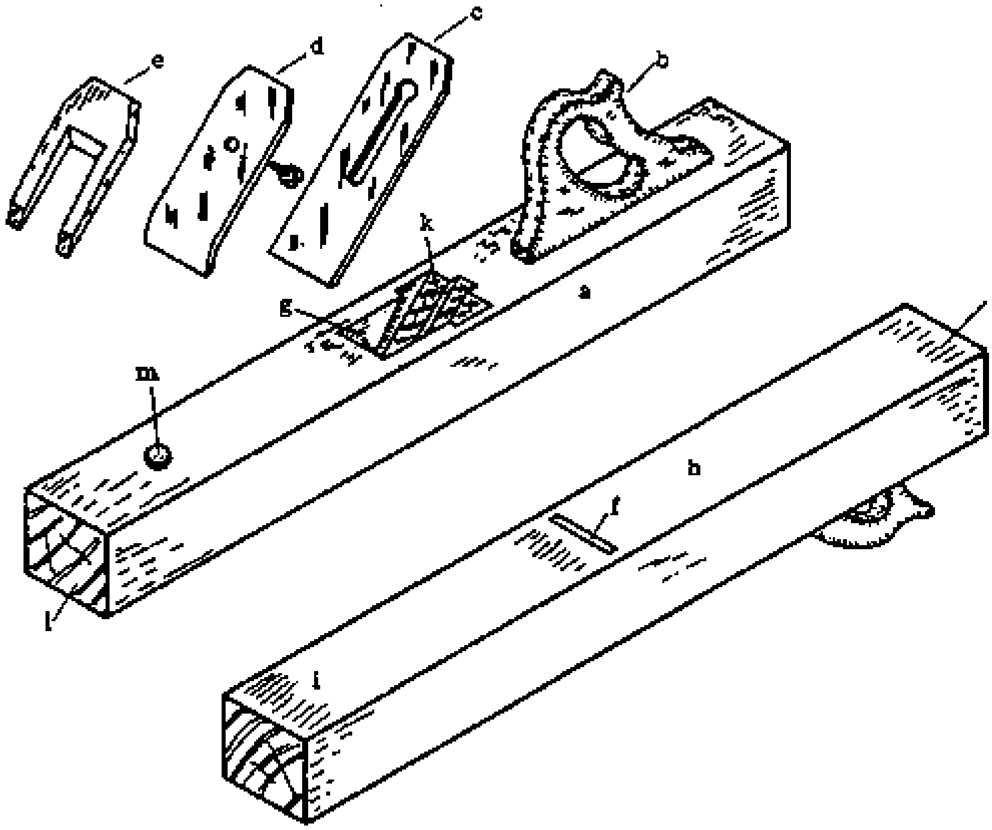

Fig. 3

PLANES

Together with the hammer, saw, try square and chisel, the plane is one of the principal tools used for carpentry work.

When timber comes from the sawmill, it is rough from the saw. Before rough-sawn timber or boards can be used for any finished work, they must be prepared so that all their sides and edges are square, flat and smooth. This preparation is done by planing them first and later smoothing them.

The tool used for the rough part of this work is called a jack plane (Fig. 1). It is used for planing the wood true and to reduce it to the correct size. The jack plane is used for general planing purposes, which is why it is called "jack", meaning generally useful.

After the board has been planed to a true surface, we use the smoothing plane (Fig. 2) to remove the rough marks of the jack plane, making a smooth surface on the board.

Other planes, used for special purposes, are discussed later in this book.

THE JACK PLANE

The jack plane (Fig. 3) consists of five main parts: the stock or body (a), the handle (b), the cutting iron (c), the cap iron (d) and the wedge (e).

The stock of the plane is made of hard wood which wears uniformly (doesn't get more worn out in some areas than in others), is tough, straight grained and keeps its shape. It is about 40 cm long. This long length lets the plane go over the low spots in the wood without cutting (Fig. 1), while it removes the high spots.

The stock holds the cutting iron, which takes off the shavings. The cutting iron sticks out through the mouth (f) on the bottom of the stock and the shavings leave the plane through the escapement (g) on top of the stock.

The bottom of the stock, which rubs along the wood during planing, is called the sole (h). The front part of the sole is called the toe (i) and the back part is the heel (j).

The cutting iron rests on the bed (k), at a 45 degree angle to the sole.

The front end of the stock is called the nose (1). To remove the cutting iron or to reduce the cut, the top of the nose is struck sharply with a hammer. In order to prevent the wood from being bruised, some planes have a small piece of metal let into the nose, to take the blows of the hammer. This is called the striking button (Fig. 3, m, previous page).

The handle is morticed into the stock behind the escapement. It should have a comfortable grip to protect the hand.

The cutting iron is made out of steel. It has a slot in the centre which ends in a screw hole. The cutting edge is ground at an angle of 25 to 30 degrees (see Maintenance of Tools, pages 92 to 99). If there is any imperfection in the cutting edge you will see a mark from it on the wood after planing.

The cap iron is made from mild steel and is secured to the cutting iron by a cheese-head screw (holding screw) which passes through the slot in the cutting iron. The cap iron helps the cutting edge to plane smoothly, by breaking up the shavings before they split ahead and tear up the fibres of the wood.

It is essential that the back of the cap iron should bed perfectly on the face of the cutting iron when they are fitted together, for even the slightest gap between the two will allow a shaving to enter and the mouth of the plane will immediately become blocked (see Maintenance of Tools, page 104).

The wedge is made of hard wood and its function is to hold the irons in place. It fits into special grooves in the sides of the escapement.

It is a good idea to keep the wooden parts of the plane in good condition by occasionally rubbing some vegetable oil, like groundnut oil (not machine oil) on them.

NOTES:

THE SMOOTHING PLANE

The smoothing plane is constructed similarly to the jack plane. It is used to finish the surface of the wood.

The smoothing plane is about 20 cm long, so it is the smallest plane that a builder uses (Fig. 2, page 54).

The smoothing plane is not used to remove large quantities of wood or to plane the wood flat and true. It is set to remove only rather fine shavings, so we use it only to make a smooth surface on the wood.

The smoothing plane has a handguard rather than a handle like the jack plane and it has the striking button on the back end of the plane instead of on the nose.

NOTES:

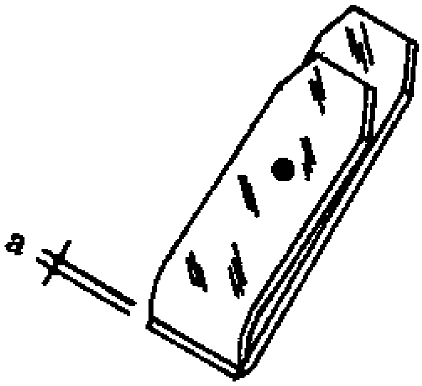

Fig. 1

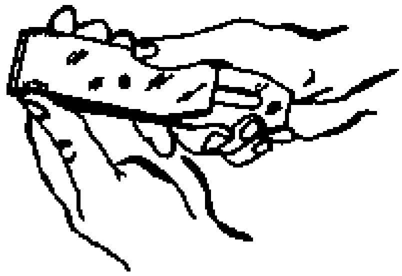

Fig. 2

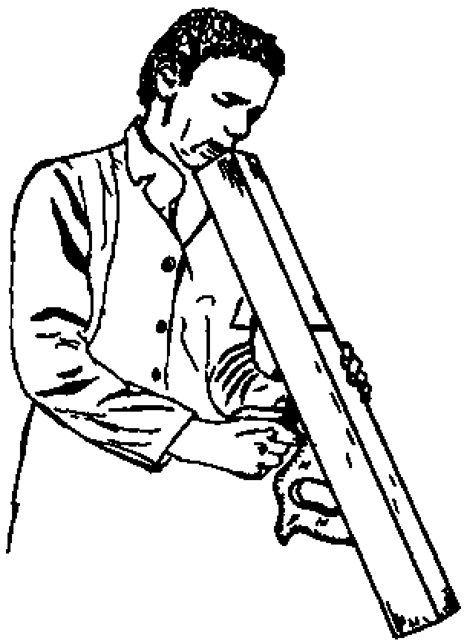

Fig. 3

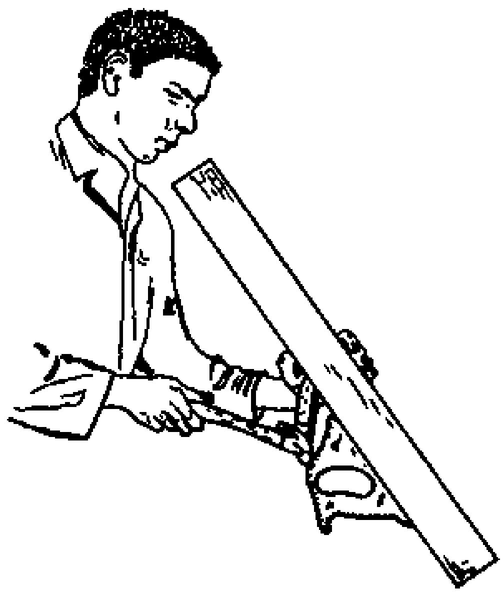

Fig. 4

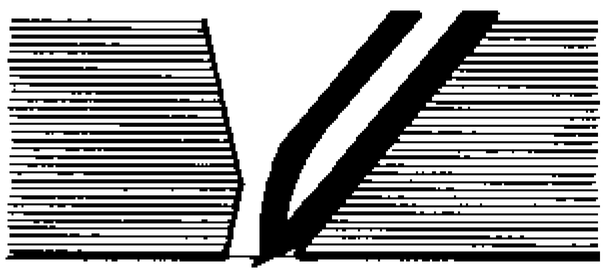

Fig. 5

HOW TO SET THE CAP IRON

The distance from the edge of the cap iron to the cutting edge is called the set (Fig. 1, a).

- The set for the jack plane should be:

  2 mm, when planing hard woods;
  3 mm, when planing soft woods.

- The set for the smoothing plane should be:

  1 mm or less.

In order to set the cap iron, first loosen the cheesehead screw which holds the two irons together; until the cap iron can move. Hold the irons as shown in Fig. 2 and be very careful that the cap iron does not touch the cutting edge as this will make it dull. Adjust the irons to the proper set and tighten the screw.

HOW TO SET THE CUTTING IRON

1. Hold the plane in your left hand and look along the sole while putting the irons in it (Fig. 3). Fix the wedge so that they are held in place lightly. Adjust them to roughly the correct position.

2. Adjust the cutting iron exactly by tapping with the clawhammer either on top of the iron (Fig. 4), so that it comes out more and takes off thicker shavings; or on the striking button to get thinner shavings.

3. After every adjustment, tighten the wedge slightly. Don't hit it too hard or you will damage the wedge.

The cutting iron should project as shown in Fig. 5 on the left page. It is important that the cutting iron projects evenly. For rough work, you will want the cutting iron to project more so as to take off thicker shavings. For fine work, where only a little wood will be planed off, the cutting iron should project less.

- After you finish using the plane, knock the cutting iron back so that it doesn't project out of the sole at all. This is to prevent damage to the cutting edge when the tool is not in use.

NOTES:

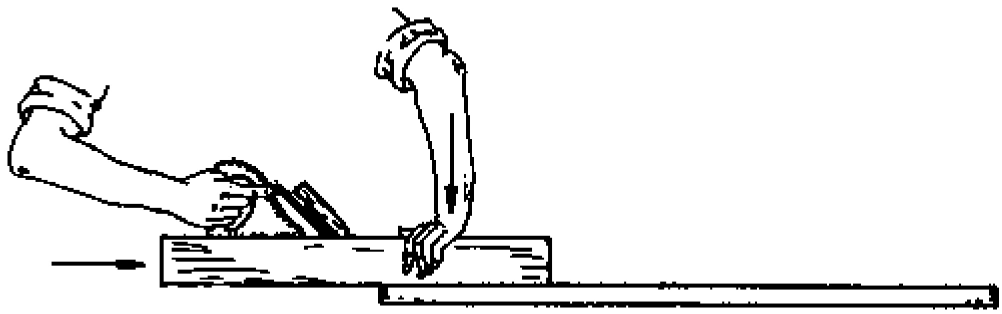

Fig. 1

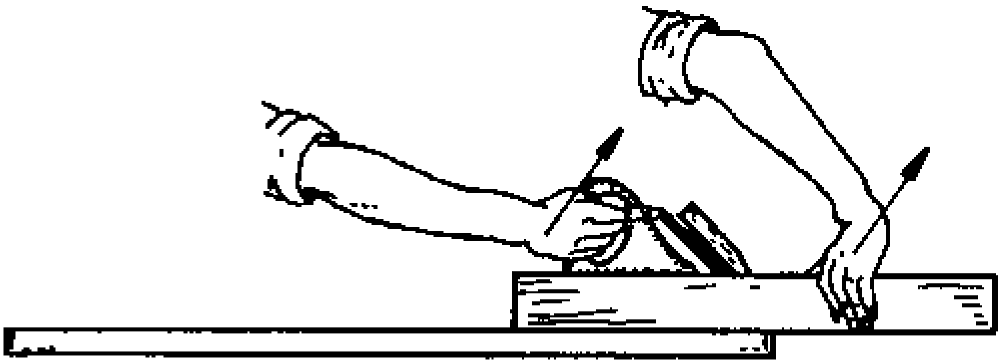

Fig. 2

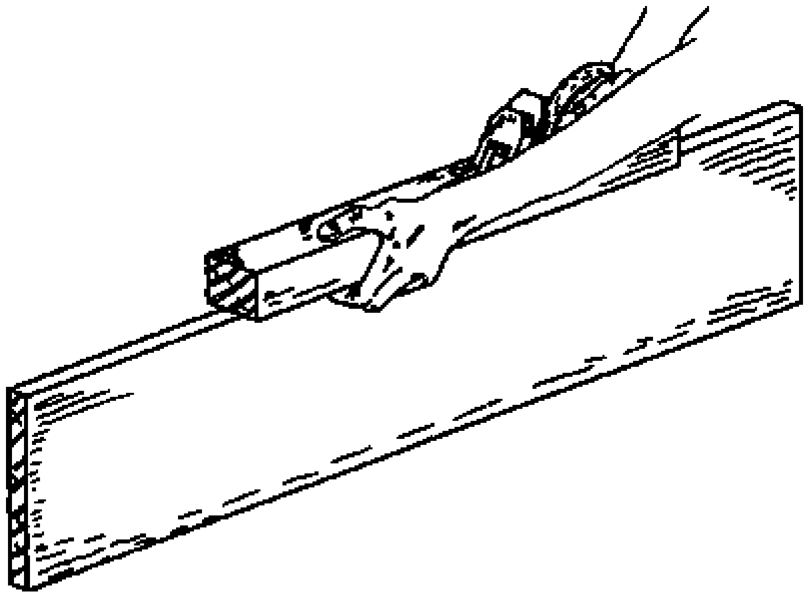

Fig. 3

PLANING

- When you use the plane, try to put pressure on it in such a way that the part of the sole which is in contact with the wood is pressed firmly to the wood surface. At the start of the stroke when the cutting iron does not yet touch the wood, put pressure on the front part of the plane (Fig. 1). When the cutting iron comes to the end of the board, press down more on the heel of the plane (Fig. 2).

- Guide the plane when you plane on edges, by curling your fingers under the plane so that they contact the board (Fig. 3).

- To obtain a good surface, always plane with the grain. If the wood is cross-grained, it is best to hold the plane at an angle to the direction of the stroke.

STUFFING

Sometimes the plane won't take off shavings anymore, but just slips over the wood without cutting it. This happens when shavings have blocked up the plane: the plane is stuffed with shavings.

- The plane may stuff when the cap iron is not fitted well to the cutting iron. Shavings can enter the gap between the irons and block the mouth of the plane (see Maintenance of Tools, page 104).

- Another cause of stuffing may be an incorrectly made plane. If you make your plane by hand, be sure to make the mouth and the escapement large enough. The mouth must not be too big however, because then it will not give a good surface when it is used to plane.

- Make sure that the ends of the wedge are not projecting over the cap iron and blocking the shavings.

NOTES:

Fig. 1

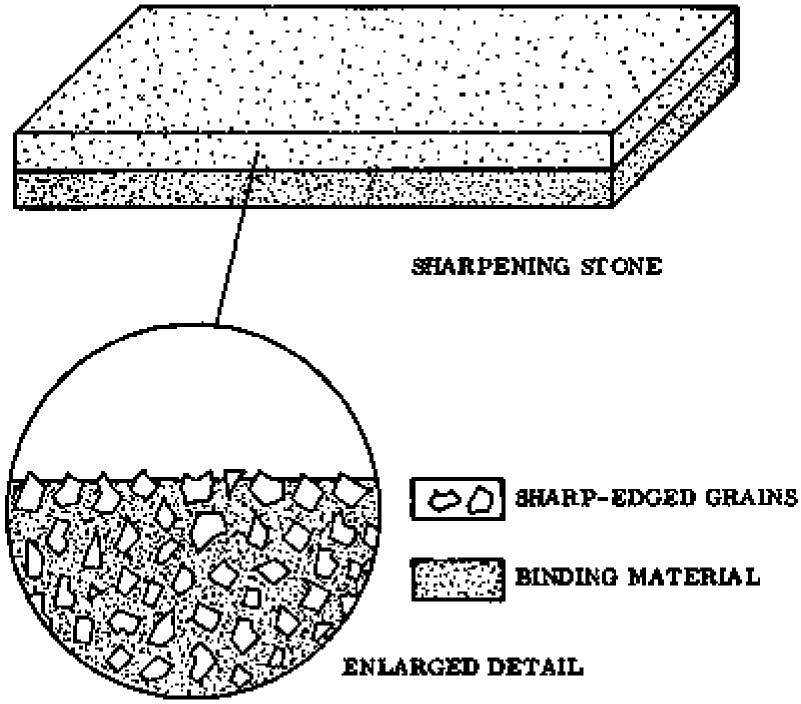

Fig. 2

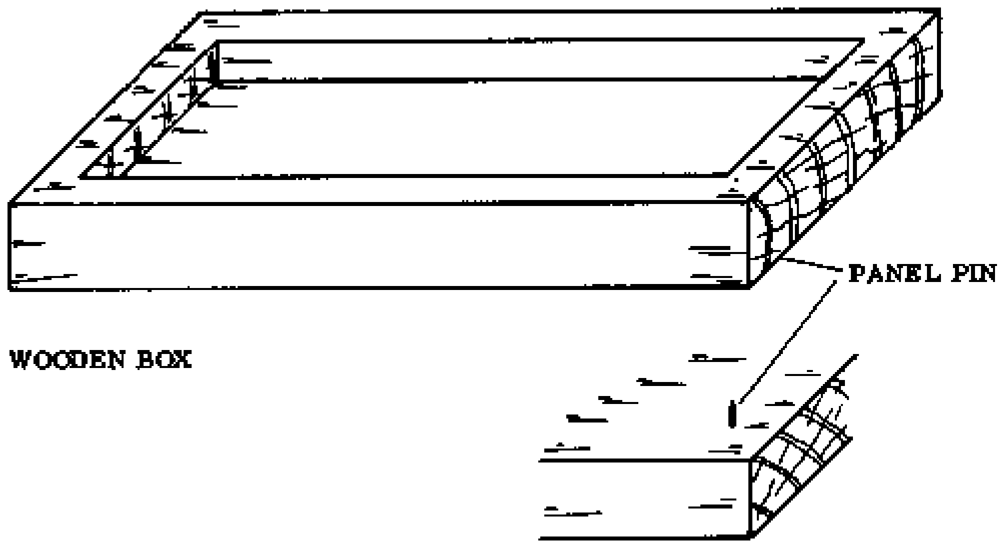

Fig. 3

THE SHARPENING STONE

The sharp edges of plane irons and chisels are made with sharpening stones. The stone acts like a file to wear away the portion of the tool that is rubbed on it.

There are natural and artificial (man-made) stones. Nowadays we use mostly the artificial ones. The grit (rough surface) of the stone consists of hard, sharp-edged grains, embedded in a binding material (Fig. 2). The bigger the grains, the coarser the stone. Stones can be coarse, medium, or fine; in Rural Building we use a combination stone, one side of which is coarse and the other fine (Fig. 1). The coarse side cuts quickly, but does not give a very keen (sharp) edge. The fine grit cuts slowly and gives a keen edge.

Take very good care of your sharpening stone. House it in a solid wooden box. On each corner of the box, drive a panel pin almost home and file the heads to sharp points (Fig. 3). The pins will anchor the box and the stone to the bench when you are sharpening tools.

HOW TO USE THE STONE

- Before using the stone, soak it in water for a few minutes. Use water during the sharpening to wash away the metal particles. After use, clean the stone with water. The water keeps the stone from glazing (becoming clogged with small metal particles between the grains, which makes it smoother and less efficient to use).

- Try to keep the stone worn down evenly and flat by using the entire surface, not rubbing just in the centre.

- The end nearest you is less easy to use, so turn the stone around occasionally to let both ends wear down equally.

- If a stone is worn hollow, it can be made flat again by rubbing it on a flat stone or cement surface, using sand and water to grind it.

NOTES:

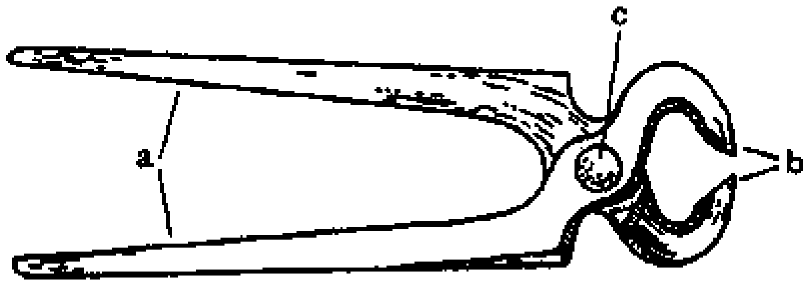

Fig. 1

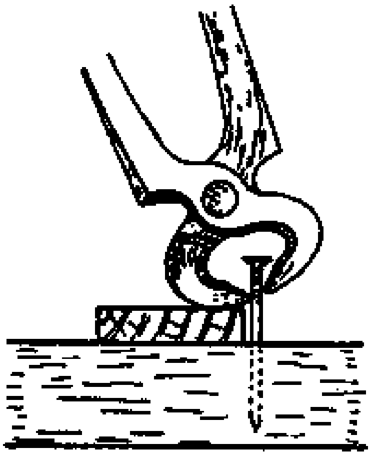

Fig. 2

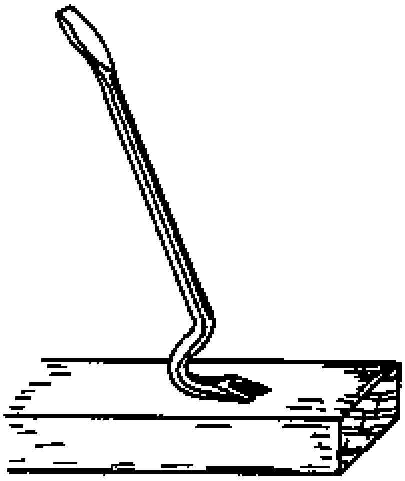

Fig. 3

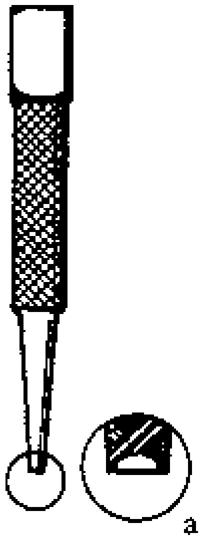

Fig. 4

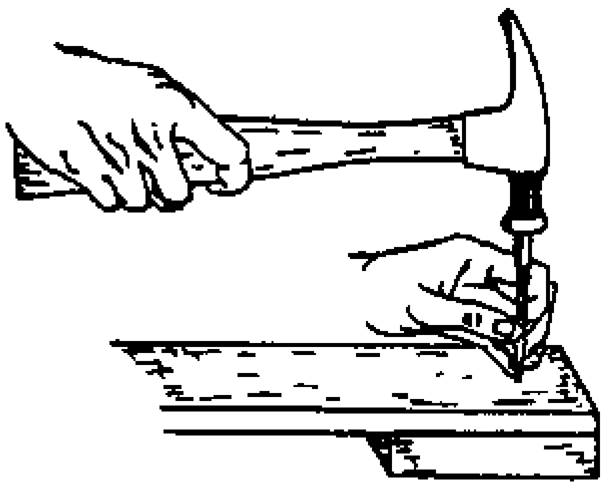

Fig. 5

OTHER TOOLS FOR EXTRACTING AND PUNCHING NAILS

PINCERS

Pincers (Fig. 1) are used chiefly for extracting nails which have become bent in driving. When using the pincers, protect the wood surface from bruising by using a small piece of wood underneath (Fig. 2).

Pincers have three main parts: the arms (a), made of steel, the jaws (b), made of hardened steel and sharpened to grip nails etc. and the rivet (c) which connects the two arms.

THE CROWBAR

This is an iron bar with a forged end (Fig. 3) used for pulling big nails out of timber and as a lever to move heavy objects. Other uses are: to open crates, or to loosen boards of concrete forms.

When a lot of force is needed to get out a nail, you use a crowbar so as not to break the handle of your hammer.

For lifting very heavy objects, an iron bar should be used in place of the smaller crowbar.

THE NAIL PUNCH

The nail punch (Fig. 4) is used along with the hammer to drive the heads of nails below the surface of the wood and to clench nails that go through to the other side of the board and stick out.

Nail punches are generally cylindrical in shape, with concave points to keep the punch from slipping off the nailhead (Fig. 4a). If no punch is available, a large blunt nail can be used instead.

- To punch a nail under the surface of the wood, hold the punch in place on the nailhead, steadying your hand on the board (Fig. 5), and hit it with the hammer.

NOTES:

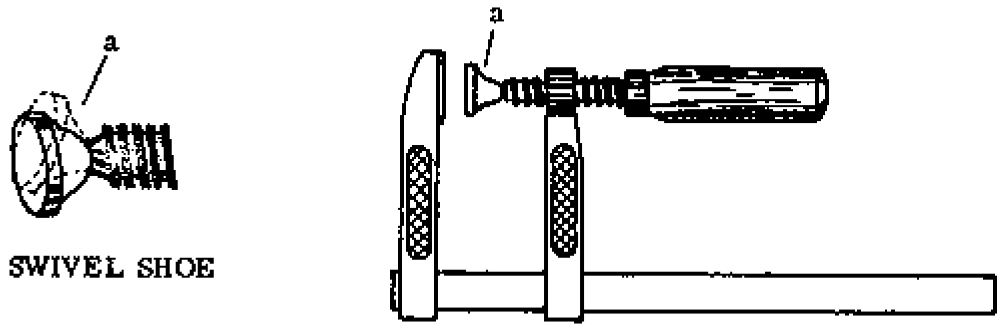

Fig. 1

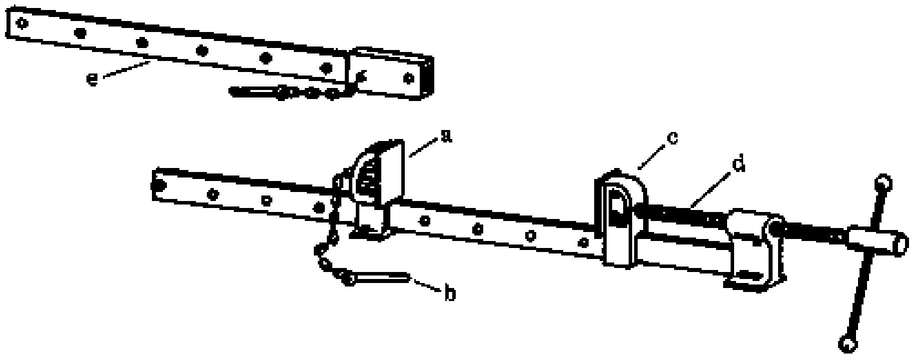

Fig. 2

Fig. 3

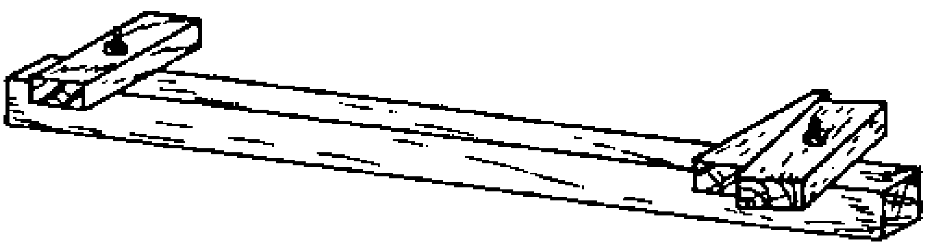

Fig. 4

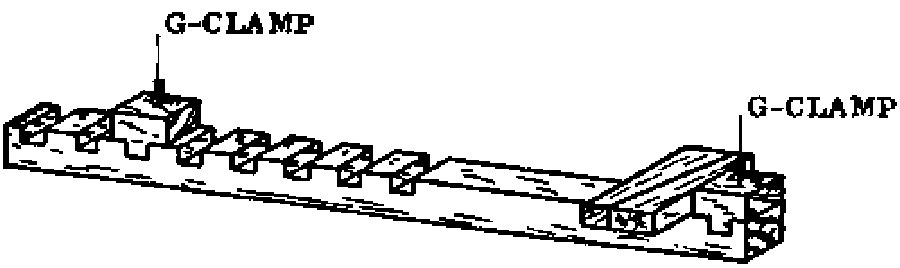

Fig. 5

CLAMPS

THE G-CLAMP

The G-clamp (Fig. 1) is used to hold the job under control while it is worked upon. It is used in the workshop as well as on the building site and can be used for holding small pieces together while they are being glued.

Except for the handle, which is made of wood, the parts are all steel. The shoe (a) is set on a swivel, which allows it to move and adapt to the surface of the job. These clamps are available in different sizes, up to 240 cm.

THE METAL SASH CLAMP

Sash clamps (Fig. 2) are used for pushing together joints and holding parts for glueing or nailing, or holding wood when making rebates.

The adjustable shoe (a) is fixed on the bar by the pin (b). The clamping shoe (c) is tightened against the job by the screw (d).

The length of the clamps can be between 100 and 200 cm, and they can be made longer by an extension bar (e).

- If more than one clamp is used on a piece, take care that they are set in line, so that they don't twist the piece.

THE WOODEN SASH CLAMP

Homemade clamps (Figs. 3, 4 & 5) can serve the same purposes as a metal one. The job is tightened by means of a wedge.

For quick jobs, a clamp can be made as shown in Fig. 3. Here the different members are nailed together according to the required size of the sash clamp.

If a more permanent, adjustable clamp is required, it can be made as shown in Figs. 4 or 5.

NOTES:

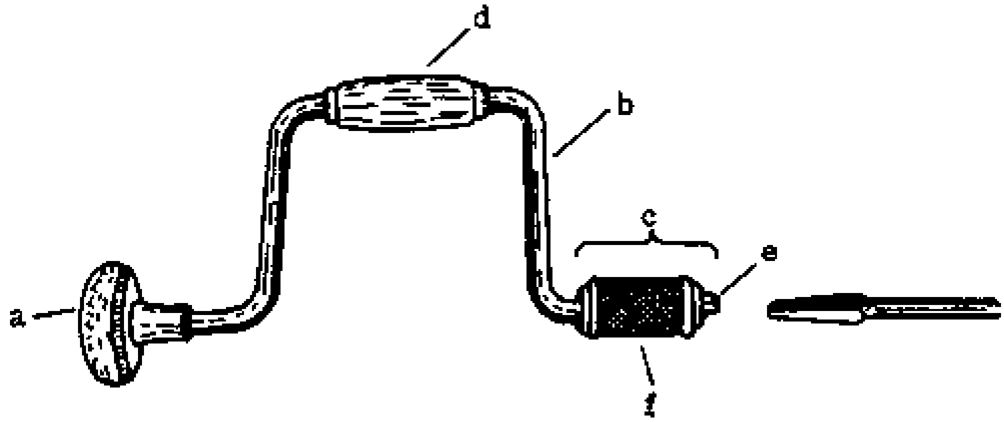

Fig. 1

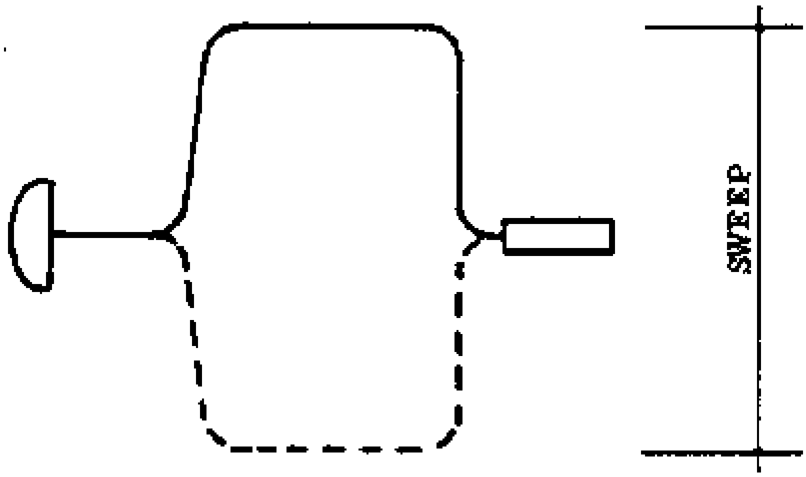

Fig. 2

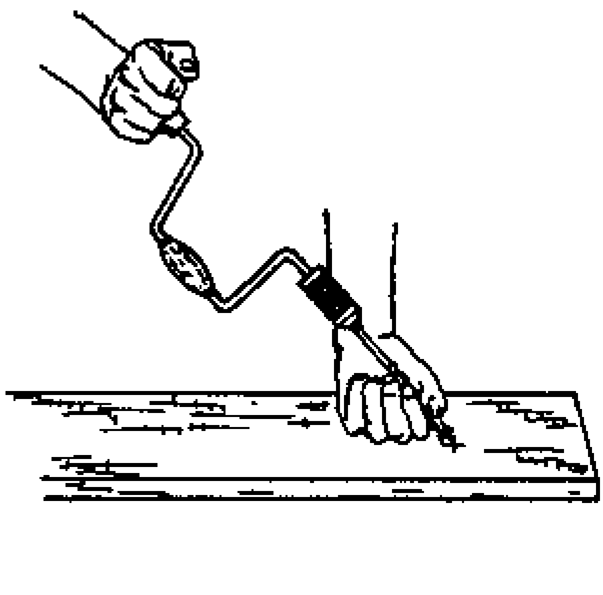

Fig. 3

THE BRACE (PLAIN AND RATCHET)

This is a cranked tool used to turn drill bits and countersinks, thus making holes in wood.

Its parts are (Fig. 1): the head (a), the crank or bow (b), and the chuck (c).

The head is a hard wooden or plastic knob, which is fixed to the bow and turns on a ball bearing.

The crank, which is formed by the rectangular bend, can be 10 to 20 cm in width giving a sweep of 20 to 40 cm, which determines the size of the brace (Fig. 2).

The wider the brace, the more force you can apply with it, but also, the distance your arm must travel is longer and more tiring and the bit may be broken more easily.

A handle (d) is attached to the crank by steel collars. It should revolve freely.

The chuck holds the various bits (the drilling parts). The bits are gripped by jaws (e). There are different kinds of jaws. The square shank of the bit fits into the square opening of the chuck. When the socket (f) is turned, it tightens the jaws over the shank of the bit.

There is a more advanced type of brace available, which is the ratchet brace. The ratchet makes it possible to use the brace in places where it is impossible to make a complete turn of the crank with an ordinary brace.

HOW TO USE THE BRACE

1. For accurate boring, first mark the location of the centre of the hole with two lines crossing each other, or by making a small hole with a sharp tool (Fig. 3).

2. With the knuckles of one hand down against the board, guide the point of the bit carefully into place, while with your other hand you exert a slight pressure on the head of the brace (Fig. 3).

3. As the bit starts boring, be careful to keep it perpendicular to the surface (unless you want the hole to be bored at an angle).

NOTES:

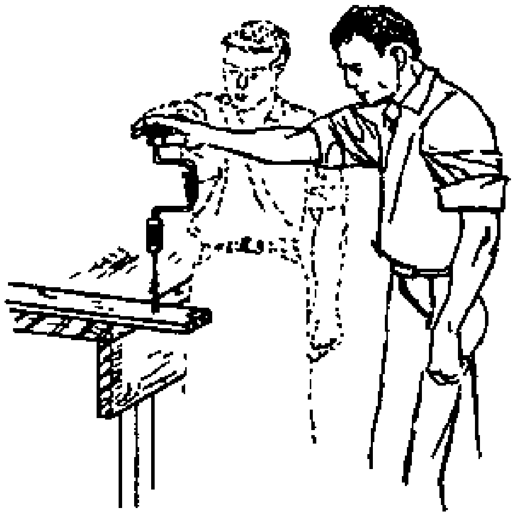

Fig. 1

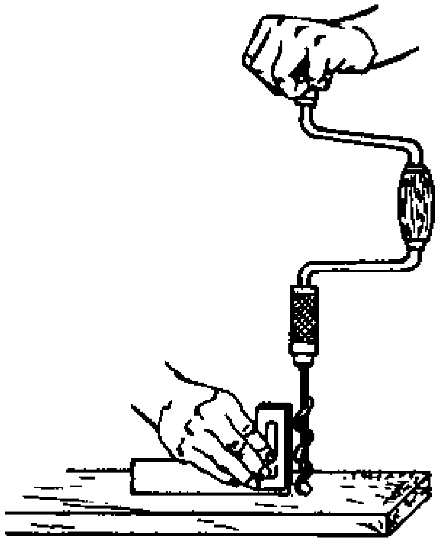

Fig. 2

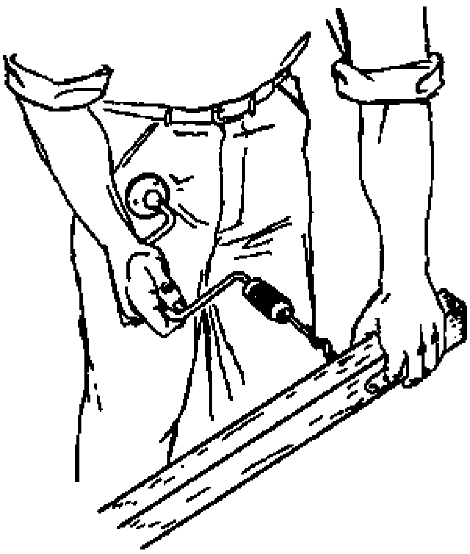

Fig. 3

It is fairly easy to tell if the brace is leaning to the right or left, but difficult to know if it is leaning away from you or towards you.

- For jobs where this is important, it is best to ask another person to stand to one side and tell you whether you are holding the brace upright.

- Another way to see whether the brace is boring square to the surface is to step. back a little, steadying the brace with one hand, and sight. Then move around and sight in the other direction, at about right angles to the first sighting (Fig. 1).

- A square can be used to check if the bit is boring straight (Fig. 2).

- If a hole is to be bored completely through a board, bore until the point of the bit can be felt on the other side (Fig. 3), then turn the board over and bore from the other side. This prevents splintering around the edge of the hole where the drill comes out.

- You can also prevent splintering by clamping a piece of waste wood on the other side of the board where the drill will come out. The drilling can then be done from one side only with no danger of splintering the wood.

NOTES:

Fig. 1

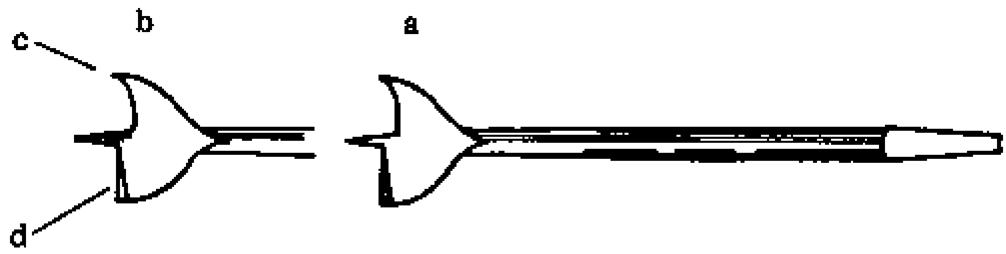

Fig. 2

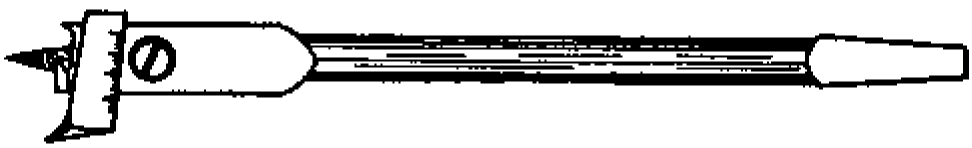

Fig. 3

Fig. 4

BITS AND DRILLS

Boring bits are used with a brace to bore holes in wood. They have a square-head shank, which fits the chuck of the brace. The shank below the head is cylindrical.

Boring drills usually have a cylindrical shank which fits into a special kind of hand operated drilling machine.

The size of the bit or drill is stamped on the shank, in mm.

AUGER BITS

The twisted part of the auger bit (Fig. 1) guides it and removes the waste. The screw-nose (a) draws the bit into the wood, the two spurs (b) scribe the diameter of the hole, and the cutter (c) cuts it.

Auger bits are used to drill deep holes. They come in sizes from 4 to 40 mm.

CENTRE BITS

The centre bit is used for boring holes in thin timber only, because it doesn't guide itself as the auger bit does.

Centre bits are available with either a point or a screw-nose (Fig. 2a or b). The screw-nose type is preferred over the type with a point, because it draws the bit into the wood.

The spur (c) cuts the rim of the hole and the router (d) removes the waste.

EXPANSION BITS

These bits are used for drilling large holes. The cutter is adjustable with a screw (Fig. 3). The size of the hole can range from 13 to 40 mm in diameter. Special types can expand up to 80 mm and more.

TWIST DRILLS

These drills have twisted flutes (Fig. 4) to bore clean holes in hard or soft woods. One of the main advantages of the twist drill is that it is available in sizes from 1 mm and up.

Besides the drill for wood, there are harder types which can drill holes in metal, stone and concrete. Even though they may look the same, you should never use woodworking drills for metal work.

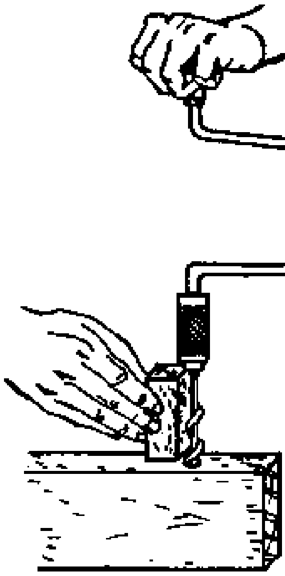

Fig. 1

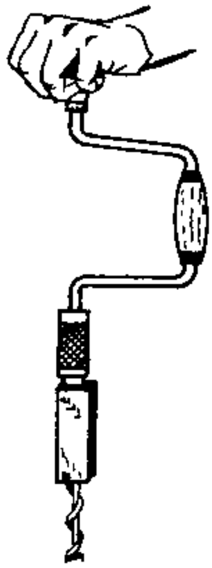

Fig. 2

Fig. 3

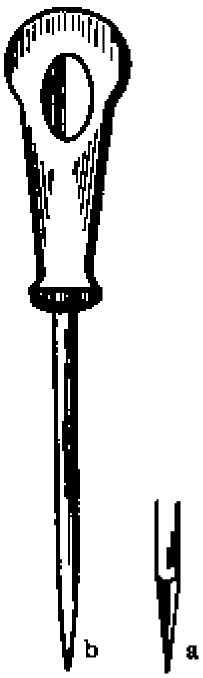

Fig. 4

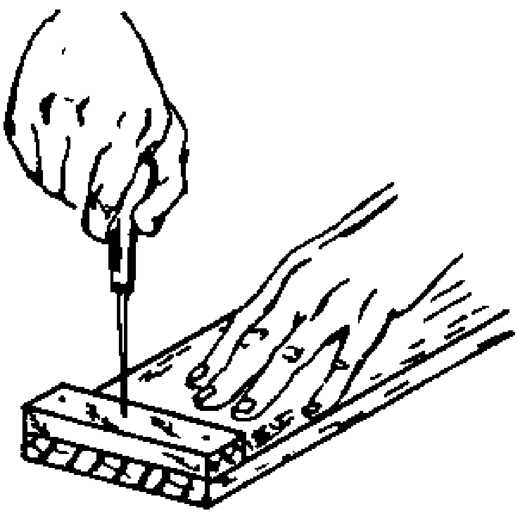

Fig. 5

DEPTH STOPS

If you are drilling a number of holes at the same depth, you can save time by cutting a wooden block to the correct size and using it as a gauge (Fig. 1), or boring a hole through the block and fitting it on the bit as shown in Fig. 2.

COUNTERSINKS

Countersinks are used to enlarge the top of a screw hole so that the screw head can fit below the surface of the wood. The most common type is the rosehead countersink (Fig. 3).

AWLS

An awl is a thin, pointed steel rod, which is fitted with a wooden or plastic handle.

Awls are used for marking or piercing holes in wood. The tip can be either square or rounded (Fig. 4a or b). Awls with square shaped tips are preferred for piercing holes for small screws or nails.

- Force the awl into the wood with a turning motion, left and right, so that it cuts its way through the wood (Fig. 5).

- An awl can easily be made from a thin steel rod, by hammering one end to a square shape and sharpening it, then fitting a handle to the other end.

NOTES:

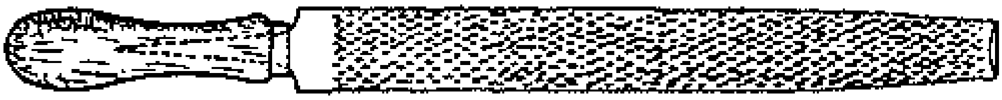

Fig. 1

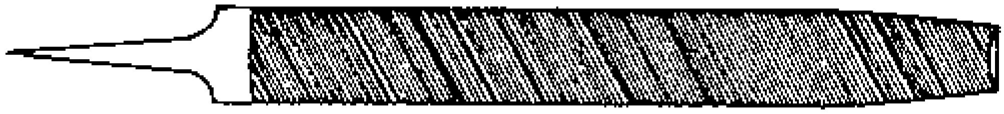

Fig. 2

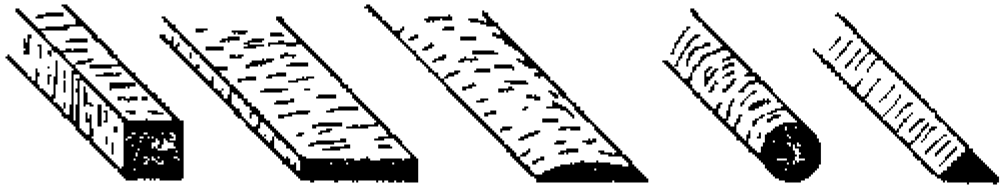

Fig. 3

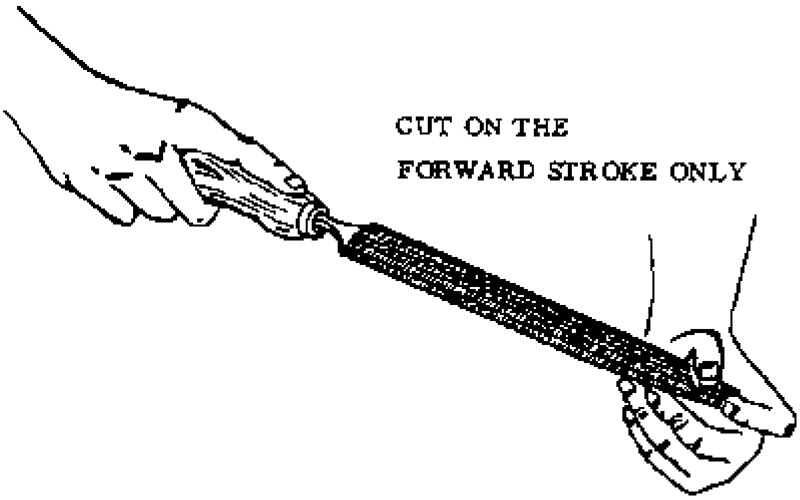

Fig. 4

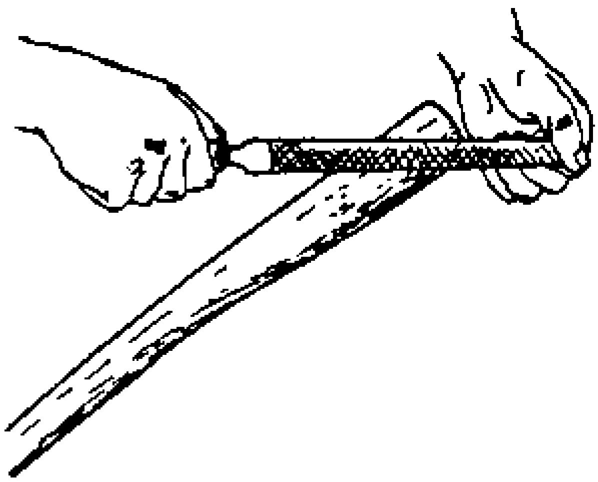

Fig. 5

RASPS AND FILES

Rasps (Fig. 1) and files (Fig. 2) are used in woodwork for smoothing wood which cannot be worked easily with any other kind of cutting tool.

- NOTE: Special metalworking files are used to work metal and sharpen tools. Never use woodworking files on metal.

The difference between the rasp and file is in the cut. Files have a series of chisel cuts across their surface, while rasps have many separate small teeth. The rasp is more coarse and cuts faster and rougher than the file.

The handles on both rasps and files must be firmly seated.

Files and rasps are available in different grades of coarseness and in different shapes. Some common shapes for files are (Fig. 3): square, flat, half-round, round and triangular (sawfiles). Rasps are usually half-round or round in section.

HOW TO USE RASPS AND FILES

- Hold the tool at a slight angle to the direction of filing (Fig. 4). By doing this, you file over a wider area and avoid making a hollow spot in one place.

- The actual cutting is done on the forward stroke only.

- When you are filing a curved piece, give the file a sideways sliding motion at the same time as you move it forwards. This is so that the file follows the curve better and doesn't produce flat spots (Fig. 5).

- The rasp is used first, to get the rough shape as quickly as possible. Then the file is used to remove the coarse marks left by the rasp.

- Do not clean rasps or files with sharp tools or steel brushes. To clean them, scrub them with a hard-bristled brush.

NOTES:

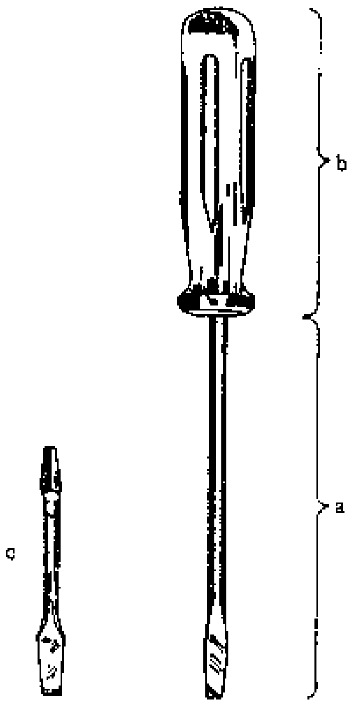

Fig. 1

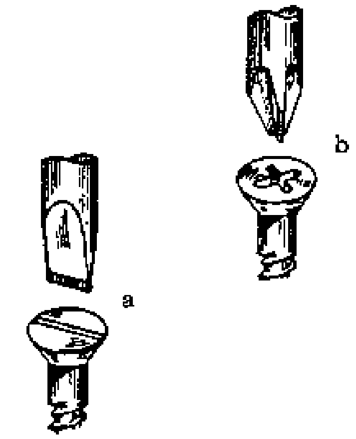

Fig. 2

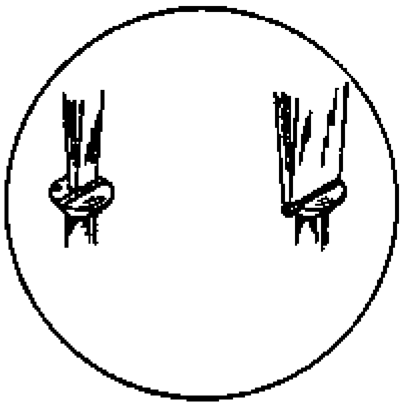

Fig. 3

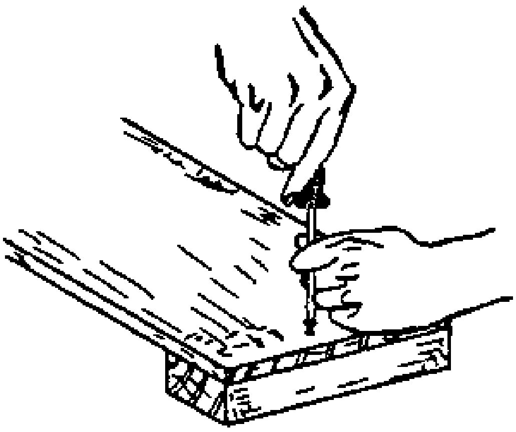

Fig. 4

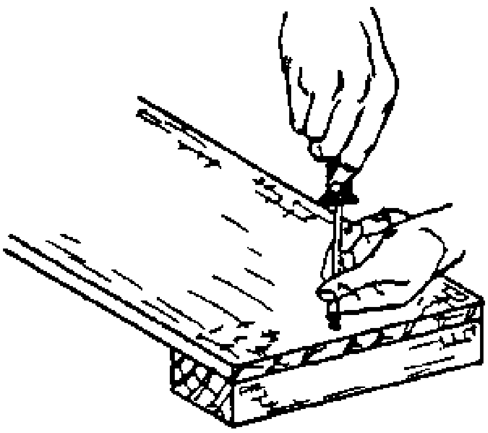

Fig. 5

THE SCREWDRIVER

Screwdrivers are used for inserting and removing screws. Many different types of screwdrivers are available. There are also screwdriver bits (Fig. 1, c) to be used with a brace.

The parts of the screwdriver are (Fig. 1): the blade (a) and the handle (b). The blade is either flat or cylindrical and the tip is either ground to a flat straight edge (Fig. 2a) or has a Philips shape (Fig. 2b) to fit different screws. The other end of the blade is shaped to a tang to fit into the handle.

The handle is made out of tough wood or plastic and is sometimes fitted with a ferrule to prevent splintering and keep the blade from turning in the handle.

The size of the screwdriver is determined by the length of the blade from the tip to the handle and by the diameter of the blade.

In order to work efficiently and not damage the slots of the screwheads, select a screwdriver with a tip that is the same width as the slot of the screw. A tip which is too small can slip and damage the slot, while one which is wider than the screwhead can scrape and damage the workface around the screw (Fig. 3).

The screwdriver tip must be properly formed (see Maintenance of Tools). A badly formed tip will cause the screwdriver to slip out of the slot and damage it.

HOW TO USE THE SCREWDRIVER

- Grasp the handle firmly in your right hand with your palm resting on the end of the handle; the thumb and forefinger extend along the handle.

- While the right hand changes grips to turn the handle, the left hand steadies the tool and keeps it in the slot. Figs. 4 and 5 show two methods of using a screwdriver.

TOOLS FOR MEASURING AND MITRING ANGLES

THE MITRE SQUARE

This is used to mark and test angles of 45 and 135 degrees. The blade is fixed at 45 degrees to the stock (Fig. 1).

THE TRY AND MITRE SQUARE

This is a combination of a try square and a mitre square. The end of the stock where it meets the blade is cut at 45 degrees (Fig. 2), so the square can be used for setting out and testing angles of 45 and 135 degrees, as well as 90 degrees.

THE SLIDING BEVEL

This is an adjustable square for marking out, testing and duplicating angles from 0 to 180 degrees. It has a stock and a slotted blade which can be adjusted to any angle and is held in place by a screw or a wing nut (Fig. 3).

A simple sliding bevel can be made by fixing two pieces of wood together with a nail or screw (Fig. 4a). Another method is to use the first section of a folding rule (Fig. 4b).

THE MITRE BOX

The mitre box (Fig. 5) is built of three pieces of wood, one forming the base and two parallel sides. It has saw kerfs in the sides at 45 degrees to the left and right to guide the saw in cutting mitres (cutting at a 45 degree angle).

THE MITRE BLOCK

This is used to mitre small sections of wood accurately. It is made of two pieces of wood with three cuts in the top piece; 45 degree cuts left and right and a 90 degree cut in the centre to help in sawing accurately square (Fig. 6).

- Mitre boxes and mitre blocks should be made of very hard wood and the saw cuts should be made with the same saw which will be used in them.

ADDITIONAL PLANES FOR THE RURAL BUILDER

THE ROUTER PLANE

This is a tool adapted from the "old woman's tooth" (Fig. 1) shown on the left page. It is used for planing the bottoms of grooves, trenches, etc. after they have been chopped out with a chisel and mallet.

There is a wooden type as well as a metal type. The wooden type has the advantage that it can be made locally (Fig. 3).

For our Rural Building course, the old woman's tooth has the advantage that an ordinary chisel can be used as a cutting iron (Fig. 2), making it unnecessary to obtain a special iron.

THE REBATE PLANE

The rebate plane is used for working along the edge of timber. It is used for making rebates as well as for cleaning them up.

The use of the rebate plane is described in the section on Rebated Butt Joints, in Rural Building, Basic Knowledge, page 132).

NOTES:

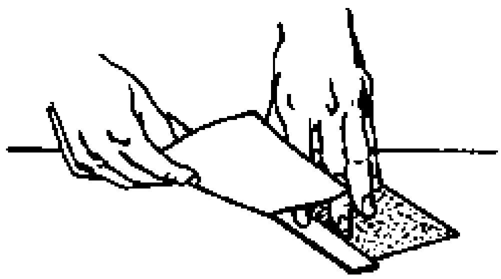

Fig. 1

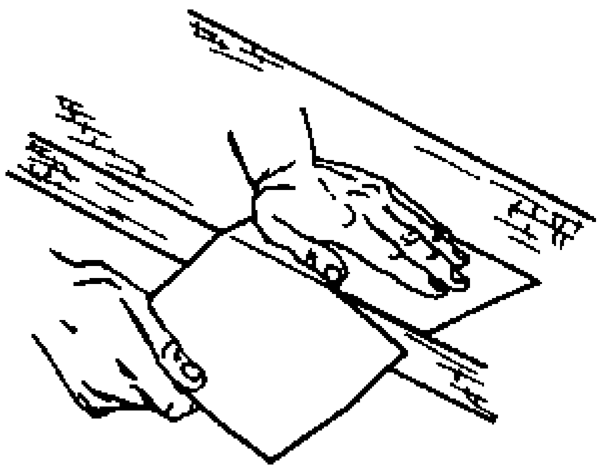

Fig. 2

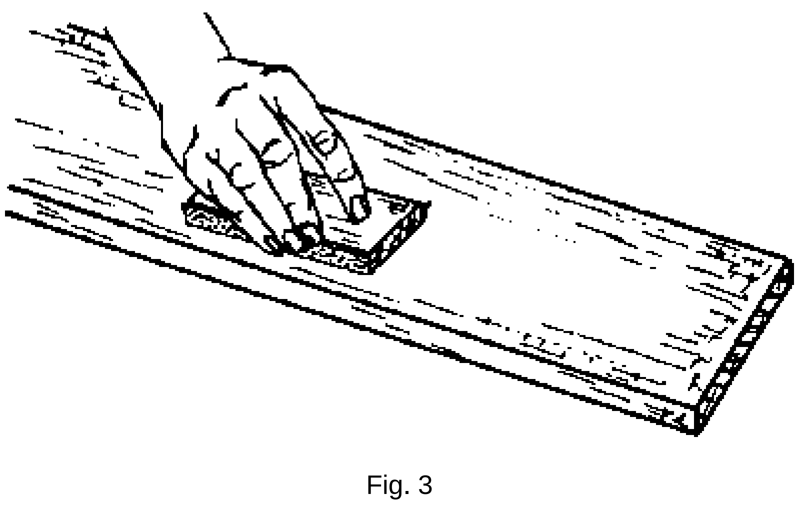

Fig. 3

SANDPAPER

Sandpaper is used to smooth wood surfaces, remove old paint, etc. It is used after all the planing work is done; sandpaper cannot be used instead of the smoothing plane.

Sandpaper is made from grains of very hard material glued to paper. The sharp edges of the grains are what cut into the surface of the wood. The sharper the grains, the better the sanding effect.

Sandpaper is graded according to the space between the grains: the more widely spaced the coarser the grade. Use coarse grades for rough surfaces or for the first sanding and finer grades for the final sanding. The commonly used grades are from No. 00 (fine) to No. 2 (coarse). Usually No. 1/2 or No. 1 is satisfactory for coarse sanding on wood and No. 0 for the final or finished sanding.

HOW TO USE SANDPAPER

- Tear the paper to the right size by creasing it and then tearing it over the edge of a bench or ruler (Figs. 1 & 2).

- Wrap it part way around a flat block of wood (Fig. 3).

- For ordinary sanding, move the block back and forth with the grain; not in a circular motion or across the grain, which will roughen and scratch the wood instead of smoothing it (Fig. 3).

- If you are sanding off old paint, this may be done across the grain.

- Keep the block flat to the wood surface, particularly on narrow edges and be careful not to round the corners.

- Use only moderate pressure on the sandpaper block. Too much pressure may cause the paper to wrinkle or tear. Keep the sandpaper free of dust by knocking and shaking it out often.

OPTIONAL TOOLS

There are many useful tools which the apprentice will eventually come into contact with and which perhaps he would like to purchase.

Although the set of tools supplied to the Rural Builder will be adequate to do the work, a good craftsman will always try to improve upon his tool set.

Therefore, the purpose of the following introduction to some additional tools is simply to round out the apprentice's general knowledge about tools.

OTHER TYPES OF TROWELS

Fig. 1 shows a triangular trowel, while the one in Fig. 2 is almost rectangular. The rectangular type of trowel is also available with a rounded tip (Fig. 2a). All three types of trowel are useful in Rural Building and the decision of which one to use depends merely upon their availability and the Builder's personal preference.

Fig. 3 shows a heavier trowel designed specially for concrete work. The head is rounded to make it easier to pick up concrete. The blade is rather thick compared to other trowels and the straight shank is connected to the blade at a 90 degree angle to reduce the flexibility of the trowel.

STEEL FLOAT

The steel float consists of a thin rectangular blade about 12 cm wide by 28 cm long. There is a handle fitted to the back side of the blade (Fig. 4).

This is a finishing tool used for smoothing surfaces such as floors and plaster.

SPOKE SHAVE

Fig. 6

OTHER PLANES

There are many varieties of planes available for different jobs. However, in Rural Building, we can do a good job with the four different planes we have and we will leave it to the future craftsman to decide if it is necessary to obtain any other plane in addition.

Below we describe briefly some other planes which might be a choice for the future builder. They are shown on the left page.

The plough plane (Fig. 1) is used to make grooves in wood.

The fillister plane (Fig. 2) is used for making rebates.

The combination plane (Fig. 3) is a combination of the fillister plane, plough plane and moulding plane.

There are various types of metal planes (Fig. 4) used for different purposes in furniture making.

The moulding plane (Fig. 5) resembles a rebate plane and it is used for making profiles.

The spoke shave (Fig. 6) is used to true and smooth edges after sawing. NOTES:

NOTES:

PART 2: MAINTENANCE OF TOOLS

The importance of good tool maintenance is something which is readily appreciated by everyone; the beginner will quickly realize that without maintenance, the finest tools are no more useful than the most inferior ones.

Apart from their general maintenance in terms of cleanliness, rust prevention and avoidance of damage from rough handling, the most important aspect of maintaining tools is in the preparation and preservation of good cutting edges.

Until one has some experience in tool maintenance, one easily overlooks the fact that from the moment that a fine cutting edge is formed, it becomes the most delicate and easily damaged part of the tool. Even the lightest touch of another piece of metal can spoil the edge, wasting the work which has gone into making it.

Such damage can be avoided in commonsense ways such as:

- By keeping the bench clear of tools which are not in use.

- By laying planes down on their sides or keeping the toe raised on a wood support so that the plane iron does not touch the bench top.

- By keeping chisels and saws in the box when they are not in use.

- By keeping the bench clear of ironmongery such as nails, screws, hinges, etc.

- And by putting tools down on wooden surfaces only.

NOTES:

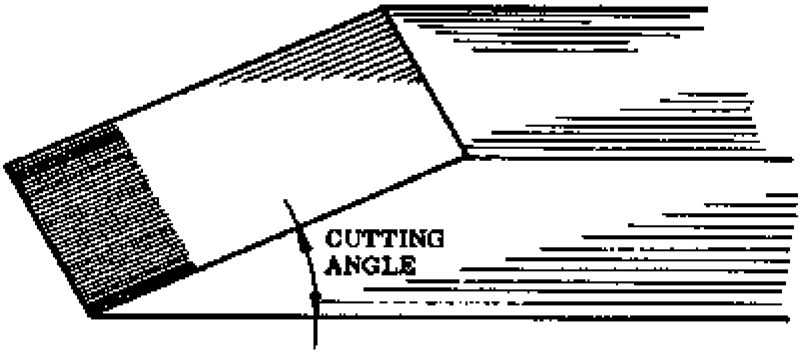

Fig. 1

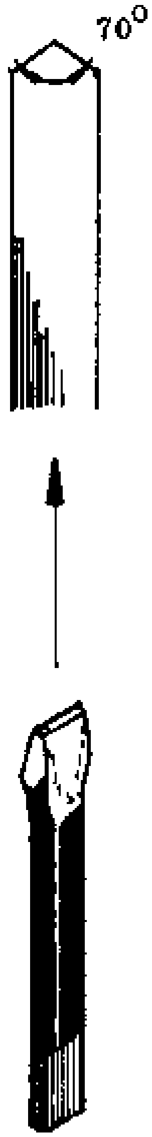

Fig. 2

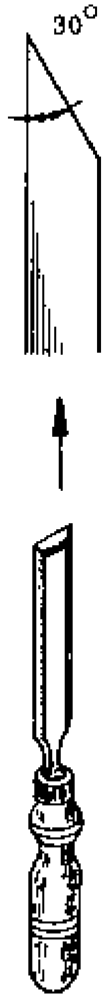

Fig. 3

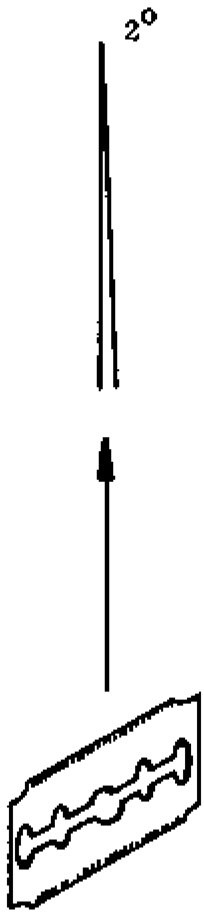

Fig. 4

CUTTING ANGLES

Before you can properly maintain your tools, you need to know something about the shape of the cutting edges on tools like plane irons and chisels. A cutting edge is formed where the two faces of a wedge come together at an angle, which is the cutting angle (Fig. 1).

In general, the harder the material that you want to cut, the larger the cutting angle you need. For example, to cut steel or stone you need a tool with a cutting angle of about 70 degrees, like the cold chisel (Fig. 2). To cut a soft material like leather, a knife or a razor blade with a cutting angle of only a few degrees (Fig. 4) will work efficiently. Of course, you would not be able to cut steel with a razor blade.

In both these cases, it is important that the cutting edge of the tools is sharp, although they have different cutting angles.

For cutting wood, we generally have one standard cutting angle for the tools like plane irons and chisels, although different kinds of wood can vary quite a bit in hardness. This standard angle of between 25 and 35 degrees is more or less suitable for all types of wood (Fig. 3). The craftsman will find with experience the right cutting angle for his needs.

Note that the smaller the cutting angle, the more easily the tool will cut and also the sooner it will become dull.

NOTES:

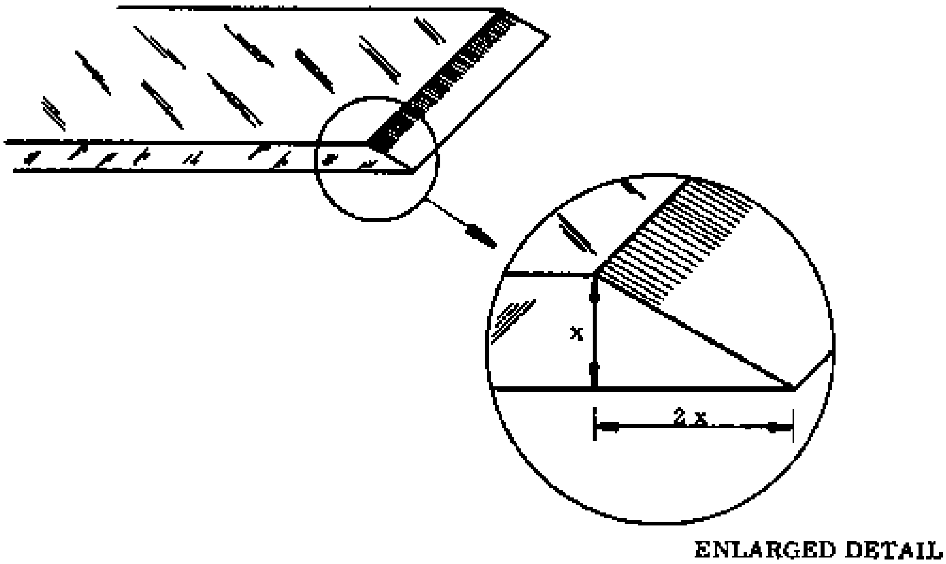

Fig. 1

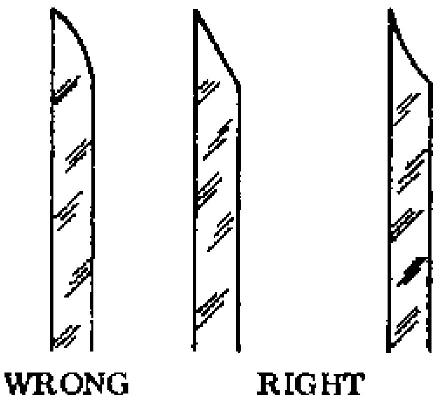

Fig. 2

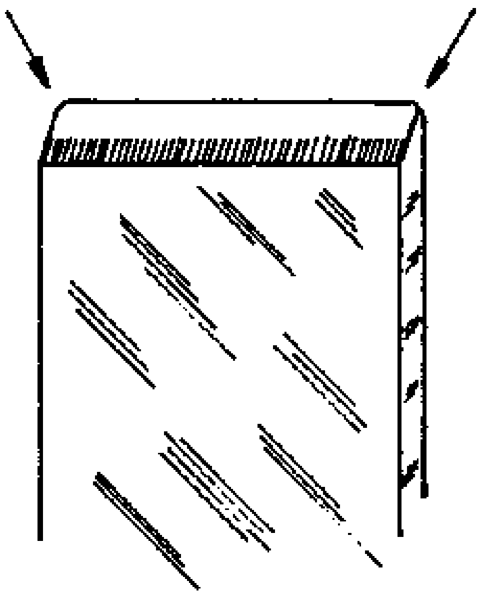

Fig. 3

SHARPENING PLANE IRONS AND CHISELS

Two different operations may be needed to produce a keen edge on these tools: grinding and honing.

Simply honing tools on a sharpening stone is all that is needed to sharpen them if they are dull but undamaged.

If the edges have been damaged, or worn down by many honings, they will need to be ground first and then honed. The grinding step is done on the rough side of the sharpening stone, or if the damage is very bad, on the grinding wheel.

ANGLE AND SHAPE OF THE CUTTING EDGE

- For normal work, grind plane irons and chisels so that the length of the bevel is a little more than twice the thickness of the blade (Fig. 1). This gives an angle of 25 to 30 degrees.

- The bevel should be ground straight or slightly concave, not rounded or convex (Fig. 2).

- For jack planes it is desirable to grind the corners of the blade slightly rounded as shown in Fig. 3. This lets the iron cut thicker shavings without causing deep grooves or plane marks in the wood surface.

- The cutting irons of smoothing planes, rebate planes and chisels should not be rounded.

- When you sharpen the cutting iron of a plane, always remove the cap iron first.

NOTES:

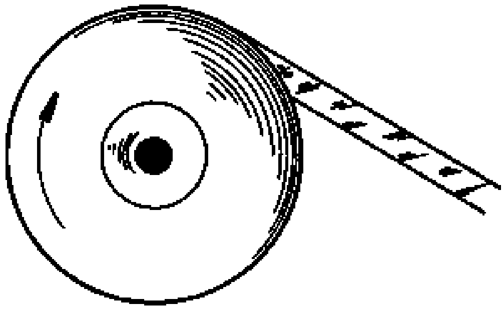

Fig. 1

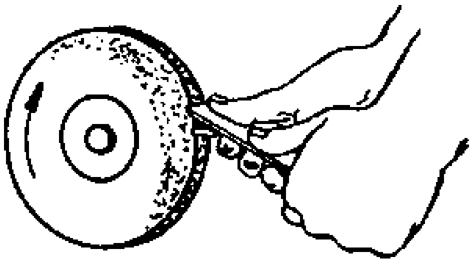

Fig. 2

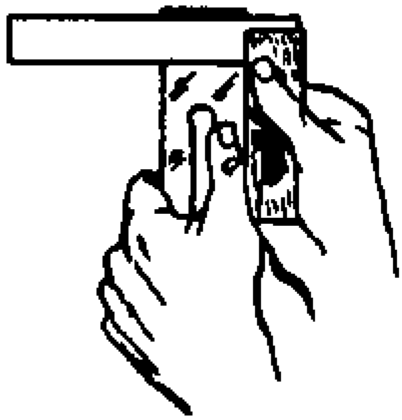

Fig. 3

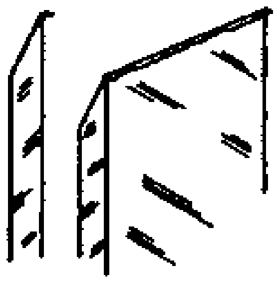

Fig. 4

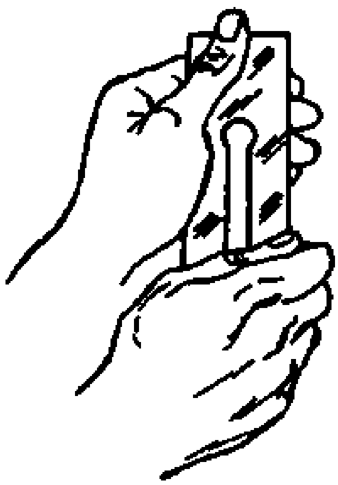

Fig. 5

HOW TO GRIND PLANE IRONS AND CHISELS ON THE GRINDING WHEEL

When the cutting edge of a tool is badly damaged, it is ground on the grinding wheel. This is done by holding the tool at a constant angle to the rotating edge of the wheel (Figs. 1 & 2).

Each grinding makes the tool a bit shorter, and thus shortens its life. Use your tools carefully so that they don't need to be reground as often.

When you grind a plane iron or chisel on the grinding wheel, the following points are important to keep in mind:

- Before grinding, test the cutting edge for squareness. Put a try square on top of the chisel or plane iron, with the cutting edge projecting slightly past the try square blade (Fig. 3). Be careful not to touch the cutting edge with the square.

- Hold the tool against the wheel in a manner that will produce a smooth, even bevel, with the desired angle.

- If possible, adjust the work rest of the grinding wheel, so that when the tool is held firmly against the rest it will come into contact with the wheel at the correct angle (Fig. 2).

- Grasp the tool so that your first finger is against the work rest; this will enable you to replace the tool in the proper position after removing it for inspection or to dip it in water (Fig. 5).

- During grinding, a wire edge or burr is formed on the tool. You can feel this burr if you run your thumb across the edge at the back (Fig. 4).

- It is important that the grinding wheel always turns towards you (Fig. 1), so that the burr that is formed remains on the blade. If the wheel were rotating away from you the burr would tear off, leaving an uneven edge.

- Turn at a moderately fast speed, not so fast that the gears whine or the grinder vibrates.

- Always work with another person on the grinding wheel, so that he can turn the wheel while you do the grinding.

- Hold the tool against the wheel with a medium firm pressure.

- Move the tool from side to side across the face of the wheel.

- Take care that the cutting edge does not become overheated and thus softened during grinding. Prevent overheating by frequently dipping the cutting edge into a tin of water.

- Inspect the edge often, to see if the tool is being ground to the proper shape and angle.

- With a bit of practice, you can check the cutting angle by eye, remembering that the length of the bevel should be a little more than twice the thickness of the blade. Use a rule at first to check the length of the bevel and the thickness of the blade.

- Continue grinding until the dull edge is removed, all the marks are removed, the edge is straight and square and the bevel has the required angle. If the edge is not square, correct it during the grinding by pressing carefully more on one side than on the other.

- Remove the burr or wire edge left by the grinding wheel by honing the tool on a sharpening stone.

NOTES:

GRINDING ON THE COARSE SIDE OF THE SHARPENING STONE

If the tool has a cutting edge with only a few marks in it and no serious damage, it can be ground on the coarse side of the sharpening stone, instead of using the grinding wheel.

- Soak the stone in water and grind the bevel of the tool on the coarse side of the stone, until a slight burr or wire edge is formed.

- When grinding, place the cutting iron on the stone so that the bevel lies flat (Fig. 1) and rub it with circular movements. Do not rub it just back and forth, as this makes the stone wear unevenly.

- Be particularly careful to move your hands parallel to the surface of the stone and do not allow them to make a dipping movement, as this will round the cutting edge.

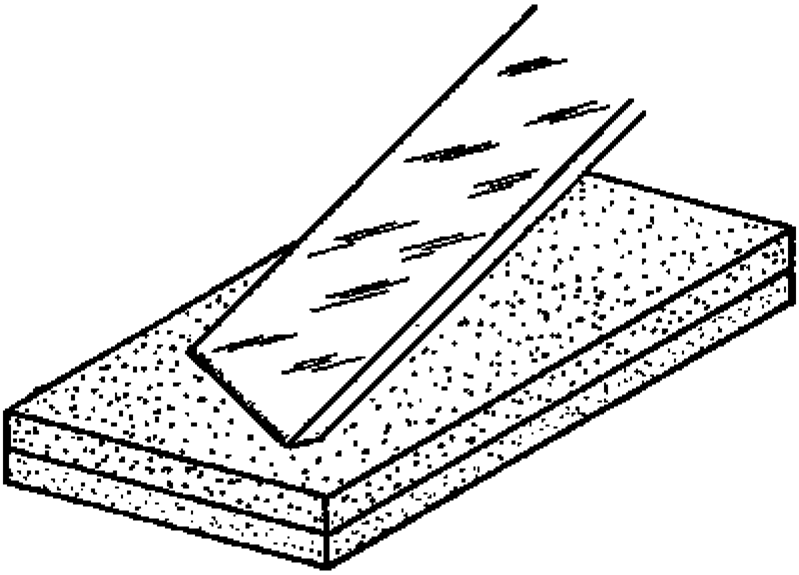

Fig. 1

NOTES:

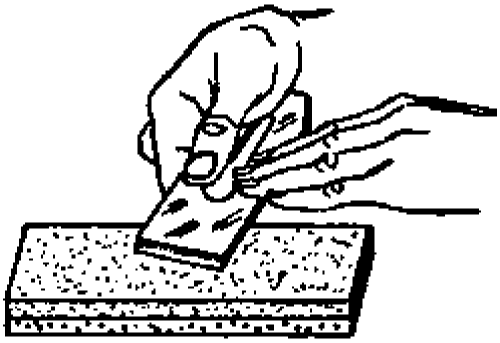

Fig. 1

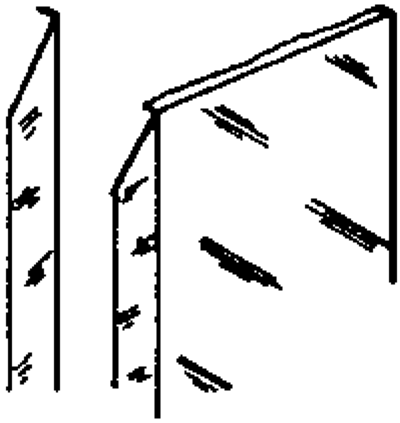

Fig. 2

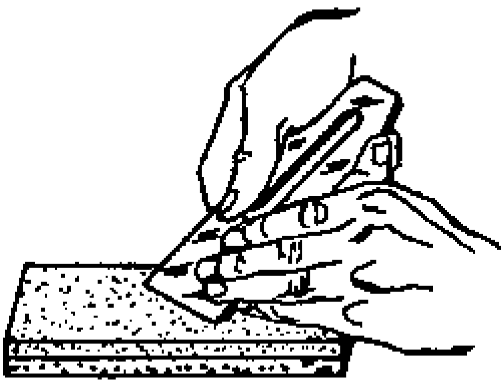

Fig. 3

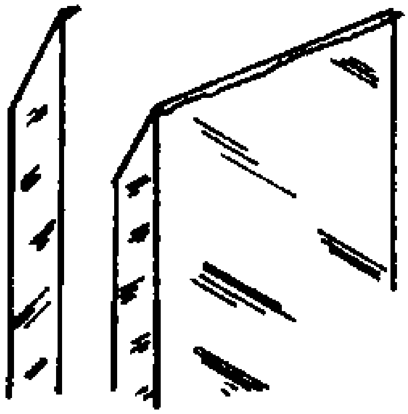

Fig. 4

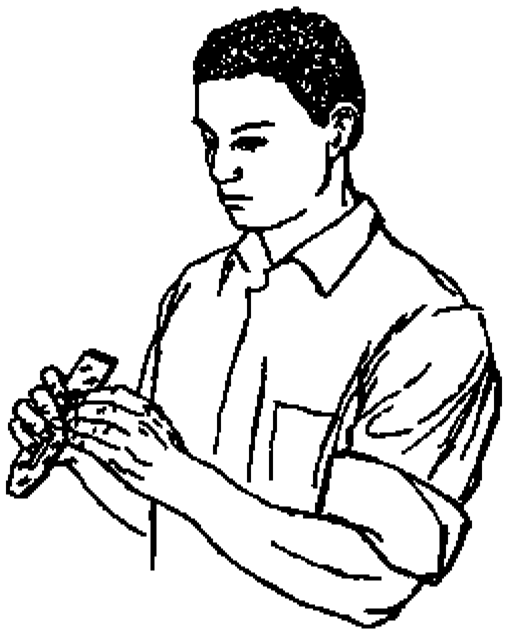

Fig. 5

HOW TO HONE PLANE IRONS AND CHISELS

Honing is done on the fine side of the sharpening stone. Honing produces a keen edge.

After a slight wire edge has been produced on the coarse side of the sharpening stone, or on the grinding wheel, it is removed by honing on the fine side of the stone.

- First, soak the stone in water. Place the tool perfectly flat on the stone with the bevel up and push it forward (Fig. 1). A few strokes will turn the burr from the flat side of the tool to the side with the bevel (Fig. 2).

- When the wire edge turns, turn the tool over so the bevel is flat on the stone and hone lightly on the bevel (Fig. 3).

- Then reverse the tool again and hone on the flat side.

If the honing is properly done, the wire edge will quickly become smaller and smaller (Fig. 4) and eventually disappear. The tool will then be sharp.

To check whether the tool is sharp, draw the nail of your thumb across the edge of the tool.

Marks, such as may have been caused by a nail, can be detected by holding the iron to the light. A sharp edge cannot be seen, while a dull one will show up in the light and appears as a narrow, shiny surface (Fig. 5).

If the tool is not held perfectly flat when the flat side is honed, a small bevel may be produced on the flat side and it will then be impossible to put the edge in good condition without regrinding it.

- In alternately honing the flat and bevelled sides, make sure that the wire edge is actually turned from the flat to the bevelled side before you reverse the tool for honing on the bevelled side (Figs. 2 & 4).

- To hone a slightly dull edge without grinding it, rub it on the sharpening stone in the same way, but only on the bevel side, not on the flat side.

Chisels are sharpened in the same way as cutting irons. Keep in mind that they are narrow and they should not be worked all the time in the centre of the stone, as this will quickly cause the centre of the stone to become hollow.

NOTES:

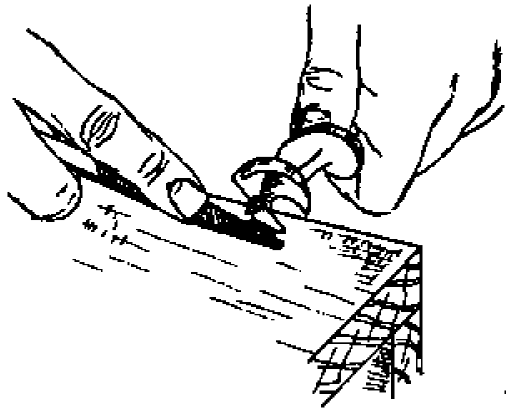

Fig. 1

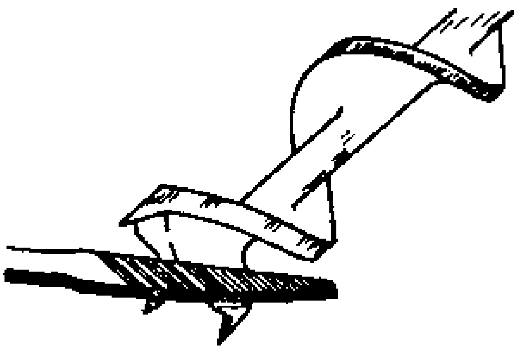

Fig. 2

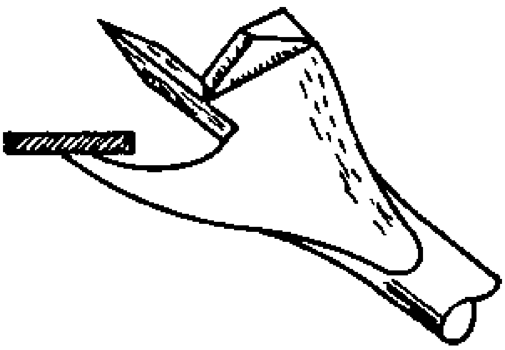

Fig. 3

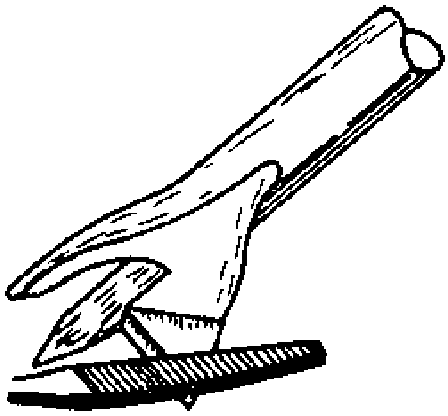

Fig. 4

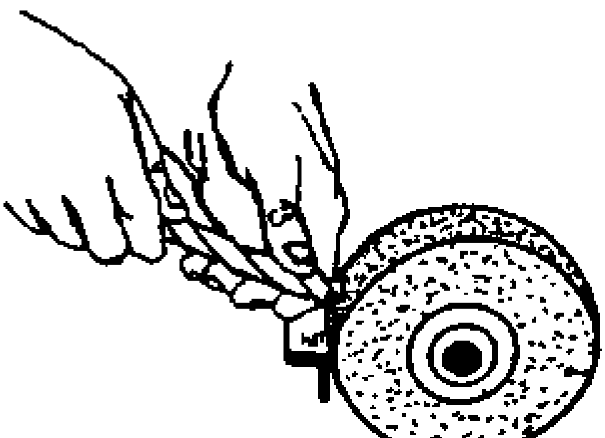

Fig. 5

SHARPENING BITS AND DRILLS

Manual wood bits are usually sharpened with a small file. It is best to avoid too much sharpening. Your tools will last longer if you use them carefully and keep them in a good case, so they won't need sharpening so often.

SHARPENING THE AUGER BIT

Auger bits are sharpened as shown on the left (Figs. 1 & 2).

- For the spurs, use a small file and sharpen from the inside face only (Fig. 1). The spurs are never sharpened on the outer faces, as this would change their diameter.

- For the cutters, file from the top side (Fig. 2). Retain the original bevel and remove about the same amount of material from each side.

- Hold the bit firmly to the edge of the bench during filing.

HOW TO SHARPEN THE CENTRE BIT

- To sharpen the spur, file from the inside (Fig. 3). To sharpen the router, file the bevel from the top side (Fig. 4).

- When sharpening the centre point, take care that the point remains exactly in the middle between the spur and the outside of the router.

HOW TO SHARPEN THE TWIST DRILL

- Grind the nose from the bottom (Fig. 5). Keep the original shape and angles and remove the same amount from each side.

- Never file the flutes as this would change the diameter of the drill. If the drill is really out of shape, contact someone with metalworking experience.

HOW TO SHARPEN AWLS

- To sharpen an awl you can use the sharpening stone, or if it is damaged rub it down with a file. Pointed awls can be sharpened on a grinding wheel.

NOTES:

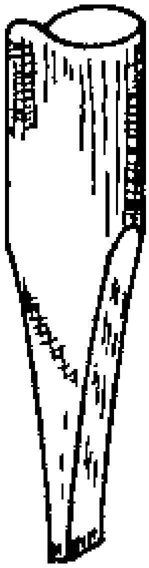

Fig. 1

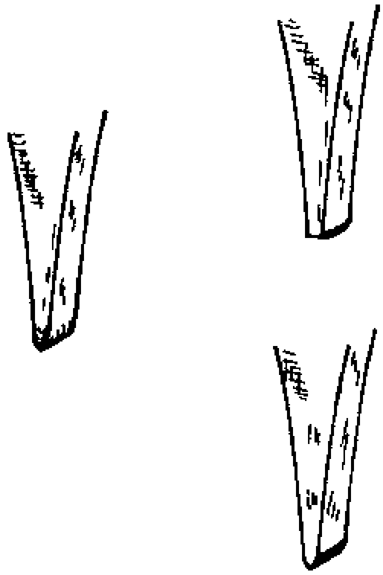

Fig. 2

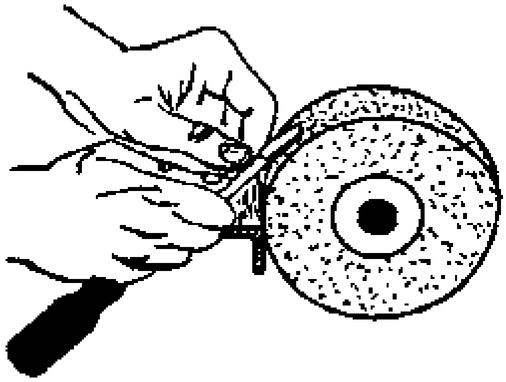

Fig. 3

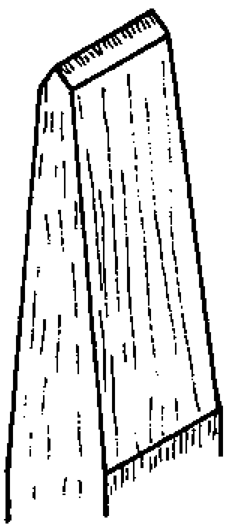

Fig. 4

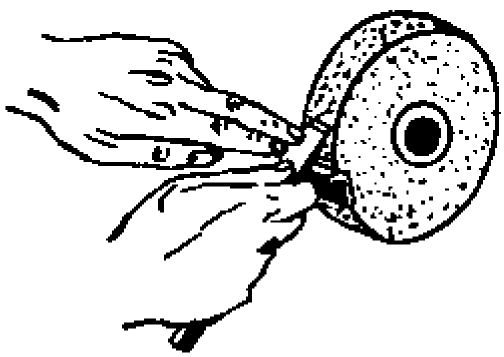

Fig. 5

SHAPING SCREWDRIVERS

A screwdriver should be ground or filed to a very blunt end (Fig. 3). The two flat surfaces should be straight and parallel near the tip. The end should be square to the flat sides, and should be "a little less thick than the width of a screw slot (Fig. 1).

If the end is rounded or sharpened to a knife edge, it will easily slip out of the screw slot and damage the slot (see Screwdrivers, page 77). In Fig. 2 there are some examples of badly shaped screwdriver tips.

SHAPING COLD CHISELS

Cold chisels should be ground or filed with the bevels on the cutting edge making an angle of about 70 degrees to each other (Figs. 4 & 5).

SHAPING BLOCK SCUTCHES

A block scutch should be shaped and filed to an angle of 70 degrees. Unlike the cold chisel, it is filed only from the inside (Fig. 6).

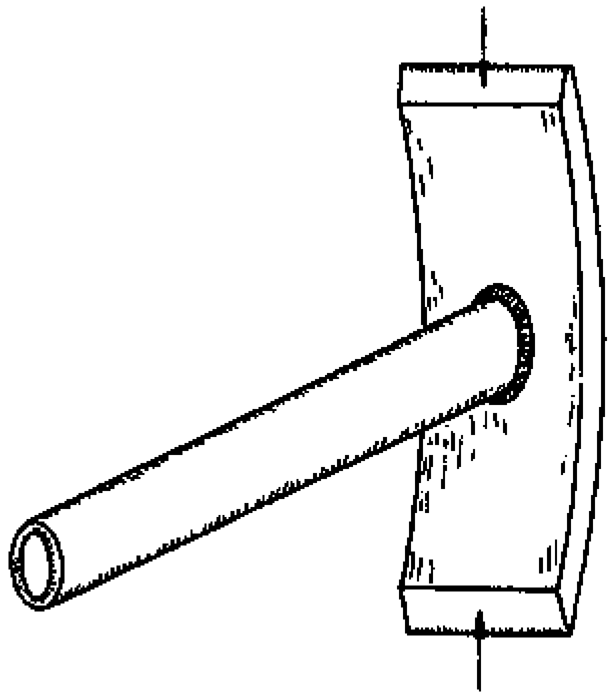

Fig. 6

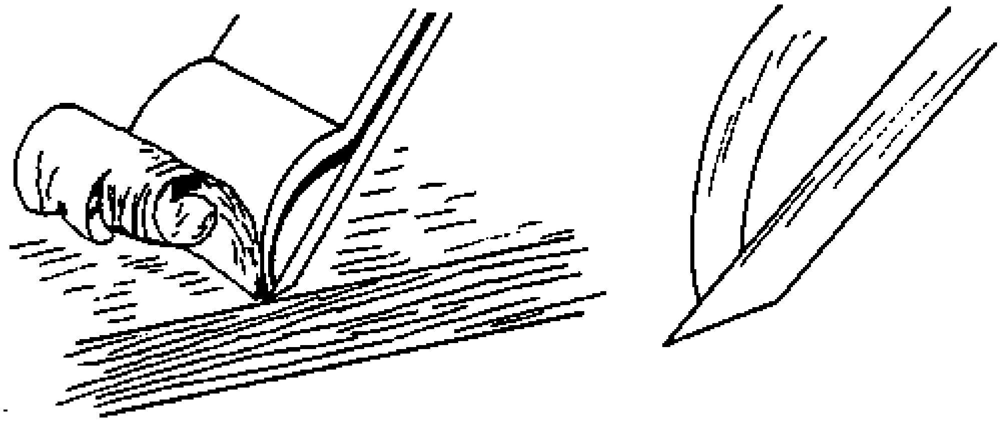

Fig. 1

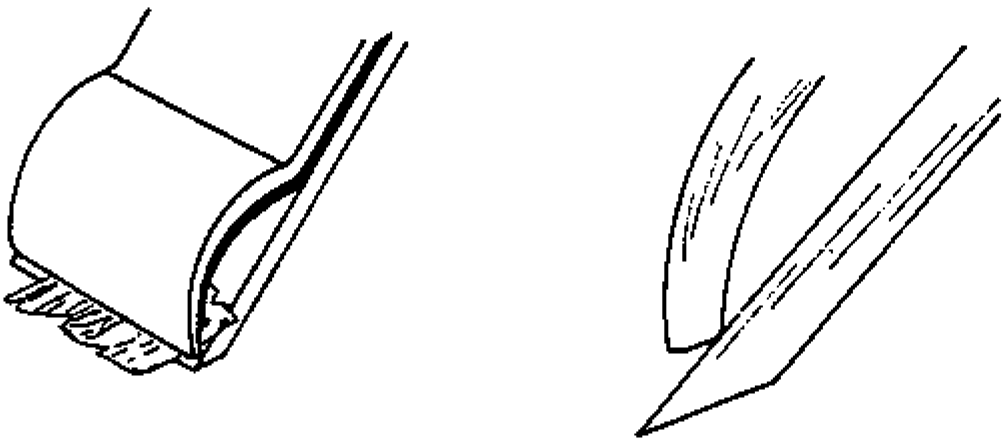

Fig. 2

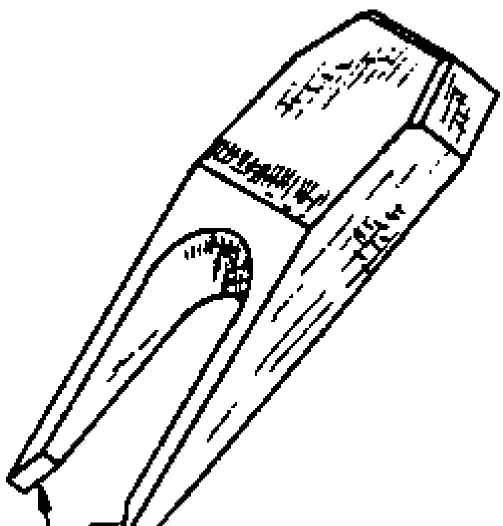

Fig. 3

MAINTAINING WOODEN PLANES

HOW TO REFACE THE SOLE

Whatever the quality of the wood stock, the soles of all wooden planes eventually wear and require refacing.

Refacing can be done on a large sheet of sandpaper, which is fastened to a true flat surface. The cutting iron of the worn plane is pulled inside the mouth, not removed, for it is best to have the stock held in the usual pressure by the wedge.

- Sand the surface down, test it with a straight edge and winding strips and oil the wood lightly.

ABOUT THE BEDDING OF THE CAP IRON

It is essential that the edge of the cap iron should bed perfectly on the face of the cutting iron when they are screwed together (Fig. 1). Even the slightest gap between the two will allow a shaving to enter and block the mouth of the plane (Fig. 2).

Usually this problem is caused by a fault in the cap iron. The cap iron should be rubbed on a sharpening stone or filed to restore the true edge. Keep the cap iron clean and shiny.

FITTING THE WEDGE

After much use, the wedge may no longer fit well into the stock. Heavy use of the hammer when knocking it in may cause the wedge to become misshapen because of the pressure.

When it becomes difficult to remove the wedge in the usual way (by hitting sharply on the striking button), the wedge should be removed, cleaned and filed or sandpapered to the correct fit again.

The ends of the wedge can become worn and cause the plane to stuff because they are too far inside the plane. If this happens, recut the ends of the wedge (Fig. 3).

NOTES:

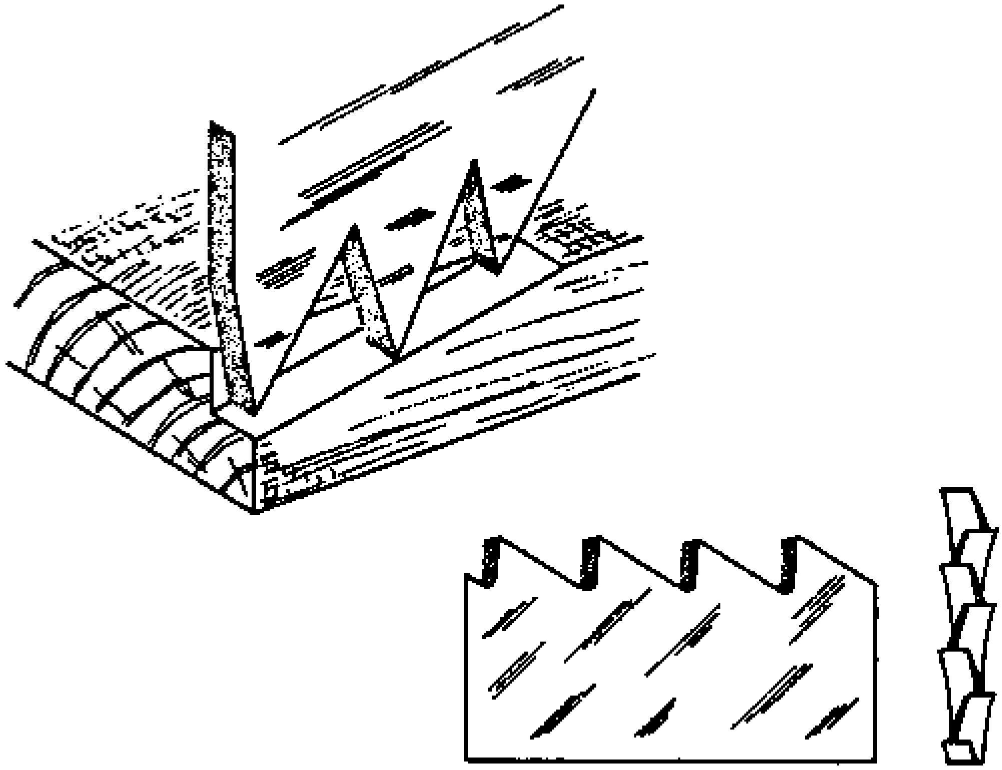

Fig. 1

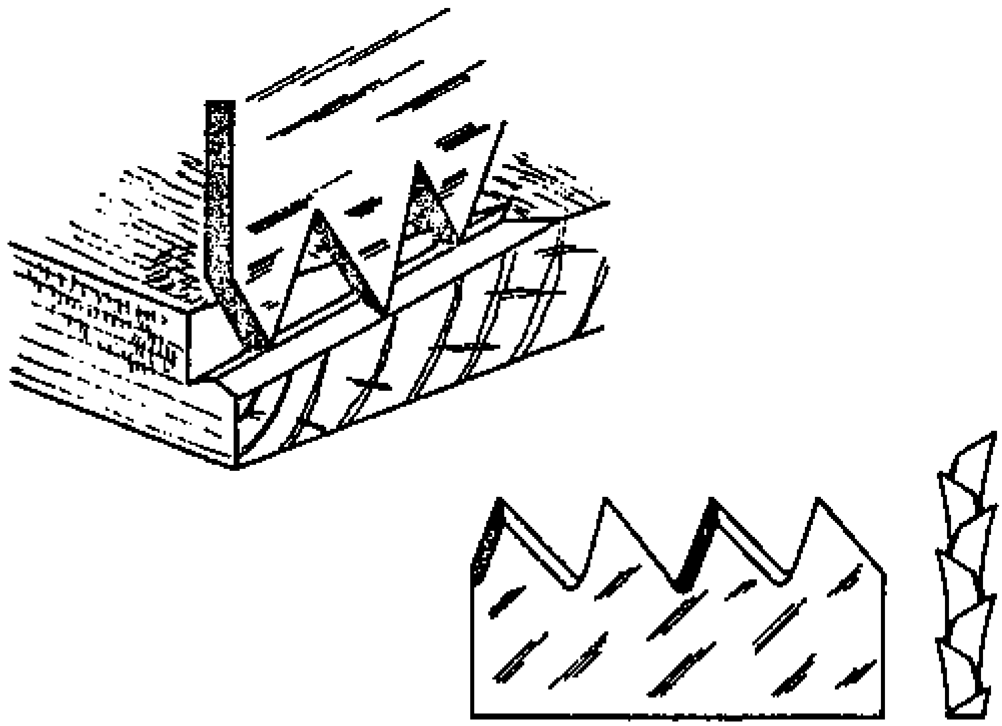

Fig. 2

MAINTENANCE OF SAWS

GENERAL MAINTENANCE

- Frequently give the saw a light coat of oil on the blade, to prevent rust. Keep the saw away from water.

- Keep the saw in the toolbox and be careful not to damage the blade by putting other tools on top of it.

- Keep the workbench uncluttered and be careful where you put the saw down.

- If the blade gets bent or buckled, straighten it at once.

THE ACTION OF THE TEETH

In order to properly maintain saws, it is necessary to understand how the teeth should look and how they work.

The ripsaw tooth resembles the cutting edge of the chisel. Its cutting edge strikes at practically a right angle to the wood fibres and the effect is as if a series of small chisels were set one behind another. Each tooth cuts out the full width of its edge and carries away the shaving (Fig. 1).

The teeth of the crosscut saw and the backsaw have a different shape, size and action from those of the ripsaw.

The form of the teeth is more like a series of knives that cut alternately on the two sides of the kerf (Fig. 2).

In sawing across the grain of the wood, the wood fibres must be cut on each side of the kerf so that a clean cut can be made. The teeth are therefore formed into sharp points on the outer side, so that they cut the fibres accurately.

The cut is started as the teeth make fine cuts, similar to the cuts of a knife, across the wood surface. Then as pressure is applied, the teeth go deeper and deeper, gradually bringing into action the full cutting edge of the teeth.

NOTES:

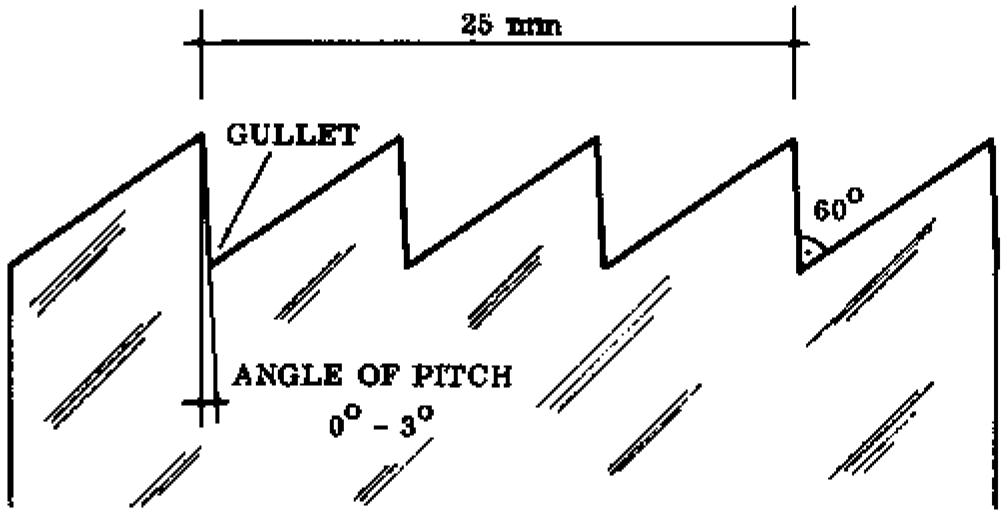

Fig. 1

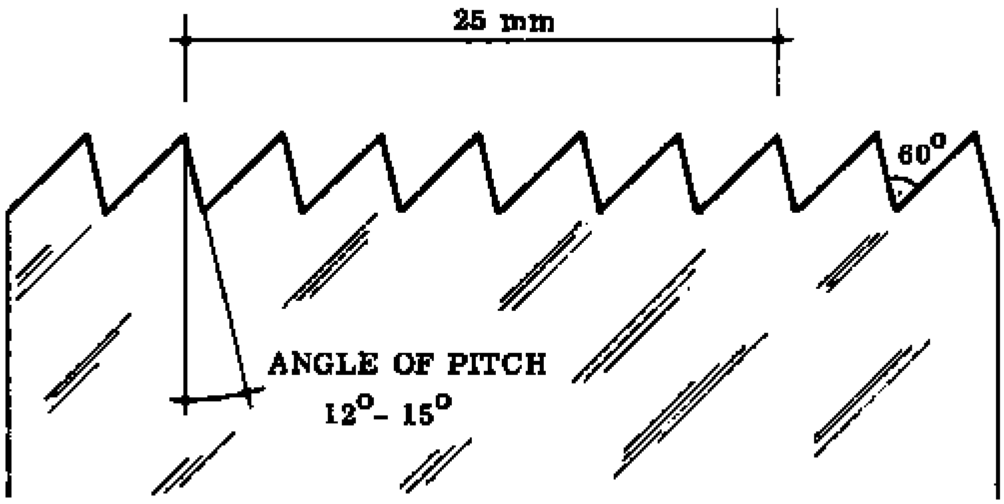

Fig. 2

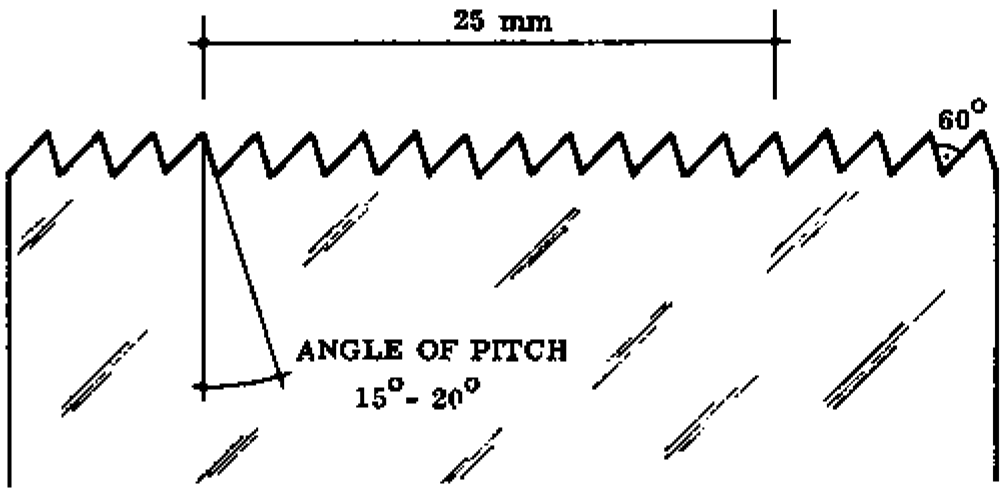

Fig. 3

ANGLE OF PITCH. SHAPE AND NUMBER OF SAW TEETH

The angle of pitch of the saw teeth is important in the maintenance of the saw. This angle is the measure of how far the face of the tooth is leaning from the vertical. The angle of pitch for the different saws is shown on the left page.

The smaller the angle of pitch, the faster the saw will cut and the more often it will need re sharpening. A large angle of pitch means a longer life for the blade, while a small angle means more frequent re sharpening and thus a shorter life.

THE RIPSAW

The blade of the ripsaw has 4 points (teeth) per 25 mm. The teeth of the ripsaw are rather big (Fig. 1).

The angle of pitch of these teeth is very small, from 0 to 3 degrees. This small angle means that the ripsaw will not cut properly across the grain, because the teeth will tend to tear the fibres. This saw is used only for cutting with the grain, where there is not any danger of tearing the fibres.

THE CROSSCUT SAW

The blade of this saw has 6 to 8 points per 25 mm, so' its teeth are smaller than those of the ripsaw. The angle of pitch of the teeth is greater in order to get cleaner cuts; this also makes the work slower. The angle is between 12 and 15 degrees for this kind of saw (Fig. 2).

Do not use this saw for cutting along the grain; it is not designed for that and it will not guide as well as the ripsaw.

THE BACKSAW

The blade of the backsaw has 10 to 15 points per 25 mm, so the teeth are still smaller than those of the crosscut saw. The angle of pitch is between 15 and 20 degrees (Fig. 3).

NOTES:

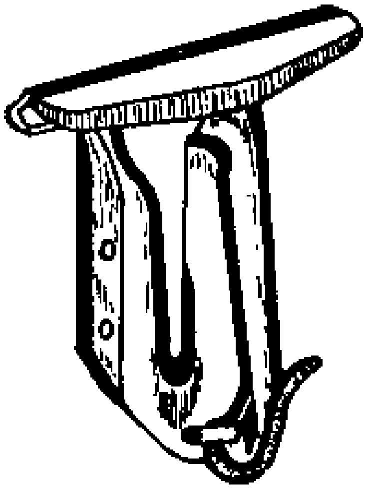

Fig. 1

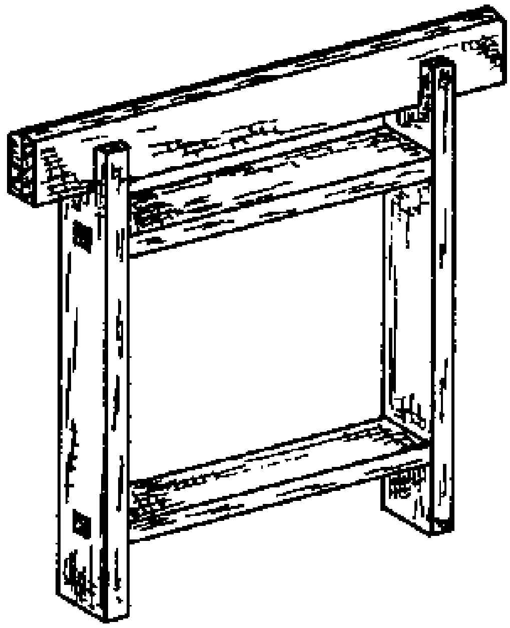

Fig. 2

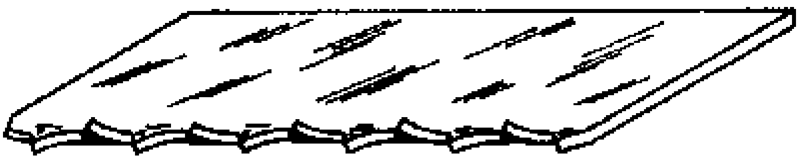

Fig. 3

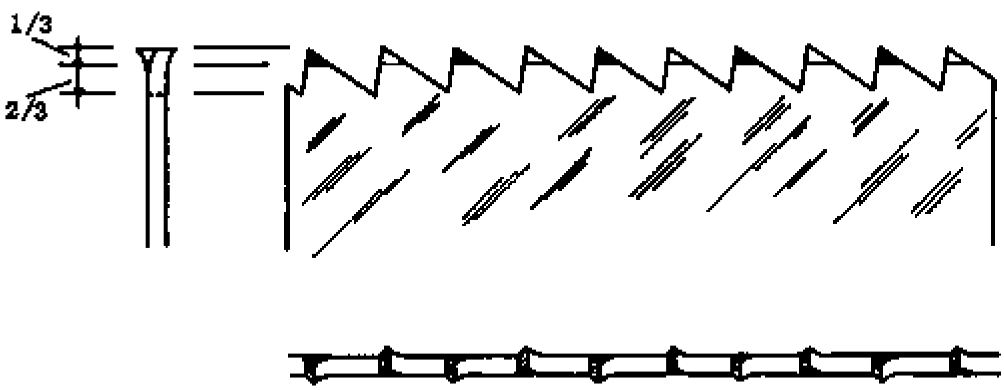

Fig. 4

SETTING HANDSAWS

There are two main operations involved in sharpening a handsaw:

a. Setting
b. Filing

In order to make sure that the saw blade moves freely in the saw cut without any side friction, the saw teeth must be set. This is done by slightly bending the teeth at their tips (Fig. 3) to give more clearance in the kerf (saw cut). A saw should never be given more set than is necessary for the blade to move easily in its kerf. Too much set will cause the blade to wander out of line, too little set can cause the saw blade to buckle.

Only the tips of the teeth are set, never more than about 1/3 rd of the length of the tooth (Fig. 4). If you set the saw deeper than that you will buckle or crack the blade.

A saw need not be set every time it is filed, particularly if only a light filing is required. A saw can sometimes be filed two or three times before it needs to be reset and filed again.

- SAW VICE: During the maintenance of a saw, it must be securely fixed in position. A saw vice is used to hold it; either the wooden type (Fig. 2) called a horse, or the metal type (Fig. 1) which grips the blade more strongly but does not grip the whole length of the blade.

Another type of wooden saw vice can be made by fixing the two wooden jaws to the handle of your toolbox.

NOTES:

Fig. 1

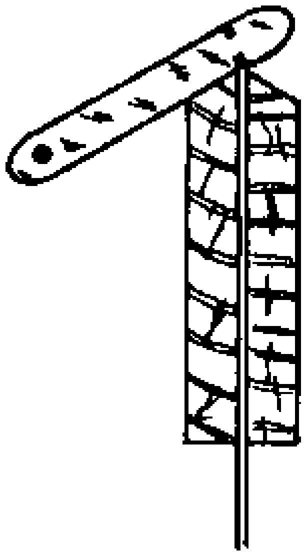

Fig. 2

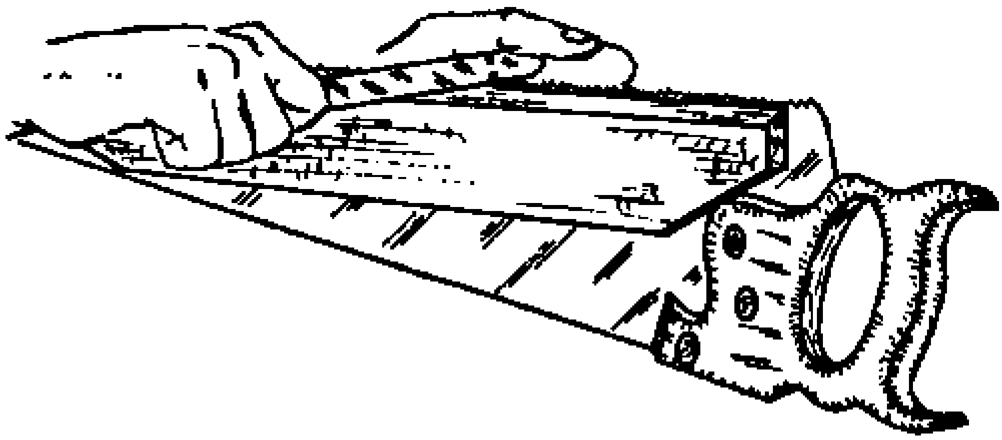

Fig. 3

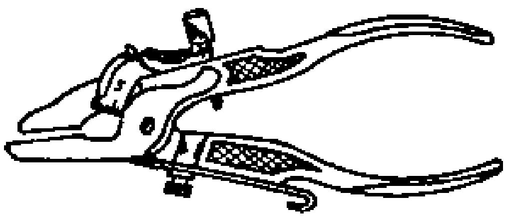

Fig. 4

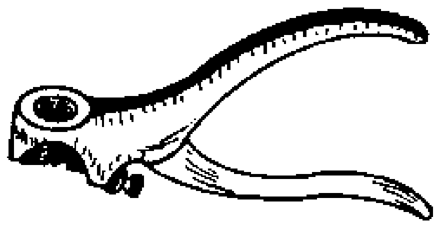

Fig. 5

HOW TO SET A SAW

To do the setting, we use a setting tool. This can be a strip of metal with some cuts in it, the cuts being the thickness of the different saw blades (Fig. 1). Setting has to be done by eye, and practice is needed to get the right bend. The top of the saw vice can be bevelled to act as a guide for the setting tool (Fig. 2).

- Hold the saw firmly in a good position. When setting the first tooth, take care that you bend it to the same side that it was bent before.

- Start at the heel of the blade and bend every second tooth. When you finish one side, turn the blade around and do the other teeth (Fig. 3).

- It is important that the set is exactly the same on each side, otherwise the saw will run (saw out of line).

Instead of the setting tool mentioned above, pincer type sawsets (Figs. 4 & 5) are often used. You simply place the set over the tooth and squeeze the handles. These sawsets are adjustable, so when you use an unfamiliar one, it is best to set a few teeth and examine them before you set the whole saw. If the teeth are set too much or not enough, you can then adjust the sawset accordingly.

SETTING THE RIPSAW

When the saw cuts with the grain, like the ripsaw, the fibres of the wood don't tend to move back into the cut, so the ripsaw doesn't need a big set to have enough clearance between the blade and the kerf.

SETTING CROSSCUT AND BACKSAWS

Crosscut fibres tend to move back into the kerf, so these saws need a bigger set to get enough clearance.

It is important to note that the wider setting of these saws makes them unsuitable for cutting with the grain, because the kerf will be too wide to guide the saw.

NOTES:

Fig. 1

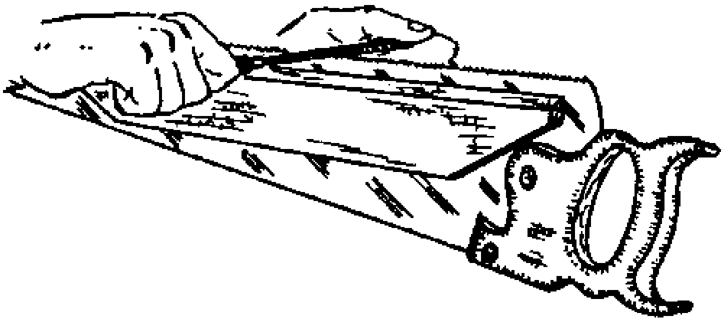

Fig. 2

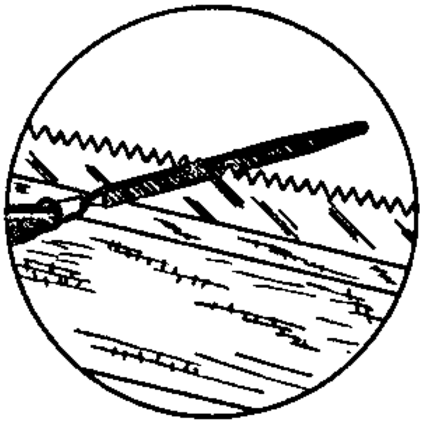

Fig. 3

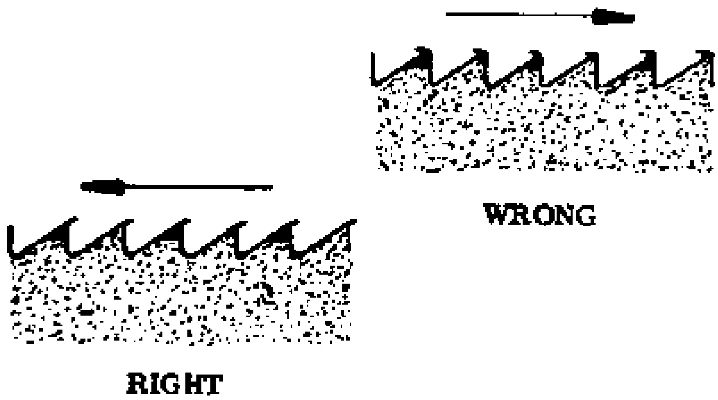

Fig. 4

FILING HANDSAWS

After the saw has been set it can be filed.

Secure the saw in a saw vice, with the teeth sticking out just a little way from the vice jaws. If the teeth stick out too far, the filing will cause a screeching sound.

The top of the saw vice should be at about the level of your armpits, or slightly below (Fig. 1). While filing, you must be able to constantly check the shape of the teeth and this rather high position enables you to see them properly.

In order to avoid eyestrain and ensure a good job of filing, it is essential to have good light. Work in front of an open window if possible, so that the light shines on the saw teeth.

USING THE SAWFILE

Small metalworking files with a triangular cross section are used for filing saws. The following points are important to remember in using the saw file:

- Hold the file handle in your right hand (Fig. 2).
- Hold the tip of the file gently between your thumb and forefinger of the left hand (Fig. 2).
- Exert pressure on the forward stroke only.
- Make long slow cutting strokes, not short fast ones.
- Keep the file level (Fig. 3).
- Use enough pressure to make the file cut, but no more.

During filing, a small burr is formed at the tip of the teeth. This burr can improve the cutting action of the saw when it is filed in the right direction. Therefore the saw must always be filed from toe to heel (Fig. 4).

NOTES:

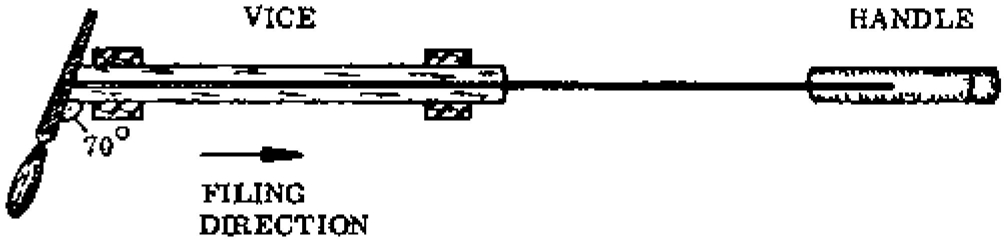

Fig. 1

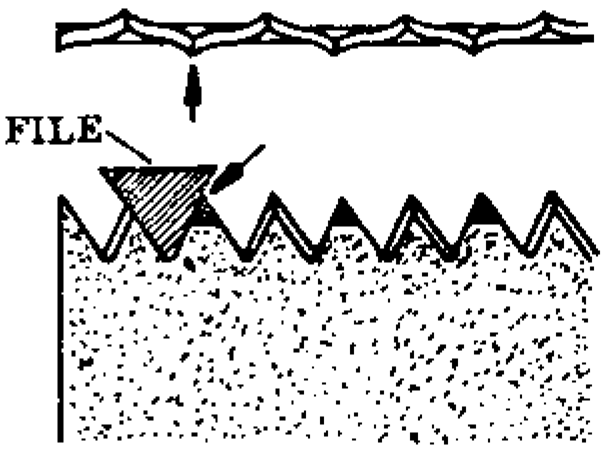

Fig. 2

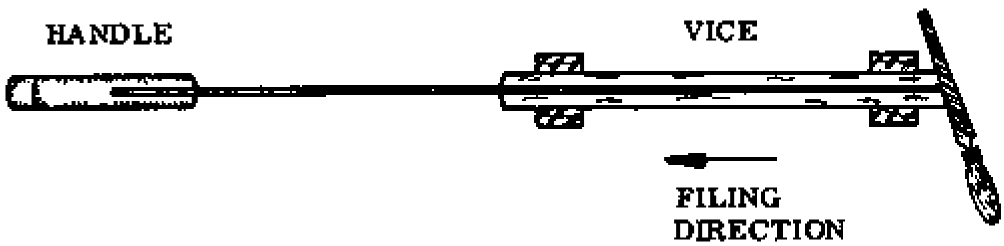

Fig. 3

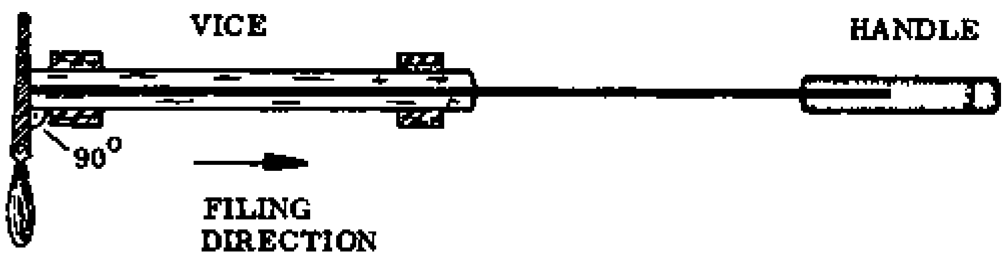

Fig. 4

HOW TO FILE THE CROSSCUT SAW

Study Fig. 1 very carefully to understand the proper starting position for filing this saw. Work according to the following sequence:

1. Place the toe of the saw in the saw vice with the handle to your right.

2. Find the first tooth in the toe that is bent towards you. Place the file in the first gullet (V-notch between the teeth) to the left of that tooth (Fig. 2, arrow).

3. Hold the file across the saw blade at an angle of about 70 degrees, with the point towards the saw handle.

4. If the teeth are of the proper shape (see section on Angles of Pitch) press the file gently into the gullet and let it find its own placement against the two teeth (Fig. 2). Remember to keep the file level.

5. Push the file forward, cutting the front surface of one tooth and the back surface of another.

6. Release the pressure on the file during the backstroke.

7. File every other gullet until you are about halfway through the saw, then make a pencil mark at this point.

8. Shift the blade in the vice until the head end is held more securely and continue filing every other gullet until you reach the handle.

9. When every other gullet has been filed from one side, turn the saw around in the saw vice so the handle is to the left (Fig. 3).

10. Find the first tooth in the toe of the saw that is bent towards you and put your file into the gullet to the right of that tooth.

11. Hold the file at an angle of about 70 degrees across the blade, with the point towards the saw handle.

12. File every other gullet as before, until you reach the saw handle.

- REMEMBER:

    - Inspect your work frequently to make sure that you are getting the teeth properly shaped. Remember that the angle of pitch must be correct.

    - Throughout the filing, give each tooth the same number of strokes with the file. This helps keep the teeth all the same size and shape.

    - If you get one tooth out of shape, don't be too concerned; it can be left as it is.

    - Turn the file occasionally, so that it is used evenly.

    - If you think you have lost your place or skipped a gullet, look for the last shiny tooth in the light.

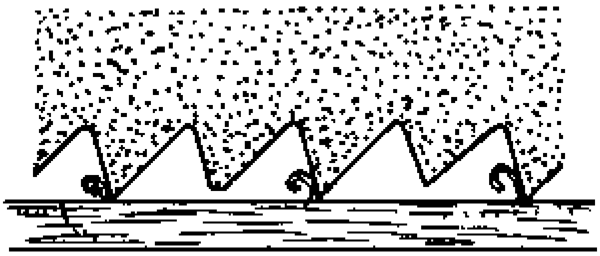

Fig. 1

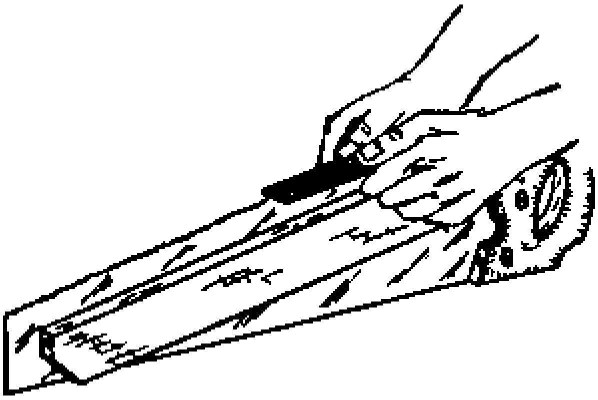

Fig. 2

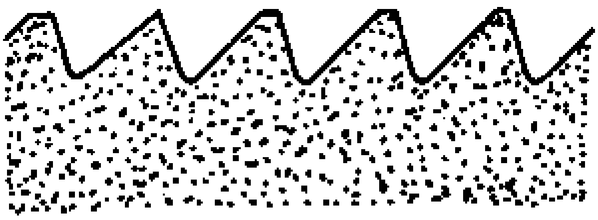

Fig. 3

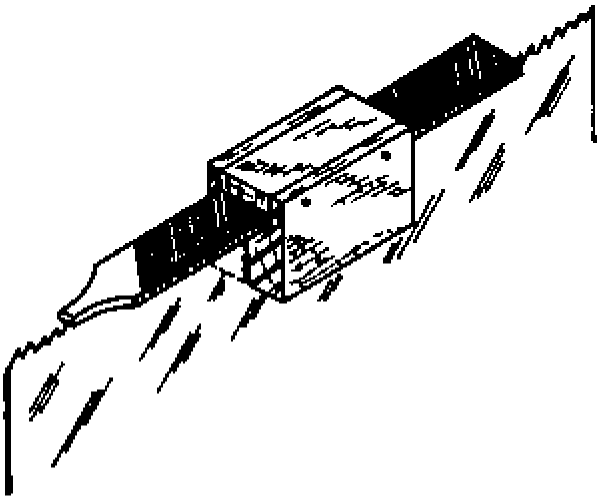

Fig. 4

HOW TO FILE THE BACKSAW

This saw is filed in the same way as the crosscut saw, except that the angle of pitch is different.

Be careful with the pressure you apply with the file, because the teeth are very small and are easily filed out of shape.

HOW TO FILE THE RIPSAW

The same general procedure is used for filing ripsaws as for crosscut saws. There are two important differences:

1. The angle of pitch is different.

2. The file is held at 90 degrees, not 70 degrees, to the blade (Fig. 4, previous page).

(Some people file the ripsaw from one direction only, filing all the teeth at once instead of filing every other tooth and reversing the saw).

TOPPING A HANDSAW

If you always file the saw correctly, without twisting the file or filing some teeth more than others, the teeth will always have the correct form and equal height.

When you make small mistakes in filing, or use the saw carelessly, the teeth will become out of line, different in height and irregular in shape. The result is that only some of the saw teeth can cut; the others don't touch the wood (Fig. 1). Topping is done to correct this problem.

WELL KEPT AND MAINTAINED SAWS NEVER NEED TOPPING!

HOW TO TOP A SAW

Topping must always be done before you set or file the saw.

- To top a saw, you run a flat metalworking file over the ends of the teeth, moving along the length of the saw. Be very careful to keep the file square to the saw blade and flat.

- One way to do this is to grasp the file in both hands by the edges, thumbs on top and the fingers under, touching the saw blade and guiding the file (Fig. 2, previous page).

- A wooden block may also be used to hold the file in the proper position (Fig. 4, previous page).

- File until there is a small shiny point on each tooth. When you have made two or three light strokes and there are still some teeth that have not been touched (Fig. 3, previous page), don't keep on filing. Too much topping will make it difficult to reshape the teeth.

- Next, file the teeth to the correct form again. This is called reshaping the teeth. When all the teeth have the same height and shape they are ready to be set and filed again after setting, to sharpen them.

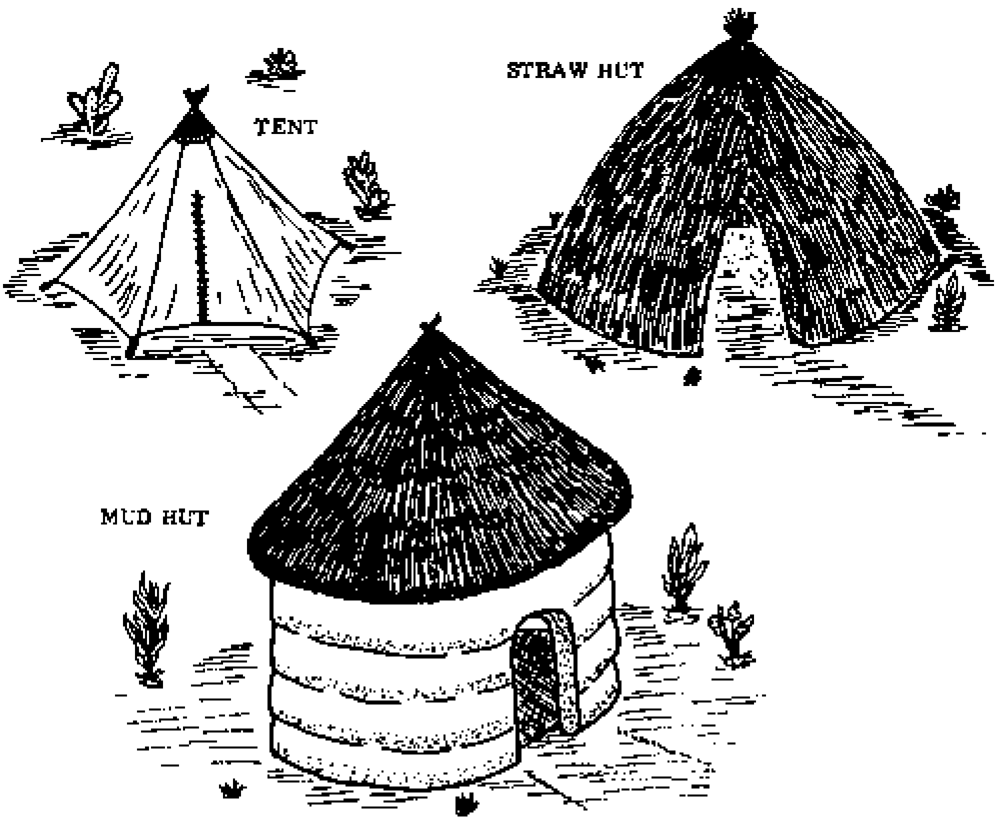
NOTES:

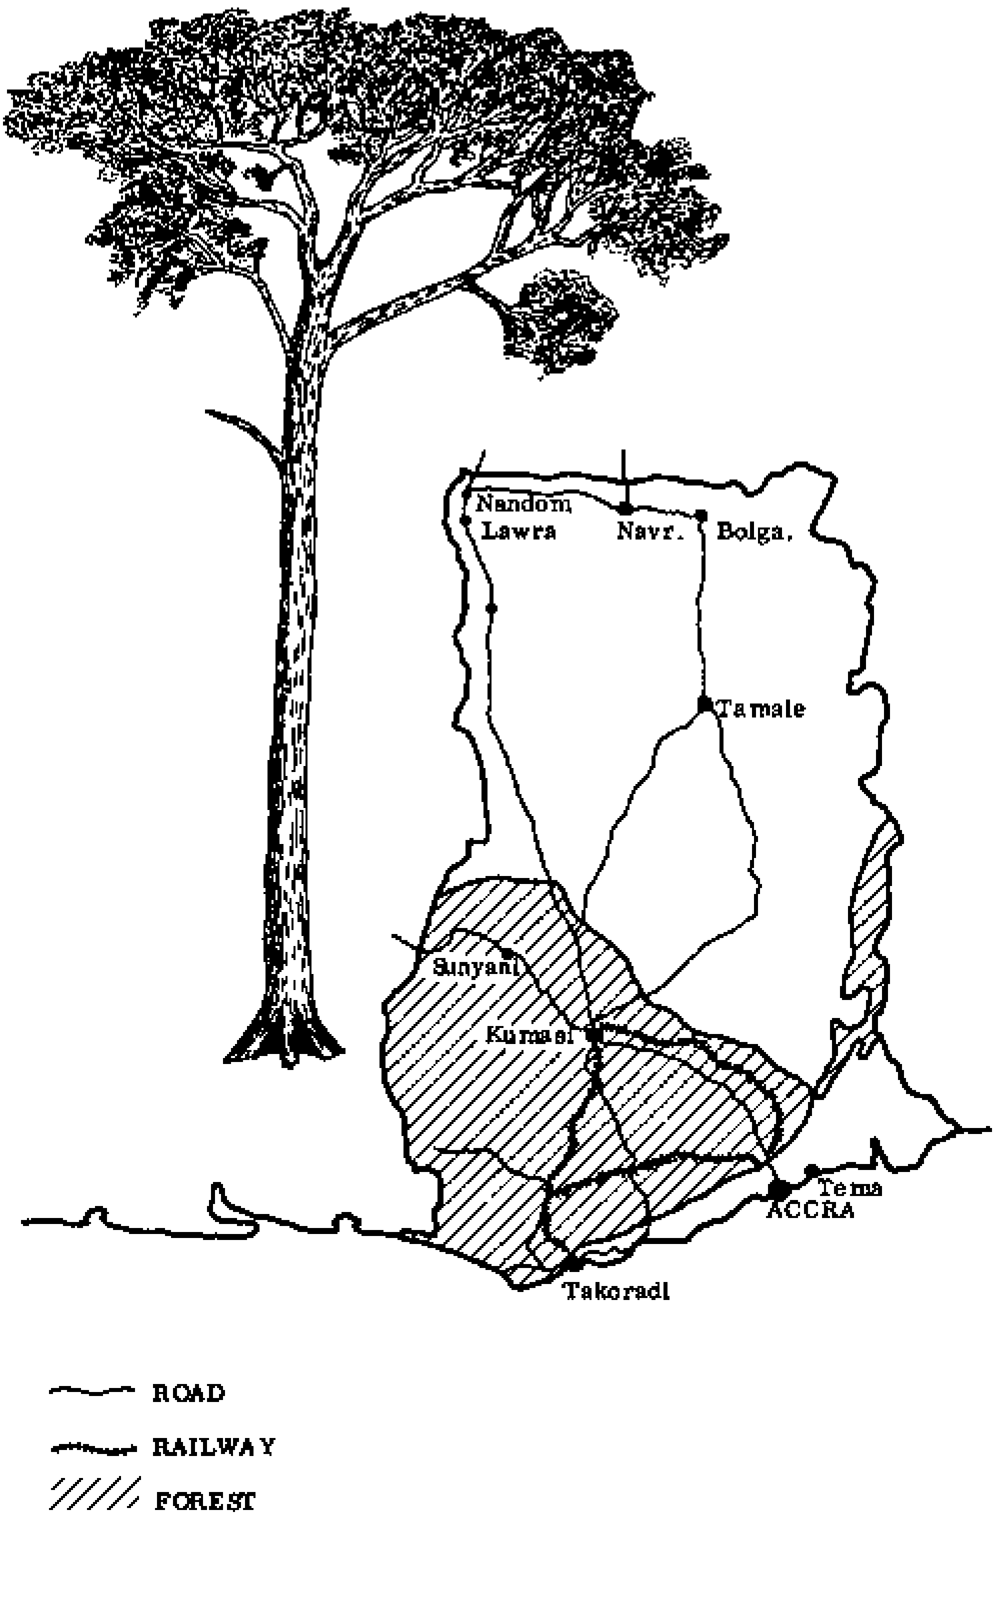
PART 3: RURAL BUILDING MATERIALS

Man learned early to protect himself from the weather as well as from his enemies by making shelters of various kinds.

The type of structure he made depended on the locally available building materials, and on whether the shelter was meant to be permanent or not. Compare the sketches below, for example.

The extreme northwest of Ghana provides the inhabitants with such universally used building materials as sand, mud, stone, laterite, timber, grass and straw. However, the traditional way of building with these materials does not always produce a very permanent structure; with the result that almost every dry season the houses must be thoroughly maintained, repaired and even rebuilt. In order to make more durable structures, the Rural Builder should include in his technical knowledge the uses of local and modern materials, and of binding materials such as lime or cement. Building materials are described in the following chapters.





Nandom
Lawra

FOREST

ABOUT WOOD IN GENERAL

In Rural Building we work a great deal with wood. Wood has always served man for many different purposes: for tools (handles of hoes, knives and axes), for weapons (bows and arrows), for housing (ladders, doors and windows), furniture and firewood.

For traditional building purposes, nearby trees and bushes are cut and the branches as well as the trunks are used.

In Rural Building, we work with sawn timber. Sawn timber is cut from the trunks of very tall trees. Such trees are not common in the northern parts of Ghana. They are found in the rainforest areas of the south, where they are felled (cut down), sawn into boards and transported to the north and elsewhere.

The most common woods we use in northern Ghana are Wawa and Odum. Others, like Emire or Mahogany, are sometimes used.

There are 85. 000 square kilometres of forest in Ghana, from which comes more than 200 different species of wood. Most of the wood that is cut is not used in Ghana but is sold to other countries to bring in money. It is one of the largest sources of income for Ghana. The principal kinds of wood that Ghana exports are Afromosia, Wawa, Utile, Sapele, Odum and Mahogany.

To make sure that these woods are available in the future, the cutting is controlled by Forestry Acts and efforts are made to reforest the cut areas. These new trees will not be ready to cut for a long time.

The map on the left page shows the areas where the trees are cut, the locations of the roads and railways that bring the wood into the harbours at Takoradi and Tema and the roads by which wood is exported to neighbouring countries. It is transported either as whole logs or as sawn timber and also as timber products made from waste wood or wood chips, like chip board or plywood. The mills that convert logs to sawn timber and timber products are located all over the forest.

THE STRUCTURE AND GROWTH OF THE TREE

A tree has three main sections: the Toots, the trunk and the crown. The crown is made up of the branches, twigs and leaves (Fig. 1, next page).

In order to grow, the tree must have water and minerals from the soil. The water and minerals are taken out of the soil by the roots and brought to the leaves through the outer layers of the sapwood (Fig. 2).

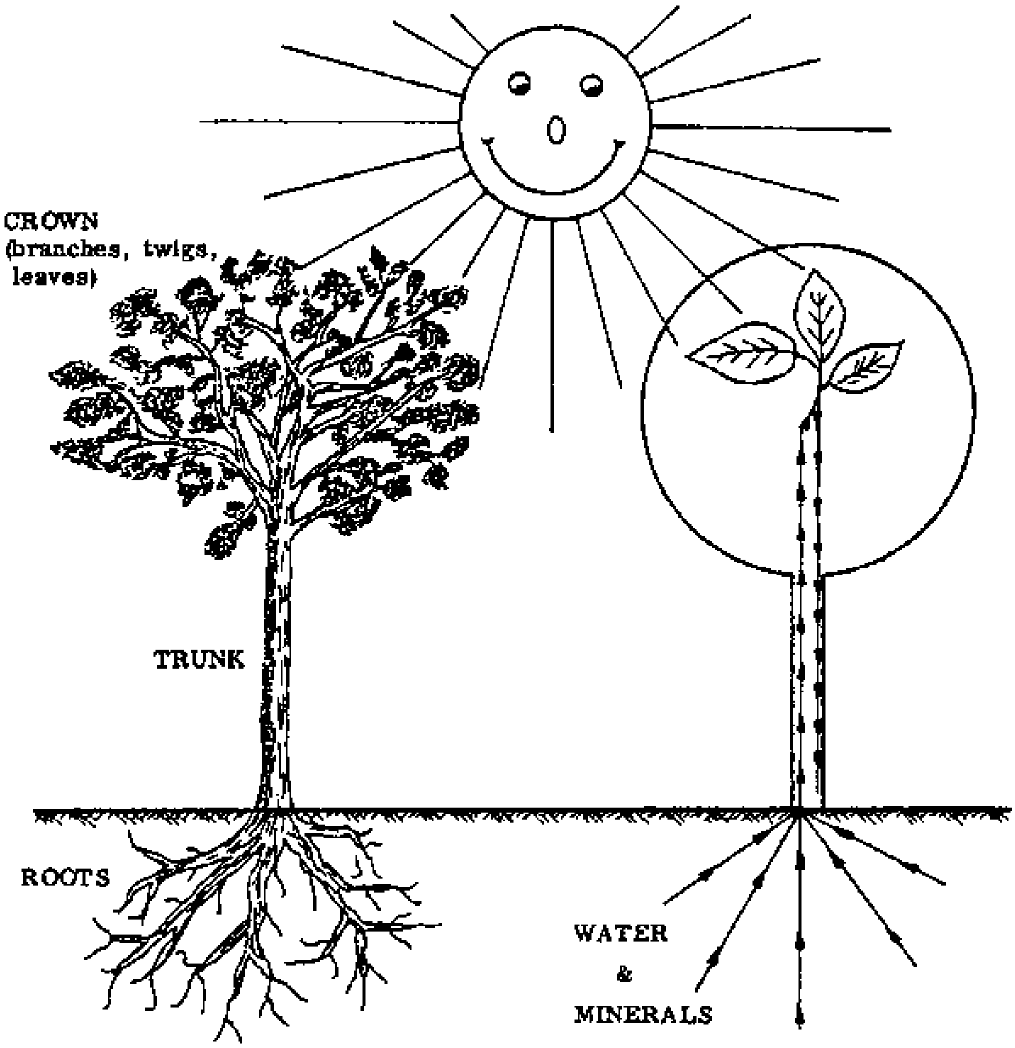

Fig. 1

Fig. 2

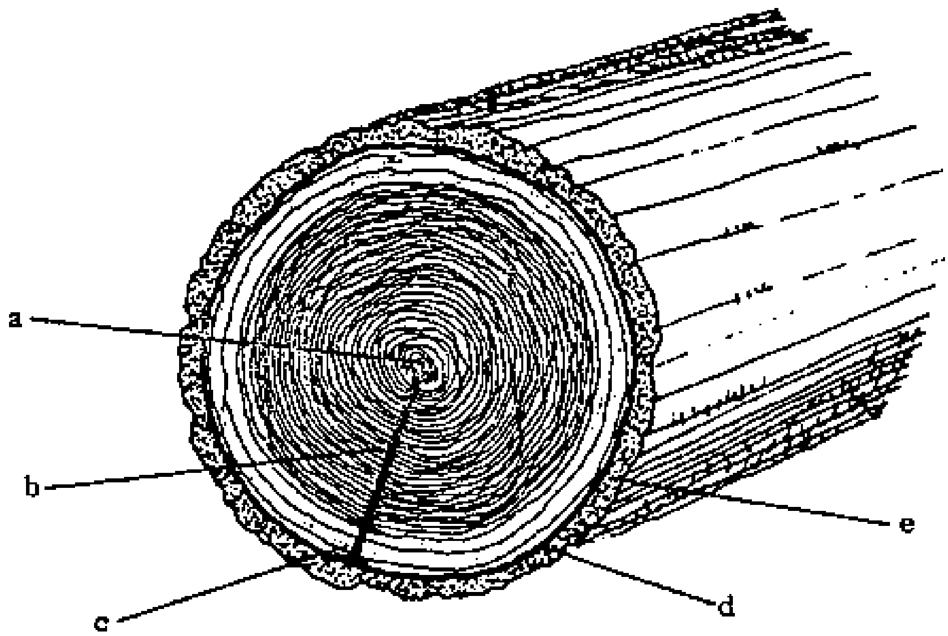

Fig. 3

In the leaves, the sunlight acts on the water, minerals and air to make the materials that the tree uses to build new roots, wood and leaves.

The material made by the leaves is brought down to the roots and growing parts of the tree by the inner layers of the bark. If the bark is damaged by cutting or bush fire, the sap can't move up and down and the tree might die.

HARD AND SOFT WOOD

We talk about two main categories of wood: hardwoods and softwoods. These categories are only trade terms, they do not indicate that the wood itself is either hard or soft. The difference comes from the way of growth of the tree. Almost all the trees that grow in Ghana are hardwoods, but the actual wood itself may be hard or soft in character. For example Wawa, which is classed as a hardwood, is actually very soft in character and easily worked.

THE STRUCTURE OF WOOD

The tree trunk is made up of five layers (Fig. 3).

The pith (a) is the centre or heart of the tree.

The heartwood (b) is the fully developed mature wood which surrounds the pith. It is usually dark in colour and hard. The heartwood does not play an active part in the growth of the tree; it is only for strength, to support the tree.

The sapwood (c) is the layer around the heartwood which is lighter in colour and softer. Sapwood is immature wood, it will harden and darken and become heartwood as the tree grows. A new ring of sapwood is added every year on the outside of the older wood.

Sapwood should not be used for construction purposes, because it is soft and easily attacked by termites. It is always removed when wood is cut for construction purposes.

The cambium (d) is a soft, greenish layer between the sapwood and the bark. It is the "factory" of the tree, making new wood at the inside and new bark at the outer side. The cambium is fed by materials brought from the leaves by the inner layers of the bark.

The bark (e) protects the cambium from cold, fires, insects and animals, and it also transports food material from the leaves to the cambium and to the roots.

The annual rings are the rings you see (Fig. 3) in the heartwood and sapwood.

These are formed by the growth of the tree, by the layer of new wood that is added each year.

The tree grows all year long but in the rainy season, when it gets more water, it grows faster than in the dry season. The new wood formed in the rainy season is lighter in colour than the wood formed in the dry season, so they appear as light and dark rings in the wood. One light ring and one dark ring are formed each year; together they make an annual ring (annual means every year).

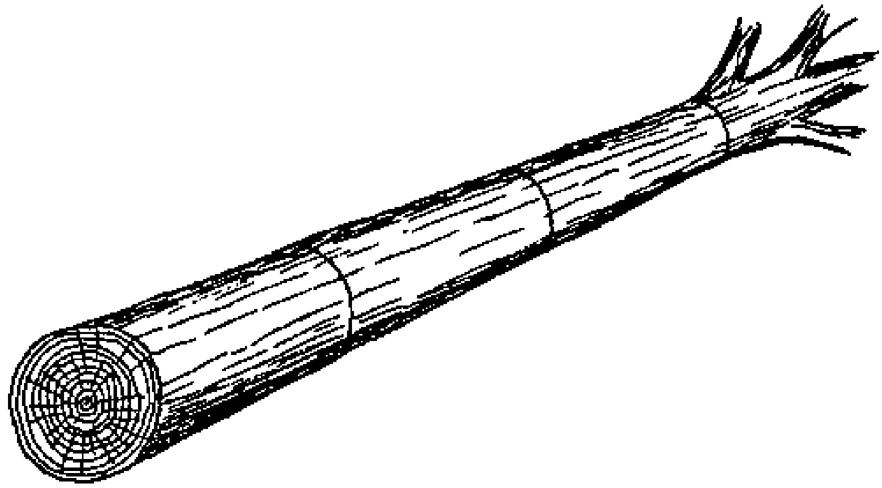

Fig. 1

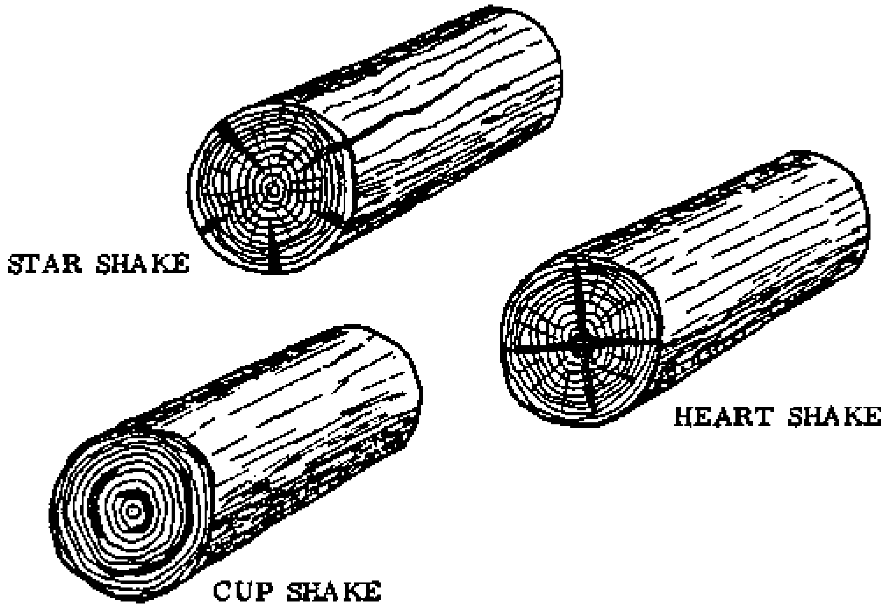

Fig. 2

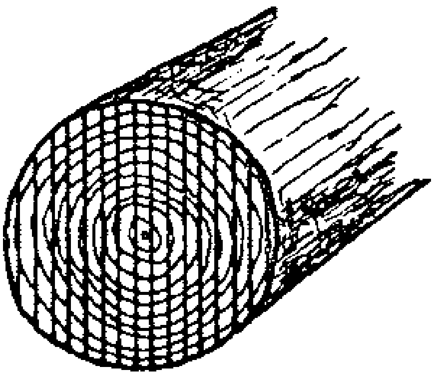

Fig. 3

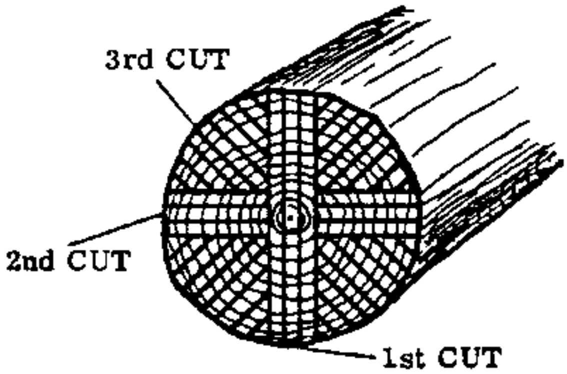

Fig. 4

Don't forget: HARD WOOD is not the same as HARDWOOD is not the same as HEARTWOOD; they all mean different things.

THE PATH FROM STANDING TREE TO SAWN TIMBER

After the tree is felled, the crown is removed and the bark is taken off so no insects can hide in it. The trunk is cut into logs up to 12 metres long (Fig. 1) for transport and handling purposes. These logs are brought to the sawmill where they are converted to sawn timber. Converting the logs to timber means sawing them into boards, planks etc., which can be used for construction purposes.

If the logs cannot be converted immediately, they are kept in water to prevent the formation of shakes. These are long cracks in the unsawn log (Fig. 2). The most common ones are: cup shakes, which occur when the annual rings fail to grow together and star and heart shakes, which can occur in the growing tree or in the cut log as it dries.

There are different ways of converting logs. The method which is chosen depends on the thickness and species of the tree, and the quality of the wood that is needed.

Plain sawing is the easiest, cheapest and most common way of converting tropical woods. It is also called the "through and through" method.

The log saw starts cutting from one side and continues, cutting off one board after another until the whole log is converted to timber (Fig. 3).

The second method, quarter sawing, requires better equipment and more work than plain sawing. With this method, almost ail of the annual rings will be square to the surface of the board, which we will see later is an advantage over plain sawn boards (Fig. 4).

There are still other methods of conversion, but they are not important for us in this course.

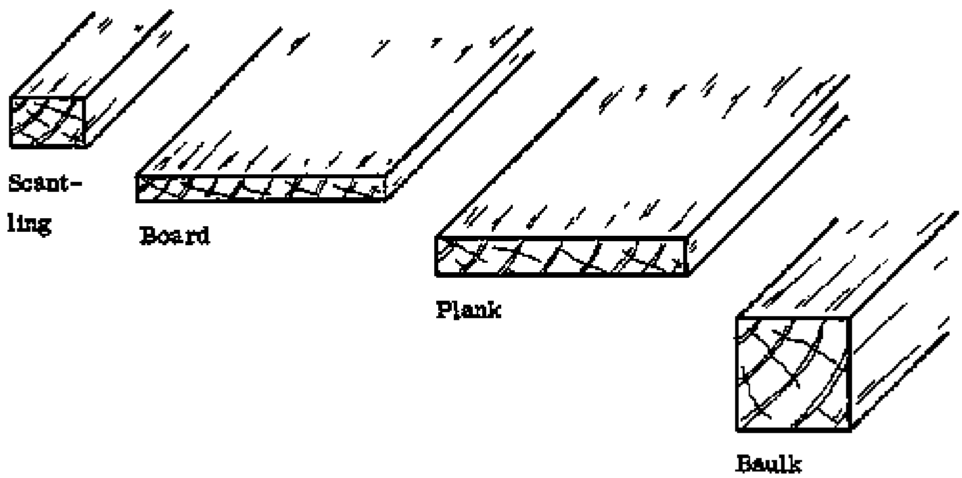
CONVERSION TERMS FOR SOLID TIMBER

- Scantlings are pieces about 75 mm wide by 50 mm thick.

- Boards are pieces more than 150 mm wide and less than 50 mm thick.

- Planks are pieces above 200 mm wide and between 38 and 100 mm thick.

- Baulks are more square shaped pieces, about 100 mm wide and 50 mm or more thick.



HOW TO ORDER TIMBER

Before you place an order for wood, make sure that you list the correct sizes, quantities and kinds of wood.

Boards are sold in different measurements. Very often the sizes are still given in the imperial system, but the metric system is becoming more common everywhere.

The surface of sawn timber is still rough, so you have to allow for planing the boards when you order timber (refer to Rural Building, Basic Knowledge, p. 90).

Example:

		Size		
No.	Kind of wood	Thickness	Width	Length
50	Odum	2,5 cm	30 cm	2,5 m up
40	Wawa	3,8 cm	30 cm	3,0 m up

If a minimum length of sawn timber is required, the word "up" is added. So "3,0 m up" would mean 3,0 m and longer.

THE PROPERTIES OF WOOD

To be able to use timber properly and store it in the correct way we need to have some knowledge about:

- the moisture content of wood, and
- wood shrinkage.

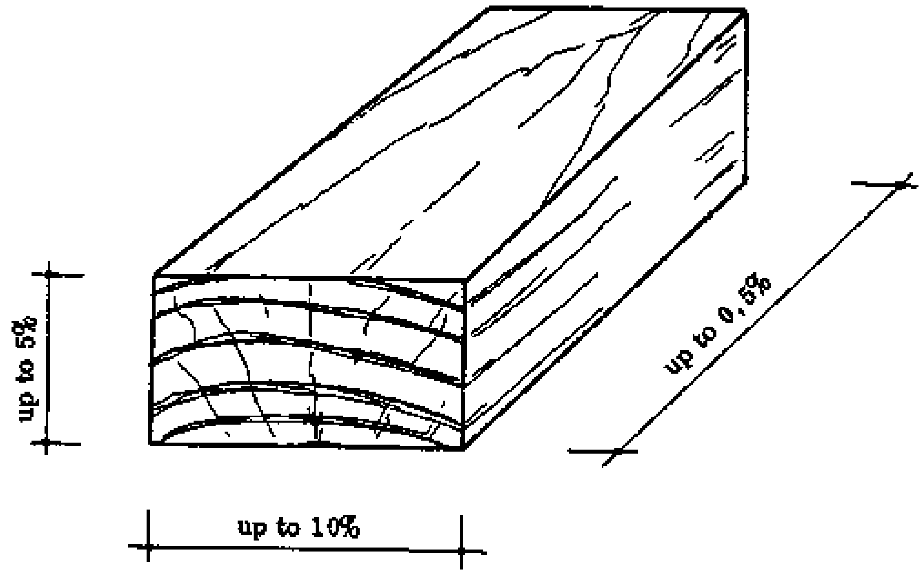
THE MOISTURE CONTENT OF WOOD

When a tree is cut down, the trunk still contains a large amount of water which has been stopped on its path through the trunk and remains trapped there. The weight of the water at this time is between l/3rd to 1/2 the weight of the tree.

Thus the moisture content (amount of water remaining in the wood) is very high when the tree is freshly cut. Some of the water evaporates (dries off) as the logs are brought to the mill and more will evaporate after the logs are sawn into timber. Each time the moisture content changes, the size of the timber also changes.

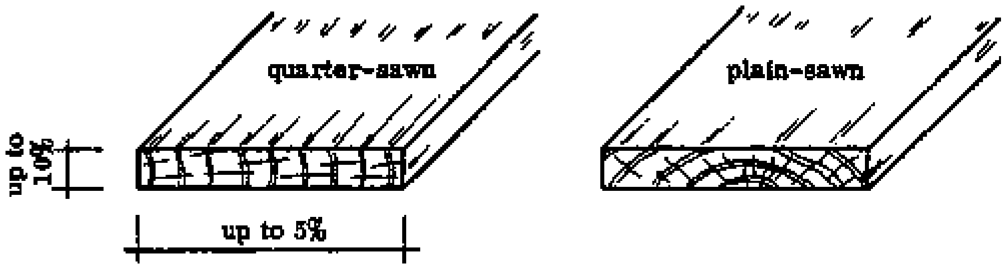
SHRINKAGE

As the wood dries, it becomes smaller in size. This is what we mean by shrinkage. Because of the wood structure, it does not shrink equally in each dimension; shrinkage will be up to 10% along the annual rings, about 5% at right angles to the rings and no more than 0, 5% in the length of the board.



Here we can see the advantage of quarter-sawn timber, in which the annual rings are mostly at right angles to the width of the board. The biggest size change (10%) will be in the thickness of the board, where it usually doesn't matter so much. The shrinkage in the width will however still be up to 5%.

In plain-sawn boards, the rings lie mostly across the width of the board and the board will shrink more and also tend to get out of shape as it dries, because the rings change directions within the board.



Shrinkage in the length of the timber can almost be ignored, and will only matter when you join boards together end to end over longer distances.

You should know that different woods shrink differently, for example Odum will shrink more than Wawa.

The weather has a great effect on the size of wood. In northern Ghana especially, the very great changes in the humidity (the moisture in the air) between the dry and rainy seasons result in a lot of problems for the builder.

The very dry air of the dry season and especially that of the harmattan causes wood to dry out too much and shrink. You will find that the boards easily crack or split when you work on them.

During the rainy season the humidity is very high and this results in a higher wood moisture content. This means that the wood actually expands quite a bit. The wood may feel wet to the touch. You might plane a board straight and true one day, and find the next day that it is bent again.

Keep the effects of the weather in mind when you construct anything out of wood. For instance, you want to build a solid door out of Odum. If you build it in the dry season it should not fit tightly into the door frame, so that it can still open when it swells in the wet season. If you build it in the wet season it should fit well, so that the gap between it and the frame is not too wide when it shrinks in the dry season.

NATURAL SEASONING

The builder should know that he must never use freshly sawn timber. The timber must first be seasoned, which means that it is dried to a certain moisture content which is most suitable for building work, so that it changes its size as little as possible after it is used in a piece of work.

The kind of seasoning we do in Rural Building is "natural seasoning", and it is done by storing the wood for some months.

After seasoning, the moisture content of the wood should be low enough to use it for building work. However, even well seasoned timber will still be affected due to the changes in humidity from the dry to rainy seasons.

Well seasoned timber will still shrink or expand up to 6% in the direction of the annual rings. For example, a board which is sawn in such a way that the annual rings are along the width (see plain sawing) might have a width of 30 cm during the dry season, while in the rainy season it can expand up to 31 1/2 cm wide. This means that whenever possible you should choose your boards in such a way that the changes in size don't cause problems in the finished piece.

NOTES:

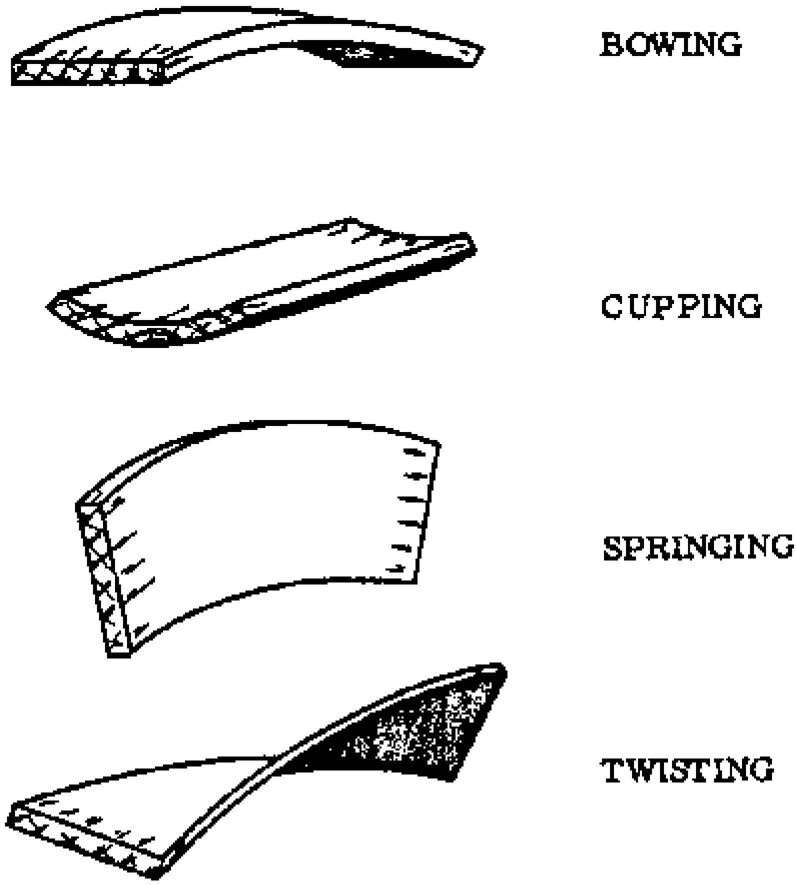
WARPING

Seasoning can cause boards to bend. This happens because the moisture content differs from one part of the board to another, especially if one part gets more sun or rain, when it is stored improperly. The boards should be stored in such a way that air can reach every side of them and all sides are equally dry.

Wood that is not straight grained also tends to warp as it dries.

There are four different kinds of warping: bowing, cupping, springing and twisting. These are illustrated below.

Warping of boards can be partly avoided by proper storage of the wood, which we will discuss in the next section. To prevent warping of finished workpieces such as door and window frames, they should be installed as soon as possible after they are completed.



TIMBER PILING

In previous lessons, we learned about why seasoning is important to reduce shrinkage. Seasoning also helps to prevent decay and attack by insects and fungi. In natural or air seasoning, the wood is kept protected from sun, rain, and insects, but air is permitted to circulate freely around the wood.

The site where we put the wood to season is very important. It must be open and well drained; all weeds and grass should be removed and the base should be covered with gravel, or even better, with concrete, to prevent growth of new weeds under the stack. Ashes can also be spread around to keep away termites.

Strict cleanliness should be observed around the stacks. Sawdust and short pieces of wood left lying around can start rotting and attract termites or fungi, or they might even catch fire during the dry season and destroy the entire stock of wood. Take extra care with Wawa, as it is easily attacked by insects or fungi.

The entire pile should be shaded from the sun, to keep the timber from drying out too rapidly. The stack should be oriented with the length in the east-west direction, to minimize the effects of rain and sun.

LAYOUT OF THE WOOD STACK

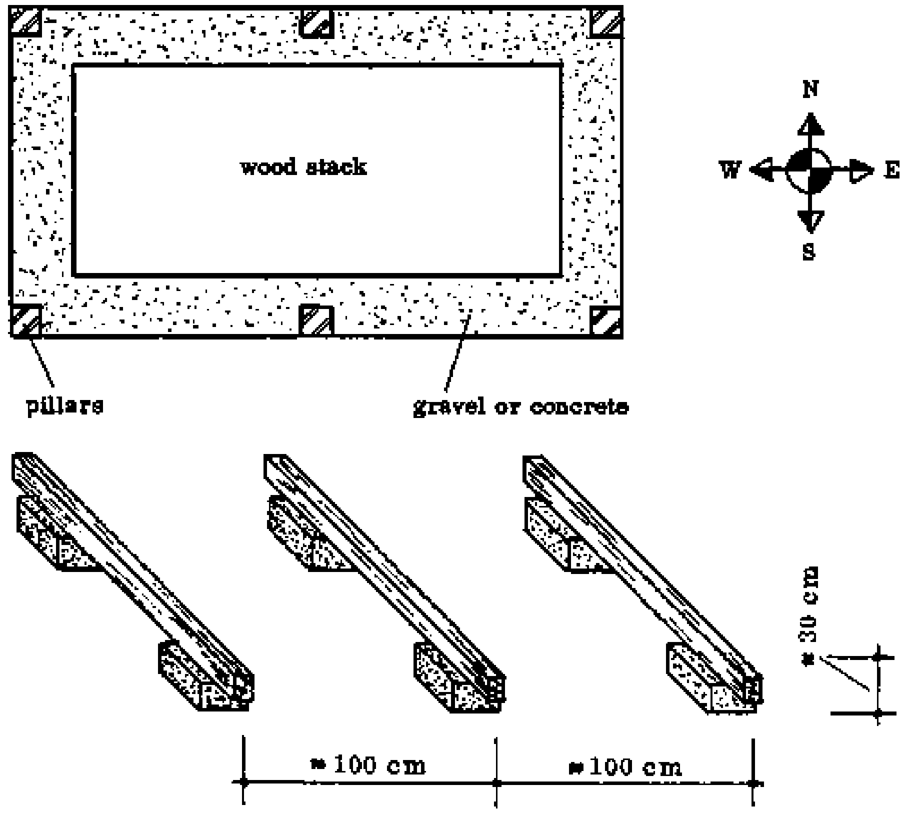


Fig. 1

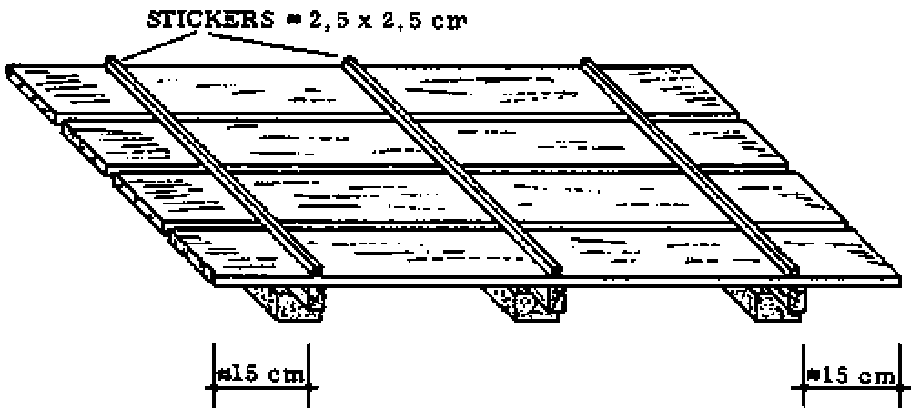

Fig. 2

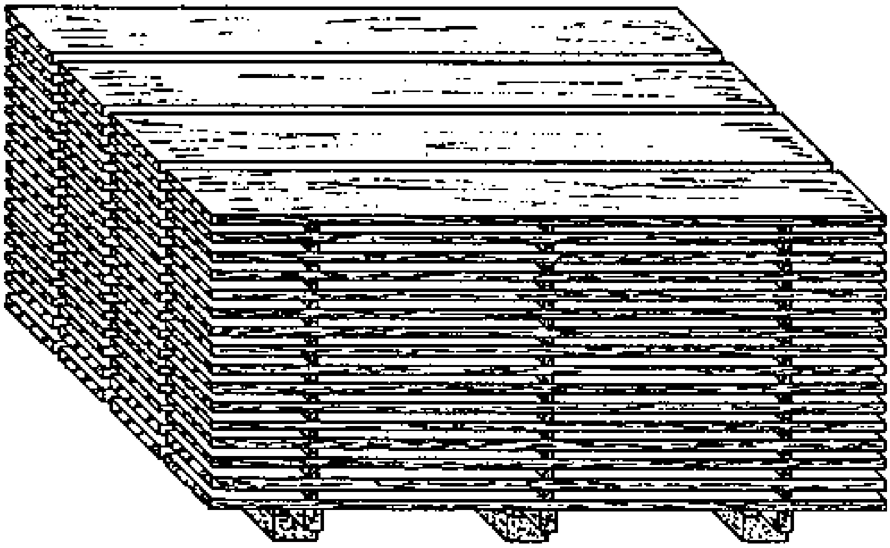

Fig. 3

MAKING THE STACKS

The bases of the stacks are sandcrete blocks (not wood, which might be attacked by termites). On these blocks we set the cross pieces, which are straight baulks without any twisting, because they must carry the whole weight of the stack. The length of the cross pieces will be the width of the stack. They should be perfectly in line on top of the bases (Fig. 1).

The pile should be level from side to side, but may slope a bit lengthwise. Place the cross pieces about 100 cm apart. The end pieces should be about 15 cm from the ends of the boards (Fig. 2).

On top of the cross pieces, put the first layer of boards. Between the layers of boards, put wood strips (stickers) to allow air to flow between the layers (Fig. 2). The stickers should be all exactly above the cross pieces and each other as we build up the stack (Fig. 3). If this is not done correctly the boards may start bending.

The stickers should be square in section so you don't have to take care to put them all flat or all edgeways. They should be around 25 mm thick. All the stickers should have the same thickness, or they may cause the boards to bend or the stack to collapse.

Always stack the wood in such a way that the pieces you will need first are on top.

If you have some wood that you want to reserve for a special purpose, it may be secured by tacking a short stick across the end of the pile.

The stack should always be covered. Make sure that you leave the stack covered and in order after you take out wood.

NOTES:

SPECIFICATIONS OF WOODS WIDELY USED IN NORTHERN GHANA

ODUM

Local trade name: Odum

Standard (international) trade name: Iroko

The tree is up to 60 m high and 7 m in girth (circumference).

Wood characteristics:

The wood is hard and of medium weight.

It is variable in colour, from yellow to dark brown. When freshly felled, it is yellowish green.

The sapwood is paler, about 2,5 to 7,5 cm wide and it is quite distinct from the heartwood.

Durability:

Odum is very resistant to decay when kept dry but it is liable to be attacked by fungi in damp situations. The sapwood is often attacked by pin-hole borers and termites.

Seasoning:

It is easily naturally seasoned.

Working qualities:

It can be worked with moderate ease by most hand tools and it finishes well. Stonelike deposits are sometimes present and these may cause damage to cutting edges. The wood can be nailed, screwed or glued with no problems. When very dry it can be difficult to nail.

Uses:

Odum is probably the most generally useful tropical African hardwood and it is widely used locally for all kinds of construction work and carpentry.

WAWA

Local trade name: Wawa

Standard trade name: Obeche

The tree is up to 55 m high and 5,5 m in girth.

Wood characteristics:

The wood is soft and light in weight. It is nearly white to pale yellow in colour and there is no clear distinction between the sapwood and heartwood. The sapwood is about 7,5 to 10 cm wide.

Durability:

Wawa is not resistant to decay. Seasoned timber is liable to be attacked by powder post beetles and termites.

Seasoning:

Natural seasoning is rapid and satisfactory, with only very little warping and little inclination to split.

Working qualities:

It works easily with all hand tools. To avoid roughening the surface, use very sharp tools. The wood is rather soft and takes nails and screws easily, but it does not hold them well under hard use.

Uses:

It is used for formwork, scaffolding and furniture, where it is not exposed to attack by termites. It can be used only where it will be protected against moisture and rain.

NOTES:

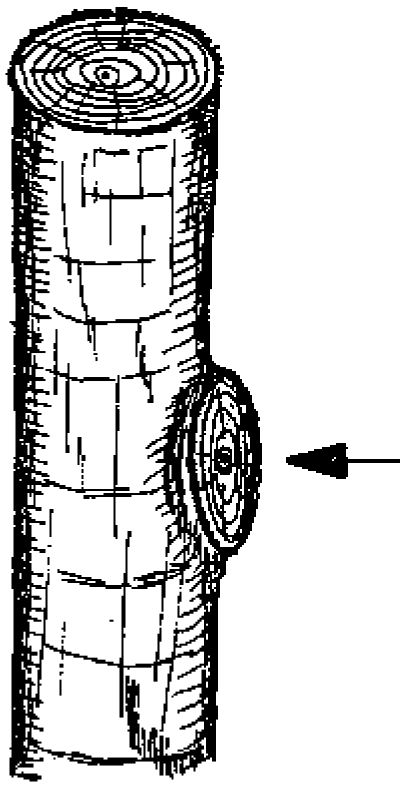

Fig. 2

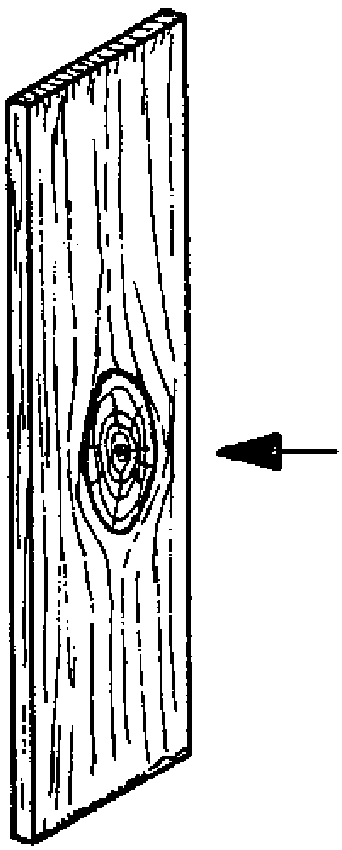

Fig. 3

DEFECTS IN TIMBER

In order to choose the right timber for the work, we need to have some knowledge about defects and diseases in timber. A defect is an irregularity or weakness in the wood which reduces its usefulness and suitability.

The common defects in timber are: knots, twisted grain, checks, wane or waney edge and deadwood.

KNOTS

The place in a tree trunk from which a branch has grown out is called a knot. Each knot marks the junction of a branch with the stem.

There are "live" and "dead" knots.

When a branch is broken off or damaged, a small piece is left attached to the tree. The tree continues to grow around the branch piece, eventually burying it in new wood. These dead pieces of branches are known as dead knots. They have no connection to the living wood, but they occupy a place in the tree, with living wood surrounding them. When the tree is converted to timber, these knots often fall out.

When a tree is felled, all the branches along the stem will be cut off (Figs. 1 & 2). They will leave a knot which is called a live knot (Fig. 3), because it comes from a living branch. Live knots are sound, healthy knots and are always firmly fixed in the wood.

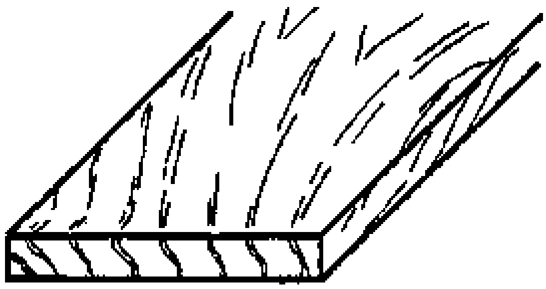
Knots are more or less common in all timber. As long as they remain in place, the presence of a few knots will not harm a piece of timber. However, knots also weaken the wood in some ways and pieces with many knots should not be used for parts which carry heavy loads.

Trees grown in the forest are usually tall, with all the branches at the crown and not along the stem where they could leave knots. Trees which stand apart from other trees tend to have more branches lower on the stem, forming knots which appear when the log is converted.

NOTES:

TWISTED GRAIN

This defect occurs when the tree grows crookedly. The sawn timber tends to twist and it is difficult to plane and chisel because of the changing direction of the grain.



Twisted grain

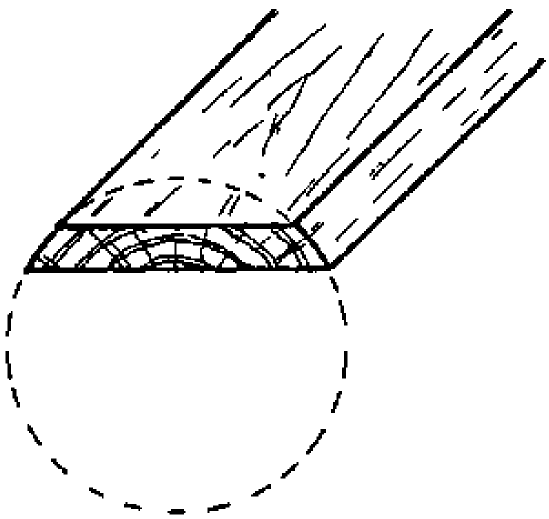
CHECKS

Splits which occur during the seasoning of the wood are known as checks.

Checks

WANE OR WANEY EDGE

This defect is due to a lack of wood on the edge of the timber, from whatever cause.



Wane or waney edge

DEADWOOD

Timber made from dead standing trees is called deadwood.

DISEASES IN TIMBER

Diseases in building timber are caused mainly by attacks from fungi and insects

FUNGAL DISEASES

A fungus is a kind of plant which is not able to make its own food from sunlight, air and water, as most plants make theirs. Instead, it must get food by breaking down dead matter such as wood.

The best places for fungi to grow are dark, damp, warm places with little air movement.

There are many kinds of fungal attack on wood. We will only deal with the most common ones, dry rot and blue stain.

Dry rot is the most common fungal disease of building timber. It spreads easily and since the fungus actually feeds on the wood, it can cause a tremendous amount of damage. Dry rot is especially a problem with built-in work such as frames or cupboards where the wood is in direct contact with masonry work, because there; it is often damp.

The appearance of the Infected timber depends on the age and the extent of the disease. In the early stages, it looks as if pieces of thread are hanging from the wood. These quickly develop into a network that looks like a spiderweb, gray in colour. If the wood is very damp, clumps like cotton wool may form and turn into brown or dark red sponge-like growths that often are greater than 30 cm in diameter. On the surface of the sponge-like mass, seeds are produced which spread the disease to the other parts of the building.

Blue stain is one of a few relatively harmless fungi which cause stains on wood. It appears as a light blue discolouration, usually in lighter coloured wood such as Wawa, in sapwood and sometimes in unseasoned timber. The strength of the timber is not affected by this stain.

NOTES:

PREVENTION OF FUNGAL DISEASES

It is always better to prevent disease in healthy wood than to wait until disease is present and then try to treat it. Infection of timber can be prevented by following some simple precautions:

- It is important to ensure that fungi cannot find the conditions that they need to live, namely warmth, dampness and poor air circulation. Therefore the places where timber is built-in should always be dry and well ventilated.

- Use only healthy, well seasoned timber.

- Workpieces should be designed and constructed so that water drains quickly away from the wood.

- Use paint or preservatives on the wood if possible.

- Wood should not be in direct contact with concrete or masonry. If that cannot be avoided, the wood must be treated with a preservative. It is best to also use tarred paper to separate the wood from the concrete or plaster.

- Good storage, especially of unseasoned timber, helps to prevent attack by fungi (see Timber Piling).

REMEDIES FOR FUNGAL ATTACKS

Dry rot is very difficult and expensive to get rid of, once the timber is infected.

- First find if the timber is still strong enough to serve its purpose, if not replace it.

- Cut off and burn the affected parts.

- Find the cause of the dampness and provide good ventilation to the area (for example, repair defective roofs). Repair the damaged areas with new timber.

- Apply preservative to the timber.

- For blue stain, simply remedy the damp conditions, and provide good ventilation to the wood.

NOTES:

INSECT ATTACK

Most damage to wood by insects is caused by members of the beetle family and by termites.

BEETLES

The eggs of the beetles are laid in cracks on the wood surface and they develop into grubs or larvae. The larvae damage the wood by making small holes in the surface and then digging tunnels into it. They chew the wood and convert it into powder. Small piles of wood powder are pushed out of the holes and these are the sign that the wood is infested. When the larvae have eaten their way through the wood, they will leave it and fly away as fully developed beetles.

PREVENTION OF BEETLE ATTACK

It is quite difficult to prevent attack by beetles, especially in Wawa wood, since most beetles can fly. Some simple precautions can help.

- Paint, varnish, wax or wood preservative should be applied on all surfaces. The smell often keeps insects away. Chemicals are available which protect the wood; you should always follow the manufacturer's directions in using these.

- Beetles usually attack the sapwood first, because it is softer than the heartwood. This is why the sapwood should always be cut off.

- If whole logs, poles or sticks are to be stored, remove the bark first. Insects quickly multiply in wood from which the bark is not removed.

REMEDY FOR BEETLE ATTACK

When you suspect an attack, immediately inspect the wood for beetles. Check whether the wood is still strong enough to serve its function. There are chemicals available to kill the insects. Use them carefully and follow the manufacturer's instructions, as most of them are poisonous.

TERMITES

The greatest damage to wood here in Ghana is done by termites. They build their tunnels from the soil into the timber, leaving the surface of the timber untouched, which makes it very difficult to detect an attack in the early stages.

PREVENTION OF TERMITE ATTACK

The best way to prevent termites from attacking wood is to make sure that they cannot reach the wood.

- The wood should never be in contact with the soil, it should always rest on concrete etc.

- All sapwood should be cut off, because that will be attacked first.

- Protect the wood with wood preservatives.

- Do not use Wawa for construction wood, because it is very likely to be attacked.

- When wood must be in contact with the ground, for example with fence posts, it can be partly protected by scorching it over a fire, or by adding ashes around it when you set it in the hole. Termites do not like scorched wood or ashes.

- When wood is stored for seasoning etc., the ground under the stack should be covered with ashes.

REMEDIES FOR TERMITE ATTACK

- Destroy the path of the termites from the soil to the wood.

- Check if the wood is still strong enough for its function.

- Apply a wood preservative or a chemical to kill the termites.

PRESERVATION AND PROTECTION OF TIMBER AND MASONRY

It is important for the Rural Builder to protect timber and masonry in some way, to make them last longer. There are two basic types of protection we use:

- timber preservatives
- protective finishes

Timber preservatives are used only for wood, and they penetrate into the wood. The deeper they penetrate the wood, the better they work.

Protective finishes are used for both timber and masonry. They work by covering the surface with a protective "skin". Protective finishes are discussed on pages 200 and 201.

NOTES:

TIMBER PRESERVATIVES

Wood used in construction is often destroyed by fungal diseases or insects, especially termites. It is very important for a builder to find ways to protect wood from these dangers.

Some methods of protection have already been discussed in the sections on fungal and insect attack. There we mentioned the uses of wood preservatives. Wood is food for fungi and insects. This food can be poisoned for them by wood preservatives. The wood absorbs these preservatives easily and the fungi and insects that try to eat the treated wood will die.

There are two classes of preservatives: waterborne preservatives and oil preservatives. The type we choose will be determined by the intended use of the wood and by what further surface treatment (painting, etc.) will be done.

- WATERBORNE PRESERVATIVES: These are usually available as powders which are dissolved in water and applied to the wood. Since water is the base the preservative can also be washed out again by water. This can happen if rain should reach the wood. For this reason use waterborne preservatives only under dry conditions and not for outside work where the rain can wash them out.

Kinds of waterborne preservatives:

- Aldrex 40 (mix 1 part of Aldrex 40 with 40 parts of water; use 1½ Ideal milk tins of the powder in a No. 28 bucket of water, which will give the correct proportions)

- Any other chemical preservative which is mixed with water.

- OIL PRESERVATIVES: These have an oil base. They not only kill insects and fungi, but also keep water from penetrating the wood. They do not wash out with water, so they are useful for outside work.

The most common oil preservatives are:

- solignum
- creosote
- used engine oil
- Aldrex 40 mixed with engine oil or kerosene; 1 part Aldrex to 40 parts oil or kerosene.

- NOTE: While it is possible to apply an oil preservative over wood that has already been treated with a waterborne type, paint or waterborne preservatives cannot be applied over oil preservatives because they cannot penetrate.

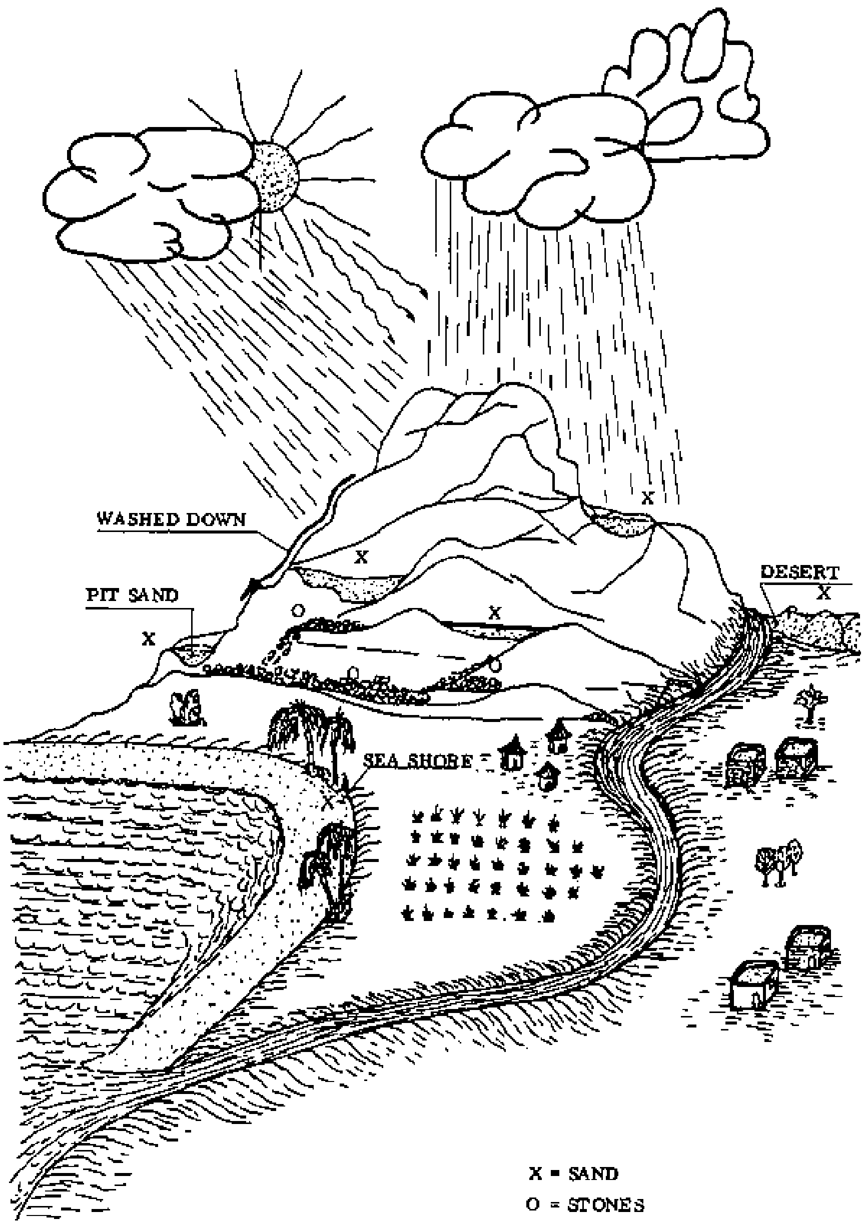


Fig. 1

AGGREGATES

"Aggregate" is the term used for the mixture of different sized stones that form the body of mortars and concrete. Ideally the stone should be graded so that the smaller sizes of stone fit exactly into the spaces between the larger ones and no gaps or holes are left in the mass of mortar or concrete.

SAND

Sand is a mass of finely crushed rock. It is either crushed naturally as seen on the sea shore, in river beds, or in deserts (Fig. 1); or it is artificially produced in crusher plants near rock quarries (where rock is dug out of the earth).

Sand is classified according to the shape of its particles (which differs depending on where the sand came from originally). It is also graded according to the size of its grains (the individual particles of sand).

GRAVEL

"Gravel" is the term commonly used for the larger sized stones of the aggregate. Originally, gravel meant an "all-in-one" aggregate, a mixture of sand and stones of all sizes which can sometimes be found all together in a natural deposit. The individual particles are rounded by the natural action of water and weather.

BROKEN STONES

These are the largest stones of the aggregate, they make up the bulk of concrete. They are found either in natural deposits or scattered on the ground surface; or they are artificially produced in crusher plants. The Rural Builder often must break up large stones with hammers, to make them a convenient size (see Tools, page 14).

- NOTE: These aggregates are the most common ones used for building in the Northern and Upper Regions of Ghana. Of course there are many other types of aggregates (chips, pebbles, rubble etc.), but as far as the Rural Builder is concerned they are of little importance.

NOTES:

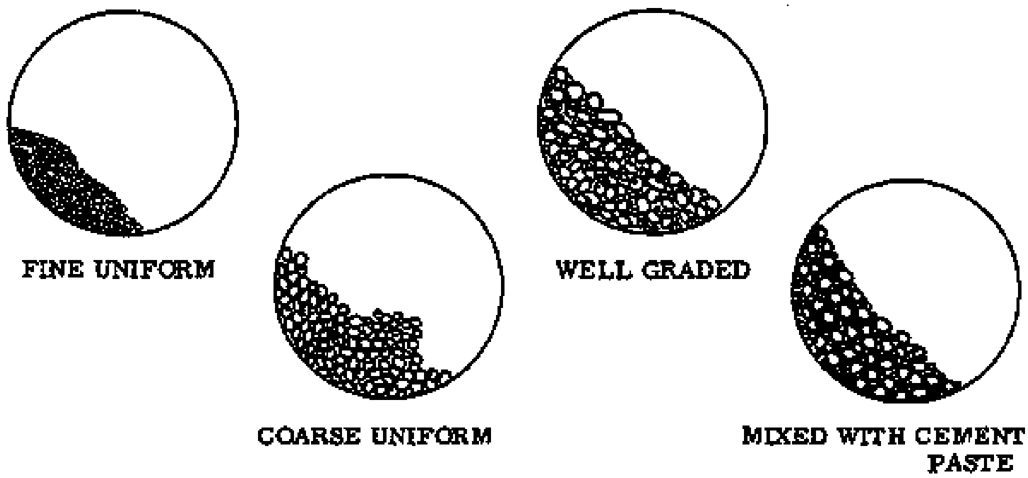
QUALITY AND PROPERTIES OF AGGREGATES

Good mortar and concrete can never be made with poor materials. The cement, sand and stones must all be good quality and the correct types. Sand and stone (the fine and coarse aggregate) together make up more than four-fifths of the concrete mass, so there can be no doubt about their importance. It is not safe to take for granted that every load of sand or gravel brought to the site will be up to standard. Remember that aggregates are either dug from a pit or river bed or they are quarried, and although they may look the same there is a possibility of variation in the quality of different loads.

Particle sizes, the shape and texture of the particles and their surface areas are all important factors in the strength and durability of the concrete or mortar.

- GRADING: A graded aggregate is one that is made up of stones or particles of different sizes, ranging from large to very small. It sometimes happens that a load of sand will have too many coarse particles to make a good mortar, while another load will have too many fine particles. Depending on the job to be done, you might have to mix the two sands together in different proportions to get a suitable aggregate. If the sand contains too many bigger particles it may be necessary to sift these out before using the sand to make mortar, but it could work well for concrete.

The idea is to come up with a "well graded" aggregate; which means that the smaller grains will fit in between the larger ones, leaving only small spaces to be filled with the cement paste. The result will be a good workable mix of adequate strength, using a minimum amount of cement (see sketches below).



- CLASSIFICATION OF AGGREGATES; For making concrete and mortar, the Rural Builder has two types of aggregate: the fine one which is sand; and the coarse one which is broken stones. Both aggregates are classified according to their grain size and are each divided into two main groups:

Fine sand - from 0-1 mm	Fine broken stones - from 5-25 mm
Coarse sand - from 1-5 mm	Coarse broken stones - from 25-50 mm

Another classification is made according to the shape and texture of the single particles. Some sands and stones have particles which are rounded, with relatively smooth surfaces. This sort of aggregate is found mainly in river beds, along the shores of lakes and coasts, and in deserts. This weather- and water-worn sand is called "river sand" or, because of its properties and workability, "soft sand" (Fig. 1).

The other type of sand has a fairly rough surface and it is found mainly in deposits close to hills and mountains. Artificially made sand made from crushed rock also comes under this classification. It is known as "pit sand" or else "sharp sand" (Fig. 2).

Whether the sand is soft river sand, or sharp pit sand; it will have various grain sizes and is classified as fine or coarse, as in the table above.

- NOTE: In the Northern and Upper Regions of Ghana, most sand is dug from river beds. This does not necessarily mean that the sand will be "soft". Often it is a sharp sand or between soft and sharp, because the particles don't get exposed long enough to weather and water to become rounded and smooth.

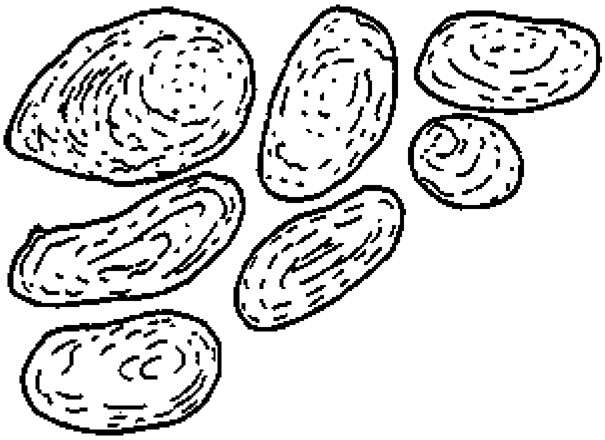


Fig. 1: SOFT SAND (SMOOTH SURFACE)

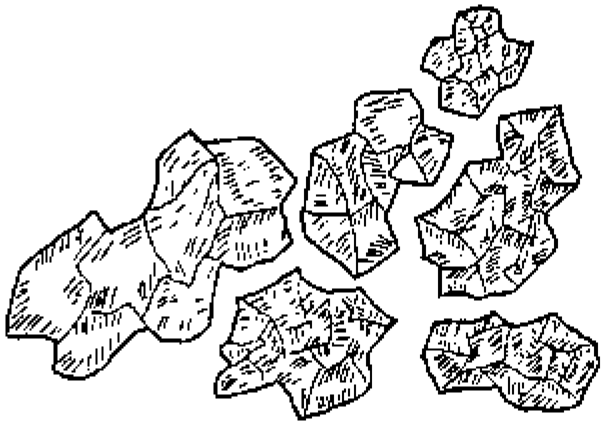

Fig. 2: SHARP SAND (ROUGH SURFACE)

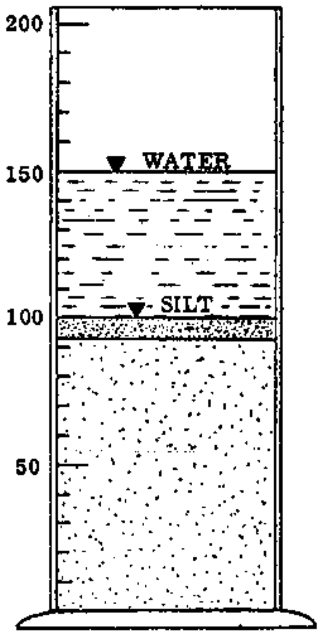
An important factor in the quality of an aggregate is its cleanliness. Clay, mud, or fine dust (known as silt) in the aggregate will weaken the concrete or mortar; while any rotting vegetable matter (organic impurities) like leaves, grass or roots may interfere with the setting of the cement.

- THE HAND TEST FOR SAND: As a first test for cleanliness, simply pick up a little sand and rub it between your hands. If your palms stay clean, the sand is clean enough. If not, the sand may contain too much silt.

- THE SILT TEST FOR SAND: You yourself can carry out a simple test to get an idea of the amount of silt in a natural sand (though not in an artificially crushed rock sand).



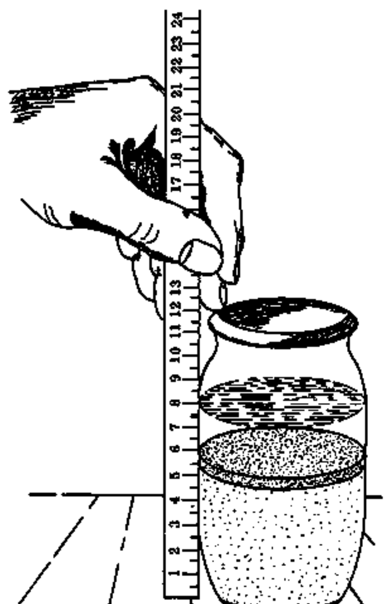
To test accurately you should have a measuring cylinder which is marked in millilitres, shown as "ml", usually up to 200 ml.

First make a salt-water solution by putting one teaspoon of salt into 1/2 litre of water. Fill this solution into the measuring cylinder, up to the 50 ml mark.

Next pour in the sand until the level of the sand is up to the 100 ml mark. Add more salt water until the water reaches the 150 ml mark, cover the cylinder and shake it well.

Stand the cylinder on a level surface and tap it gently until the top surface of the sand is level. Leave it to settle for 3 hours and then measure the height of the silt layer on top of the sand. This should be no more than about 6 ml, or about 6% of the total amount of sand.

- NOTE: If the sand contains more than 6% silt, you would have to use more cement and the concrete would shrink more during the hardening process, causing cracks in the product.



If you have no measuring cylinder, you can use a 0,5 kg jam jar, though this may not be quite accurate.

Put about 5 cm of sand loosely into the jar and pour some salt water on it until you have about 2, 5 cm. of water above the sand. Now cover and shake the jar, and leave it to stand for about 3 hours.

You will see a layer of silt on top of the sand. Measure the depth of the layer, and measure the sand below it. There should be no more than about 3 mm of silt, or about 6% of the amount of sand.

- ORGANIC IMPURITIES: The Rural Builder can carry out a test for organic impurities using a glass jar. Put sand into the jar and fill up the rest of the jar with water. Cover and shake the jar and leave it standing for some minutes. If the water above the sand is brown or very dirty, the sand contains organic impurities and cannot be used.

Better sand can be found by simply removing the top layer of sand, about 5 cm deep, before taking sand from a dry river bed. This top layer consists mainly of excessive silt as well as organic impurities such as vegetable matter and cow dung. None of this is wanted, because it would cause problems with the concrete or mortar.

- REMEMBER: Wherever your sand comes from, it must be clean and suitably graded. If you use dirty sand, you may find that it mixes very nicely, but you will find problems before the job is finished. The impurities in it may affect the rate of setting and hardening of the concrete or mortar, and decrease the final strength of the work. The fine appearance of the just finished work may be spoiled by cracking and flaking as it dries.

BINDING MATERIALS

LIME

Litre is a very fine white powder, used in mixes for mortar, plaster and render. It is made from limestone or chalk which is burnt in a kiln and becomes quicklime.

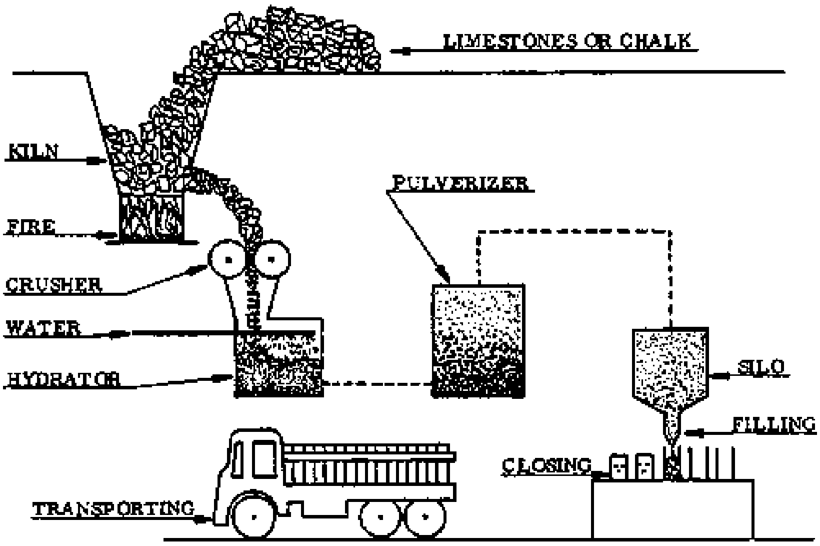
The quicklime is usually passed through a machine called a hydrator, where it combines with water and becomes hydrated lime. This is dried, crushed to a fine powder, then bagged and sold. Below is a diagram of the whole process.

Sometimes the lime is sold as quicklime, and the builder adds the water to it himself. This process is called "slaking" the lime or "running it to putty", and it is not described here.

Slaked lime and hydrated lime are chemically the same, but slaked lime has more water in it.

Hydraulic lime is made from limestone or chalk containing clay. It hardens when combined with water; and it also hardens well in damp places or even under water. It is stronger than other limes, although weaker than Portland cement.

Non-hydraulic lime comes from the purest limestones and chalks. It hardens by drying out and then slowly combining with the carbon dioxide in the air.



PORTLAND CEMENT

Portland cement is a fine grey powder. Among the various kinds of cements, it is the most commonly used as binding material. It is made of a mixture of chalk or limestone and clay.

The following description of the manufacturing process is illustrated below.

The limestone or chalk and the clay, in appropriate proportions, are fed into a "wet grinding mill" and reduced to a creamy substance known as slurry. The slurry is pumped to a large cylindrical "kiln" which is about 90 m long and 3 m in diameter. The slurry enters the kiln at its upper end while pulverized (crushed) coal, gas or other fuel is blown in at the other end. The temperature inside the kiln at the lower end is very intense, approximately 1500 degrees C; gradually decreasing towards the top end. So the slurry as it moves down the kiln is first dried, then heated, and then finally burnt. It leaves the kiln in the form of very hard "clinkers" shaped like small balls and of a dark brown to black in color. The clinkers are ground up to an extremely fine grey powder, which is the cement. The cement is packed in paper bags of 50 kg capacity.

HISTORY OF CEMENT

Some sort of binding substance has been used since ancient times to hold together the stones, bricks etc. used in building. The earliest building cement was probably clay or ordinary mud. The Romans were master builders in brick and stone, and a large part of their success was because of their discovery of a cement that was made by mixing a volcanic ash with burned lime. The Romans also made pure lime mortars and gypsum plasters. These materials were the only building cements until modern times.

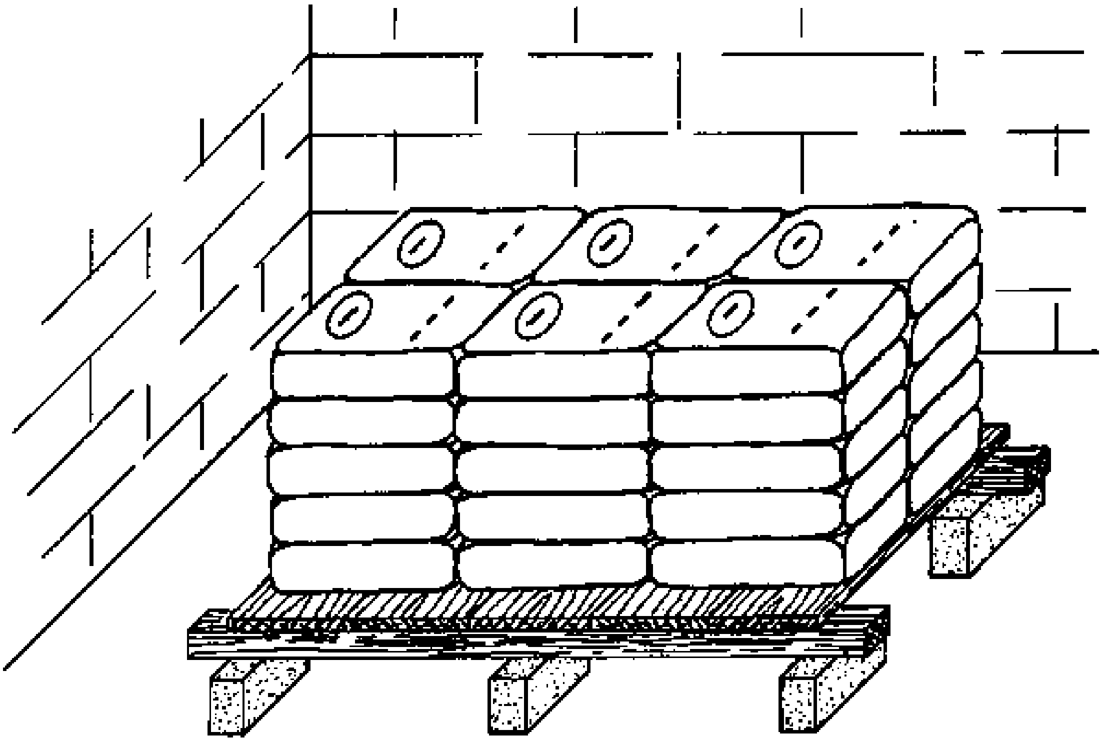
The modern era of building cements began about 1760, when an English engineer discovered the most suitable composition for hydraulic cements. These are cements which will harden even under water (Fig. 1). A few years later, in 1824, another Englishman invented Portland cement. He named it because of its similarity in appearance to a natural stone from Portland in England.

- DEFINITION: A cement is any material which attaches or unites two surfaces, or serves to combine particles into a whole.

- TYPES OF CEMENTS (Fig. 2):

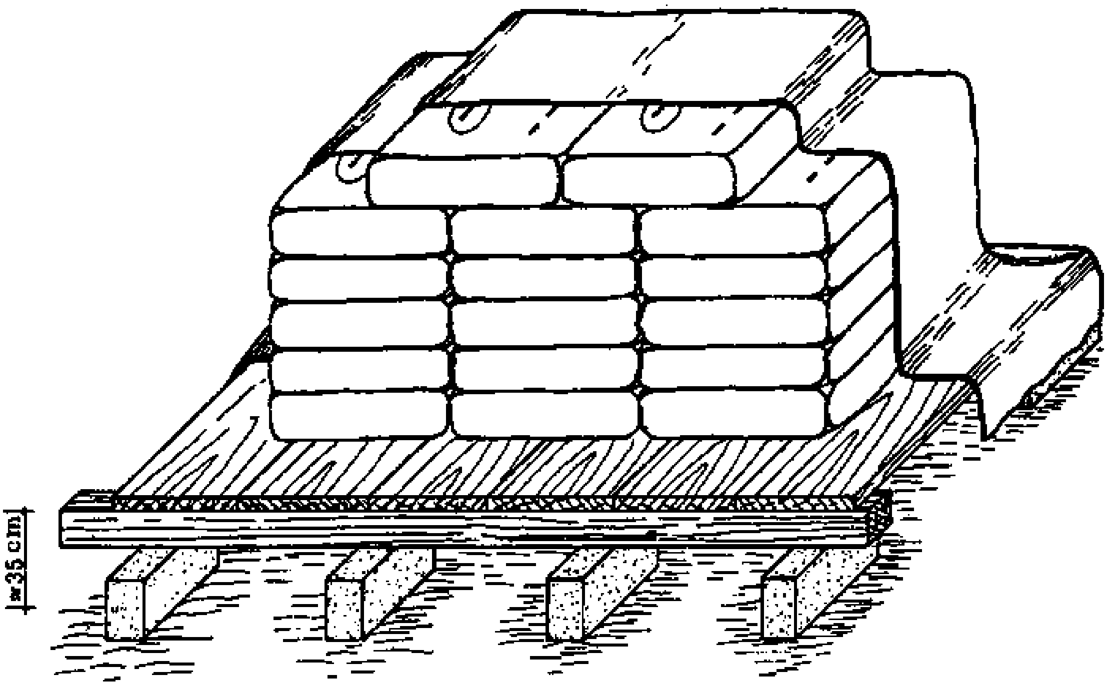
a - Building cements (eg. Portland cement and lime)
b - Bituminous cements (eg. tar and asphalt)
c - Adhesives (eg. animal glues and synthetic resins)

NOTES:



HOW TO STACK BAGS OF CEMENT IN A STORE

Fig. 1



HOW TO STACK BAGS OF CEMENT IN THE OPEN

Fig. 2

STORING BINDING MATERIALS

The quality of mortar and concrete depends on so many factors, but one of the most important of these is the cement. Cement must be stored properly, to prevent it from setting (hardening) before it is used. If the cement gets damp, it will become unusable. Everyone knows that cement should be kept dry, but they don't always realize that contact with damp air can do as much harm as direct contact with water. On all jobs where bagged cement is used, there should be a shed or room to store it.

- STORING IN A SHED: Make sure that the shed or room is water-tight and has a sound, dry floor. If the floor is not dry, make a platform out of boards set on blocks and timber, to raise the bags off the ground (Fig. 1). Stack the bags closely together to keep out air, and away from the walls so that they are not in contact with any dampness on the walls. In very large sheds it is better to cover the bags with plastic sheeting to keep out damp air, especially during the rainy season.

Check the bags from time to time for termites: these may damage the bags and with them the cement. Check also that the roof doesn't leak and that the walls are waterproof.

- STORING IN THE OPEN: On some jobs, bags of cement may have to be stored in the open, with no more protection than a dry base and a covering of tarpaulins or plastic sheets. The sheeting must be properly overlapped to keep out the rain; and the top sheet should lay over all the ones below like a roof, so that the rain can run straight off without getting into the tarpaulin "tent" and wetting the cement.

Even if the cement is to be stored in the open for only an hour or so, there must be a dry platform raised about 35 cm above the ground for the bags to lie upon (Fig. 2).

Whether the cement is stored indoors or out, arrange the bags so that the first batch brought in can be the first ones used, and the old bags don't get left at the bottom of the stack and never used. Prevent accidents by keeping the piles to a height of about 1, 20 m, and never stack them more than 10 bags high.

- REMEMBER: The important thing with cement is to always KEEP IT DRY! Cement starts to set about 30 minutes after mixing or coming into contact with water or moisture.

MORTAR

Mortar consists of the body or aggregate, which is fine sand; and the binding material, which is cement mixed thoroughly with water.

Mortar is used to bed blocks as well as for plastering. A good mortar should be easy to use and should harden fast enough that it does not cause delays in the construction. It must be strong enough, long lasting and weatherproof.

TYPES OF MORTAR

The best mortar for a particular job is not necessarily the strongest one. Other properties like workability, plasticity or faster hardening can be more important, though the strength of the mortar must of course be sufficient for the job.

Mortar should neither be much stronger or much weaker than the blocks with which it is used.

- CEMENT MORTAR: This sets quickly and develops great strength. It is used in proportions of one part cement to three parts sand (1: 3), which makes quite a strong and workable mix; down to a 1:12 mix, a lean mix which will be rather harsh and difficult to use.

- LIME MORTAR: This is usually very workable and does not easily lose water to the blocks, but it is weaker than cement mortar and hardens slower. Lime mortars are nowadays largely replaced by cement mortars or combinations of lime and cement.

- CEMENT-LIME MORTAR: This combines the properties of cement and lime to give a workable and strong mortar. The cement makes the mortar stronger, denser, and faster setting; while the lime makes the mortar workable and reduces the shrinkage during drying, because it retains the water better.

In some areas, lime is not always available, so in this book we will concentrate on the use of cement mortars.

NOTES:

SELECTING THE RIGHT KIND OF SAND

Sand for plaster, mortar and renderings must always be chosen with care. The sand used to make mortar for blocklaying should be well graded, sharp and must not be too fine if a strong mortar is needed (eg. for footings).

The more fine particles the sand contains, the better its workability in the mix, but more cement paste will be needed to cover the surfaces of the particles. This means that in order to improve the workability while maintaining the same strength, more cement must be added which results in higher costs.

The Rural Builder is always faced with this problem and it takes a lot of experience to be able to find a good compromise.

If the sand is found to be too sharp so that it makes a mortar with poor workability, we suggest replacing about 1/3 of it with fine soft sand; but don't replace more than about 1/2 unless you add more cement.

We can do this because the common mix proportion of our mortar is 1:6, while the sandcrete blocks are mixed in a proportion of 1: 8 (cement: sand). When the fine sand is added, the strength of the mortar is reduced to about the same as the strength of the blocks, which is acceptable.

The information above is meant to show the problems concerning the selection of the right sort of sand for a particular job. This book will address these problems repeatedly as we introduce the different kinds of blocks as well as the different jobs.

- REMEMBER: A good mortar should:

a - be easy to work with
b - harden fast enough not to delay the construction
c - stick well to the blocks
d - be long lasting and weatherproof
e - if possible, be as strong as the blocks.

BATCHING

By the term "batching" we mean that we measure the proportions of the various ingredients of a mix. We already know that the ingredients for a mortar should be mixed in certain proportions. To help us to obtain the correct amounts we can make boxes with the appropriate sizes; this method is known as "batching by volume".

Since a common mix proportion is 1:6 and some special jobs require a mix of 1:3, two batching boxes are made with corresponding measurements. The smaller one for cement measures 15 cm high, 30 cm wide and 38 cm long (inside measurements) giving a volume of 17,1 litres, which is about half a bag of cement or one slightly heaped headpanful (one bag of cement contains 34,1 litres or two slightly heaped headpans).

For the sand, a bigger box is made which must hold exactly three times as much as the smaller one. Therefore its inside measurements are: 30 cm high, 30 cm wide, and 57 cm long. This gives a volume of 51,3 litres, which is 3 x 17,1.

Both boxes are bottomless; they are only frames in order to make it easier to work.

- PROCEDURE: Before you start batching and mixing, it is advisable to make a mixing platform out of lean concrete for all future mortar and concrete work. This provides a firm and clean place so that your mix will not become dirty, no cement paste will be lost, and shovelling will be easier.

For small jobs, the mixing platform can measure approximately 1,5 m by 2 m and may be 5 to 7 cm thick.

For a 1: 6 mix, place the bigger box on the platform and fill it with sand flush to the top edge. Then lift it up and set it down again next to the first pile and refill it in the same way (Fig. 1, stages 1 to 3).

Now put the small box on top of the sand-filled big one, and fill it with cement. It must be filled flush to the top edge in order to get the right proportions (Fig. 1, stage 4).

Now lift up the lower box, taking the smaller one with it and emptying both at once. The result is a heap of sand (6 parts) covered with cement (1 part), ready to be mixed (Fig. 1, stage 5).

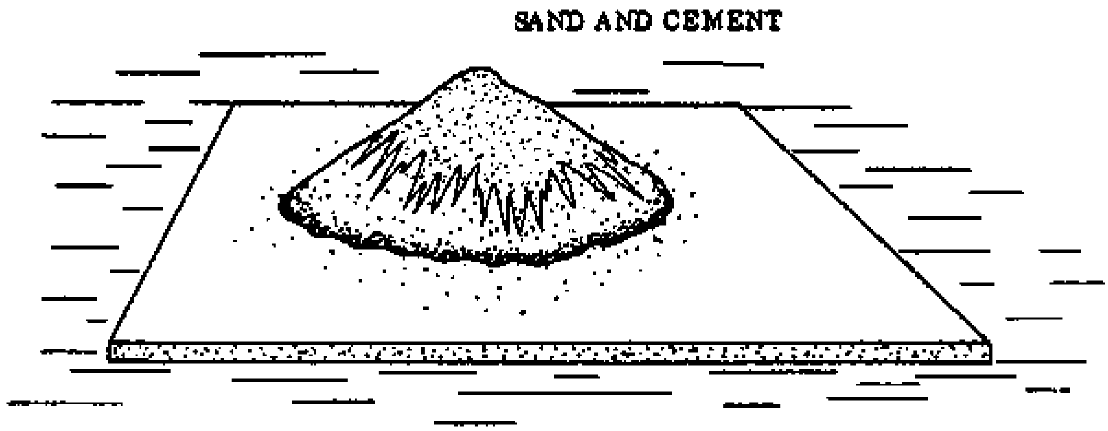

Fig. 1

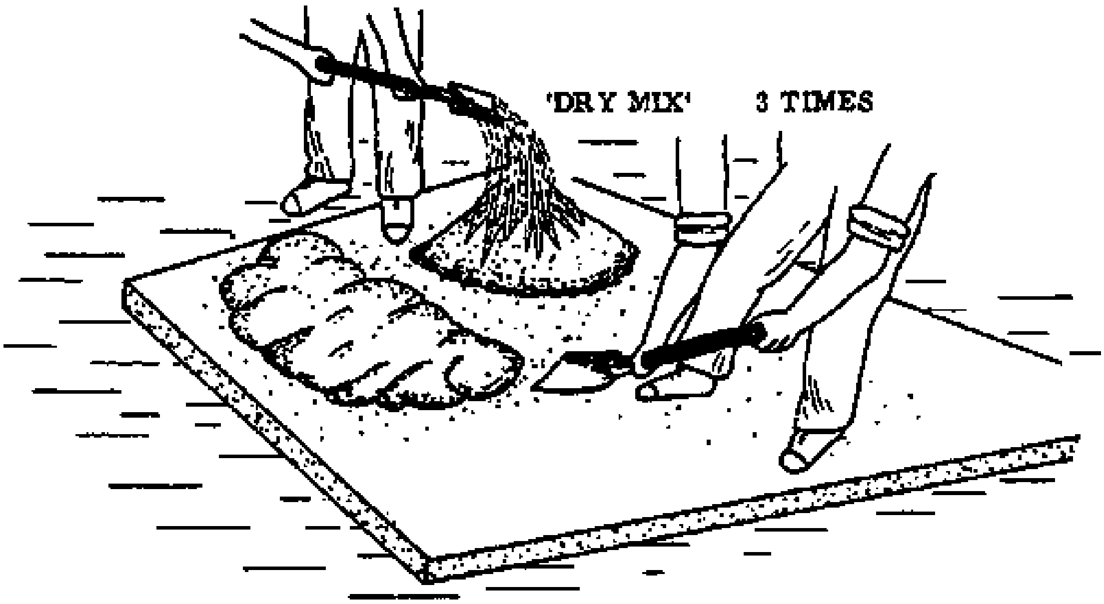

Fig. 2

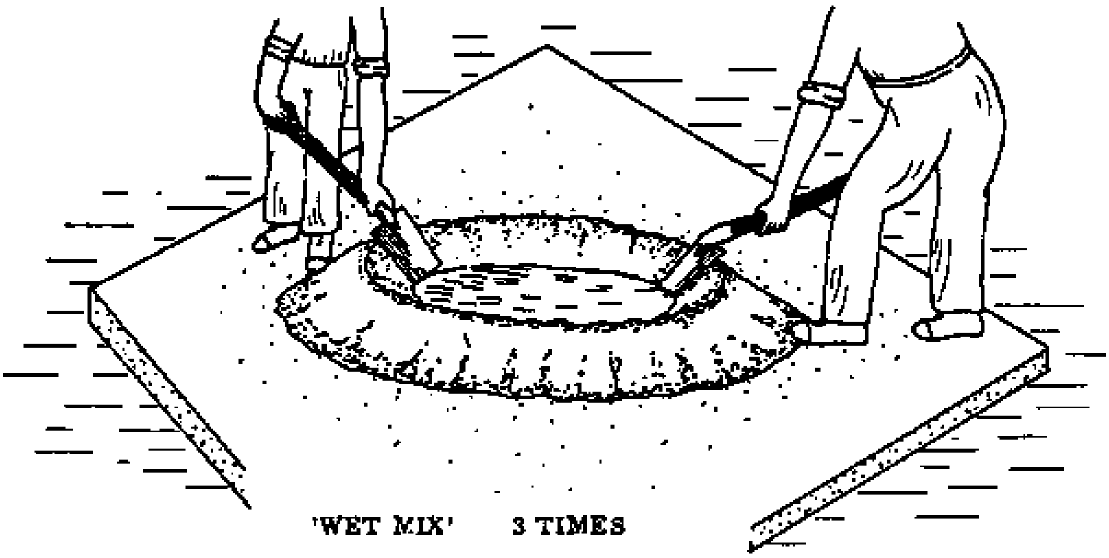

Fig. 3.

MIXING THE MORTAR

Mixing is one of the most important stages in the process of making mortar because the workability and strength of mortar depend so much on the way it is mixed and on the amount of water added to the mix.

- WHAT WATER DOES: Water in the mix does two things: it makes the mortar workable and it combines chemically with the cement to cause hardening. However, only about half the water is required for the chemical reaction and the rest will remain or evaporate slowly as the mortar hardens, leaving small holes or "voids" in the cement.

Obviously, the more water there is in the mix, the greater will be the number of voids and the weaker the mortar.

For your 1:6 mixture, a maximum of 15 litres of water should be added (almost one headpanful); never any more than this even if the mix appears to be too dry, as sometimes happens in the first stage of mixing.

- THREE TIMES DRY: The sand and cement is measured on one end of the mixing platform. With two men facing each other across the pile and working their shovels together, turn the whole heap over once to form a pile at the other end of the slab (Figs. 1 & 2). This turning must be repeated twice and results in a so-called "dry mix".

The correct method for turning over is to slide the shovel along the top of the platform, pick up a load and spill the load over the top of the new pile. The main point is that each shovelful runs evenly down the sides of the cone. This is the best and easiest way of mixing dry mortar and all other motions should be eliminated. When the dry mix is a uniform colour throughout, it is considered to be well mixed.

- THREE TIMES WET: Form the heap of dry mix into a crater or pool, with the sides drawn out towards the edges of the mixing platform. There should be no mixture left in the centre of the pool.

Now gently pour about 3/4 of the total required water into the crater. Turn the shovel over and with the edge scraping along the platform, push some of the dry mix into the pool in such a way that it spreads out, without separating the sand and cement. Handle the shovel carefully so that no water can, escape by breaking through the ring (Fig. 3).

When all of the dry mix has been heaped up in the centre of the platform, it should have taken up all the free water and have a rather stiff consistency (earth-moist).

Now make a second pool, add the remaining water and repeat the rest of the mixing procedure. This will result in a mortar of a plastic consistency. To make sure the mixing is thoroughly done, turn the mortar over a third time,

- CONSISTENCY TEST: You can carry out a simple test to get a rough idea whether the consistency of the mortar is correct (this means the water content).

Fill a headpan with mortar and smooth the surface (Fig. 1). With the blade of your trowel, make a straight cut clear through the mortar to the bottom of the headpan (Fig. 2). Now push the trowel flat under the mortar along the bottom of the headpan, so that the cut in the mortar centres the length of the trowel.

When the trowel is lifted up 2 or 3 cm, the gap in the mortar must open into an oval shape along the outer edge but remain closed along the bottom (Fig. 3).

- NOTE: If you want to improve the workability of the mortar by adding water, remember that this will also decrease its strength. You are therefore strongly advised to add both cement and water in equal quantities (for example 1/2 bucket of water plus 1/2 bucket of cement).

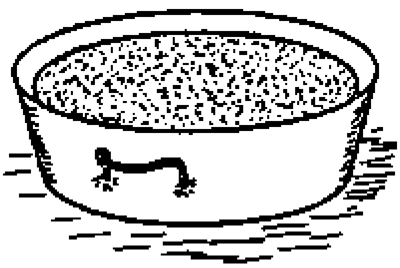

Fig. 1: FILL HEADPAN HALF FULL AND SMOOTH THE SURFACE

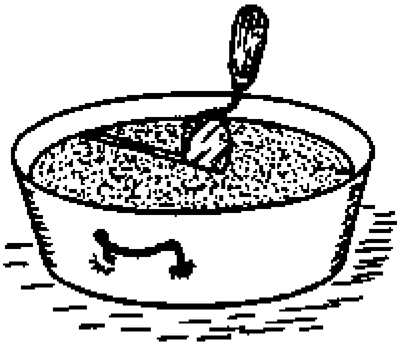

Fig. 2: MAKE A CUT WITH THE TROWEL

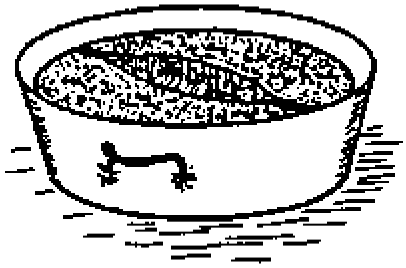

Fig. 3

- REMEMBER: Ready mixed mortar starts setting after only 30 minutes! Never prepare more mortar than you can use within this time.

It is certainly better to mix smaller amounts more often than to allow mortar to spoil; or to do the work very quickly (and sloppily) in order to get rid of the mortar.

Always cover freshly mixed mortar with empty cement bags to keep it from drying out.

NOTES:

CONCRETE

To concrete something means to form it into a mass, or to solidify it.

As far as building is concerned, the term concrete means an artificial stone made by mixing sand, stone, Portland cement and water. This mixture, cast into a form of the desired shape and size, hardens into a stone-like mass: the concrete.

There are basically three materials we start with to make concrete:

- The aggregate, which is made up of the fine and coarse aggregates together, ie. the sand and broken stones. The aggregate makes up the main mass of the concrete; its function is mostly just to add bulk.

- The water.

- The binding material, which is usually Portland cement.

When the three materials are mixed together, the cement and water combine chemically to make a cement paste, which surrounds the particles of the aggregate and holds them together.

NOTES:

CEMENT PASTE

The cement paste component of concrete is what causes it to harden, the aggregate simply remains passive (inactive).

Thus the cement paste must completely cover the surface of every single particle of the aggregate. This means that each stone, no matter whether tiny or big, must be covered all over by a thin layer of cement paste.

This is achieved by mixing all three components very thoroughly and in the correct proportions (see Batching, and Mixing The Mortar, pages 160 to 163).

The cement paste fills up all the spaces between the particles of the aggregate and bonds them firmly together as it hardens.

The hardening process requires a certain amount of water; how much depends on how much cement is added to the mix. The correct proportions can be found in the Tables of Figures, page 234.

After it is set, the hardened cement paste cannot be dissolved again (except by the use of certain acids).

An undesirable further reaction of the cement paste is the drying shrinkage as it hardens. Because of the evaporation of the extra water, the volume of the concrete is gradually reduced. The concrete shrinks and develops cracks.

This reaction can be effectively reduced, if not prevented, by correct curing; as will be discussed later in this book.

Also to prevent cracking, large areas that are covered with concrete; such as floors, should be divided up into bays.

PROPERTIES OF CONCRETE

Concrete has many properties, but most of them are of little interest to the Rural Builder. Therefore this chapter deals only with the three most important properties:

- a - Compression strength
- b - Tensile strength
- c - Protection against corrosion.

NOTES:

- COMPRESSION STRENGTH: It is commonly known that concrete becomes very hard and can withstand enormous pressures; a property which is called compression strength.

This compression strength depends mainly on the properties and quality of the cement paste and the aggregate.

- If the aggregate consists of a soft or weak material, the concrete will be weak also.

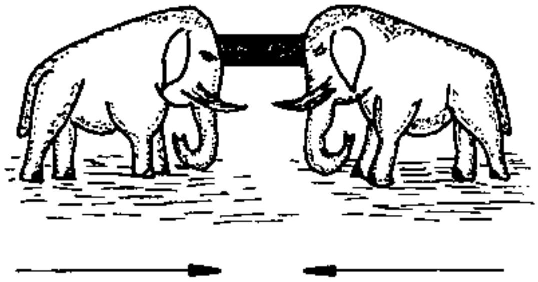
- If the aggregate is so dirty that there is no direct contact between the surface of the particles and the cement paste, the concrete will again be weak.

Provided that all the rules for producing a good concrete are observed, the strength of the concrete can be controlled by choosing the mix proportions. For example, a mix proportion of 1:10 is weaker than a 1:3 mix. This is because in a 1:10 mix the particles of aggregate are not completely coated with cement paste, but in the 1:3 mix they are fully embedded in it.

- If not enough water was added to the mix, the cement paste remains too dry and stiff and the concrete will be weak.

- If too much water was added, making the cement paste too thin, the concrete will again be weak.

Therefore the Rural Builder must always carefully follow the correct concrete recipe.



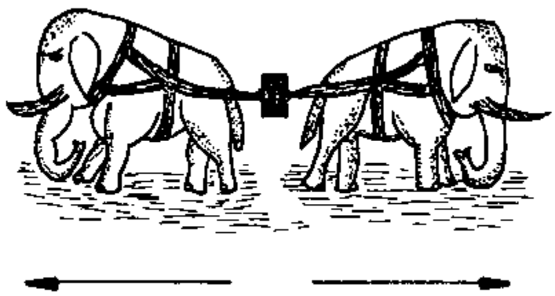
COMPRESSION STRENGTH

- TENSILE STRENGTH: The tensile strength of a material means its capability of being stretched to a certain extent without breaking.

Although concrete becomes very hard, its tensile strength is very limited. It is so low that in practice, the tensile strength of concrete is regarded as being nonexistent. This is why sometimes concrete members of a structure must be reinforced by steel bars embedded in them.

Some types of wood, while they are softer and have a much lower compression strength than concrete, have a far higher tensile strength because of their fiber structure. The wood fibres act in a way like the reinforcement iron embedded in concrete.

Wood is a good building material because of its tensile strength. However, its flexibility makes it subject to bending under loads. Because of this problem, short-span constructions are chosen; or, among other possibilities, reinforced concrete can be used instead of wood.



TENSILE STRENGTH

NOTES:

- PROTECTION AGAINST CORROSION: Corrosion means a wearing away, a slow destruction caused by a reaction with air, water or chemicals.

Reinforcement iron which is left unprotected and exposed to air and humidity will eventually start to corrode on the surface and become rusty.

If this process is not halted in time, the rust goes into the bar and it becomes too weak to be used.

In order to maintain the strength of steel-reinforced concrete, the steel has to be protected from rust. This is partly done by the hardened cement paste and partly by structural means.

Ideally, the hardened cement paste hermetically seals the iron so that direct contact with air and humidity is cut off. Even slight rust stains on the iron cannot do any harm because the cement paste protects it against further corrosion.

The protection will not be enough however, unless the builder observes the following rules:

- The reinforcement bars must be completely covered by concrete which is well compacted and without voids.

- The concrete cover must be sufficiently thick, and without cracks.

- In most cases ordinary Portland cement is used and the mix proportion should be no less than 1: 5 for reinforced concrete. (see Tables of Figures, page 234).

Apart from these, all the other rules for producing a good concrete must be observed.

- NOTE: Quality concrete is not a brand. It does not have a trademark on it to say "This is quality concrete". Sometimes the concrete does not even look different from poor concrete, but it is different. This depends not only on the mix proportion, but on the awareness and skill of the builder.

NOTES:

PART 4: RURAL BUILDING PRODUCTS

REINFORCEMENT STEEL

To reinforce a material means to add something to it, in order to make it stronger.

One of the strongest reinforcement materials available is steel or iron. In reinforced concrete, a concrete member is strengthened with steel bars or metal netting embedded in it.

TYPES OF REINFORCEMENT STEEL

There are various types of reinforcement steel; how they are used depends on the function, shape and dimensions of the reinforced concrete member as well as on the required strength.

Reinforcement steel is classified according to its shape and surface texture. The most common reinforcement is single round bars which can have either a smooth or a ribbed surface.

- CIRCULAR BARS: Round, smooth bars are called circular bars and are available in diameters ranging from 5 mm to 28 mm (Fig. 1, next page). The four sizes most often used in Rural Building have diameters of 6 mm (1/4"), 10 mm (3/8"), 12 mm (1/2") and 18 mm (3/4").

- RIBBED BARS: The round bars with a ribbed surface are called ribbed bars and are available in diameters ranging from 6 mm to 40 mm, if the bar is cross-ribbed (Fig. 2, next page). For obliquely ribbed bars, the diameters range from 6 mm to 28 mm (Fig. 3, next page). This last type of reinforcement is also called "tentor bar" and it is the strongest reinforcement steel available.

The standard length of reinforcement bars is 9 m.

- ADVANTAGES / DISADVANTAGES: Although the strength of circular bars is sufficient for all Rural Building purposes, it is advisable to purchase ribbed bars if they are available in the market. Ribbed bars are preferred because their rough surface texture provides a better grip to the concrete. This, along with their greater strength, allows the Rural Builder to space the ribbed bars wider apart, thus saving materials and reducing the total weight of the member.

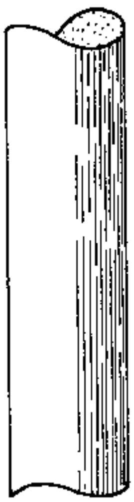


Fig. 1

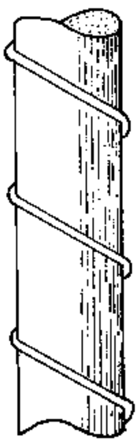

Fig. 2

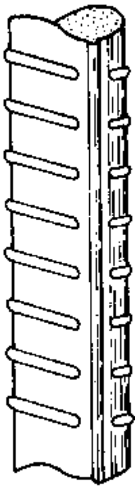

Fig. 3

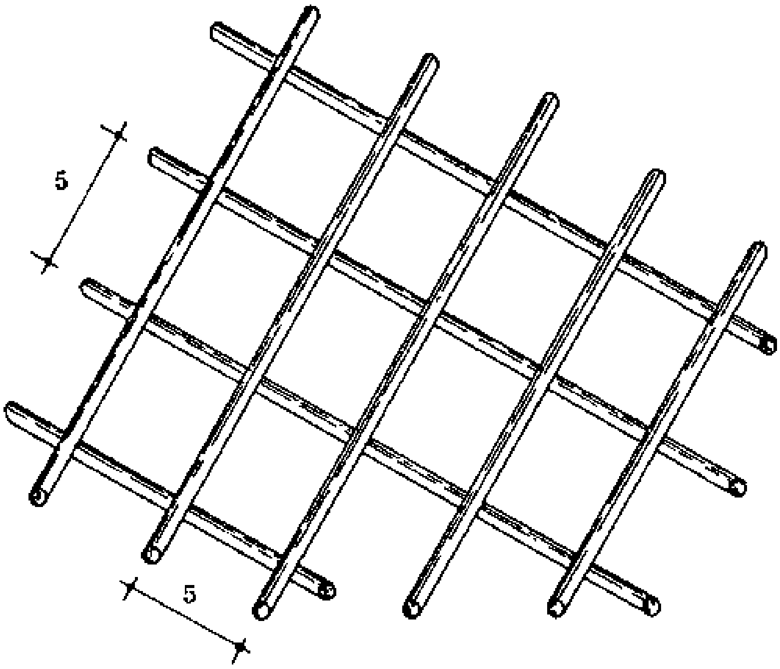

Fig. 4

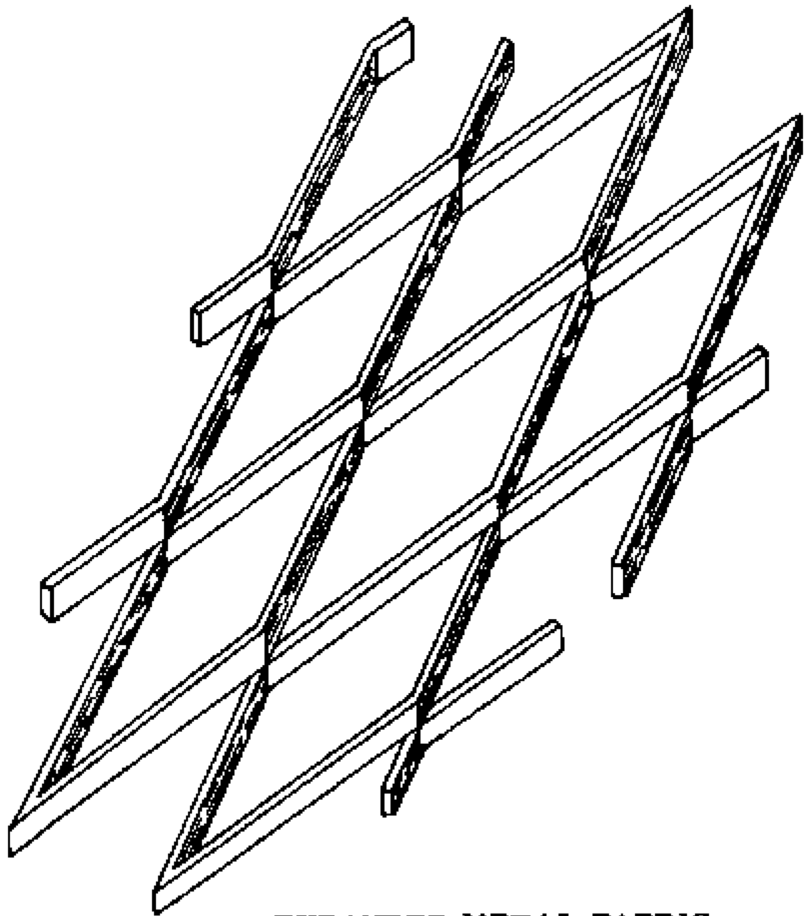

Fig. 5

REINFORCEMENT MATS

A variety of reinforcement mats are available. They are usually made out of two layers of reinforcement bars laid across each other and secured together by welding.

The mats are either square or oblong in shape. They reduce the work needed to reinforce large members of the structure such as floors, walls, slabs, etc.

Regular reinforcement mats are hardly necessary in Rural Building, but two special kinds are frequently used for burglar proofing and to reinforce thin concrete slabs like manhole covers, draining boards in kitchens, and coping slabs.

These two are "expanded metal fabric" and "steel wire netting".

- STEEL WIRE NETTING: The most common steel wire netting (Fig. 4) has square meshes measuring 5 by 5 cm and is manufactured in the same way as reinforcement mats. The same kind of wire mesh can also have oblong meshes.

- EXPANDED METAL FABRIC: This is made by slitting metal sheets and then stretching them to form a diamond-shaped mesh (Fig. 5). Always wear leather gloves when working with expanded metal fabric, as the edges are very sharp.

Reinforcement mats are sold in sheets approximately 2,15 m wide and 5 m long.

Expanded metal fabric and steel wire netting can be purchased in sheets of about 1,5 m wide and 2,5 m long.

BINDING WIRE

This is a soft steel wire about 1 mm in diameter, used for binding reinforcement bars at the points where they cross each other. It is bought in rolls and may also be called lashing wire, annealed wire or tying wire.

NOTES:

LANDCRETE BLOCKS

One of the smallest but most important members of the structure is the block. Almost all walls in Rural Building are erected with blocks, preferable landcrete blocks.

-LANDCRETE: This word comes from the words laterite, land, and concrete.

The land on which we live provides us with the laterite; the first syllable is a combination of the first two letters of laterite and the last two letters of land.

Concrete as well as landcrete contains cement. In order to show this, the last syllable of the word concrete is used, making the word LANDCRETE.

Landcrete is a low cost, long-lasting and attractive building product. This chapter is about making landcrete blocks using a hand operated block press.

- LATERITE: This type of soil is found throughout the tropics. Its colour can vary from white-grey to a dark red, depending on the iron content. Laterite consists mainly of fine and coarse sand mixed with clay.

Laterite has been used to make houses for a long time, but such walls break down easily and get washed away by rain. Pressing the soil into blocks makes it easier to build the walls, and they are stronger and more resistant to rain. By adding some cement to the laterite it is stabilized and makes even better blocks. The basic material, laterite, costs nothing and is usually found on the building site. It is easy to find good soil for building or to mix it with sand or clay to make it good.

The basic steps of the operation to make landcrete blocks are fairly simple: first good soil is found and tested; then it is prepared for the block press, with the addition of cement or lime if available. The soil or soil-cement is put into the press and compacted, raised out and removed for curing.

- NOTE: If the blocks do not contain cement they are not called landcrete; they are simply called "laterite blocks".

REQUIRED MATERIALS

a - Laterite soil: composed of sands, silt and clay
b - Water: to wet the soil; it should be clean
c - Cement: to stabilize the soil.

- NOTE: If you have no cement you can use lime (twice as much as the amount of cement recommended) or else just make plain laterite blocks.

REQUIRED EQUIPMENT

a - Block press with proper mounting rails and a wooden handle (2,5 m long)
b - Box for shrinkage test
c - Headpan, box or bucket for batching
d - Pick-axes and shovels for digging, mixing and filling.

TESTING AND CHOOSING THE SOIL

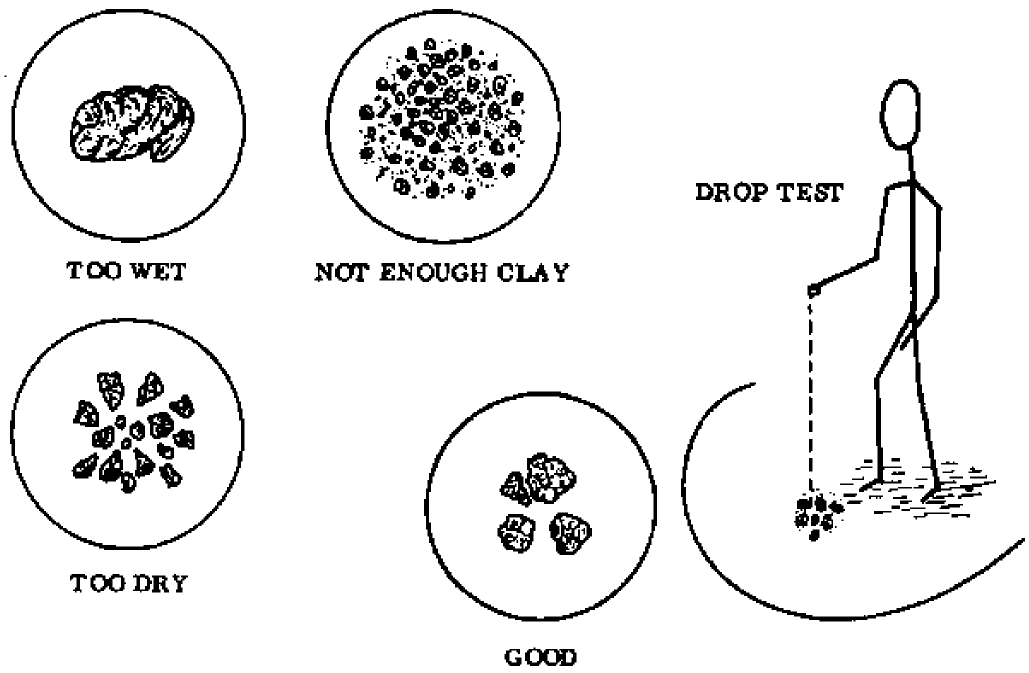
Most soil is suitable for making blocks, but it must be tested first to find out how much sand, silt and clay it contains.

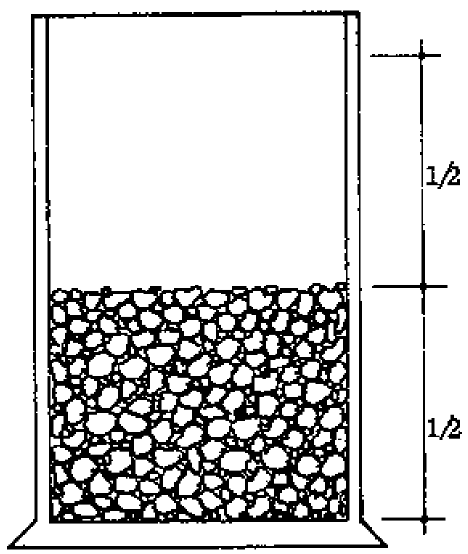
Dig a small pit for testing. First remove and set aside the top soil where plants or grass may be growing (25 to 50 cm deep). This soil should not be used for blocks. Dig out the soil under the top soil. The deeper soil may be sandier, which is usually better for making blocks.

Now make three tests: a - Drop test b- Jar test c - Box test.

- DROP TEST: Take a handful of soil which is wet enough to form a ball, and squeeze it in your hand, but not so tightly that the water is squeezed out.

Drop the ball from about one meter high onto hard ground. If it breaks up into only a few pieces, the block-making quality is good. If it breaks completely up, there is either not enough water in it or not enough clay, and the quality is bad.





FILL GLASS JAR HALF FULL WITH LATERITE SOIL

Fig. 1

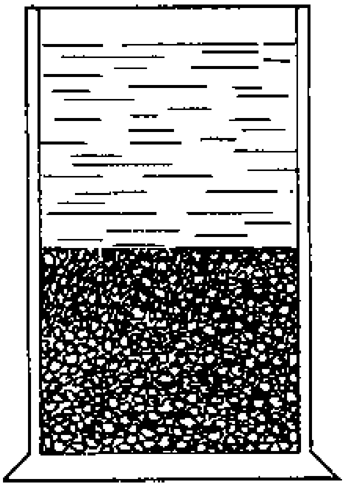


Fig. 2

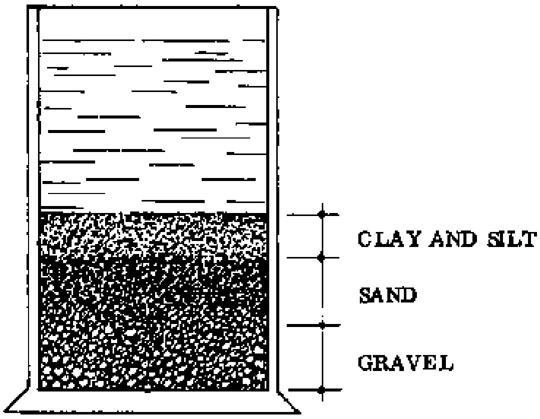

Fig. 3

- JAR TEST: This test separates the sand from the clay and silt, so that we can measure the quantity of each.

First dig out some soil (not top soil). Fill a glass jar half-full with the soil (Fig. 1).

Fill the jar up with water and add two teaspoons full of salt, to make the particles settle faster (Fig. 2).

Cover and shake or stir the jar for two minutes to mix the water thoroughly with the soil.

Set the jar on a level surface and leave the soil to settle for several hours. Sand and gravel will settle to the bottom, leaving the silt and clay on top (Fig. 3).

Measure the height of each layer to find the total amount of sand and the amount of clay and silt, compared to the total amount of soil.

The soil you use should contain at least 30% sand (about 1/3), and between 5% and 30% clay and silt. If there is not enough clay add more or else find some better soil. You can also add sand if necessary.

NOTES:

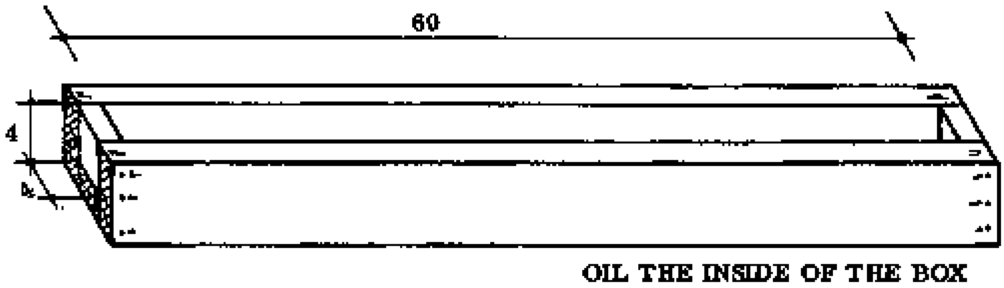

Fig. 1

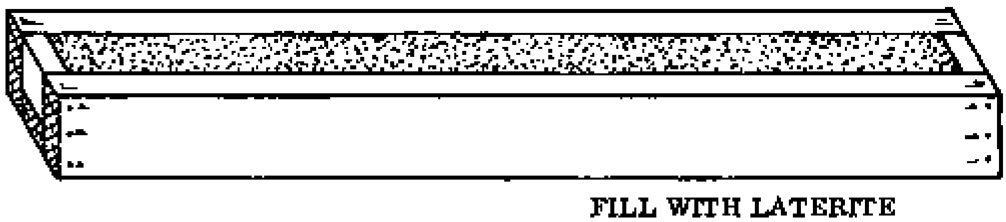

Fig. 2

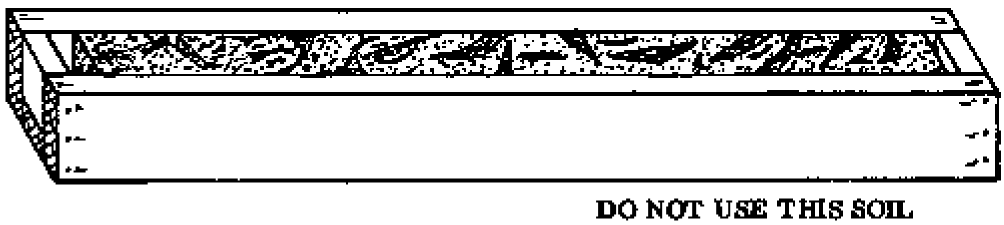

Fig. 3

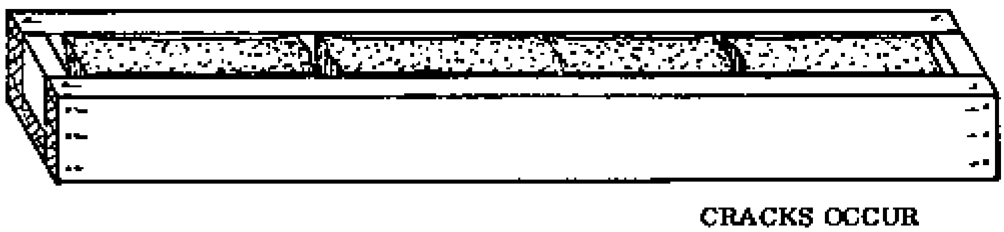

Fig. 4

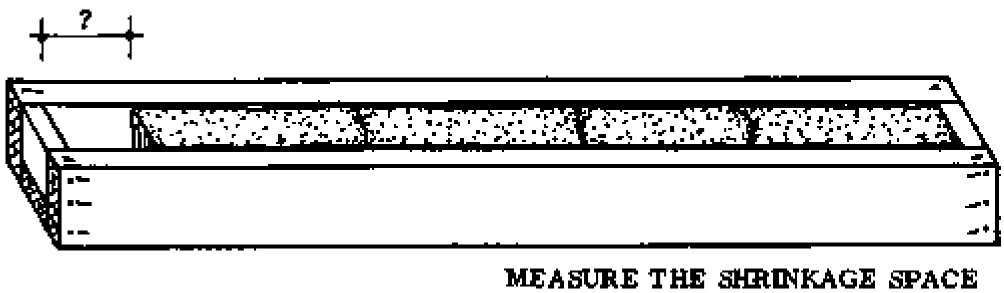

Fig. 5

- BOX TEST: This test shows the quality of the soil and allows you to determine the amount of cement you should use with it.

Use an open wooden box with inside measurements of 60 cm by 4 cm by 4 cm (Fig. 1). Oil or grease the inside of the box.

Fill the box with very wet soil. Compact it well, especially in the corners, and level off the top with a stick or the edge of your trowel (Fig. 2).

Put the box in the sun for three days to dry, or in the shade for seven days. It should be protected from rain.

The soil will shrink as it dries. Do not use soil for blocks if it has many cracks in it (Fig. 3) or if it has arched up out of the box. Don't use soil if it has shrunk more than 5 cm. Either find some better soil, or improve the soil by adding sand, since it is the clay which causes shrinkage.

Measure the shrinkage by tapping one end of the box on the ground so that all the soil slides down to one end (Fig. 4). The cracks will close and you can measure the shrinkage space at the top end (Fig. 5).

The amount of shrinkage tells you how much cement you should use. The more shrinkage, the more cement is needed. Use the table below as a guide for the amount of cement to be added to the laterite.

- TEST TABLE:

Shrinkage	Cement to soil
0-10 mm	1: 35

MAKING BLOCKS

- PREPARATION OF THE MIXTURE: After you have found good soil and the correct amount of cement to use with the help of the box test, the soil mixture must be prepared for the block press.

If you have no cement and must make laterite blocks, you follow the same sequence as described below.

a - Remove the top layer of soil (Fig. 1).
b - Dig out the soil you want to use and pile it (Fig. 1).
c - Measure the required proportions of laterite and cement.
d - Make a dry mix of the batch.
e - Add water and make a wet mix.
f - Check the moisture content using the drop test.

If you are making laterite blocks, steps c and d are of course left out.

Before you start batching, the laterite must be broken up so that no lumps remain. This is usually done by beating the soil with the back of a shovel or with a piece of wood. Large stones are removed.

- MIXING: Use flat, hard ground for mixing. If no such place is available, prepare a mixing platform before you start working.

Spread the laterite out until it is about 10 cm thick. Spread the cement evenly over all the soil. Mix the cement and soil with a shovel until the mixture is of an even colour throughout (about 3 times - see Rural Building Materials, page 163).

Spread the heap again, sprinkle a little water over it and mix. At this point, test the mixture for moisture with the drop test. If it is too dry, spread it out again and add more water.

The soil-cement mixture is now ready for the block press. There should be enough mix for about 7 or 8 blocks in one batch at a time.

- NOTE: Never prepare more than you can use up within 30 minutes (about three batches). It is better to mix small amounts more often.

NOTES:

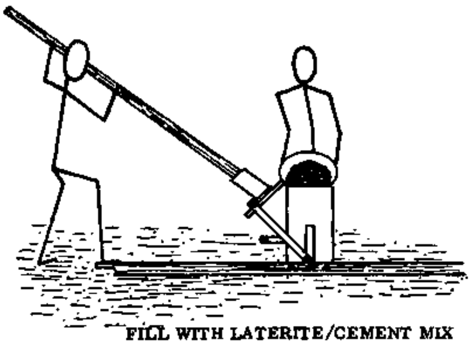

Fig. 1

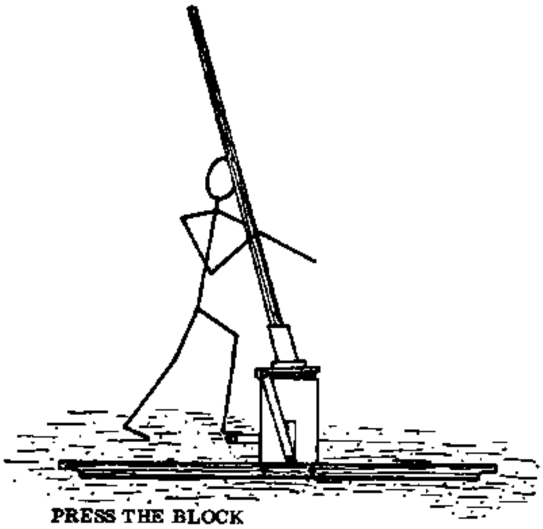

Fig. 2

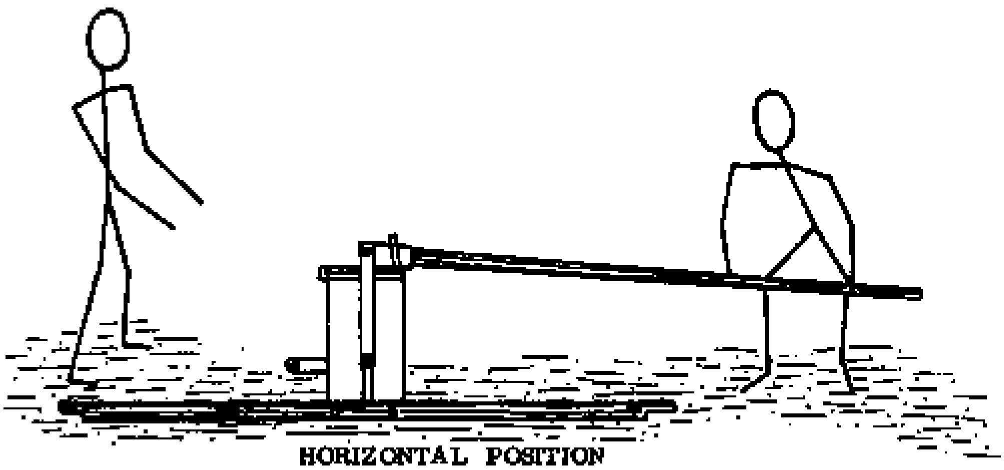

Fig. 3

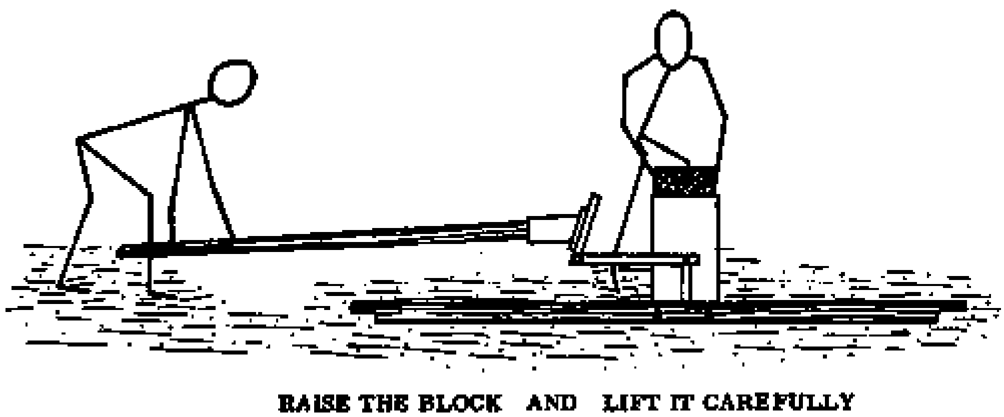

Fig. 4

- PRESSING THE BLOCK:

a - Place the block press in its rails on flat, solid ground near the mixing platform.

b - Open the mould box by swinging the handle down to the lower roller.

c - Half-fill the mould box with the laterite cement mix (Fig. 1).

d - Press the mix firmly into the corners with a piece of wood.

e - Fill the mould to the top and compact the corners again.

f - Add a little more so that the mould is filled flush to its top edge.

g - Swing the handle quickly over to the other side and press the block until the handle has reached a horizontal position (Figs. 2 & 3).

If the mix is too dry, the handle will not go all the way down to the horizontal position. In this case do not force it, as the handle may break.

Instead, eject the unfinished block so that you can refill the mould box after adding a little water to the mix.

On no account should more than one man at a time work the handle!

h - Raise the block out of the mould box by swinging the handle back against the lower rollers (Fig. 4).

i - Lift the block carefully off the machine and place it for drying.

The freshly made block is not strong yet. If it breaks or cracks very easily, the mixture is not correct. Try a different mixture.

Hold the block in such a way that your fingers are not caught under it when you put it down, so as not to crumble the edges.

NOTES:

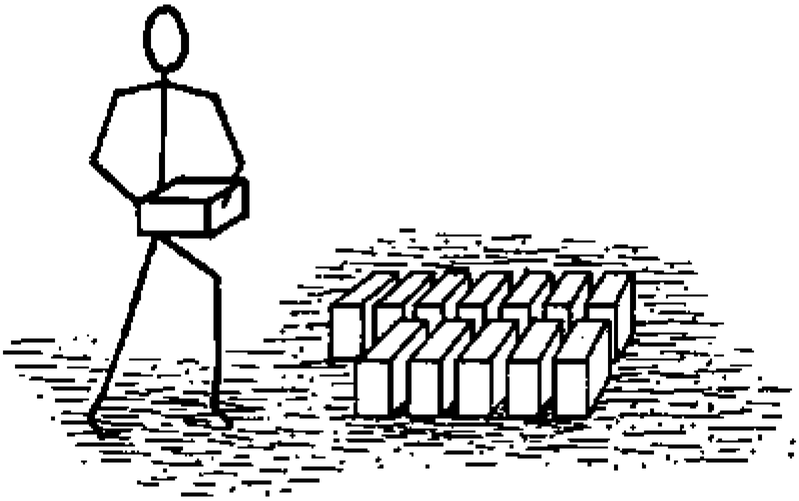

Fig. 1: DRYING FOR ONE DAY

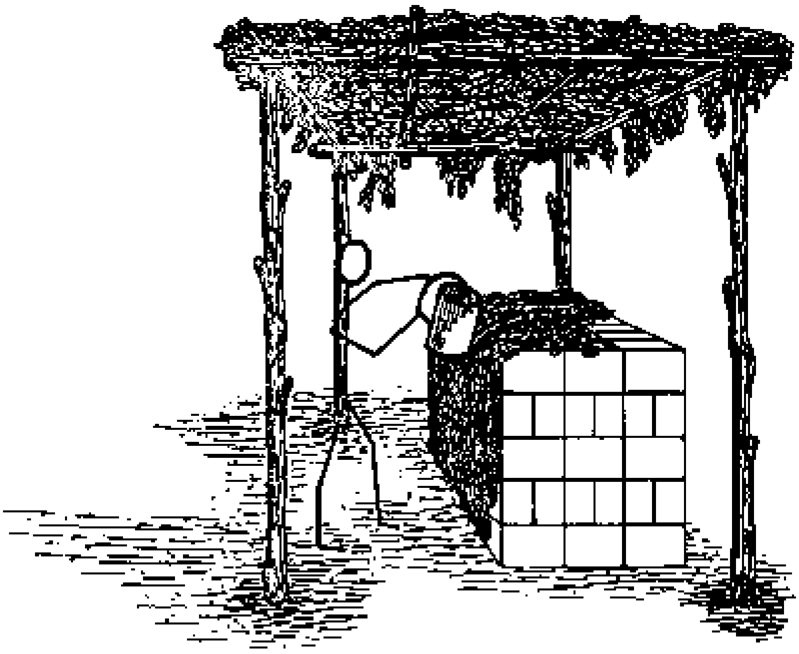

Fig. 2: STACKING FOR FURTHER CURING

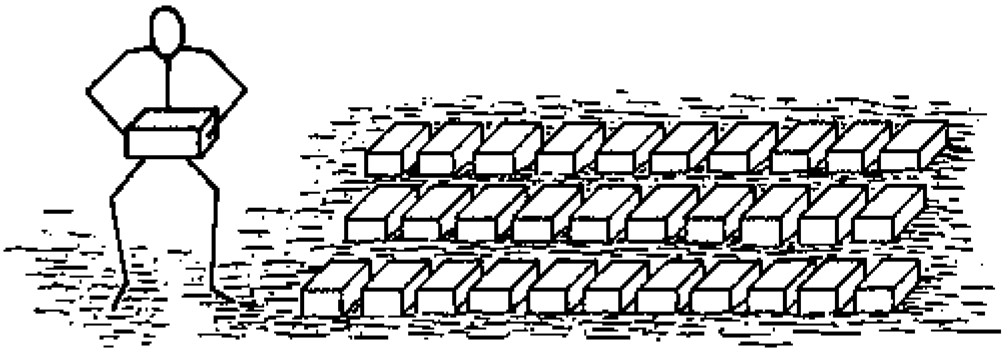

Fig. 3: BLOCKS WITHOUT CEMENT - SUN DRYING

- CURING: This is the term originally used to describe the chemical change in glues when they set, meaning when they become strong and hard.

As far as cement products are concerned, curing simply means the after-treatment of any of those products.

If the blocks contain cement, we talk about "curing". If the blocks don't contain cement, we talk about "sun-drying".

The blocks with cement must now be cured for about two weeks while the cement sets. It is important to follow the directions for curing. If you do not, the blocks may be weak and full of cracks, and therefore unusable for building.

a - Remove the block from the block press, holding it carefully.

b - Place it on leaves, grass or boards on flat ground. The block should not touch the ground (Fig. 1).

c - The blocks should be under shelter or covered with something so that they are out of the rain and sun for at least the first day.

d - Let the blocks dry like this for one day.

e - After one day the blocks are a little stronger so that they can be stacked for further curing.

Stack the blocks on boards or on very flat, hard ground up to five blocks high. Place them so that they touch each other. Make the stacks under a cover if possible, to keep them out of the sun (Fig. 2).

f - The blocks must be kept moist by sprinkling water on them twice a day. Put grass or leaves on top to help keep them moist (Fig. 2).

g - After two weeks of watering the cement has set properly and the blocks can dry completely. They are now ready for use.

Blocks without cement simply need to be dried in the sun. Let the blocks dry in the sun for two weeks; then they are ready for building (Fig. 3).

Fig. 1

PLANNING THE WORK

- PLAN OF OPERATIONS: Good planning can make the work of block-making go faster and easier.

The places where the different steps are carried out should be as close to each other as possible, so that there is a continuous step by step flow of laterite from the soil pit to the finished wall. The soil and blocks should be transported as little as possible.

If there is more than one building to erect, some operations can be moved.

There should be a smooth flow (Fig. 1) of:

a - digging
b - transporting
c - batching
d - mixing
e - testing
f - filling
g - pressing
h - raising
i - removing/drying
j - stacking/curing
k - walling up

You can make a layout like the one in the picture (Fig. 1) or you can lay out the operations in a straight line; or anything in between, whatever suits you and the situation best.

Several factors can be important in deciding what sort of digging pits you will have. If the good soil goes deep, all the soil can come from one pit. However such a large pit might be ugly and undesirable; several small pits could be a better solution in some cases.

The possible future uses of the pits should also be considered. They could form a part of a drainage system, a water storage tank, a sewage pit, a soak-away, and so on. This of course, provided that the planning is done beforehand.

</table>

Fig. 1

Stacking, curing and transporting the blocks to the actual place of building can be done every morning by the soil diggers.

They can do this only if they have dug some soil in advance during the previous day, so that the rest of the workers have the materials to continue their operations of batching, mixing etc.

- LABOUR: From one to fifteen men can work on block-making. If there are plenty of workers, they should be organized to keep the block press going constantly, so it is used to maximum efficiency.

To do this, there must be a steady supply of soil-cement mix ready to put into the machine. Make the mixing platform big enough so that there is room for one pile of already mixed landcrete and one pile which is being mixed.

You can use the rough table at left as a planning guide to divide the labour, but experience will be the best guide (Fig. 1).

In any case the work should be divided so that everyone is busy all the time. If the block press filling worker has to stop and wait for prepared landcrete, he or another man should be switched to doing soil preparation.

Workers should relieve one another in their jobs every few hours to prevent boredom with the work. After a few days of such rotations, the workers will each become skilled and efficient at three or four of the different steps of block-making.

It is important to share the work fairly to keep up the morale and enthusiasm among the workers.

- NUMBER OF BLOCKS: You should know from the start approximately the number of blocks that will be needed for the building. This is necessary to be able to schedule the block-making, curing and building.

To find the approximate number of blocks to be made, you must know the size and plan of the building. Take measurements of the lengths of the walls and add these up to get a total. Multiply this wall-length by the total height from the plinth course to the top of the wall; this gives you the total wall area in square meters. This number, multiplied by 13, 5 (the approximate number of blocks per square meter) gives you the total number of blocks to be made.

- REMEMBER: Wall area in square meters × 13,5 = Number of blocks. (Also, see the Tables of Figures, pages 237 and 238).

Fig. 1

SANDCRETE BLOCKS

The term sandcrete comes from "concrete" by replacing the first syllable "con" with the word "sand". This is done to make it clear that this building product contains only sand as an aggregate, and no stones. It can also be called "fine-grained concrete" but the new term sandcrete is preferred as it corresponds to landcrete.

A pallet is put into the mould box of the machine (see page 29) and the box is filled with a mixture of cement and sand; then the lid of the machine is used to compact the material to the required size (for proportions of the mix, see the Tables of Figures, page 234).

Unlike landcrete blocks, sandcrete blocks have to be made upon a pallet, as they are too soft to be carried when freshly made. Differently shaped blocks can be made with this machine by changing the height of the pallet or by using inserts.

MAKING THE BLOCKS

Making blocks with this machine is similar to making landcrete blocks.

a. Put one or more pallets into the mould box, according to how thick you want the blocks.

b. Half-fill the mould box with the ready mixed sandcrete.

c. Compact the corners with a piece of wood.

d. Fill the mould box completely and again compact the corners. Add a little more if necessary to fill the box flush to the top edge.

e. Compact the sandcrete by repeatedly banging the heavy lid on it, until the lid fits exactly in its lowest position. Sometimes the lid does not close properly because the mould box is too full. In this case, scrape off a small amount of sandcrete with your trowel and repeat the compaction. If you fail to do this the block will be wedge-shaped and difficult to set in the wall.

f. Open the lid wide and pull the handle to push the block out.

g. Remove both pallet and block at the same time and set them in place for hardening and curing.

- NOTE: Before use, the pallets must be soaked in water thoroughly, to prevent them from bending during the drying process. If this is not done the pallets will probably bend and crack the blocks.

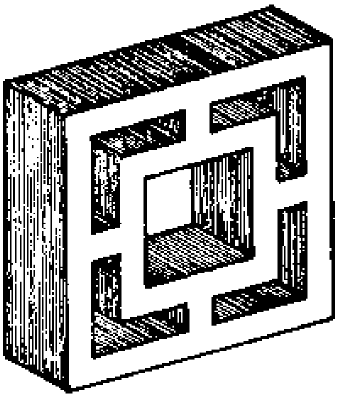

Fig. 1

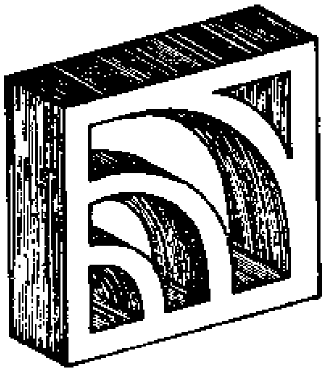

Fig. 2

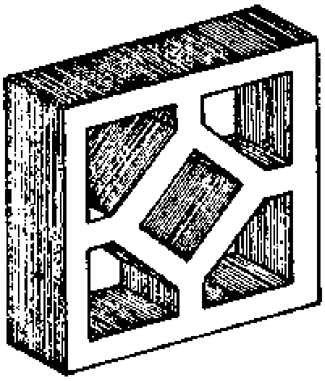

Fig. 3

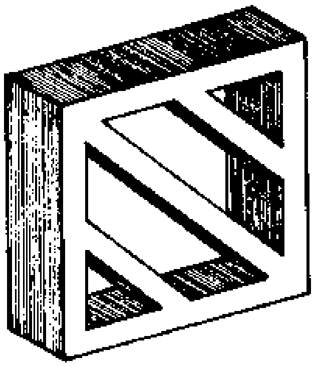

Fig. 4

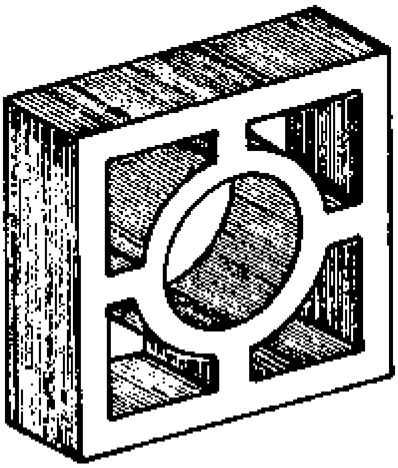

Fig. 5

PLANNING THE WORK

As in the plan of operations for making landcrete blocks (page 187), for sandcrete blocks also the speed and ease of the work depend on how well it is planned.

Fig. 1 on page 190 shows how the block-making can be planned.

DECORATIVE BLOCKS

Originally, a decorative block was understood to be a solid block with decorative textured faces. What we now commonly call decorative block is in fact part of a decorative openwork screen built into an opening. The correct term is "decorative grille" (also spelled "grill").

This kind of block is made in a special iron mould. It can serve several purposes:

- To give an attractive appearance

- To provide light without installing burglar-proofing or any kind of louvres, shutters, etc.

- To provide permanent ventilation without using ventilation blocks

- Or a combination of two or three of the above requirements.

The illustrations of blocks on the opposite page show that almost any design is possible, given a fertile imagination. Remember however that the strength of the blocks depends also on their shape (Figs. 1 to 5).

- NOTE: To make it easier to empty the mould, short pins can be welded onto each corner at the top of the mould. This allows you to tap the pins gently on a hard, level surface; thus loosening the block from the mould (Fig. 6).

Drilling small holes into the bottom of the mould can also make it easier to remove the block. The holes allow air into the mould as the block comes out.

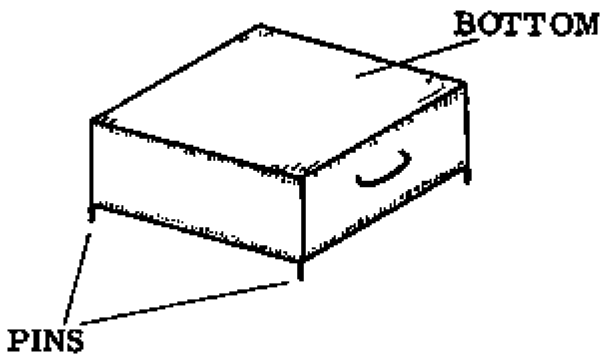

Fig. 6

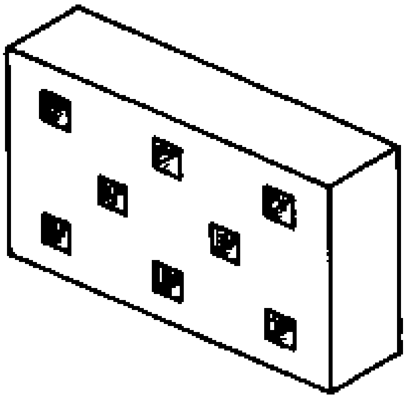

Fig. 1

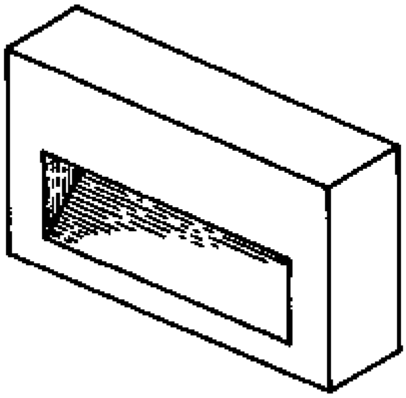

Fig. 2

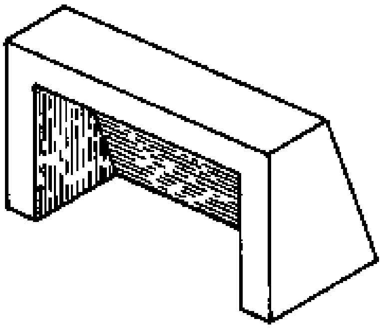

Fig. 3

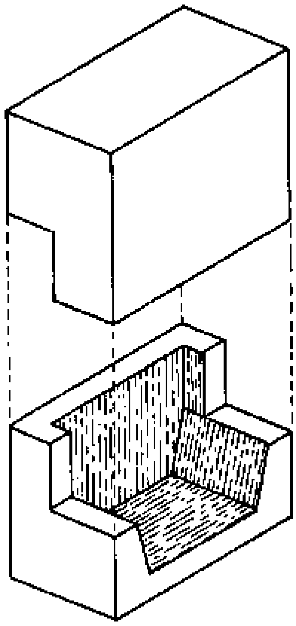

Fig. 4

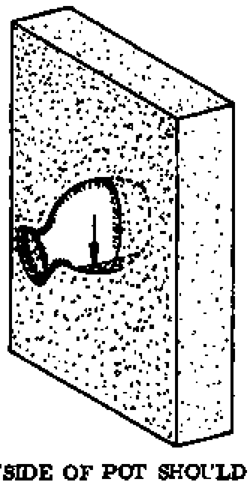

Fig. 5

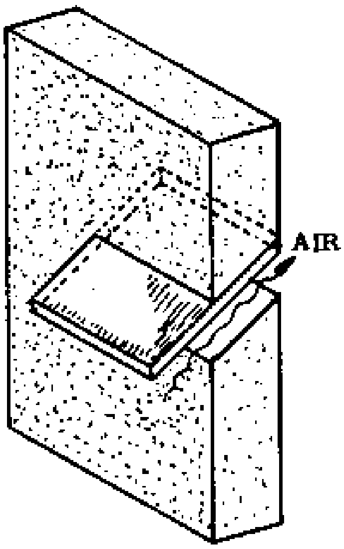

Fig. 6

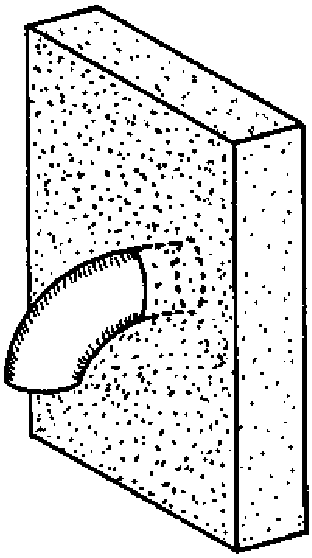

Fig. 7

VENTILATING BLOCKS

These are blocks which have an opening (or several openings) in them. They are used to ventilate rooms, stores, the spaces above ceilings etc.

There are various types of ventilating blocks. Some are designed to keep out rain, others include mosquito-proofing or a decorative front face (Figs. 1, 2 & 3).

In cases where a maximum amount of ventilation is desired, it is advisable to make a ventilating unit which is constructed out of two identical halves (Fig. 4). The inside of this unit can be painted in a bright colour, to increase the amount of light inside the room.

Simply shaped blocks for ventilation can be made in the sandcrete block machine by inserting wooden blocks according to the desired shape.

More complicated designs usually require a specially made wooden mould. The advantage of this kind of mould is that any size and shape of block can be made.

Pre-cast sandcrete or concrete are not the only choices of materials for ventilating units. Local potters' skills in baking earthenware can be used and one can design ventilating units from clay. Existing clay shapes can be used, such as tiles and pots (Figs. 5 & 6) or new shapes can be invented (Fig. 7).

When designing these ventilating units keep in mind the direction of the driving rain. Make sure that the inside of the unit is higher than the outside, and that there is no place for water to become trapped inside the unit to make a breeding place for mosquitos (Fig. 5).

Apart from the above considerations, there is no limit to the imagination of the Rural Builder in designing different shapes and kinds of ventilating units.

PRECAST CONCRETE MEMBERS

Many of the components of a building are prefabricated. This means that they are made in advance at any time and place, and can be used for any building. The most common examples are the various sorts of blocks, plywood, roofing sheets etc.

In the same way, many reinforced concrete members of the structure can be made well in advance so that they are ready to be used as the construction proceeds and they are needed. These are referred to as "precast" members, as opposed to the "cast-in-situ" members.

Generally speaking, prefabricated construction is divided into two classes with regard to buildings:

a - Prefabricated units produced in a factory and transported to the building site
b - Units produced by the contractor in a yard next to the building site.

Since Rural Building is understood to be conventional building and not factory production, the first method does not apply to us.

It is becoming more and more common however for the contractor to prefabricate members near the building site, although the possibilities of this method are limited to small-scale applications.

In Rural Building the most frequently made precast concrete members are:

- REINFORCED CONCRETE LINTELS: These cannot exceed 1,5 m in their length, as otherwise they will be too heavy and impossible to set in place without using a lifting device.

- REINFORCED CONCRETE POSTS: For fencing purposes (Fig. 1).

- REINFORCED CONCRETE PILLARS: These should not be too heavy to be set up under rural conditions.

- CONCRETE COPINGS OR CAPPINGS: These are of various shapes, with or without reinforcement (Fig. 2).

- REINFORCED CONCRETE SLABS: Of limited size and thickness, used to cover manholes or to serve as draining boards in kitchens, etc.

NOTES:

PLANNING THE WORK

All the plans and if possible, detailed drawings must be available before you start to make precast concrete members. Careful planning, supervision and performance are all necessary in order to obtain the desired product.

- SAVING TIME: As soon as the required materials are available, a group of the workers can start production of precast concrete members. The earlier they begin the better, because the concrete needs to be cured for some time before it is used in the building. By the time the precast member, for example a lintel, is needed the curing process will be complete and the lintel can simply be set into place.

In contrast to the cast-in-situ method, this method allows construction to proceed without delays caused by waiting for concrete to harden; and without being hindered by shuttering and strutting. In this way the total construction time is shortened.

This time-saving can become very important, for example if the wet season is approaching and the building has to be done before that time.

- SAVING MATERIALS: Since precast concrete members can simply be made on levelled ground, there is no need for poles and braces or other strutting to hold up the shuttering. Curing is also made much easier.

In addition, the same formwork can be used repeatedly if several members of the same size and shape have to be made.

If there is no proper storage space for the cement on a job, it is better to precast as many members as possible; thereby using up the cement before it gets spoiled.

> - NOTE: The more time, materials and money you save, the happier your client will be. Not only that, but your reputation as a Rural Builder will grow in the eyes of the people around you and be appreciated in the society.

NOTES:

GLUE

Glue is a liquid which is used to stick materials together, particularly on wooden surfaces.

In Ghana's Upper Region, the Rural Builder cannot use glue very often, because of the problems caused by the difference in humidity between the dry and rainy seasons. Glue is sometimes applied to make joints stronger, but it should not be used alone. There must always be some additional fastening; either screws or nails. To rely on joints fastened simply with glue is asking for trouble.

Three points should be kept in mind when you use glue:

a - The parts to be glued have to be in close contact.
b - There must be a large area of contact for glueing.
c - End-grain does not glue well, so a joint which consists mostly of end-grain will be weak.

There are many different glues but in Rural Building we use only two kinds; synthetic glue and contact glue.

- SYNTHETIC GLUE: The most common synthetic glue is PVA (polyvinyl acetate) glue. It is a milk-white glue.

The parts to be glued should be clean and well-fitting. The parts are squeezed together immediately after the glue has been applied, and clamped together until the glue has set hard. The joint will have considerable strength after the glue has set for one hour. PVA glue is not waterproof. If the joint must be waterproof, special kinds of glue have to be used.

- CONTACT GLUE: This glue is used primarily to glue laminated plastics such as Formica or similiar materials to sheet materials.

The glue is spread evenly over both surfaces. A toothed spatula can be used for this purpose. After fifteen minutes the surfaces are pressed together. It is important to take care that the surfaces are exactly in the correct position when they are put together. Once the surfaces stick they cannot be separated again for adjustment.

Take care that no air is trapped between the two surfaces when they are glued, because afterwards it will be impossible to get the air bubbles out.

PROTECTIVE FINISHES

In Rural Building we have the following finishes which are applied on wood or masonry work:

- Oil paint
- Synthetic paint
- White wash
- Cement paint
- PVA Emulsion paint
- Varnish

OIL PAINT

The traditional type of oil paint has a vegetable oil base (linseed oil) and a pigment which gives it colour.

Oil paint is usually applied in three coats. Each coat is of a different composition and they cannot be mixed.

- Priming coat
- Undercoat
- Finishing coat

Follow the directions on the tin when using these paints. Oil paints can be diluted only with thinners, such as turpentine.

SYNTHETIC PAINT

Synthetic paints have a chemical base and a pigment. These paints dry more quickly than oil paints and they are more weather resistant.

Read the directions on the tin before using the paint.

WHITE WASH

White wash is often used for interior work. It is composed of lime and water and it is not water resistant. Its lack of water resistance and its poor wearing qualities make it inferior to emulsion paint as a finish for outside surfaces.

White wash is often used as a priming coat for emulsion paints. It fills in the pores in cement or plaster and makes the surface smoother so that less emulsion paint is needed.

After mixing the lime with water it is advisable to leave the white wash for a day to stand, to be sure that no more chemical reactions are taking place. Follow the manufacturer's directions on the label when mixing the white wash.

CEMENT PAINT

Cement paints are often used externally. They contain white or coloured Portland cement and are sold in powder form. This paint should be made workable with water only; when dry it forms a waterproof seal on the concrete or masonry.

PVA EMULSION PAINT

Polyvinyl acetate emulsion paint has a latex (rubber) base and a pigment for the colouring. This paint is used mostly for internal and external masonry work.

The latex paint can be diluted with water if necessary to improve its workability. The paint should be applied in thin layers and the directions on the label should be followed. Read them before you start work.

VARNISH

Varnishes are used to protect wood. There are two kinds of varnish: oil or spirit. Oil varnish can be used for external work. It is diluted if necessary with turpentine.

Spirit varnish is only used for internal work such as for furniture. This varnish is not very strong or water resistant. Spirit varnish can be diluted with commercial alcohol.

PAINTS AND VARNISHES: PURCHASING

Paints and varnishes are sold in containers of one or more litres. On each container there should be a description of how to apply the paint or varnish. There should also be a date stamped on the container, to indicate how long the paint or varnish will last (when it will be too old to use any longer).

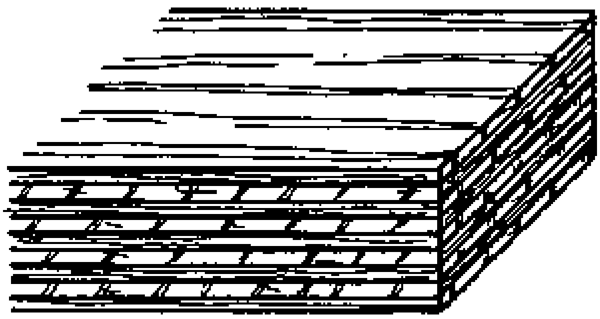
Fig. 4



9-PLY-BOARD

Fig. 5

SHEET MATERIALS

Even as new and wonderful materials are becoming available to the Rural Builder, timber is still in very great demand. Wood is easy to work with, adaptable and durable when cared for properly.

Sheet materials manufactured from sawmill wastes are used more and more, both because they save money and because they do not have some of the problems with shrinking or splitting that affect natural materials.

The sheet materials we deal with in Rural Building are: plywood, blockboard, hard board, chip board and decorative laminated plastics.

PLYWOOD

Plywood manufacture is the oldest means of improving the properties of timber. Large sheets can be made, free from defects and unaffected by shrinkage and splitting.

The plywood is made by glueing together several thin layers, called plies or veneers, so that the grains of each run crosswise to its neighbours. There is always an odd number of plies so that the grains of the two outer layers run in the same direction. This is so that the plywood remains flat (Fig. 1).

Plywood is so useful because of its special properties:

- It is stable and will not expand or shrink like solid timber; however it will absorb moisture and may tend to curl as the surface layers expand a bit.

- It is very strong because of the crossed grain structure. Even the thinnest plywood cannot be split.

The number of plies can be from 3 to 9, making sheets which are 3 to 25 mm thick (Figs. 2 to 5).

NOTES:

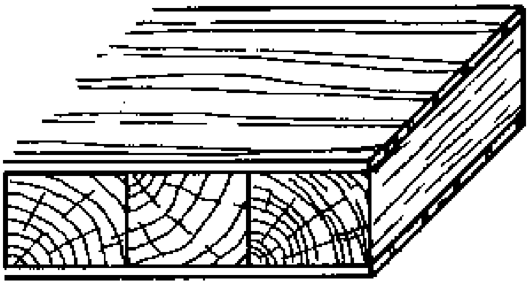


Fig. 1

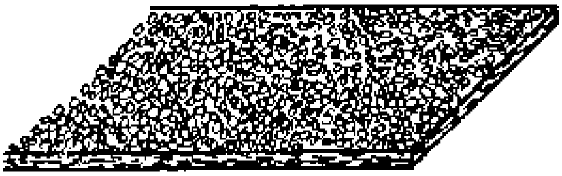

Fig. 2

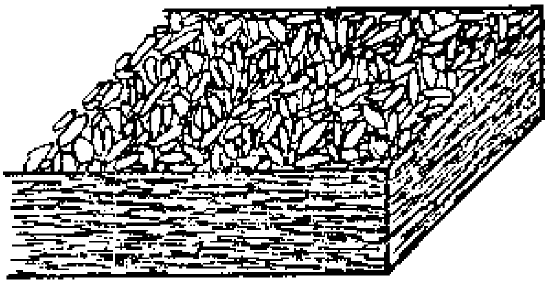

Fig. 3

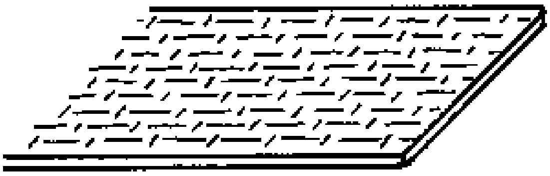

Fig. 4

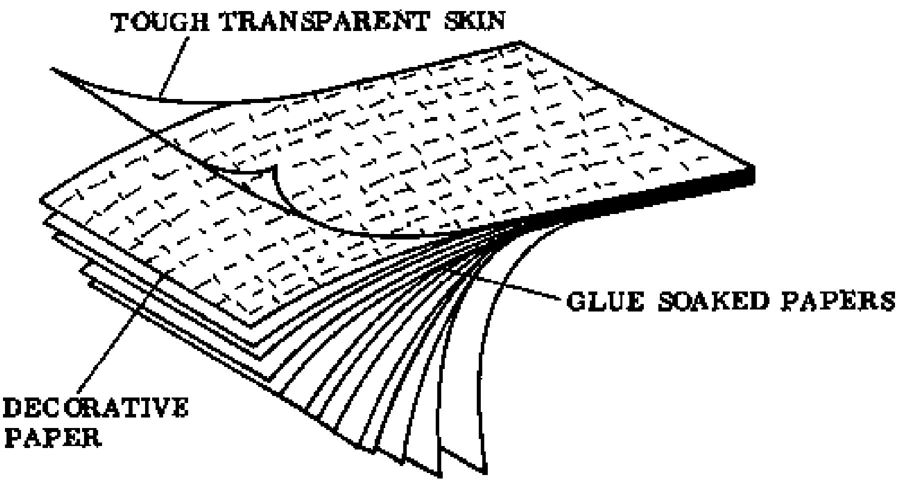

Fig. 5

BLOCK BOARD

This is a variation of plywood. A core of wood strips is glued together and faced with one or more veneers on each side (Fig. 1).

HARD BOARD

Low quality wood and wood wastes are ground and combined with water and glue to form a pulp. This mixture is spread between smooth aluminium sheets under great heat, forming a board. Hard boards have a smooth surface and a coarse side. They are available in thicknesses from 3 to 6 mm (Fig. 2).

CHIP BOARD

This is made from wood chips bonded together with glue. The chips are sorted, dried and mixed with the glue. Then they are spread on a plate and bonded with great heat and pressure. Chip boards are made in thicknesses from 6 to 60 mm (Fig. 3).

The edges of chip boards should always be protected, as they tend to split. This is done by glueing wood strips around the edges.

DECORATIVE LAMINATED PLASTIC

Laminated means consisting of a number of thin layers. Laminated plastics such as Formica (Fig. 4) are made by assembling many paper sheets soaked in glue. A decorative paper, also soaked in glue, is laid on top and over this is laid a transparent paper soaked in a very hard transparent glue which gives a tough surface. The assembled layers are placed between polished steel sheets and pressed at a high temperature (Fig. 5).

Decorative laminated plastics are durable, clean looking, smooth and attractive. They are made in a variety of patterns.

WOOD FASTENINGS

NAILS

Nailing is a fairly strong, cheap and quick method of fastening wood (see Rural Building, Basic Knowledge, page 92).

Nails have a head, shank and point and are usually made from mild steel wire. Galvanized, copper-plated or aluminium nails are used for work which will be in contact with water.

In Rural Building we use mostly wire nails. We group these into two classes: wire nails with flat heads and wire nails with very small heads, known as lost head nails. Some nails are used for special purposes, like staples, concrete nails and roofing nails.

- WIRE NAILS WITH FLAT HEADS: These are nails with large flat heads (Fig. 1). The head prevents the fastened member from being pulled off over the head of the nail.

These nails are available in sizes from 7 to 310 mm long.

- WIRE NAILS WITH SMALL HEADS (LOST HEAD NAILS): These are wire nails with very small heads which can be punched or set below the surface of the wood and covered with putty. The disadvantage of this nail is that the nailhead can be easily pulled through the wood, so it cannot be used for heavy construction work (Fig. 2).

These nails are available in sizes from 7 to 100 mm long. Small lost head nails are called panel pins.

- CONCRETE NAILS: These are hardened steel nails, available in different shapes and sizes. They are used to fix things to concrete or masonry (Fig. 3).

- STAPLES: These are U-shaped nails (Fig. 4) with two points. They are used to fasten wires and screens to walls or timber.

- ROOFING NAILS AND WASHERS: Special roofing nails are used for fixing corrugated sheet materials. They should be aluminium or galvanized metal to prevent rust, which could cause the nailhead to break off. The nails must be long enough to go at least 2 cm into the wood.

Drive screws, or screw nails as they are sometimes called, are commonly used for roofing (Figs. 5 & 6) and they have largely replaced nails with plain shanks (Fig. 7). The drive screws are galvanized and the shank is 2 mm or more in diameter, with a steep thread around it.

Drive screws can be driven in with a hammer, but they are very difficult to pull out again.

There are different types: either with a metal washer already attached to the head of the nail (spring head roofing nail, Fig. 6, page 206), or with loose metal washers (Figs. 5 & 7, page 206)

The washers or the spring heads prevent the nails from being pulled through the roofing sheet. They should be thick and wide enough (at least 2 cm in diameter) so that they secure the sheets well.

Roofing felt is always used under the washer to prevent leaking. The felt should be larger in diameter than the washer. Place the washers correctly: the hollow side should face the roofing felt and the sheet.

ORDERING NAILS

When ordering nails, state the kind of nail; the thickness (in 1/10 mm) and the length (in mm). Also state the material of the nails.

Example: Lost head nails; 16 x 30; steel

NOTES:

SCREWS

After nails, screws are the next most common type of wood fastener used In Rural Building. Screws are superior to nails because:

- they have greater holding power,
- they cause less shock to the work when driven into it,
- and they are easily removed, without damage to the work.

Screws are made of mild steel, brass, copper or they are galvanized. Usually mild steel screws are used because they are stronger than the copper or brass ones.

The parts of a screw are: the head (a), the slot (b), the shank (c), the thread (d), the point (e) and the core (f) (Fig. 1, page 210).

Screws are classified according to the shape of their heads:

- Countersunk head screws (Fig. 1, page 210)
- Round head screws (Fig. 2, page 210)
- Raised countersunk head screws (Fig. 3, page 210)
- Coach screws (Fig. 4, page 210).

Posidriv or Phillips screws have a head which is not slotted across the full width like common wood screws. They have a cross-shaped recess into which a special screwdriver fits (see page 76).

- COUNTERSUNK HEAD SCREWS: The head of this kind of screw is flat on top and tapering underneath. The length is measured from the point to the top of the head (Fig. 1, page 210).

These are general purpose screws, used where the head of the screw must be flush with or below the surface of the wood.

- ROUND HEAD SCREWS: The head of these screws is round on top and flat underneath, and the length is measured from the underside of the head to the point (Fig. 2, page 210).

These are used only where the head can be visible and can project above the surface of the wood, and when fixing light metal, where the metal is too thin for countersinking.

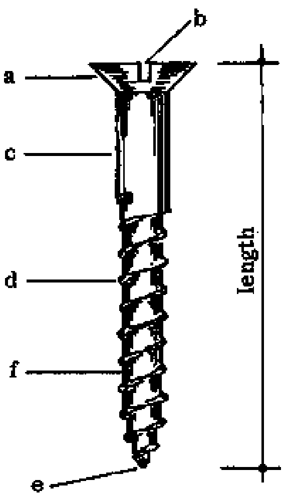

Fig. 1

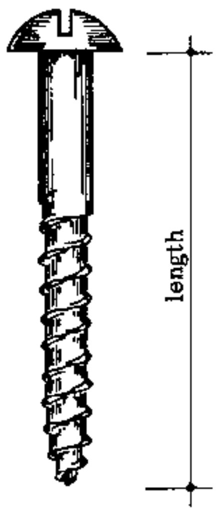

Fig. 2

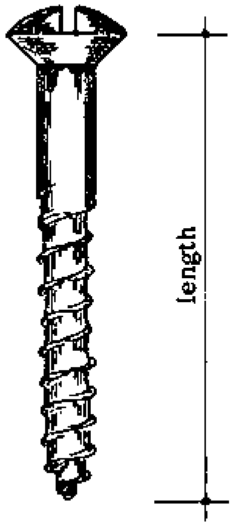

Fig. 3

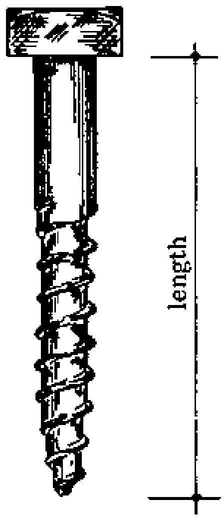

Fig. 4

- RAISED COUNTERSUNK HEAD SCREWS: The head of this screw combines the round and countersunk heads; round on top, tapering underneath. It is stronger than the round head screw because the head is less likely to break off. The length is measured as indicated in Fig. 3.

These screws are used in fixing heavy fittings and thick sheet metal, where strength is needed.

- COACH SCREWS: This is a strong screw with a square head. Unlike other wood screws, it is turned with a spanner. Always put a metal washer under the head to prevent damage to the wood surface. The length is measured from the point to the underside of the head (Fig. 4).

These are used for heavy construction work, for gate hinges, carriage work etc, where the head doesn't interfere.

ORDERING SCREWS

Screws are sold by number or in boxes containing a gross (144 screws). When ordering screws state the following in the order:

- thickness in mm
- length in mm
- kind of screw
- kind of metal
- amount needed

For example: 3 × 30; round head; brass screws; 3 gross or,
5 × 50; coach screw, mild steel with washers; 2 gross.

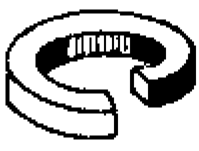

Fig. 4

BOLTS AND NUTS

Bolts and nuts are yet another means of fastening two pieces together. Bolts have hexagonal heads and are tightened up with the nuts. Bolts and nuts are used for heavy construction work (Fig. 1).

If bolts are used in timber, washers must be laid under the nut to prevent it from sinking into the wood (Fig. 3).

COACH BOLT

These bolts have oval heads and a square shank just under the head. This is so that the bolt grips the wood and doesn't turn when the nut is tightened up (Fig. 2).

The advantage of these bolts is that the head doesn't project up, since it is rounded and pulled into the wood.

WASHERS

A washer must always be used under the nut with both coach and regular type bolts. Never put a washer under the head of a coach bolt.

Washers can be made locally from a square piece of metal with a hole drilled in it.

SPRING WASHER

To prevent the nut from loosening when it is fastening metal to metal, a spring washer can be put between the metal and the nut. (Fig. 4).

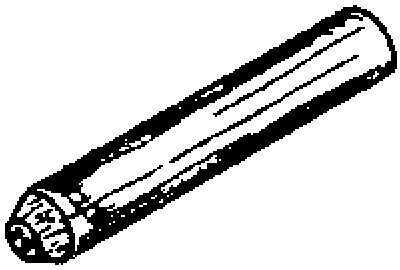

Fig. 2

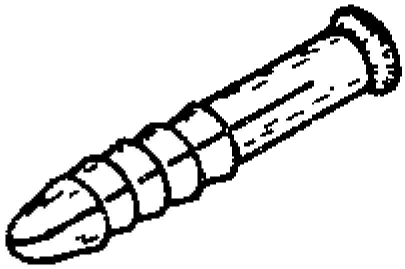

Fig. 3

ANCHORS

Fastening wood or other materials to concrete or masonry can be a problem. Often a screw will not hold in a landcrete block, or will not grip in concrete. Anchors can be used to solve this problem.

Anchors can be classed in two groups:

- anchors fixed during the initial construction and
- anchors which are fixed after the initial construction.

The first type of anchor can be an iron rod set into the wall during walling or casting, as is often done with the door frames. Threaded iron rods can be used, to receive a nut later on (Fig. 1).

Another way is to insert wooden blocks in the masonry; into which screws, etc. can be driven later. For maximum strength the wooden block should be dovetail shaped (Fig. 1) and it should be cut and fixed in a way that its shrinkage will have as little effect as possible on the wall.

The second group are the devices used to fix a piece to an already existing masonry or concrete work. The most simple of these is a wooden plug. A hole is chiselled or drilled into the masonry and into that hole is inserted a cylindrical plug of wood, which has the same diameter as the hole. The length of the plug should be a little less than the depth of the hole. The plug is made out of hard dry wood and the end which enters the wall is chamfered to enter smoothly. When a screw is driven into the plug, the wood will expand or even crack and the screw is wedged into position (Fig. 2).

More complicated devices, all sharing the same principle of holding a screw or nail by expanding, are now available. The most common one is a plastic plug (Fig. 3).

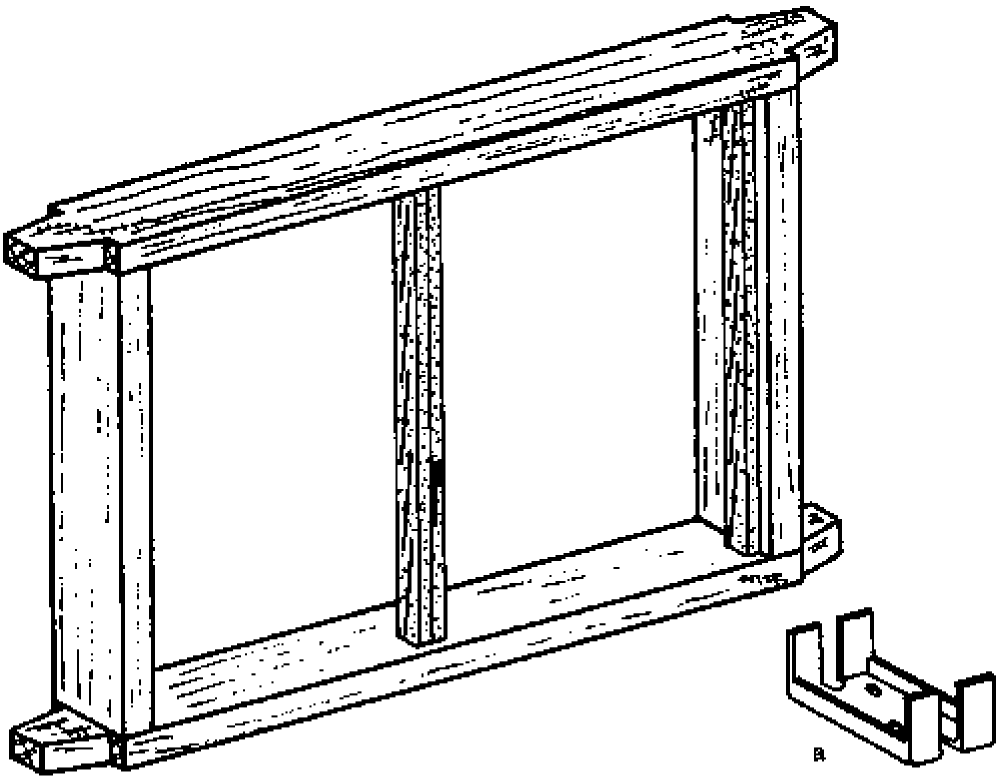

Fig. 3

DOOR AND WINDOW HARDWARE

LOUVRE WINDOWS

Windows with glass louvres are often used in the tropics because of their various advantages: they can be opened without any waste of space in the room and in the closed position they still admit light to the room. Their disadvantage is that it is very difficult to make them water-tight.

Louvre windows are installed ready-made into the window frame (Fig. 1). When the glasses are inserted in the window, wooden beads or ready-made aluminium waterbars are fitted to the head and cill to keep out dust and rain (Fig. 2).

In wide windows where two sets of louvres are installed in the frame, the metal posts of the louvre frame are fixed together in the middle, forming a metal mullion (Fig. 3). A separate wooden mullion is therefore not necessary. We will learn more in the Construction book (windows) about the installation of a self-mullioning louvre frame. Specially made mullion connectors are sold in a separate set (Fig. 3a).

Louvre windows are available in mild steel or aluminium frames. The aluminium frames need very little maintenance, but they are more expensive and less strong.

The size of the window frame is determined by the size and number of the louvre glasses. The inside width is:

- the length of the glass plus 3, 8 cm (the thickness of two frames).

If two or more louvres are set across the width of the window, then for each additional glass 3, 8 cm, plus the glass length must be added to the inside width of the frame.

The inside height of the window frame is determined by the number of louvre glasses.

Inside height (in cm) of window frames according to the number of louvre glasses:

No.	2	3	4	5	6	7	8	9	10	11	12	13	14
Ht.	30,5	44,5	58,4	72,4	86,4	100,3	114,3	128,3	142,2	156,2	170,2	184,2	198,1

All the above measurements are for 6 in. (15 cm) glasses. If you have other sizes, follow the manufacturer's instructions.

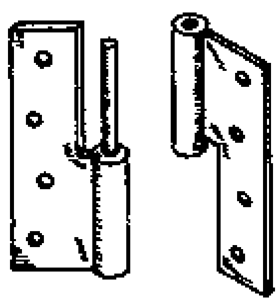

Fig. 2

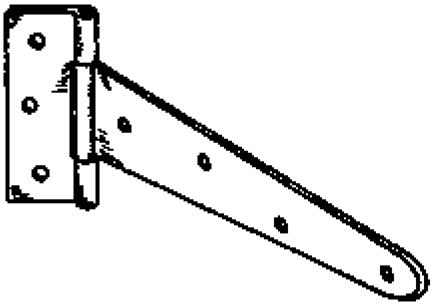

Fig. 3

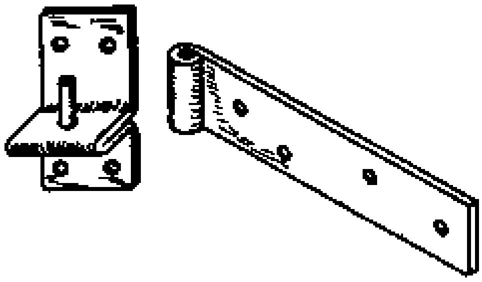

Fig. 4

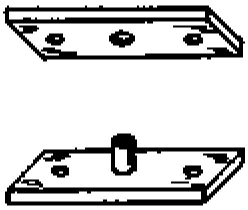

Fig. 5

HINGES

Hinges are available in almost countless different shapes, sizes and materials. The most common materials are steel, brass, and copper; or sometimes the hinge is only plated with brass or copper.

In Rural Building, we deal only with the most common types of hinges, which are butt hinges, H-hinges (Parliament hinges), T-hinges, band-and-hook hinges, and pivot hinges.

- BUTT HINGE: The ordinary steel butt hinge is cheap and durable, and it is the most common hinge for doors and casements (Fig. 1). It consists of two halves, also called leaves or flaps, held together by a pin. The pin may be removable or permanently fixed. If the pin can be removed from the outside when the door is shut and locked, the door is not burglar-proof.

When the door is shut, the two leaves (one attaches to the door post and the other to the hanging stile of the door) are folded together. The leaves are usually set into recesses in the door and post.

- H-HINGE (PARLIAMENT HINGE): The H-hinge, sometimes called the Parliament hinge, is similar to the butt hinge. It consists of two leaves, each with a knuckle. The pin is set permanently into the knuckle of one leaf. The H-hinge is installed in the same way as the butt hinge (Fig. 2).

- T-HINGE: T-hinges are mostly used for large and heavy doors, gates and ledged and battened doors. They are available in different sizes.

The hinge (Fig. 3) consists of a long mild steel strap, which is fixed to the outside of the door; and a cross bar which is hinged to the strap and attached with screws to the post of the door frame.

For security reasons, the strap of the T-hinge should be fixed to the door with at least one coach bolt, so that no one can unscrew the hinge to enter the building.

NOTES:

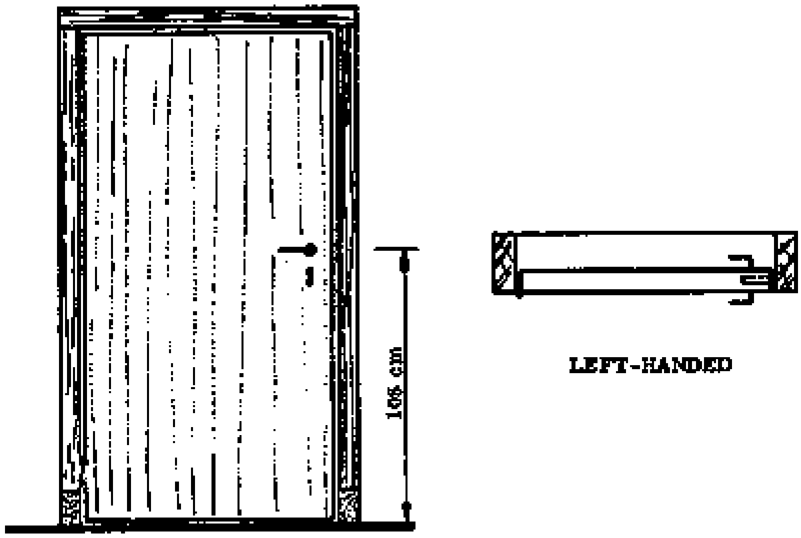

Fig. 1

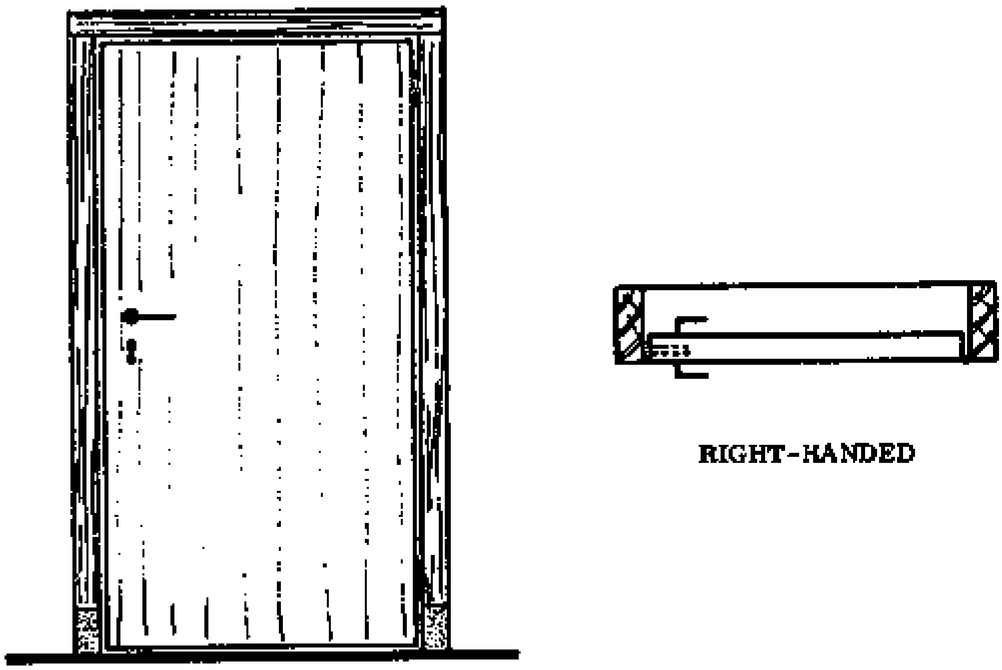

Fig. 2

- BAND-AND-HOOK HINGE: The band -aid-hook hinge is closely related to the T-hinge. It consists of an iron strip called the band, which drops onto a pin called the hook, which is attached to the frame of the door or window (Fig. 4, page 218).

They are used and installed in the same way as T-hinges.

- PIVOT HINGE: For windows, we sometimes use pivot hinges. These consist simply of a plate with a pin, which fits into a hole in another plate (Fig. 5, page 218).

LOCKS AND FITTINGS

There are many kinds of locks and fittings available for doors and casements. The choice between them depends on the type of door or casement and its function.

Doors and casements may be either left or right-handed. When the door opens towards you with the hinges on the left, it is a left-handed door (Fig. 1); if the hinges are on the right, the door is said to be right-handed (Fig. 2).

Some types of locks can be used on only one type of door, either right or left-handed. Therefore, we have to know whether the doors are right or left-handed before we order the locks, so we can buy the correct ones. Some types of locks have a latch bolt which can be changed to work in either type of door.

The most common types of locks are:

- the mortice lock
- the rimlock
- the padlock

The most common types of fittings are:

- the hasp and staple
- the barrel bolt
- the tower bolt
- the casement fastener

Locks are normally fixed at a height of 105 cm, measured from the floor to the centre of the handle (Fig. 1).

NOTES:

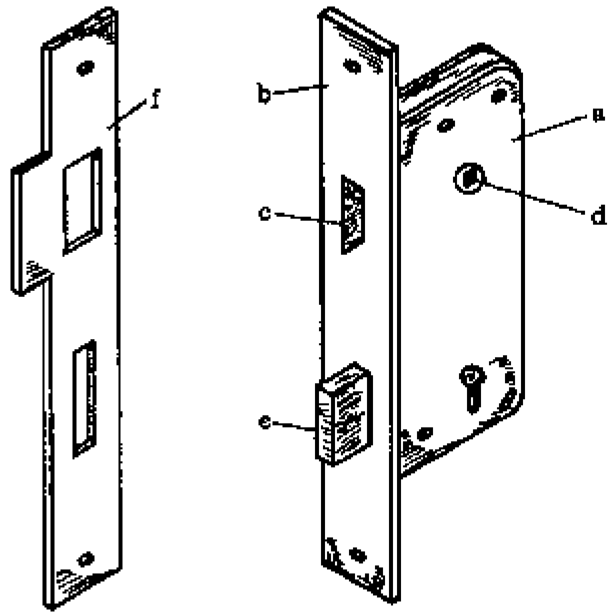

Fig. 1

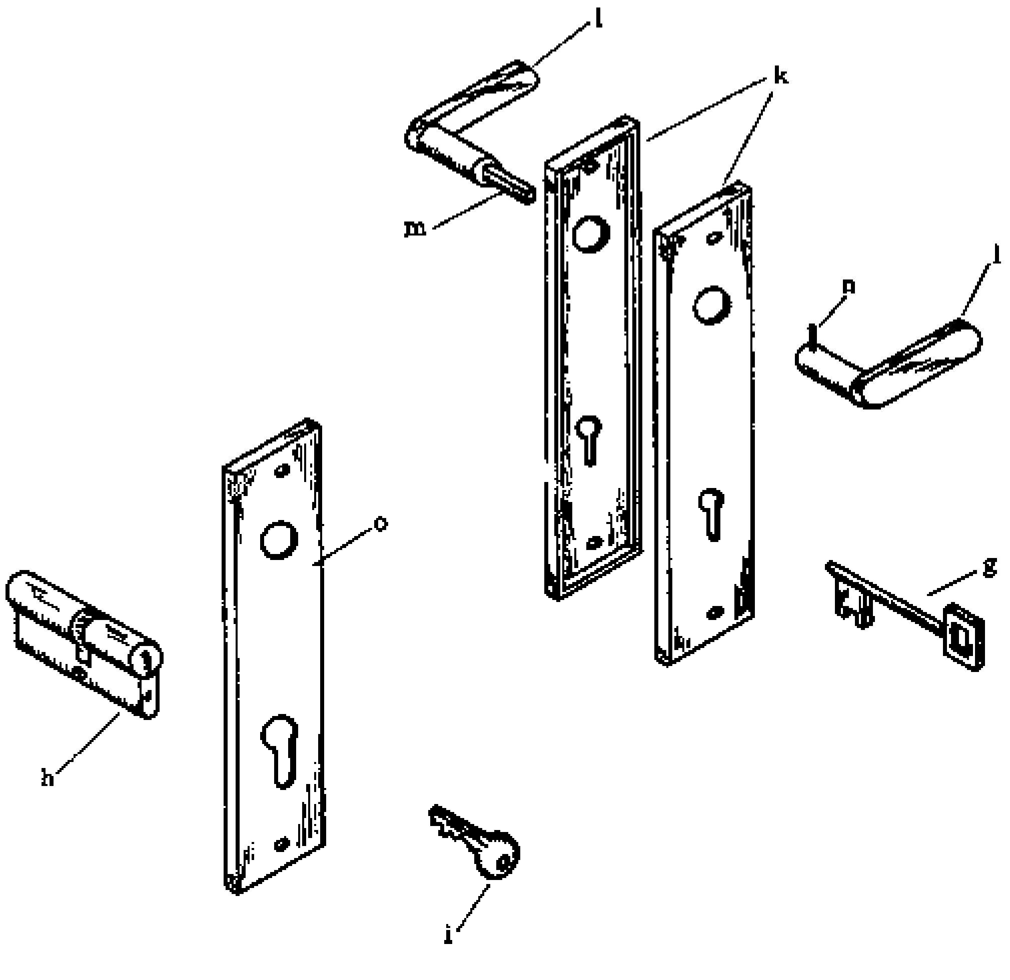

Fig. 2

- MORTICE LOCKS: Mortice locks (Fig. 1) consist of a stock (a), faceplate (b) and the latch bolt (c) moved by the handle. The handle fits into the bush (d) and there is a lock bolt (e) moved by the key. The two bolts fit into holes in the striking plate (f) which is attached by screws to the door post.

As the name suggests, the mortice lock fits into a mortice in the edge of the door. The stock should fit tightly against the sides of the mortice so that the door itself takes the strain, not the screws which only hold the lock in position.

Mortice locks can only be installed in doors which are thick enough to receive a mortice. They are difficult to force open, since they are inside the door.

Mortice locks are locked either with an ordinary key (g), which moves small levers inside the stock to push the lock bolt in and out, or with a locking cylinder (h), which operates the locking mechanism inside the stock. The advantage of the locking cylinder is that it is more secure, since a special key is needed to open and lock it (i).

- DOOR FURNITURE FOR MORTICE LOCKS: The door furniture (Fig. 2) consists of two leaf plates (k), two handles (1) and a spindle (m). The spindle is permanently fixed in one handle and secured in the other by a pin (n). The handle with the pin should always be inside the door, so that the pin cannot be loosened from the outside.

The leaf plates are attached to both sides of the door with screws; or better, with specially made bolts which cannot be torn out easily. The leaf plates hold the handle in place and prevent damage to the keyhole. Sometimes separate leaf plates are used for the keyhole and the handle.

The leaf plate for a mortice lock with a cylinder (o) has an opening into which the locking cylinder fits, instead of a keyhole.

NOTES:

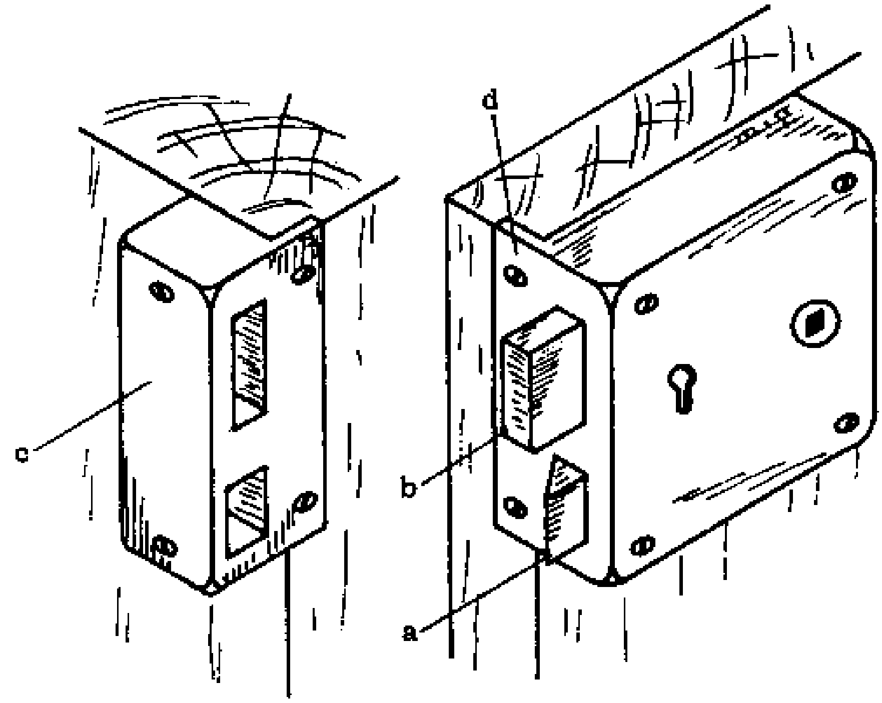

Fig. 1

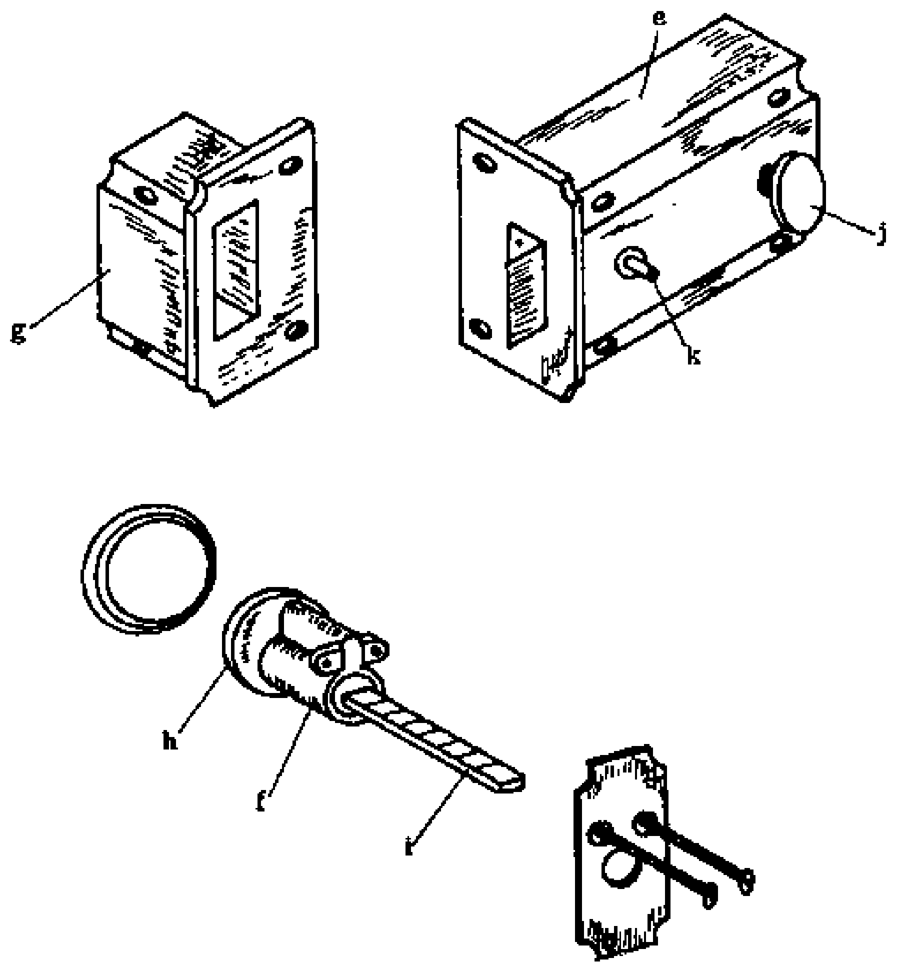

Fig. 2

- RIM LOCKS: Rim locks (Fig. 1) have a latch bolt (a) operated by a handle and a lock bolt (b) operated by a key from the outside or inside of the door. This kind of lock is attached with screws to the inside face of the door and the bolts shoot into a staple (c). There is a face plate (d) which is attached with screws to the door edge.

On the outside of the door, two round plates are attached with screws, one to hold the handle and the other to cover the keyhole. The handles have a square spindle which fits into the bush of the lock.

These locks are used on doors which are too thin to have mortice locks installed in them. Like the mortice lock, the rim lock is available with either an ordinary key locking system or with a locking cylinder.

- CYLINDER RIM NIGHT LATCH: This is a special kind of rim lock. It consists (Fig. 2) of a latch (e), a locking cylinder (f) and a staple (g). There Is a face plate (h) which is part of the shell of the cylinder. The spindle (i) is fixed in the cylinder.

The latch bolt is operated from the outside by a key which rotates the spindle. The spindle moves the bolt mechanism inside the latch.

The bolt may also be shot back from the staple by turning the knob (j) of the latch from the inside. The locking arm (k) is used to fix the bolt in place, so that it cannot be operated from either side by the key or the knob, making the lock more secure.

- PADLOCKS: Padlocks have a ring which locks into a body. The locking mechanism can be either a lever mechanism or a locking cylinder, as with the mortice lock.

NOTES:

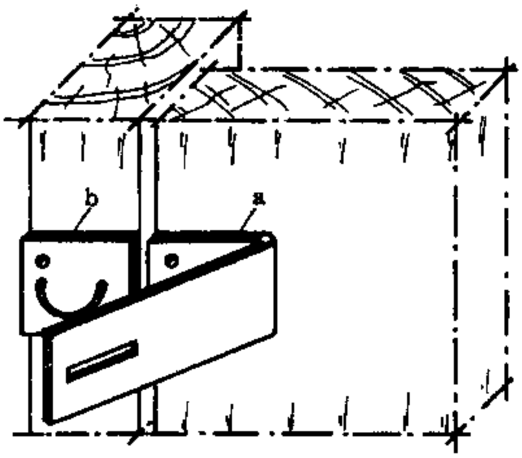

Fig. 1

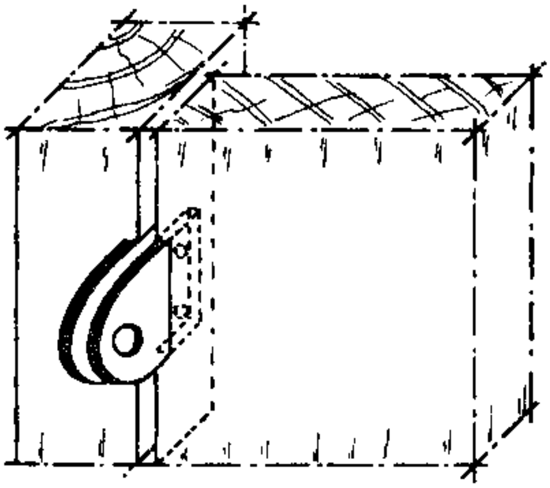

Fig. 2

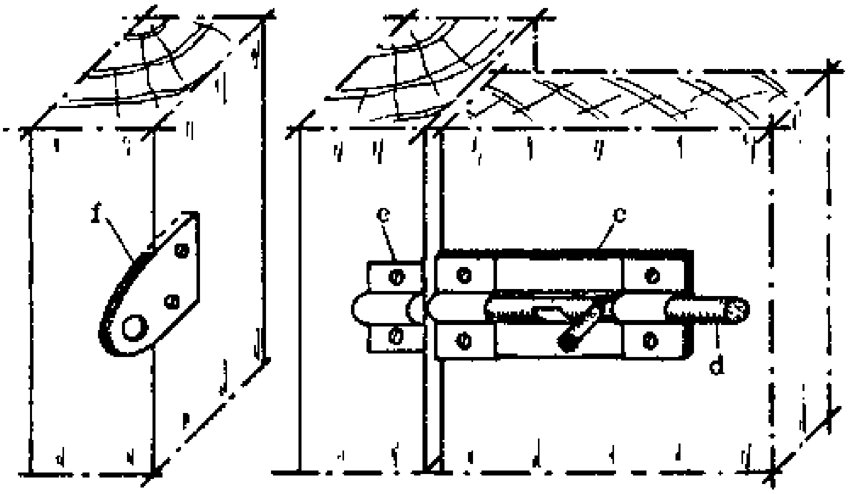

Fig. 3

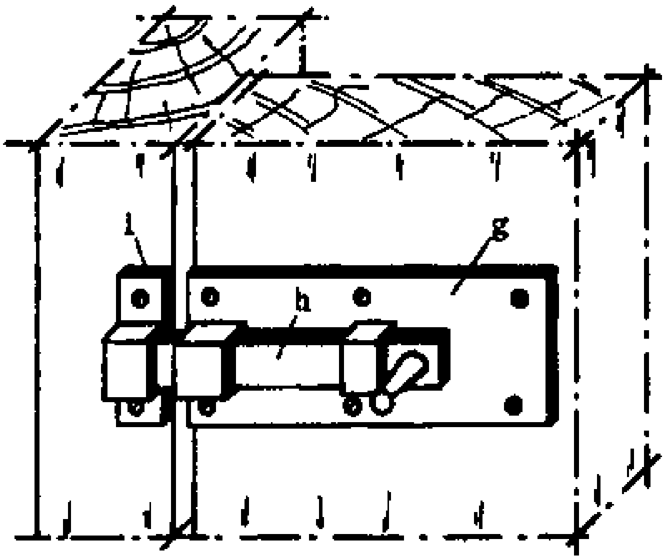

Fig. 4

- HASP AND STAPLE: The hasp and staple (Fig. 1) is usually used in combination with a padlock. It is installed on doors which do not have to be opened very often, as it takes time to open it.

The hasp (a) is screwed to the door or casement and the staple (b) to the frame. Some types of hasp and staple can be unscrewed from the outside. For security reasons, these types should be attached with bolts and nuts rather than with screws. The leaf of the hasp should be installed so that when closed it covers the screws.

An alternative to the hasp and staple is the device shown in Fig. 2. This is an efficient way of locking doors with a padlock and the parts can be made by hand. Two small plates have holes drilled in them for the padlock and screws to pass through. The plates are attached with screws to the edge of the door and the post.

- BARREL BOLTS: The barrel bolt (Fig. 3) consists of a plate (c) with a round bolt (d). The bolt engages in a staple (e). The plate is attached with screws to the inside of the door or window and the staple is attached to the frame. Barrel bolts are often used to lock casements.

A more effective staple can be made by hand (f), in the same way as the device in Fig. 2 above. It provides more security than the staple normally supplied with the barrel bolt since the screws are on the inside face of the post and cannot be so easily forced out. The bolt plate can also be attached with bolts and nuts to make it more secure.

- TOWER BOLTS: A tower bolt (Fig. 4) consists of a plate (g) with a flat bolt (h) fitted in it. The bolt engages in a staple (i) or in a striking plate in the frame. the plate and bolt are usually fixed on the door or casement.

NOTES:

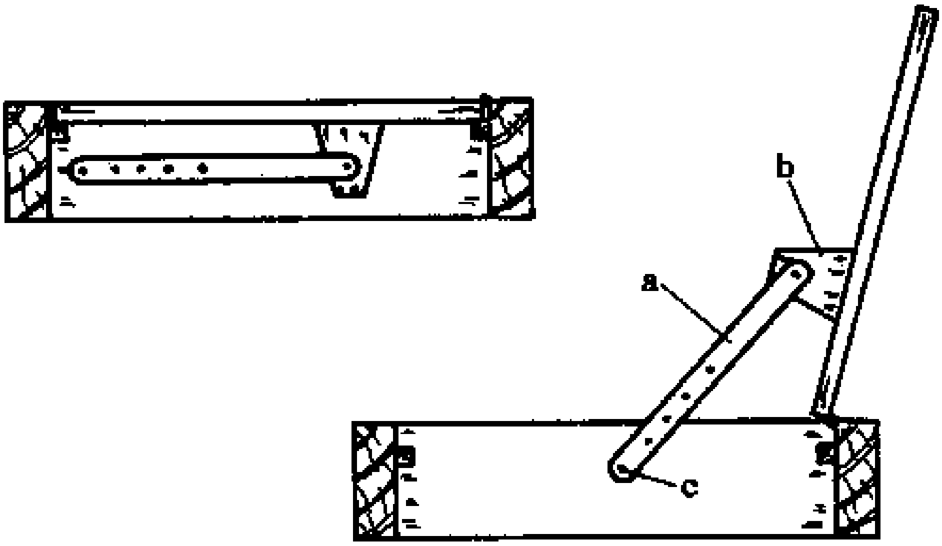

Fig. 1

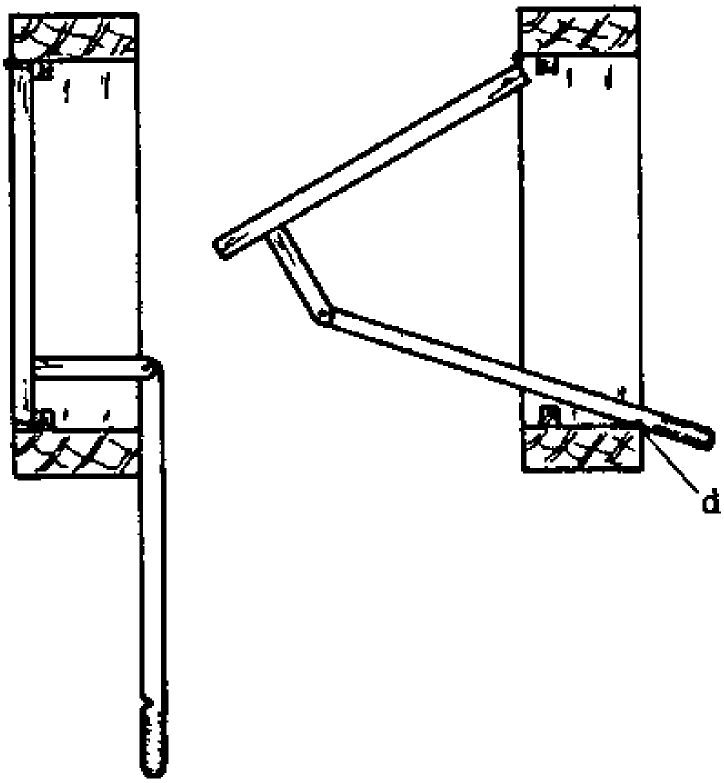

Fig. 2

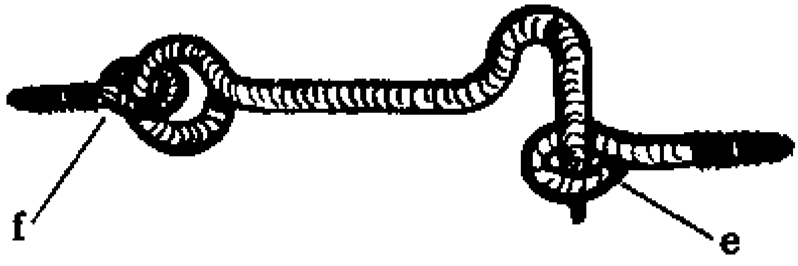

Fig. 3

- CASEMENT FASTENERS: Besides the barrel bolt and the tower bolt, there are some other methods for keeping casements in a closed or open position. These are the casement stay and the cabin hook.

The casement stay serves to keep the casement in the open position. It consists of a handle (a), either wooden or metal, which is fixed onto a plate (b) screwed to the casement. A hole in the handle fits over a small pin in the cill of the frame when the casement is open and holds the casement in position (Fig. 1, c).

If the casement opens upwards, the stay can be constructed so that it also serves as a lock when the window is closed (Fig. 2). A notch (d) holds the stay on the cill when the window is open.

The cabin hook (Fig. 3) is used to hold the casement in the closed position. It consists of a hooked bar which fits into a screw eye (e). The other end of the bar is held by a second screw eye (f) which is fixed on the door or casement.

- LOCKING DEVICE FOR LARGE DOORS: The drawings below show a locking device used for large doors on stores etc, where trucks or other vehicles may have to enter to deliver goods (Fig. 4). It consists mainly of a long baulk (a) which can hold the two doors securely shut. The baulk is fixed with a coach bolt (b) onto one of the doors.

Two wooden blocks (c) hold the baulk in position when the doors are closed and a catch (d) prevents the baulk from swinging open by its own weight or from a gust of wind (Fig. 5). A piece of flat iron (e) bent as shown in Fig. 4, keeps the baulk in the locked position. This iron should be firmly attached to the door.

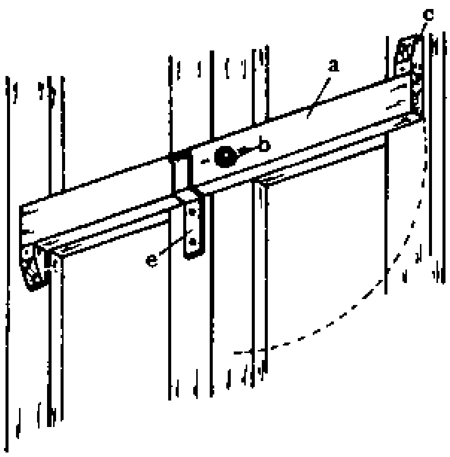

Fig. 4

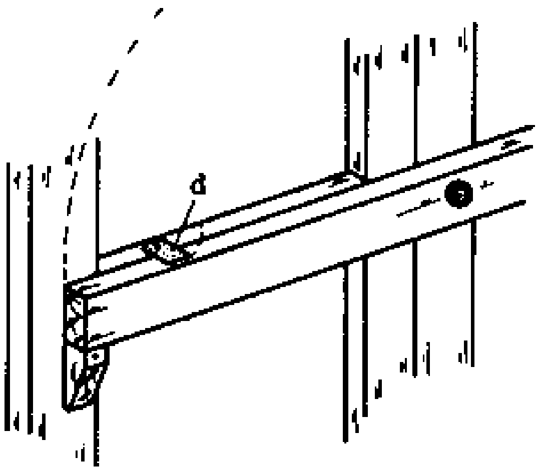

Fig. 5

ROOF COVERINGS

When we talk about roof covering, we mean the non-load-bearing clothing of the roof. In Rural Building, we deal with three different types of roof coverings. These are:

- corrugated aluminium sheets,
- corrugated galvanized iron sheets and
- corrugated asbestos cement sheets.

All of these sheets are corrugated because that makes them stiffer so that they can go across the gap between the purlins without sagging.

CORRUGATED ALUMINIUM SHEETS

This roof covering is lighter and far more durable than the other types. Lightness is important so that the sheets can be easily transported. Aluminium sheets are rust-proof, easily installed and have a bright reflective surface which helps to keep the building cool.

However, the thinner gauge sheets are especially vulnerable to being dented, punctured, or torn off by storms. The sheets also creak a lot when temperature changes make them expand or contract.

Aluminium roof covering is available in a variety of shapes and sizes. The sheets can be from 61 to 76 cm wide and 200 to 400 cm long. Sheets up to 18 metres in length can be ordered from the factory.

In Rural Building, we mostly deal with sheets which are 61 cm wide and 244 cm long. This size is the most commonly used and readily available.

The sheets are available in different thicknesses or gauges. The thinnest is 26 SWG (Standard Wire Gauge; 26 SWG = 0,446 mm) and the thickest is 18 SWG (=1,22 mm).

Store the sheets in a dry place. Avoid putting them in contact with fertilizer, lime or cement.

Further details and instructions concerning aluminium sheets can be obtained from:

Ghana Aluminium Products Limited
P.O. Box 124
Tema

Also look at the Tables of Figures, pages 239 and 240, for more information.

CORRUGATED GALVANIZED IRON SHEETS

These are steel sheets which are corrugated and galvanized on both sides. They are usually thicker and heavier than aluminium sheets, so they lack some of the drawbacks of the aluminium, like being easily punctured or torn away in storms.

The most common size of these sheets is 61 by 244 cm.

CORRUGATED ASBESTOS CEMENT SHEETS

This kind of roofing sheet is also widely used. The disadvantage of these is that they are brittle and break easily if they are walked on or if a heavy object falls on them. They can also break if the roof construction warps due to the humidity changes in different seasons. Another problem is that they are heavy, and so they are difficult to transport.

The standard size is again 61 by 244 cm.

HOW TO ORDER SHEETS

When ordering sheets, you must keep in mind that the overlap of two corrugations on each sheet must be subtracted to find the effective width of the sheet.

RIDGE CAPS

Ready made caps for covering the ridge of the roof are also available. They are made from aluminium, galvanized iron or asbestos cement, to fit with the roofing sheet material.

Ridge caps can be made locally out of aluminium or galvanized iron sheets as will be explained when we come to roof construction.

The caps have to overlap the sheets on both sides of the roof. In the case of a roof which has the ridge along the direction of the prevailing wind (in northern Ghana, this is the east-west axis) the cap must overlap the sheets by 20 cm on each side. If the ridge lies across the direction of the prevailing wind (north - south) the cap has to overlap by 30 cm on each side (see Tables of Figures, page 239).

NOTES:

APPENDIX I: TABLES OF FIGURES

WEIGHT OF AGGREGATES

Dry sand weighs about 1800 kg per cubic metre, or 1,8 tons.

Broken stones weigh about 1700 kg per cubic metre, or 1,7 tons.

One slightly heaped headpanful of dry sand weighs about 30,5 kg.

One slightly heaped headpanful of broken stones weighs about 29 kg.

TABLE OF LOADING CAPACITIES FOR VEHICLES

Loading capacity	Maximum number of headpans	
	dry sand (fine and coarse)	broken stones (small and medium)
1 ton	33	34
1,5 tons	49	51
2 tons	65	69
2,5 tons	82	86
3	98	103
3,5 tons	115	120
4	131	138
4,5 tons	147	155
5	164	172
5,5 tons	180	189
6 tons	197	207
6,5 tons	213	224
7 tons	229	241
7,5 tons	246	258

- REMEMBER: Never overload the vehicle! Observe the above quantities strictly.

NOTES:

TRANSPORTATION OF AGGREGATES

Supposing we have a 3,5 ton lorry available for transporting the aggregates, we can now figure out how many trips with the lorry will be necessary. If we know the total amount needed of each aggregate, we can find the number of lorry loads needed from the table on the left page.

For example, we need for the whole building:

429 headpans of fine sand;
152 headpans of coarse sand;
181 headpans of small broken stones;
165 headpans of medium broken stones.

The number of lorry loads required is found by dividing the number of headpans above by the number found in the table for the 3,5 ton lorry:

- Fine sand: 429 divided by 115 equals 3,73 or approximately 4 loads.
- Coarse sand: 152 divided by 115 equals 1,32 or approximately 1,5 loads.
- Small broken stones: 181 divided by 120 equals 1,5 loads.

- Medium broken stones: 165 divided by 120 equals 1,37 or approximately 1,5 loads.

- NOTE: It is always better to have a little extra material. Therefore, it is better to fill the lorry with every trip rather than take back a half-load. The cost of the transportation will be about the same anyway.

NOTES:

KEY FOR USE CODES

1 = foundations
2 = sandcrete blocks*
3 = mortar*
4 = plaster/render*
5 = floors
6 = columns
7 = beams/lintels
8 = slabs
9 = screed mortar*

- NOTE: Any reinforced concrete member of the structure must contain at least 270 kg of cement per cubic metre; and must be free of medium and large sized stones. Therefore, the figures in the upper part of the table are never used in mixing reinforced concrete.

* The items marked with a star are those which contain only sand as an aggregate. The amount of sand required is obtained by adding together the amounts of all the aggregates: fine and coarse sand, small and medium broken stones.

HOW TO USE THE TABLE

When the plans for the building are completed, the builder can make calculations to find how much cement needs to be ordered. From the dimensions in the plan, the volume in cubic metres can be found for the various parts of the structure such as the foundation, floor, footings, etc. This is done by multiplying the width, length, and height of a part to get its cubic volume.

The examples below show how to calculate the cement required once you have found the volumes.

- FOUNDATIONS: Mix proportion = 1:10, volume = 5,75 cubic metres.

- FOOTINGS: Mix proportion of sandcrete blocks and mortar = 1:8, volume = 3,3 cubic metres.

-FLOOR: Mix proportion = 1:7, volume = 2,4 cbm.

- CALCULATION:

  FOUNDATIONS: According to the table, the mix proportion of 1:10 requires 3 bags of cement per 1 cbm. Therefore, we multiply 5,75 cbm x 3 = 17,25 bags of cement.

  FOOTINGS: The mix proportion of 1:8 requires 3,5 bags of cement per cbm. We multiply the volume of 3,3 cbm x 3,5 = 11, 55 bags of cement.

  FLOOR: The mix proportion of 1:7 requires 4 bags of cement per cbm. We multiply the volume of 2,4 cbm x 4 = 9,6 bags of cement.

We now add up the three results above and obtain a final result:

17,25
+ 11,55
+ 9,6
38,40 bags

The total of 38,40 means that 39 bags of cement have to be ordered.

Do not forget to include all the members which contain cement in your calculations: landcrete blocks, mortar, lintels, concrete ring beam, etc.

The cement requirements for landcrete blocks varies according to the soil used. For approximate values see the table on page 179.

NOTES:

When the cement requirements have been determined, we can use the table to find the quantities of aggregates that are needed. This is done by multiplying the same volume measurement by the appropriate number in the table.

- FOUNDATIONS:

5,75 cbm × 20,5 equals approximately 118 headpans of fine sand.
5,75 cbm × 18,5 equals approximately 106 headpans of coarse sand.
5, 75 cbm × 22,5 equals approximately 129 headpans of small broken stones.
5,75 cbm × 20,5 equals approximately 118 headpans of medium broken stones.

- FOOTINGS: Since the sandcrete blocks and the mortar require only sand, all four quantities under aggregates (fine sand, coarse sand, small and medium broken stones) are added together and the result is multiplied by the volume of the footings: 20 + 18 + 22 + 20 = 80; 80 × 3,3 cbm = 264 headpans of sand.

- FLOOR:

2,4 cbm × 19, 5 equals approximately 47 headpans of fine sand.
2,4 cbm × 17,5 equals 42 headpans of coarse sand.
2,4 cbm × 21,5 equals approximately 52 headpans of small broken stones.
2,4 cbm × 19,5 equals approximately 47 headpans of medium broken stones.

NOTES:

HEIGHT MEASUREMENTS FOR WALLS

This table can be used to calculate the height of a wall (not including copings, tie beams, or foundations) or to calculate the number of courses in the wall in order to make it a certain height.

LC = Landcrete wall; NC = number of courses; SC = sandcrete wall.

USING THE TABLE

- FOR EXAMPLE: The walls of a common house (not including wall plate or ring beam) are supposed to reach a height of 3 m above the finished floor level. We find with the aid of the above table that the plinth course of sandcrete blocks must be followed by 12 courses of landcrete blocks to reach a height of: 0,25 m + 2,88 m = 3,13 m. The floor is 10 cm thick, so the height above the finished floor level will be 3,13 m - 0,10 m = 3,03 m.

- ANOTHER EXAMPLE: The bottom of a water tank must be at a height of 4 m above ground level. With the aid of the table, the Rural Builder can easily figure out that he needs to make 24 courses of flatwise sandcrete blocks to reach this height.

LENGTHS OF WALLS

LC = Landcrete blocks, length of wall (cm); No = number of blocks; SC = sandcrete blocks, length of wall (cm).

USING THE TABLE

Suppose you are planning a wall which is about 6 metres long, made from landcrete blocks. In this case it would be best to choose either 5,87 m or 6,18 m as the final length, so that it is not necessary to cut blocks to fit.

The table makes it simple to read off the number of blocks required per course, so it is easier to calculate the building materials that will be required. For example, a 34, 70 m landcrete wall contains 112 blocks per course. The number of courses required to reach a certain height can be found in the table on page 237.

ROOFING SHEET REQUIREMENT

This table is to help you to find the number of roofing sheets that need to be ordered, according to the length of the planned building. The number of sheets in this table refers only to the sheets along one side of the ridge line; so if you want to make a gable roof you have to double this number to get the number of sheets that will cover both sides of the roof. In addition, if the building is wide, so that more than one sheet is needed to cover the distance between the ridge and the lower edge; then the number from the chart has to be multiplied by the total number of sheets across the whole width of the building (see the example given on the next page).

The figures below are for the most commonly used roofing sheet size, which is 61 cm by 244 cm. The effective width of the sheets (minus 2 corrugations overlap) is approximately 50 cm (see pages 230 and 231). The figures include an allowance of 20 cm extra at each gable end.

NS = Number of roofing sheets; L (m) = the length of the building in metres.

NS	L (m)	NS	L (m)	NS	L (m)	NS	L (m)
3	1,1	14	6,6	25	12,1	36	17,6
4	1,6	15	7,1	26	12,6	37	18,1
5	2,1	16	7,6	27	13,1	38	18,6
6	2,6	17	8,1	28	13,6	39	19,1
7	3,1	18	8,6	29	14,1	40	19,6
8	3,6	19	9,1	30	14,6	41	20,1
9	4,1	20	9,6	31	15,1	42	20,6
10	4,6	21	10,1	32	15,6	43	21,1
11	5,1	22	10,6	33	16,1	44	21,6
12	5,6	23	11,1	34	16,6	45	22,1
13	6,1	24	11,6	35	17,1	46	22,6

SHEET REQUIREMENT FOR RIDGE CAPS

When the ridge of the roof is oriented in the direction of the prevailing winds (the direction from which the wind usually comes; in northern Ghana this is the east) then the ridge cap has to overlap 20 cm on each side of the ridge. Thus a common roofing sheet (244 cm long) will provide 6 ridge caps, each 40 cm long. To find the number of sheets required for the ridge caps, use the figure you get from the table above and divide it by 6.

For example: The building will be 10 metres long; looking in the table you find the figure of 21 sheets. Divide 21 by 6; this gives 3,5 (or approximately 4) sheets which are required for the ridge caps.

When the ridge of the roof is oriented across the direction of the prevailing winds (in northern Ghana this would be north-south), the ridge cap has to be wider so that the sheets are held better against the wind. In that case, the caps have to overlap each side of the ridge by 30 cm; therefore the roofing sheet can be cut into 4 pieces, each 60 cm long. To find the number of roofing sheets required for the caps, divide by 4 instead of by 6. Thus in our example, 21 divided by 4 gives 5,25 (or approximately 6) sheets required for the ridge caps.

ROOFING SHEET REQUIREMENT / WIDTH OF BUILDING

In order to avoid unnecessary waste, the Rural Builder should decide on the width of the building with the size of the roofing sheets in mind (see Construction, pages 158 & 159). The table below gives the span of the roof for a gable roof according to the number of sheets required to reach from ridge to eave level on each side of the roof. The sheets are standard 244 cm long roofing sheets, the roof has a 20 degree pitch, and there is an allowance of 50 cm extra on each side for the sheets to overhang (overhanging eave).

NS = Number of sheets; W (m) = Width (span) of the roof truss.

NS RIGHT	W (m)	NS LEFT
1	3,65	1
1	4,65	1½
1½	5,65	1½
1½	6,8	2
2	7,95	2
2	8,95	2½

NS RIGHT	W (m)	NS LEFT
2½	9,95	2½
2½	11,1	3
3	12,3	3
3	13,3	3½
3½	14,3	3½

- EXAMPLE: If the roof is to be 21 m long and 8 m wide (span of the truss), with a pitch of 20 degrees, and oriented with the prevailing wind, the number of sheets required can be figured as follows:

From the table on the proceeding page, we see that 43 sheets will fit along the ridge line. The table above shows that 4 sheets are required to cover the width of the house. When we multiply both numbers, we get the total amount of sheets which is 172 sheets.

We must also find the number of sheets required for the ridge caps. Dividing 43 by 6 gives approximately 8 sheets, making a total of 180 sheets to be ordered.

APPENDIX II: GLOSSARY

Most new terms are explained in the text as they come up, but after that they are used without explanation. To make it easier for you, the words which tend to come up again and again are explained here once more, and references are given when possible to more thorough explanations in one of the text books.

- NOTE: The other books referred to here are given as abbreviations: the Basic Knowledge book is referred to as "BK"; and the Construction book is written as "Con". Where the page number only is given, it refers to the page in this book.

<u>TERMS</u>

- AGGREGATE: The sand, rocks or gravel which make up the greater part of concrete, sandcrete blocks, mortar, plaster or render (see page 147)

- ANCHORAGE: This refers usually to iron rods which are embedded in one part of the building and serve to hold another part in place, for example the roof anchorage which is embedded in the walls and holds the roof construction in place.

- ANGLE OF PITCH: This means the slope of the face of a saw tooth (see page 109); or else it refers to the slope of the roof construction (roof pitch), depending on the context where it is used (see page 158, Con).

- BATTEN: This usually refers to a small piece of wood that is used to help fix another piece, or it refers to the lengthwise boards of a battened door (see page 93, Con).

- BEVEL: A sloping edge; the edge of a piece which is cut off so the angle is no longer 90 degrees (see page 72, BK).

- BOND: This refers to the arrangement of blocks in a wall, in Rural Building usually a half-block bond (see page 8, BK).

- BRACE: A piece added to a construction to make it stronger or more stable.

- BUILDING UNIT: This is usually used with reference to blocks to specify the measurement of a block in the wall, including the thickness of one cross joint and the bed joint (usually 2 cm) (see page 4, BK).

- CAST: To pour concrete into a mold so that it hardens to a particular form.

- CAST-IN-SITU: This means that the concrete member is cast in its permanent position (page 170, BK).

- CHAMFER: An edge which is cut to a 45 degree angle; this is a special kind of bevel (see page 72, BK).

- CLEARANCE: Free space; or space to allow movement between parts.

- CLENCH: To secure a nail by bending the point over where it comes through the piece of wood (see page 94, BK).

- CONCAVE: This describes a surface which is hollow or curved inwards.

- CONCRETE: This is a mixture of sand, stones, cement and water which hardens into a rock-like substance (see page 166).

- CONVEX: This means that a surface is curved outwards, like the outer surface of a ball.

- COUNTERSINK: This means to enlarge the top of a screw hole so that the head of the screw will be flush with the surface (see page 96, BK).

- COURSE: This refers to a horizontal layer or row of blocks in a wall, including the mortar bed (see page 2, BK).

- CROSS-GRAINED: The wood fibres do not run parallel to the length of the piece of wood, so it is difficult to work with the wood.

- CURING: This refers to the process of hardening for any product which contains cement. The piece must "cure" for a period of days or weeks before it is ready to carry out its function.

- CUTTING ANGLE: The angle to which a cutting edge is shaped (see page 91).

- DIMENSIONS: The measurements of the length, width, and height of an object.

- END GRAIN: The end surface which is exposed when wood is cut across the grain (see page 72, BK).

- FACE SIDE OR FACE EDGE: This is the first side or edge to be prepared when wood is planed for use in a work piece, usually the best side or edge (see page 84, BK).

- FLUSH: When we say that two surfaces are flush, we mean that they are in the same plane, they form one flat surface together.

- FOOTINGS: These are the first courses of flatwise blocks which are laid on top of the foundations (see page 36, BK; also page 43, Con).

- FORMWORK: This is the wooden structure which holds and supports the concrete pieces while they are being cast (see page 170, BK).

- FOUNDATIONS: The solid base, usually concrete, on which the building rests. It is the only part of the building which is in direct contact with the ground (see page 15, Con).

- GAUGE: A measure, a means of comparing sizes (for example, see pages 13 and 39).

- GRAIN: The natural arrangement of the wood fibres (see page 72, BK).

- GRIND: To polish or sharpen by rubbing on a rough hard surface (see page 95).

- HEADER: This is a block which is placed in a wall in such a way that the smallest face is exposed (see page 2, BK).

- HONE: To give a final polished keen edge to a tool by rubbing it on the smooth side of a sharpening stone (see page 99).

- KERF: The cut made by a saw blade.

- LANDCRETE BLOCKS: This is a mixture of laterite soil, cement and water which is pressed into blocks in a landcrete block machine (see page 2, BK).

- LEVEL: A line or surface which is parallel to the horizon; horizontal. This can also refer to the tool, the spirit level (page 5) which is used to determine whether a surface is level.

- LINTEL: The wooden or reinforced concrete member which bridges the opening of a door or window at the top (page 164, BK).

- MARKING OUT: This means to make marks on a surface to show where later operations have to be carried out; for example marking out joints on frames or marking out foundations on the ground.

- MILD STEEL: This is the same as iron. Hardened steel is iron which has been hardened by a special process.

- MITRE: This refers to a joint where the two pieces are cut at a 45 degree angle so that they form a corner where the connection between them bisects the angle of the corner (see page 98, BK).

- MORTAR: A mixture of sand, cement and water which is used to form the joints between blocks; or as plaster or render, depending on the proportions of the mix (see page 158).

- MORTICE: A hole which is cut in a piece to recieve the end of another piece (see page 104, BK).

- PLASTER: The mortar layer which is applied to the inside walls of a building to make them smoother and more durable (page 174, BK).

- PLINTH COURSE: This is usually one course of edgewise laid sandcrete blocks which is laid on top of the footings (see page 36, BK).

- PLOT: An area limited by certain boundaries, it may contain one or more building sites (see page 140, BK).

- PLUMB: Vertically straight, perpendicular to the horizon.

- PRECAST: This means that the piece is cast beforehand and set into into its permanent position after it is hardened (see page 170, BK).

- PREFABRICATED: This means that the piece or part of the building is made ready before it is installed in its final position in the structure. In Rural Building we usually mean those things which are manufactured on the site such as doors, casements or frames. We also call this "ready-made".

- QUOIN: The outside corner of a wall (see page 26, BK).

- REBATE: A step-shaped rectangular cut in the edge of a piece (see page 72, BK).

- REINFORCE: To make something stronger by adding another material, for example the iron rods which are sometimes used to make concrete pieces stronger (page 171)

- RENDER: The mortar layer which is applied to the outside of the building to make the walls water resistant so that the blocks are not destroyed by rain (see page 174, BK).

- RIGHT ANGLE: A 90 degree angle.

- RIPPING: This means cutting a board along the grain, using a saw (page 45).

- SANDCRETE BLOCKS: These are blocks made with sand, cement and water, shaped in a sandcrete block machine (see page 2, BK).

- SCALE: In a drawing, this means the relation between the size of the drawing and the actual size of the object which is drawn; for example a building may be drawn in a scale of 1:100 (cm), which means that 1 cm on the drawing represents 100 cm in the actual building.

- SCREED: This refers to a strip of mortar which is laid on the wall to act as a guide during plastering (see page 176, BK); we also talk about floor screeds, by which we mean the 2 cm mortar layer which is laid on top of the base layer during floor construction (see page 179, BK).

- SETTING OUT: Marking the dimensions of an excavation with pegs and lines, or marking the positions of the walls on the footings, etc., sometimes called lining out.

- SHUTTERING: This means the parts of the formwork which are in contact with the cement (page 170, BK).

- SITE: This is the piece of land on which a building is made; a plot of land can contain one or more building sites (see page 140, BK).

- SOFFIT: This refers to the under-surface of a piece; in a concrete form, the bottom board of the shuttering is called the soffit board.

- SPECIFICATIONS: This means a detailed description of something.

- SQUARE: By this we usually mean that a piece has all its sides at right angles to each other, or that all the angles are right angles; or it can mean a rectangular surface where all the sides have the same length.

- STRETCHER: This means a block which is laid so that one of the long faces is exposed (either the top face or a long side) (see page 2, BK).

- STRUTTING: These are the supports which hold the shuttering in place when the concrete piece is cast (see page 170, BK).

- TAPER: This means that something is thinner at one edge than at the other.

- TRUE: This is a description meaning that a surface is completely straight and flat.

- VENTILATION: The air movement in and out of a room or area.

- WARP: This is any change of shape in a piece of wood which is caused by uneven shrinking or expansion (see page 132).

- WEDGE: A piece, usually V-shaped, which is used to hold other pieces under pressure, usually to hold pieces together as for example the handle and head of a hammer are fixed together by wedges (see page 41).

1. Introduction

Udo Bude & Keith Lewin

As a follow-up to the World Conference on Education for All in 1990 several countries in southern and eastern Africa started analysing and revising their examination systems with the ultimate aim of improving the quality of teaching/learning. Examinations in countries of the region are a well established feature of the educational systems reaching back to colonial days. The achievements of pupils during the primary school cycle are in most cases tested in end-of-cycle examinations, whereby the performance of a pupil is tested in comparison with other pupils sitting the examination (norm-referenced tests). Such assessment procedures do not provide the full picture and fail to deliver sufficient information about the success of an education system in imparting those skills and competencies as laid down in the curricula.[1] In order to find out how proficient a pupil is in a particular subject, concept or skill without referring to other norm groups of pupils a different approach is required. This may have several elements which include greater use of school based assessment, evaluation of project work and techniques of continuous assessment. It may also seek to define competencies in terms of criterion statements against which performance can be judged. Criterion-referenced assessment is attractive since it sets standards that do not depend on the performance of other pupils and should provide reliable data on what has been achieved during the primary school years. Some countries in the region e.g. Botswana and Swaziland are already experimenting with this kind of approach to assessment.

[1] See Kellaghan, Th. & Greaney, V. (1992) Using Examinations to Improve Education. A Study in Fourteen African Countries. World Bank Technical Paper No. 165. The World Bank, Washington D.C.

Applying more comprehensive concepts of assessment is a significant step towards the improvement of the quality of teaching and learning. National examination systems are mostly designed to judge the individual pupil's achievements for selection purposes and to deliver comparative information about the performance of individual schools and regions. They are often an unreliable guide to actual levels of achievement.

Three aspects have to be taken into consideration when constructing most forms of assessment instruments:

(1) the validity of assessment instruments (do they measure what they claim to be measuring? do they predict future performance adequately if they are to be used for selection?);

(2) their reliability (do they work a consistent measure of performance which could be repeated with similar results? are measurement errors reduced to acceptable levels?);

(3) their technical efficiency (is the system secure, cost-effective, or as appropriate time scale, free of bias towards or against different groups of candidates?).

For most pupils in the region primary education ends after seven to eight years with a national examination. The more selective such examinations are the greater is the attention and importance given by society, because the results of such annual exercises determine significantly the future of many children and the hopes and ambitions of many parents for their offspring.[2] The outcome of the examinations also have severe repercussions on the schools on learning and teaching methods, and on the teachers' role in local communities and within the education system (see box: »Vihiga plan« is the way out/Fortunes change for Kikuyu).

COMMENT

'Vihiga plan' is the way out

PARENTS in Sabatia Division of Vihiga District have embarked on an ambitious programme to improve education standards in the area.

Part of the master-plan lies in setting up an in-service training centre for secondary and primary school teachers and their deputies. Those who attended the leaders' meeting on how to improve education in the area made proposals of providing lunch to all examination classes in future.

However, whereas there is no so much novelty in advocating for managerial skills for headteachers, or even starting schools' feeding programme, it is important that parents are ready to initiate the scheme on a harambee basis.

Going by the results of the last year's Kenya Certificate of Primary Education (KCPE), one can just understand the urgency of having efforts to improve education in Vihiga. Out of 56 districts and municipalities, Vihiga was number 41.

By all standards, those results were not rosy, but perhaps the most important aspect is that parents are prepared to reverse the situation.

But even then, they are throwing a big challenge to the Ministry of Education and the Teachers Service Commission (TSC) whose responsibility is train and appoint of headteachers.

In the past, appointment of headteachers in both primary and secondary schools has been done in total disregard of experience and competence of headteachers and their deputies. Poor supervision of schools added to the problem.

As the leaders' meeting at Vokoli Girls Secondary School noted, there is paucity in supervision of headteachers, who more often become their own masters and oppressors of parents and other people who refuse to toe the line, or who question their decisions.

It is also important for the Ministry of Education to acknowledge community based programmes, and support them.

Fortunes change for Kikuyu

By STEPHEN [illegible]

The performance of the Kenya Certificate of Education has greatly improved in Kikuyu Division, according to the local educational officer Alan [illegible].

He said the division which used to come last out of seven in the district was now number three.

Kikuyu came third after Lari and Githunguri in last years KCPE results.

Addressing a prize-giving ceremony at Kikuyu Township Primary School recently, the officer [illegible] teachers, pupils and parents to work harder to get better results.

The remarking of [illegible] Gitau Primary School KCPE papers elevated it up from 110th to fourth position with a mean score of 420 marks in the district's 209 schools.

The Zonal Inspector of Schools, Mr James [illegible] and the Teachers Advisory Centre (TAC) tutor, Mrs Magdalene Kiambuthi, praised teachers for their work which had enabled Muguga to produce six of the top 10 schools and also six of the top 10 pupils in the district.

Kabete produced the best candidate in Samuel Munyua from Mahia-ini Primary School.

Daily Nation 4/3/95

Tuesday, February 28, 1995

Despite the great attention paid to matters of testing and examining at the end of primary education, the examination results rarely provide sufficient information on the effectiveness of the educational system to make confident judgements on educational quality and learning problems. If we are interested in influencing the teaching-learning process in the classroom positively we may have to start with improvements in the ways pupils are assessed. This can indicate what is not being understood and assimilated, and can point the way to strategies to improve levels of achievement.

Any assessment system provides opportunities for teachers, pupils, and educators (e.g. curriculum developers, examination-/testing specialists) to monitor progress and learn from failures as well as successes. However, if large parts of examinations consist mainly of straightforward recall questions where pupils are simply asked to reproduce from memory, opportunities for a more comprehensive assessment of learning outcomes are lost and much teaching will follow objectives narrowly defined by a restricted range of questions. The mere recollection of facts or names does not give any hint of the pupil's problem-solving skills, often so strongly emphasized in the primary school curricula as essential outcomes of learning. Repetition of whole sections from textbooks fails to indicate whether learners are able to apply their knowledge and skills to different situations. Poorly constructed multiple-choice tests leave much space for guess work and may encourage rote learning. They need to be replaced by a broader concept of assessment testing more complex cognitive processes. Consequently, the first step in a reform of conventional examinations is to analyse existing tests in terms of whether and to what extent they contain items requiring higher-order thinking and application. The next step is to develop or improve test items which examine pupils' abilities to apply what they have learned to less familiar situations and problems or which require them to link events or facts to each other in a consistent way.

The development and design of test items is mainly the domain of examination specialists and/or curriculum developers. The work of all those involved in examinations should, but often does not, include a strong research component in order to find out what kind of assessment procedures deliver the most valid and reliable results efficiently and have the greatest positive influences on classroom teaching. Educationists responsible for the design and analysis of national examinations in eastern and southern Africa are trying hard to improve their assessment systems and to answer the challenges of new ideas and requirements.[3] During recent years new subjects were added to previous core subjects, i.e. like Languages and Mathematics. In many primary school systems History, Geography and Civics or Social Studies have been included, along with science based subjects like Science, Agriculture, Environmental Science, Home Economics. Most or all now feature in the national examinations. Writing meaningful tests for the more practical subjects which go beyond recalling facts requires familiarity and experience with the respective school curriculum as well as with the possibilities and limitations of different types of assessment. Often the demanding curriculum objectives of subjects like Science or Agriculture are not easily tested in an appropriate way. Developing test items assessing pupils' understanding and application of knowledge and skills to new situations require sophistication in constructing assessment instruments even where testing is restricted to multiple-choice questions for reasons of cost and administrative feasibility.

[1] See Njabili, Agnes F. (1993) Public Examination: A Tool for Curriculum Evaluation. Mture Publishers, Dar-es-Salaam.

Education experts responsible for revising national examinations to improve the quality of education can learn from the approaches adopted to reform in different countries in the region, particularly in the following areas:

- widening the range of skills tested and the instruments used;

- redesigning examination items to include more which test skills of higher-order thinking;

- gradually shifting the basis of testing from a norm-referenced to a more criterion-referenced system (measuring pupils' success or failure in relation to criteria which represent competencies independent of the performance of other pupils);

- considering the possibilities for introducing continuous assessment alongside or instead of terminal examinations, and using pupils' records and

- profiles which can reflect the acquisition of demonstrated competencies of a wider range of different types than can conventional examinations.

One country in the eastern and southern African region has over many years spearheaded new developments in using national examinations for monitoring and meaningful assessment purposes. Kenya started reforming primary education examination in 1974 with the declared aims of making the examination more relevant, improving the quality of education and ensuring greater equity in the access to secondary schools. Two major strategies for reform were employed; changing the content of the examination papers, and introducing an information-feedback system. »It was hoped that changes in the questions set would make the CPE more relevant as a leaving examination, more equitable to pupils in less-privileged socioeconomic groups, and more reliable as a selection instrument. The introduction of an information-feedback system would, it was hoped, do something to improve the overall quality of the primary school system and to reduce quality differences between high performing and low performing schools.«[4]

[4] Somerset, Anthony (1988) Examinations as an Instrument to Improve Pedagogy. In: Heyneman, Stephen P. & Fägerlind, Ingemar (eds) University Examinations and Standardized Testing - Principles, Experiences and Policy Options. World Bank Technical Paper No. 78, Washington D.C., pp. 171-194, p. 174

The experience and expertise developed in Kenya over nearly twenty years is therefore very relevant to the present discussion on revising national examination systems in other countries of the region. The Kenya Certificate of Primary Education can serve as an example of possibilities and as entry point to become acquainted with assessment techniques at the end of primary school in the subjects SCIENCE and AGRICULTURE, and for monitoring primary schools in general.

The success of the reform of the primary school examination system has not been achieved without problems. Over the years Kenya has become more and more »exam-ridden«. The results of primary or secondary school examinations receive more and more public attention. Even to the extent that candidates' results are announced over public radio! Regions and school districts compete vigorously to top the lists in the national examinations, very often to the disadvantage of pupils who are unlikely to score highly and those who succeed but do so as a result of long hours of repetitive 'cramming'. The incentives to cheat and find illegal means to pass the test have also created many problems. Heavy emphasis on examinations leads to a neglect of the broader pedagogical tasks of the schools. The school curriculum may be only taught according to the importance of examination subjects and other aspects of the national examination ignored. The »examination tail is wagging the curriculum dog«! John Keeves reminds us of the real purpose of national examinations, »There is little doubt that a national examination has a substantial influence on the teaching that occurs in schools not only during the year at the end of which the examination is held, but in all years that have gone before... it is important that the examinations should have beneficial effects on the teaching and learning that takes place at all earlier stages of schooling«[5]

[5] Keeves, John P. (1994) National examinations: design, procedures and reporting. UNESCO: IIEP, Paris, p. 98.

The design and conduct of national examinations is therefore not an affair of one group of specialists alone. Examination specialists, curriculum developers, psychometrists and teachers have to cooperate to maximize the beneficial influence of the examinations on practical teaching and avoid excessive testing and examination preparations in the schools. Despite all good intentions on behalf of those setting the national examinations it seems to be extremely difficult to prevent examination »fever« once such examinations have gained too much importance in society as the means through which credentials are obtained, promotion through the school system rationed, and jobs in the labour market allocated.

The manual on IMPROVING TEST DESIGN tries to assist those educationists who are responsible for the design, conduct and control of national examinations in developing higher quality assessment instruments which can provide better information on pupil achievement, a fairer basis for selection, and influence learning and teaching to improve educational quality. It can also be used as a kind of source for training those assisting in the development or processing of examinations. The manual consists of two parts:

Volume 1: Constructing Test Instruments, Analysing Results and Improving Assessment Quality in Primary Schools in Africa,

Volume 2: Assessment of Science and Agriculture in Primary Schools in Africa; 12 Country Cases Reviewed.

Both volumes are the result of two pilot training workshops in Kenya dealing with the development of test items for Science, Agriculture, and Environmental Science and the use of national examinations for improving the quality of primary education. These workshops were jointly organised and conducted by the German Foundation for International Development (DSE), Education, Science and Documentation Centre, and the Kenya Institute of Education (KIE) in cooperation with the Kenya National Examinations Council. Participants came from different countries in eastern and southern Africa. Each country invited was asked to nominate one curriculum developer and one examination specialist, thus guaranteeing that the curriculum aspects for Science, Agriculture, Environmental Science were equally considered with the examination requirements.

Volume one deals with the practical aspects of test construction, analysis and the improvement of assessment procedures. In addition Prof. Keith Lewin (University of Sussex) takes up some of the theoretical aspects, especially the possibilities and limitations of criterion-referenced assessment and test development in general. The practical exercise on developing and administering tests draws to a large extent on the experiences with assignments carried out during the second training workshop in Kenya, where participants designed test items, conducted tests in primary schools and analysed the test results in groups. The experiences of twenty years of examination reform are presented in two analyses authored by education specialists from the Kenya National Examinations Council and the Kenya Institute of Education. Finally, abstracts and papers are documented indicating the discussion and direction of examinations and test constructions in eastern and southern Africa.

Volume two starts with an account and analysis of the present situation regarding primary school leaving examinations of countries in the region. Detailed information for each country is provided in a tabulated overview illustrated by original examination papers in Science, Agriculture and Environmental Science mainly from 1993 and 1994. In few countries Science and Agriculture feature only as part of a larger »General Paper«. In these cases the items covering Science or Agriculture have been included in the documentation. South Africa and Namibia are also included, although presently they have not yet started end-of-primary examinations, but discussions on the composition and design of examinations are in progress. Furthermore, examples of follow-up communications after the examinations from different countries are presented.

2. End of Primary School Examination in Eastern and Southern Africa - An Overview

Udo Bude

The evaluation of pupil's learning achievements is an essential part of the school curriculum. However, methods and scope vary among and within countries. Information on how schools and teachers carry out their tasks as suggested in curricula is of great importance to educational planners, curriculum developers and examination specialists in ensuring acceptable standards of attainment and in guiding the improvement of the quality of education.

In most countries of eastern and southern Africa the dominant tradition is to use formal examinations as a means of assessment at both individual and school level. Very often such examinations consist of a mixture of aspects of assessment procedures inherited from colonial systems mixed with recent developments in assessment methods. In the following chapter we will focus on examinations taking place at the end of primary schooling in the region. Children finish their first school cycle after seven or eight years. They are expected to sit examinations that test mainly their knowledge and skills in Languages and Mathematics, and in a range of subjects ranging from History and Geography to Religion, Science and Social Studies. Sometimes Science is a separate subject, in other cases it is examined with one or more others.

Tests in Education

Formal examinations and tests have not always been a part of education. The first formal examination in a university occurred at the University of Bologna in 1219. Oral exams were a part of the European university systems from the middle of the seventeenth century, and in 1803 formal written exams were introduced at Oxford University. The efforts of Joseph M. Rice in the late 1800s were instrumental in establishing standardized tests as part of the American educational system. Rice was trained as a physician, but he spent most of his professional life developing tests to assess educational achievement. Another significant figure in the history of educational tests is E.L. Thorndike. In the early 1900s Thorndike and his students at Columbia Teachers College contributed tests of arithmetic, handwriting, spelling, and other academic abilities. Today, routine achievement tests are a part of virtually every academic endeavor.[1]

Note: Achievement tests were already applied over 2000 years ago in China. Candidates had to pass a public examination for the entry into the Chinese Imperial Service.

[1] Graham, John R./Lilly, Roy S. (1984) Psychological Testing. Prentice Hall, Englewood Cliffs, New Jersey, USA, p. 6.

The primary school leaving examination is usually only the first of a series of examinations that take place throughout the educational system. But even at the age of twelve to fourteen such an examination determines the future of many children and is also valued by many communities as an indicator of teachers' abilities and of school quality. Consequently, teachers as well as pupils put great effort into the preparations for the examinations, the more so because in most countries only the results in the final examination count for certification and selection for secondary school.

Examinations have a tremendous influence on classroom instruction, particularly in the years immediately preceding the end of primary school education. Where there are hardly any paid jobs available after primary school and secondary places are limited, the competition to enter secondary schools becomes more and more intensive and the all important terminal examination the centre of attention. In the end the backwash effect of this examination may penetrate the whole primary education system. Not surprisingly, one even finds teachers in standard/class 1 of primary schools trying to encourage pupils to practise multiple-choice questions once their pupils have learnt to master the very basics of the 3 Rs. In some countries formal tests are even being arranged in kindergartens.

Teachers know that they have to assess their pupils to build up a detailed understanding of each student's strengths and weaknesses. Without such formative knowledge teachers cannot be in a position to help and to assist. Summative testing is also valued and seen as an indispensible part of teaching allowing overall judgement on the successful attainment of educational objectives. Teachers often question why such testing cannot be left completely to them. One reason is designing meaningful and valid tests is not an easy job. If simple »pencil-and-paper« tests are conducted by teachers as the only means of assessing pupils' performance this will not do justice to the complexity of the learning objectives set out in the curriculum. Nor is it likely to be technically sound as a valid and reliable measurement given that few teachers are adequately trained in test design and many have no formal training at all.

Furthermore, there is concern that over reliance on teacher set tests may undermine balanced teaching of the curriculum because teachers may give undue emphasis to some parts while neglecting others. In the end those parts of the total school curriculum which are tested may be the only parts that are taught, and each teacher may value different topics.

Examinations rarely cover the full range and depth of the curriculum prescribed for the different subjects. Thus, what should have been learned is only partially examined. In many countries in eastern and southern Africa the examination questions set over the years come to define the school curriculum in the last two years of primary school in a narrow and stereotyped way.

»Teaching to the test«

Examinations and testing programmes have grown and multiplied with the expansion and diversification of participation within education systems and probably also as the consequence of an increasing demand for information on the development of 'human resources' in the wider economy and society. Most of them have probably not been specifically designed to help improve learning as such, but simply to verify or 'assess' whether the student has certain knowledge, values and attitudes, skills or capabilities. Both of the two main types of assessment information -criterion-referenced (can X and Y do Z?) and norm-referenced (can X do better than Y on Z?) - are clearly in demand though for different purposes. Within education systems, in cases where resource constraints require that only a limited number of individuals within a given reference group (e.g., a cohort or class) be selected for particular courses of study, the demand is for norm-referenced information; when teachers simply need to know if students have acquired prerequisite knowledge and skills before progressing to more advanced stages of learning, the demand is for criterion-referenced information. In both cases the student is challenged to perform a certain task or tasks, and there is little doubt that the prospect of such a challenge can provide a stimulus to learning. Indeed, the major end-of-cycle public examinations in many countries often are the cause of anxiety and even anguish among parents as well as students because they are so determining for life chances.

If, as is common, the knowledge and skills assessed by examinations are the ones that teachers, students and parents concentrate on to the exclusion of what else is in the curriculum, then there occurs the biggest single unwanted side-effect of external assessment. Proponents of 'measurement-driven' or 'assessment-led' instruction have argued that if 'teaching to the test' produces higher test scores, then at least some learning has occured. Critics have questioned whether those higher test scores represent useful and enduring learning which will convert into future achievement -as opposed, say, to mere memorization of facts which are quickly forgotten. Despite the amount of testing going on in the world, many scholars probably would agree that there still is very little known about whether preparing for and taking tests actually causes useful and enduring learning to occur.[2]

[2] from: UNESCO (1991) World Education Report, pp. 82, 83

The heavy reliance of developing countries on external examinations is in great contrast to experiments in some European countries aimed at abolishing formal examinations at primary school level and replacing them by more formative, school-based and pedagogically integrated assessment. In Switzerland, for example, an experimental project has started where children's progress was regularly evaluated through diagnostic methods (see Box). Such a demanding approach, however, requires teachers with sufficient professional experience and a thorough academic and pedagogic background.

> In Switzerland, interesting experimental work is taking place which appears to have general applicability to the problem. Research there and elsewhere has shown that the traditional evaluation of pupils' performance often fails to achieve its objectives. Commonly, it does not help the pupils to improve, it does not accurately inform parents of their child's progress, and it does not give sufficient information to educationists to enable them to plan the child's educational future. Difficulties arise partly because the main function of marking is not clear; there can be no single all-purpose mark that is simultaneously predictive, a credentialling device, and a diagnostic tool, but that is what teachers have tried to employ. In primary schools, the process of assessment is also sometimes distorted by marks being used to punish or reward. In addition, teachers find it difficult to transform a record of under-achievement into a prescription for remedying it.
>
> The Swiss research indicates that while formal evaluation instruments and data banking have a role to play, the main solution lies elsewhere. Thus, in one experimental project, teachers were encouraged to prepare their own diagnostic tests, and marks were not given though mistakes were carefully analysed and explained to the pupil. Twice a year remarks, not grades, were entered in parents' notebooks giving an account of the child's progress. Each June an evaluation of the whole year was noted in the pupil's record. Teachers recorded the achievement made during the year but there was no comparison between pupils - in other words, the purpose of this evaluation was diagnostic not rank-ordering. Surveys showed that parents and teachers favoured the new evaluation despite the work load involved, but there was a clear need for teachers to receive more training with a view to encouraging them to discard their old ideas about marking, and to develop their skills in being more precise about objectives and in the construction of their own diagnostic materials. The great advantage of this evaluation project has been the emphasis on the professional expertise of the teachers and their need to communicate more effectively both with pupils and with their parents. At primary level, it has been considered appropriate to give the diagnostic function of evaluation priority over the other functions.[3]
>
> [3] OECD (1989) Schools and Quality. An International Report. Paris, p. 102

Such well-trained professionals are, under normal circumstances, not available in developing countries and their lack would easily jeopardize such an approach.

Investigation of the end of primary school examinations in the Africa region reveals that most of the countries have started reforming their examinations in recent years, particularly since 1990. Countries are well aware of the limitations of examination systems that depend heavily on multiple-choice tests. There is a great need and demand for reviewing and redesigning the written examinations to reduce simple recall items to a minimum and include more items that test higher cognitive skills. The latest trends include:

- experiments with continuous assessment, and
- introduction of more criterion-referenced tests.

Swaziland has been experimenting with continuous assessment in primary schools for three years. The trials cover English and Mathematics and are intended for the full primary school cycle (up to Std. VII). Criterion-referenced tests were introduced to assess the performance of individual pupils. The trial programme aims at improved quality of teaching and hopes to reduce repetition and dropout rates. At the same time it is planned to extend the primary basic education cycle from 7 to 9 years with a final examination at the end of Std. IX. The major constraint to the implementation of continuous assessment is the low level of teachers' training. The introduction of forms of continuous assessment in the primary education system is also envisaged in Uganda. However, Uganda's Examinations Board is aware of the problems involved, especially of the need to sensitize and train teachers thoroughly and to establish spot-checks and controls at local level. In addition a national assessment exercise is planned every two years to determine country-wide levels of performance (to find out about rising or falling standards).

Lesotho's experiences with continuous assessments have had less success. The trials did not encourage a general country-wide introduction. Teachers were unable to handle the assessment instruments correctly. Children were promoted without ensuring appropriate learning outcomes. Thus, the usual end of primary school examinations have been retained.

Because of the limitations of the norm-referenced testing system Botswana began in 1992 to experiment with criterion-referenced testing. It is hoped that a shift from the present testing strategies to criterion-referenced testing will ensure that the examinations mirror the aims and objectives of the primary school curriculum more closely. The new examination will be supplemented by a process of continuous assessment.[4]

Zimbabwe	Grade 7 Examination	Examinations Branch, Ministry of Education and Culture	306, 706	6	4	English	X		1990	$5^{1/2}$-6	7	-

Note: Namibia and South Africa have not been included. In Namibia presently examinations only take place after junior secondary school (class 10); primary school examinations are planned for 1997. In South Africa the Independent Examinations Board, a non-governmental organisation, offers national examinations since 1994 for Std, VII leavers. Common exams are also set by the Provincial Departments of Education.

Zambia is the only country in eastern and southern Africa which includes in the Grade VII Composite Examination at the end of the primary education two papers testing verbal and numerical reasoning. In English and Mathematics pupils are asked to answer 50 questions for each subject. The multiple-choice items can be answered in 60 minutes for English and in the same time for Mathematics.

Tanzania has seen changes in the structure of the primary school examination over the last years. For reasons of examination security the country used to be divided into different zones, controlled centrally from the capital. From previous five zones in 1990 the »examination zones« were gradually reduced to two in 1993. For each examination paper different versions are produced according to the number of existing zones by the National Examinations Council. Since 1994 Tanzania has produced only one set of examination papers for the whole country. This development was accompanied by the creation of examination centres in the regions and the compulsory presentation of candidates' photographs for identification purposes.

The number of subjects tested in the end of primary school examinations in the different countries of the region range from 14 (Kenya) and 11 (Malawi) to 6 (Uganda, Zambia, Zimbabwe) or 5 (Botswana); 8 subjects are tested in Lesotho and 9 in Swaziland and Tanzania, including Zanzibar. However, these subjects do not necessarily feature in the examinations with papers of their own. Only the main subjects, like Languages and Mathematics appear as separate papers, all others are presented in combination with other subjects. The general impression prevails that the greater the number of subjects combined in one paper, the smaller the range of the subject's curriculum covered in the test. Zimbabwe e.g. tests three subjects in a combined General Paper (Religious & Moral Education/Social Studies/Environmental Science) with the result that the whole curriculum of each subject has to be reflected with 15 or 20 questions!

Pupils in all parts of the United Republic of Tanzania receive their examination questions in the national language Kiswahili, and can answer in the same language. In all other countries of the southern and eastern African region English is used as the official language, English is required for understanding and answering the tests. Only the papers in the local/regional language subjects use the respective languages as the medium of education and assessment.

The test items for the different subjects are either developed by national examination boards or councils or by national curriculum centres. In Lesotho the national curriculum centre is responsible for setting the examination questions. All other countries of the region charge the national examination boards or councils with this task. Over the years different procedures for setting the examination questions have emerged. As a rule, specialists from different educational institutions like curriculum development centres, examination boards, teacher training colleges, universities and sometimes practising teachers etc. are invited to forward sample items which are later moderated by specialists, sometimes trial tested and analysed and finally compiled for the annual examination paper. Nearly all countries try to involve experienced primary school teachers and inspectors at this stage. Only Malawi and Tanzania refrain from using practising primary school teachers' experience for the design of test items.[5] Half of the countries appear to analyse pre-test results in the development of items.

[5] See also table 2: Groups involved in setting examinations.

CRITERION-REFERENCED TESTING	NORM-REFERENCED TESTING
ADVANTAGES	
• Fair and informative to students, parents, and educators. • National educational progress may be evaluated meaningfully in terms of increased achievement. • Career guidance information can centre on specific abilities fostered by the curriculum. • Diagnosis of individual's deficiencies in relation to curriculum objectives is more possible. • Meaningful curriculum-based continuous assessment of students that are comparable from school to school are possible.	• Readily reflects the achievement of each examinee in relation to the norm group. • Smaller samples of content can provide sound comparisons of student's relative achievement, provided large samples of students are used. • May promote student competition and competition between schools that is based on relative standing in the norm group.
DISADVANTAGES	
• Student achievement is not so easily compared. • Smaller samples of content provide weaker generalisations about a student's performance in the curriculum domain. • May discourage student competition that is based on relative standing in a norm group.	• Fair but less informative regarding what levels of achievement were attained. • National progress may be evaluated but comparisons over the years are difficult. • The information obtained may be less helpful to target in-service training to specific aspects of the curriculum. • Diagnosis limited to broad areas of curriculum (e.g. Math vs English) and in terms of a student's curricular strengths relative to other students in the norm group. • Curriculum-based continuous assessments are less meaningful and limited to relative standing in the local classroom.
Note: Adapted from Ministry of Education, Department of Curriculum Development and Evaluation, CRT Implementation Committee (1992) Criterion-referenced Testing. Rationale for Implementation. Republic of Botswana, p. 13	

Many members of the groups involved in setting examination questions for the end of primary education as indicated in table 2 may have no formal training in assessment and simply draw on experience.

A closer look at the situation of science subjects in the end of primary school examinations reveals that Science features in all examinations, but the importance attached to this subject differs from country to country. Science is either a compulsory paper like Mathematics and Languages (e.g. in Botswana), or is part of a compulsory »General Paper« (e.g. Tanzania, Zimbabwe), or appears only as an optional paper in the examination (e.g. Malawi). To stress the importance of Science in primary education and ensure appropriate teaching, the discussions in Zimbabwe have resulted in proposals to establish Science as an additional compulsory paper in its own right, rather than to examine it with Social Studies and Religious Education which are not cognate subjects.

Table 3: Science Subjects in End of Primary School Examinations

Country	Subject paper	Type of items	No of questions	Time available for subject (minutes)	Remarks
Botswana	Science	Multiple-choice (4 options)	60	60	Agriculture not examined in Primary School Leaving Examination.
Kenya	Science & Agriculture	Multiple-choice (4 options)	60	120	30 questions for each subject.
Lesotho	Science	Multiple-choice (4 options)	70	90	Agriculture included in Science paper.
Malawi	• Science and Health Education	Short answers	31	120	Answers in English/From 1995 on only one paper called »Science Incorporated« (incl. Science, Agriculture
	• Agriculture	Short answers	25	120	and Health Education) will feature as an optional paper in the exam consisting of multiple-choice items.
Swaziland	• Science				Two papers are given in Science, one with multiple-choice items, one requesting short answers in English. Agriculture is examined as an additional optional paper.
	Paper I	Multiple-choice (4 options)	40	90	
	Paper II	Short answers	6	120	
	• Agriculture				
	Section I	Multiple-choice (5 options)	30	90	
	Section II	Short answers	12		

Country	Subject paper	Type of items	No of questions	Time available for subject (minutes)	Remarks
Tanzania	General Knowledge incl. Science	Multiple-choice (5 options)	20	30	General Knowledge paper consists of History, Geography, Civics, Science, Agriculture, Health and Home Science. 20 questions for Science.
Uganda	Basic Science and Health Education	Short answers	**55**	135	Answers in English; Agriculture included in the Basic Science and Health Education paper.
Zambia	Environmental Science	Multiple-choice (4 options)	50	60	Agriculture included in Environmental Science paper.
Zanzibar	Science				Agriculture not examined.
	- Section A	Multiple-choice (4 options)	20	90	
	- Section B	Short answers	6		
Zimbabwe	General Paper incl. Science & Agriculture	Multiple-choice (5 options)	20	40	General paper consists of Religious & Moral Education, Social Studies, Science & Agriculture.
Note: Tabulation based on the 1994 examination papers.					

Agriculture as a separate subject in the examinations faces even greater problems finding adequate recognition. Only one country does not include Agriculture in the examinations (Botswana), but in most cases the subject is included as a subtopic in the compulsory Science or General Paper. Agriculture appears as a separate, but optional paper only in Swaziland.

Throughout the countries Science and Agriculture are tested in the national examinations with using multiple-choice questions. The latest country to adopt this style of testing is Malawi which started applying such items from 1995 on. The decision to use multiple-choice items in the examination was preceded by two research analyses of the previous examination system.[6]

[6] See: Chimwenje, Catherine (1993) Evaluation of the Primary School Leaving Examination in Malawi: How the Examination meets its educational and selection Goals. PhD-thesis. Univ. of Sussex/England; Bradbury, Richard (Oct. 1992) Primary Science School Leaving Examinations. Malawi-German-Primary Science Project, Occasional Papers No. 1.

The opposite happened in Uganda, where 1983 multiple-choice questions in the examinations were completely abolished and pupils had to get used to giving short answers in English to each item. As a consequence of this revision the number of questions was reduced allowing more time for the written statements from pupils allowing assessment of a wider range of attainments. Swaziland has tried to compromise between multiple-choice and open-ended questions by combining both. Science as well as Agriculture are tested in the end of primary examination with two papers each. For example the Science test consists of a paper with 40 multiple-choice items and another with six questions where short answers are expected.

What kind of multiple-choice questions are used in the examinations? The claims of those responsible for the design of the examination papers do not match the results shown by analyses of the actual papers intended to test pupils' performances in the science subjects. With the exception of Kenya all the other countries appear to include large proportions of recall questions in Science and Agriculture. On average two thirds of the test items fall under this category. Questions which test pupils' ability to apply what they have learned to new situations, or which require an understanding of how facts are linked to one another, are much less frequent, and in most countries account for 25 to 35% of all Science questions. The case of Kenya demonstrates that the application of skills and knowledge acquired in schools can be at the centre of the examination with 50 to 60% of all items intended to work at this level. This leaves a substantial proportion of the total number of questions to test higher order skills (10-20%).

The structure of examination questions in the science subjects shows a clear concentration on those multiple-choice items testing simple knowledge. Higher-order skills or the capacity for applied thinking are rarely tested. The good intentions of those setting the examinations to evaluate achievement based on the educational objectives of subject curricula seem to run into difficulty when skills are valued which require evidence of comprehension, application and communication skills. In a provisional analysis of Environmental & Agricultural Science in the national primary school Grade 7 Examination in Zimbabwe, Lewin shows that most items he analysed in the General Paper required only the recall of information. Knowledge items accounted for 66% of all Science items, comprehension items for 28% and application items for only 6% of the total items in the 1990 and 1991 examinations papers. »Though the skills of comparison and classification can be tested with multiple-choice items they appear not to be. There are very few items that deal with measurement skills. A small number of items are concerned with interpreting data. Thus opportunities seem to have been missed... to interrelate the cognitive demand of examination items with the science skills identified in the syllabus document«[7] Although most of the countries only use multiple-choice items for their tests in Science and Agriculture, examination specialists are aware of the limitations of such a test method, particularly with regards to encouraging the expression and originality of the pupils.

[7] Lewin, Keith (May 1992) Provisional analysis of national examination papers 1990 and 1991, Environmental and Agricultural Science in Zimbabwe. Preliminary analysis, p. 4.

All countries of the region included in this survey report different performances of girls and boys in the end of primary school examinations. On average girls achieve lower scores than boys. There is some evidence that boys perform better on multiple-choice questions, whereas girls show greater talent in free response items.[8] It is also probable that, since no examination construction procedures specifically filter out items with strong gender differentiation in performance, that differences in performance are partly a result of the way items are chosen. The 30 items developed during the training workshop in Nyeri/Kenya in 1994 and tested in six different primary schools with more than 300 pupils showed gender differences in pupils performance. This mock-examination in Science/Agriculture indicated that boys did much better in all items referring to more abstract/technological questions (levers, pulleys etc.). Girls however did significantly better on weather recording (charts) and on agricultural problems dealing with maize growing. Interestingly in the best performing school where girls and boys are boarders from Std. I and enjoy the advantages of a well-staffed and well-equipped elite school, girls and boys scored equally highly on all items. Systematical checks of test items to prevent gender biases are still to be included in the designs of primary school leaving examinations.

[8] See also Keeves, John P. (1994) National examinations: design, procedures and reporting. UNESCO: IIEP, Paris, p. 71.

Multiple-Choice Items

Advantages:

• Because multiple-choice questions take little time to answer, a test can measure a broader range of content than is possible with a test which relies solely on essay items or performance tasks.

• They are less costly to score. If specially prepared forms are used, they can be machine scored, allowing thousands of answer sheets to be scored in a very short period of time. Marking is also more reliable.

• They are an efficient way to measure recall of factual knowledge and some skills.

Disadvantages:

• It is more difficult to design multiple-choice questions which measure higher levels of thinking and problem solving.

• It is more difficult to design questions which measure more complex, real-life types of skills and thinking.

• They take more time to develop because of the need to construct four or five response choices.

• Multiple-choice tests promote multiple-choice teaching - that is, teaching where students are always looking for the one right answer.

• There is a significant chance of being able to get the correct answer by guessing, which is not the case with performance tasks or essays. If a multiple-choice question has four options, the student has a 25 percent chance of guessing the item correctly. Though this may not change the rank order of pupils, it may give a misleading impression of actual achievement.[9]

[9] Adapted from Capper, Joanne (March 1994) Testing to Learn... Learning to Test. A Policymaker's Guide to Better Educational Testing. Executive Summary. Academy for Educational Development, Washington, D.C.

Further efforts are needed to ensure that end of primary examinations are of a high quality and help at the same time to improve meaningful teaching/learning in primary schools. The application of multiple-choice questions in national examinations influences classroom teaching. »If the examination primarily contains items which have students selecting from among options, then students are likely to spend much of their time preparing for the test with worksheets in which they select the correct answer. This type of behavior is less likely to help students make the extensive web of mental connections which help them to understand and use what they learn in school«.[10] Future examination reforms need to pay attention to three priority areas:

(1) Devising assessment tasks which are stimulating and test active, problem-oriented thinking, in valid and reliable ways;

(2) selecting questions which are as fair as possible to all groups involved (especially to girls, pupils living in remoter or rural areas, and to pupils from less privileged socio-economic backgrounds);

(3) including some open-ended tasks in the assessment process to avoid sole dependence on multiple-choice questions (see BOX »Multiple-Choice Items«).

[10] ibid., p. 23.

Over the last decade one country in the region has successfully improved the internal quality of the examination at the end of primary education to make examinations more meaningful and relevant to the things taught in school based on the curriculum. By changing the type of questions asked in the Kenya Certificate of Primary Education examination from simple recall questions to items testing intellectual skills, the examination reform has supported curriculum changes. »... the whole success of such an operation in Kenya, as elsewhere, depends on building up the skills not only of those who devise the items but also ultimately of the children who read them, since a 'thinking type' question almost invariably employs more difficult language structures than a 'recall type'«.[11]

[11] Hawes, Hugh & Stephens, David (1990) Questions of Quality - Primary Education and Development. Longman, p. 170.

Another problem causes even greater headaches. The increasing importance of examinations has negative repercussions on classroom teaching and leads to all different kinds of manipulation during and after the examinations. Uganda's National Examination Board reported a situation typical for nearly all other countries:

• Primary schools concentrate solely on those subjects featuring in the national examination;

• those subjects not tested in the examination (like Art & Crafts, Music, Physical Education) disappear from the schools' timetable;

• children spend much more time in school than officially planned, because of many mock-examinations;

• even during vacations tutoring (against payment) for examinations takes place in schools;

• private coaching clinics for end of primary school examinations flourish;

• examination cramming texts are bought in preference to official curriculum materials.

Similar experiences are also reported from Kenya. The struggle for being amongst the top performing primary schools in the country and having as many pupils as possible placed in the country's elite secondary schools has produced a classroom situation where children are continuously assessed through written examinations throughout the year. Mock-examinations are designed and set by a panel of teachers and parents have to pay fees for those »tests«. On the average children write nine examinations per year and subject. The third term of the last year in primary school is completely devoted to former examination papers of the Kenya National Examinations Council. Thus, large parts of the curriculum for Std. VIII are not covered properly. Every administrative unit (zone, division, district) organises special mock-examinations to provide as much opportunities as possible to getting prepared for the final national examination. Most worryingly perhaps, practical activities which provide opportunities to apply knowledge and concepts are relegated to occasional activities with little coherent purpose.

In many countries, much more effort needs to be made to ensure that the examinations are of the highest possible quality. Apart from the psychometric qualities of validity and reliability, the following three criteria are suggested for judging the quality of examinations.

• **Active thinking.** Testing only recall information is to be avoided. Active ideas are held in the mind as pictures in which elements are linked to each other in patterns. Knowledge-based questions should test understanding of these patterns. Such questions should be concerned with causes, consequences, and reasons; with relationships, trends, and general ideas. In other words with understanding. The assimilation of the knowledge is a characteristic of active thinking. Examinations in some subject areas should include a number of data-based questions requiring students to read and interpret new information. Examinations should also include questions testing the application of knowledge to new situations including drawing inferences, making predictions, or solving problems. There is always the problem that what is new to one student may not be new to another but, in general, it is possible to construct questions which are known not to be in the major textbooks that have been used. The above points have been well known since Bloom's Taxonomy of Educational Objectives« (Bloom et al, 1956) appeared but surprisingly are often ignored.

• **Equity.** The examination should, to the maximum extent possible, be fair to all groups: to girls, to students living in rural areas, particularly in remote parts of the country, and to those from less-privileged socioeconomic backgrounds. Biases in individual questions are often unavoidable (especially in questions which are experience-based). However the question setters should attempt to ensure that, over the examination as a whole, these biases counterbalance each other as much as possible. This is, however, no easy task. The performance of students in the remote and less privileged schools is nearly always adversely affected by the quality of the education they receive and therefore it is important to ensure that avoidable biases in examination questions do not compound their disadvantage.

• **Open-ended questions.** Even when there is evidence to indicate that, from an assessment point of view, the examination of open-ended questions does not provide additional information for prediction purposes it is nevertheless desirable to include open-ended items simply to ensure that teachers do not only use multiple-choice items. It must also be remembered that it is impossible to assess students' ability to develop a logical argument, to defend a point of view, to write essays and the like with multiple-choice items.[12]

[12] Ross, Kenneth N. & Mählck, Lars (eds.) (1990) Planning the quality of education. The collection and use of data for informed decision-making. UNESCO: IIEP. Pergamon Press, pp. 28, 29.

In this way children are continuously assessed throughout their school career, starting with tests in Std. I. Teachers have become so used to these assessment exercises and the related fringe benefits like additional income, that they defend the tests as a necessary means for providing better education and increasing children's chances to pass the examination. As a result teaching/learning in Kenya's primary schools has become examination-oriented to an extent that the pedagogical objectives of the curriculum are more and more neglected. »The learning process is to fit the cut-throat competition for high grades in public examinations. The teachers use all tricks they can to enable their children to perform well in public examinations, including drilling them on how to answer examination questions and giving frequent trial test, known in Kenya as mock examinations«.[13] To counteract these unhealthy developments the Kenya Institute of Education now tries to design model items to assess children at different stages in primary school to reduce the inflation of mock-examinations and improve their range and quality.

[13] Mulusa, Thomas (1992) Pluralistic education in sub-Saharan Africa. An Overview. In: PROSPECTS, Vol. XXII, No. 2, pp. 159-170, p. 162.

Pupils' knowledge and abilities can be measured in many ways. Because the different formats of assessment have their advantages and disadvantages some countries try to include various kinds of question formats in their examinations, like Swaziland using multiple-choice items and open-ended questions in the Science paper. Performance tasks are a further possibility to measure pupils' understanding of processes and the ability to demonstrate skills and techniques in real-life situations. »Students at the primary level can learn to classify and observe - two basic and essential elements of the scientific process. Hands-on science tests at this level might involve students in putting seeds and beans into categories and explaining why they selected those categories, or measuring and recording various objects, such as their hands, feet, or pulse rate before and after exercise«[14] The use of performance tasks in examination however faces a number of constraints: Teachers need intensive training and assistance in learning how to teach such tasks, and the administration and scoring is time-consuming, costly and rather complex.

[14] Capper, Joanne, op. cit., p. 20.

Pros and Cons of School-Based Assessment

Arguments can be advanced in favor of and against school-based assessment (Heyneman 1988; Pennycuick 1990). Arguments in favor go as follows:

• Since assessment by teachers is a crucial component of good learning and teaching, every effort should be made to improve teachers' competence in this area (Crooks 1988). If school-based assessment becomes part of the certification process, it is likely that greater effort will be invested in improving teachers' general competence in assessment, and this should have beneficial effects on teaching and learning.

• School-based assessment provides immediate feedback information to teachers on student achievement and teaching effectiveness.

• Since school-based assessment is carried out over time and by a person who knows students well, it is likely to provide a more valid and reliable appraisal of a student's achievements than can a single external terminal examination. In this context, one commentator in Zambia has observed that the school is »the only place where there is enough information to do reasonable justice to a pupil« (Kelly 1986, p. 20).

• School-based assessment permits an extension of the range of curriculum topics to be examined. The present system of examinations limits the range of achievements that can be assessed and must narrow the curriculum in schools. Aspects of achievement that cannot be satisfactorily assessed in a terminal examination include a student's ability to plan and organize a project and persevere with it over time. While the assessment of oral and practical skills may be carried out in a terminal examination, inevitably it will be limited, artificial, and expensive.

• School-based assessment reduces the undesirable back-wash effects of external examinations.

• School-based assessment, if spread over the year, can increase the level of pupil motivation and application throughout the year.

Some of the following arguments advanced against the use of school-based assessment in the certification of students:

• Its use can change the nature of the relationship between teachers and students towards making the judicial aspect of the teacher's role more prominent.

• Marking standards in school-based assessment are likely to vary both within and among schools. While moderation procedures can help, they tend to be expensive.

• School-based assessment can subject teachers to considerable parental pressure, especially during the periods leading up to and immediately after critical public examinations.

• School-based assessment requires teachers to devote more time to assessment and recording.

• School-based assessment gives rise to a variety of administrative problems for schools, such as what to do when students are absent for tests or when students transfer from one school to another.

• Teachers' assessments are subject to a variety of biases.

• In many instances, it is difficult if not impossible to apply school-based assessment to non-school-based candidates.

• Teachers' assessments are often technically unreliable and may have low content and predictive validity.[15]

[15] Adapted from: Kellaghan, Thomas and Greaney, Vincent (1992) op. cit., pp. 42, 43.

The assessment of practical subjects in the final examinations poses particular problems. Should e.g. in Art & Craft pupils produce something for the examination or should the progress made over a certain period being continuously assessed and taken into consideration for the ultimate judgement? Some countries have therefore started to experiment with some kind of continuous school-based assessment. The advantages and disadvantages of school-based assessment are well summarised by Kellaghan and Greaney in a study of fourteen African countries (see BOX). Again, as in the case of using performance tasks, teachers need to be trained carefully for this type of assessment. Furthermore, parents and communities must have faith in the fairness of such examination procedures.

3. Country Reports/Examination Papers

3.1. Botswana

3.1.1. Overview

End of Primary School Examination

1 Title of examination:	Primary School Leaving Examination
2 Amount of fees charged:	Nil
3. Examination after years in primary school (6, 7, 8 years):	7 yrs
4. Children's entry age in primary school:	7 yrs
5. Number of pupils sitting examination in 1994:	36,158
6. Examination subjects offered:	• Setswana, • English • Mathematics • Science • Social Studies. The Setswana and English papers have an essay component in addition. The other papers are objective papers.)
7. Language of examination:	English (except for Setswana paper)
8. Institution setting the examination questions:	Department of Curriculum Development and Evaluation, and Examinations, Research and Testing Division
9. Have there been any reforms in the examination questions?	Yes
When? (year)	1991
What kind?	The examination papers were nine and they were cut down to five, thus excluding the aptitude testing papers which were previously used for selection. All the questions now test skills prescribed by the curriculum. Criterion-referenced testing is considered for implementation.

10. Stages of development of examination questions (please describe):	• Appointment of Chief Examiner by Examinations Unit. • Convening of the item writing workshop, involving primary school teachers, Curriculum Development experts, Examinations experts, Research and Testing experts, and Education Officers. • Compilation of the paper by the Chief Examiner. • Shredding session comprising Curriculum Development Unit, Examinations Unit, Research and Testing Centre, Chief Examiner and invited educationists. • Trial testing. • Item analysis. • Compilation of final paper by Chief Examiner.
11. Type of examination questions and distribution of different kind of questions.	Details vary from subject to subject.
12. Is continuous assessment incorporated in the final examination?	Yes [ ] No [x]
13. Are examination items pretested?	Yes [x] No [ ]
14. Which professional groups are involved in setting the examination questions?	• Primary school teachers • School inspectors • Tutors of TTCs • Curriculum Developers • Research Testing Officers (Technical Expertise) • Education Officers (in-service)
15. Are the same professionals who set the examination questions involved in marking papers?	Yes [x] No [ ] The essay components (English and Setswana) of the Primary School Leaving Examination are marked by primary school teachers.
16. How are examination results used for improving teaching in primary schools?	Examination reports are sent to schools to describe the behaviour of each item during marking and how markers view it generally. The reports of the results are given to Members of Parliament, Education Officers, schools, the district administrators and all government departments. The authorities are motivated for future planning by the type of result achieved.
17. To what other uses are the examination results put?	They were formerly used for selection to secondary education. With universal access to nine years of Basic Education the selection purpose fell away in 1993.
18. Main problem with Primary School Leaving Examinations?	./.

3.1.2. Primary School Leaving Examinations: The Case of Botswana

by Mookgweetsi Masisi, Curriculum Development and Evaluation Department

The Primary School Leaving Examination in Botswana is the joint responsibility of the Examinations, Research and Testing Division, and the Department of Curriculum Development and Evaluation at the Ministry of Education. It must be mentioned at the outset that practising primary school teachers play an extremely significant and active role throughout the process.

Functionally, the Examinations, Research and Testing Division is responsible for the administration of examinations and for ensuring that what needs to be done at various points gets done. The actual development of examination items is carried out at an item writing workshop. Participants of a primary school leaving examination item writing workshop are practising teachers who are selected mainly by their Education Officer in collaboration with the responsible Research and Testing Officer and/or Curriculum Officer. More as a matter of principle than as a rule, upper primary school teachers are selected for the workshop. This is because the examination is constructed from those topics and objectives that are taught in standards five, six and seven. It is primarily the responsibility of the Examinations, Research and Testing Division to ensure that such a workshop gets held, and to ensure that all the necessary criterial attributes of test development are given due attention throughout the workshop. The Curriculum Development and Evaluation Department, which takes part in such workshops, is responsible for ensuring adherence to the test plan (curriculum spread). Curriculum objectives or extrapolations of the topics serve as a guide when designing items. The intention is to produce items that are positively related to the stated objectives.

The reality of this is obviously mitigated in subjects that either do not have stated objectives or have »fuzzy« objectives. The Examinations, Research and Testing Division itself plays an enabling role of administration - ensuring that schedules are not disregarded. The same division bears the responsibility for appointing a chief examiner. It is at this state also that the first evaluation by professionals takes place as regards validity of the items. Whilst the Examinations, Research and Testing Division personnel will ascertain adherence to the internal qualities of the items, the curriculum officers as well as the teachers will ascertain the curricular validity of the items in the context of the syllabus and classroom.

Following the item writing workshop, at which items are generated, the chief examiner puts together a draft paper which is presented for discussion at a shredding session. Professional personnel from the Curriculum Development and Evaluation Department, the Examination Research and Testing Division, education officers and teachers are present and take an active part in the deliberations. At such a shredding session, attention is given to the construct, face and curricula validity and the shredding (editing) is undertaken with these in mind. All observations and recommendations are noted by the chief examiner and followed by corrective measures. This having been done, a paper is prepared by the chief examiner who then hands it over to Examinations, Research and Testing Division for trial testing. Through the trial test, analyses of individual items are derived. The trial test establishes the item difficulty. The item discrimination is also established which checks the internal consistency of the test. It is the trial test results together with the professional opinion of the chief examiner and the curriculum officer which determine the ingredients of the final paper.

Stages in Examination Development Process/Item Examples

1. Appoint chief examiner

2. Hold item writing workshop

3. Chief examiner compiles a draft paper

4. Shredding session

5. Chief examiner reconstructs draft paper

6. Trial testing and item analysis

7. Chief examiner constructs final life paper

At this juncture, examples of some items from some past Primary School Leaving Examination papers are in order. The statistics presented with them are the actual ones from their trial testing. Given that Agriculture has only recently been offered at the primary school level and elements of Environmental Science are currently being tested under the auspices of Science, only the Science examples are provided.

Below are five examples from past examination papers.

1. A certain season has the longest days, another has the longest nights. What are they?

A	Autumn, spring	.08	-.14
B	Summer, winter	.61	.33
C	Spring, summer	.12	-.16
D	Summer, autumn	.16	-.16

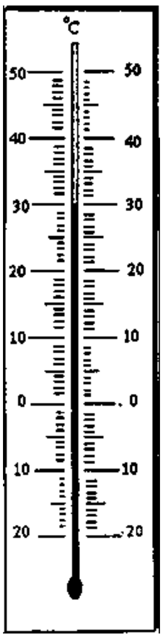
Source: Item 6 Science PSLE 1989

2. During a thunderstorm, light is sensed before sound because

A	light is not as heavy as sound.	.13	-.20
B	eyes work more quickly than ears.	.05	-.15
C	light travels faster than sound.	.75	.33
D	ears do not react as fast as eyes.	.04	-.14

Source: Item 7 Science PSLE 1989

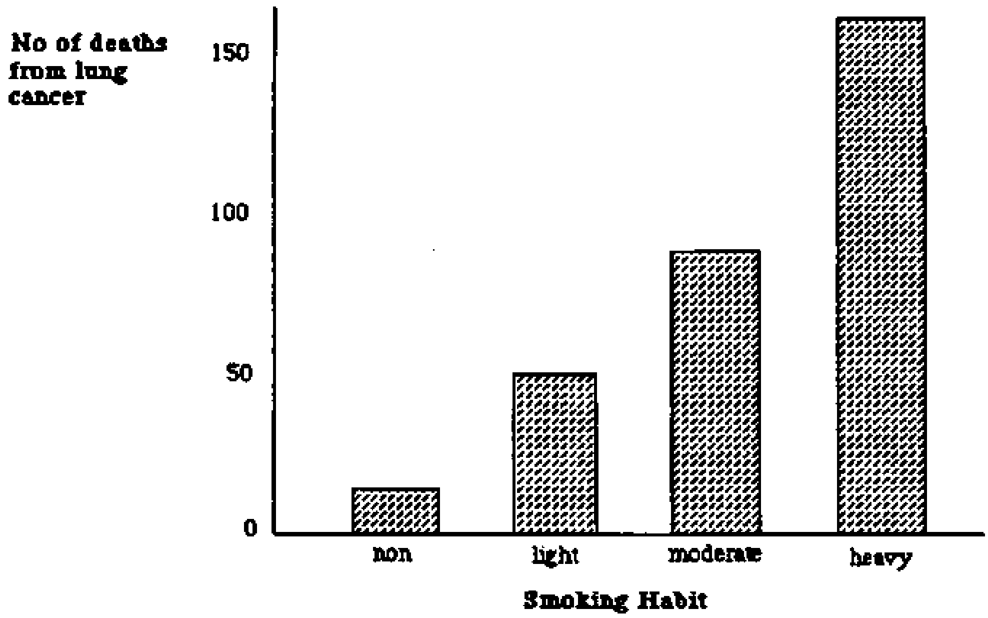
3. What is the temperature shown by the thermometer below?



A	30°C	.22	-.32
B	31°C	.72	.41
C	32°C	.02	-.11
D	33°C	.02	-.15

Source: Item 8 Science PSLE 1990

The graph below shows the smoking habits of people who have died from lung cancer.



4. From the information in the graph which of the following statements is correct?

A	People who do not smoke can also die of lung cancer.	.15.	.06
B	Only people who do not smoke die of lung cancer.	.05	-.21
C	Smoking reduces chance of death from lung cancer.	.57	.07
D	The less one smokes the greater the chance of dying from lung cancer.	.20	.00

Source: Item 28 Science PSLE 1990

Four farmers planted their crops for four years in the following way.

	Farmer A	Farmer B	Farmer C	Farmer D
Year 1	beans	sorghum	potatoes	maize
Year 2	maize	potatoes	maize	sorghum
Year 3	sorghum	maize	beans	maize
Year 4	beans	potatoes	melons	sorghum

5. Which of the four farmers **A**, **B**, **<u>C</u>**, and **D** had the best pattern for crop rotation?

.18 -.10
.08 -.12
.49 .22
.23 -.06

Source: Item 34 Science PSLE 1990

It will be realised that given the nature of our PSLE, an inordinate emphasis is placed on achievement norm-referenced testing. Part of the reason is its convenience for selection, but frankly it is also easier to undertake. The utility of using such tests for selection is diminishing over time as access to the next level is expanding.

Data Capture and Processing

Achievement scores are captured through machine scorable sheets. The sheets are scanned and item responses recorded on to magnetic types at the Examinations, Research and Testing Division (ERTD). Programmes for merging student name files and test scores, checking inconsistencies and missing data are run by the Government Computer Bureau (GCB). The ERTD does error checking and editing of the merged files.

The raw scores for each candidate are standardized to T-scores. The standardization formula is as follows:

$$10\left(\frac{x-\bar{x}}{SD}\right)+50$$

Where x = subject core
$\bar{x}$ = subject mean
SD = subject standard deviation
10 = given standard deviation
50 = given mean

The transformed subject scores are graded into A, B, C, and D. Sample:

Student 001									
	Sets Essay	Sets Obj. T.	Eng Essay	Eng 1	Eng 2	Maths 1	Maths 2	Soc Stu	Science
Row Scores	25	39	26	40	43	40	36	32	37
T - scores	58	47	60	58	57	63	60	53	55

Student 002									
	Sets Essay	Sets Obj. T.	Eng Essay	Eng 1	Eng 2	Maths 1	Maths 2	Soc Stu	Science
Raw Scores	24	33	25	33	33	22	26	18	24
T - scores	56	50	58	51	48	44	46	38	41

The transformed scores are then added together and averaged to obtain an aggregate which is graded into A, B, C, and D.

Sample:

Student A				
	T-Scores	Grades	Aggregate Score	57.76
Maths 1	63	A	Pass Level	B
Maths 2	60	B		
Science	55	B		
Soc Stu	53	C		
Eng 1	59	B		
Eng 2	57	B		
Sets	58	B		

Grading

There are set cut off points used for grading both subject test scores and aggregate scores.

<u>Subject Grading</u>

Grade	Standard Score
A	63 - up
B	55-62
C	46-54
D	45 - down

Aggregate Grading

Grade	Standard Score	SD Range	Approx. % of Candidates
A	63.01 - up	+ 1.00 SD & over	8
B	55.01 - 63.00	+ 0.5 SD - 1.00 SD	24
C	46.01 - 55.00	- 0.5 SD - + 0.5 SD	42
D	46.00 - down	- 1.5 SD & below	26

It is the aggregate score that is used in the merit list which in turn is used for selection where and when applicable.

Reporting

Various reports are produced by the Government Computer Bureau for the Examinations, Research and Testing Division. These are procedural reports some of which are used internally and the rest for public consumption. The internal reports are the Raw Scores, the Transformed Scores and Item Analyses.

Sample: Item Analysis

Question	Answer	A	B	C	D	None	Multi
		.04	.73	.20	.01	.00	.00
001	B	-.11	.36	-.29	-.09	.00	.00
		.14	.72	.07	.06	.00	.00
002	B	-.15	.34	-.19	-.19	-.01	.00
		.10	.19	.05	.64	.00	.00
003	D	-.10	-.29	-.14	.39	.00	.00

The Examinations, Research and Testing Division also receives a merit list which is used mainly for selection purposes by the Secondary Education Department

Sample:

Merit List

Pass level	Aggr Score	Sets	Eng 1	Eng 2	Maths 1	Maths 2	Soc Stu	Science
A	79.30	0	74	71	82	89	81	79
A	78.45	78	76	71	83	83	79	80
A	78.07	0	78	72	81	82	79	78
A	77.73	0	75	72	82	84	80	74

All government departments, schools, primary education officers and parastatals receive the overall results document which shows subject grades (A, B, C, and D), aggregate pass levels (A, B, C, and D) and various summaries. The results are shown by centre. At the end of each centre's results are summaries for the centre. The document also contains national summaries showing the overall number of candidates per district, the breakdown per grade level and the percentage of candidates in each grade A, B, C, or D. These summaries can be used to tell how districts perform against others.

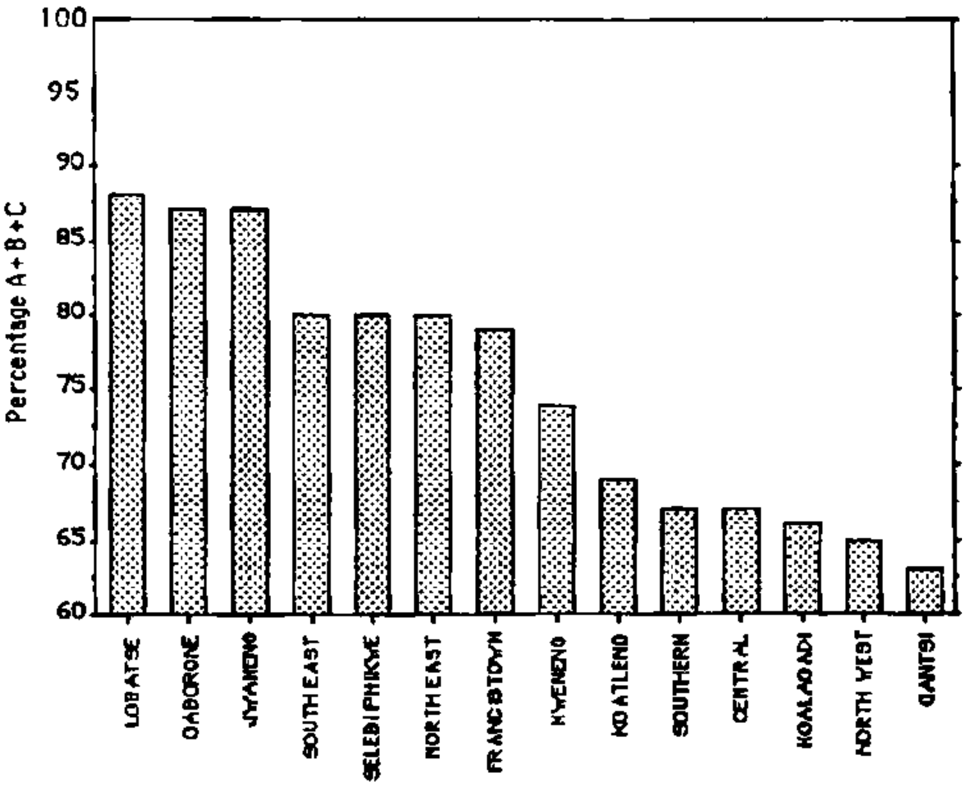
Sample:

Actual Results

Pass level	Sets	Eng 1	Eng 2	Maths 1	Maths 2	Soc Stu	Science
B	c	B	A	A	A	A	A
A	B	A	A	A	B	A	A
C	C	C	C	B	C	B	C
c	c	B	C	C	C	C	D
B	A	B	B	B	B	A	B

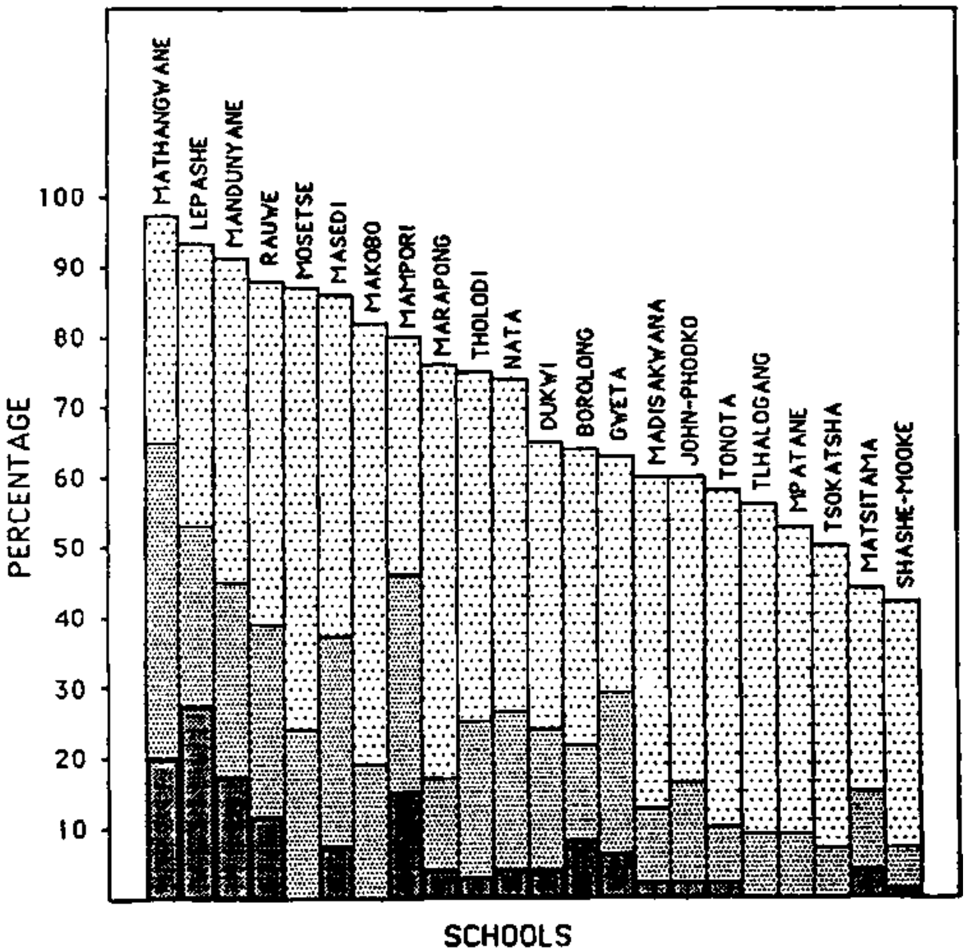
A - 29 B - 34 C - 24 D - 6 Total - 93

Members of Parliament too can receive reports on request for their political districts. Most leaders have provided their constituencies with trophies as encouragement and so with the help of the reports they are able to tell how the different schools in their constituencies perform over time. The reports can be used to attempt to establish causality of success or the lack of it, hopefully followed by remedial action.



1991 PRIMARY SCHOOL LEAVING EXAMINATION PERCENTAGE A+B+C CATEGORIES BY DISTRICT - Sample

The Examinations, Research and Testing Division produces some reports for education officers only on request. An education officer would be in a position to provide services to schools based on their performance from year to year. For instance a school might require inservice training, more qualified teachers, more classrooms etc.



PROPORTIONS OF STUDENTS OBTAINING "A", "B" AND "C" PASSES ON THE 1991 PSLE: CENTRAL NORTH WEST REGION - Sample

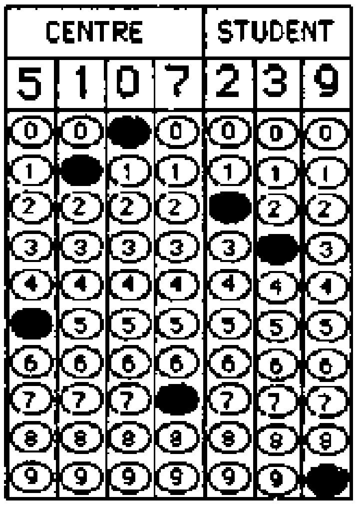
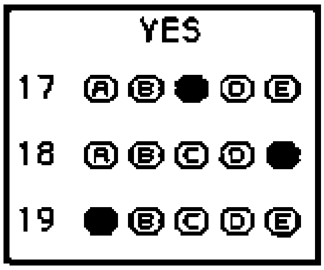
Directions

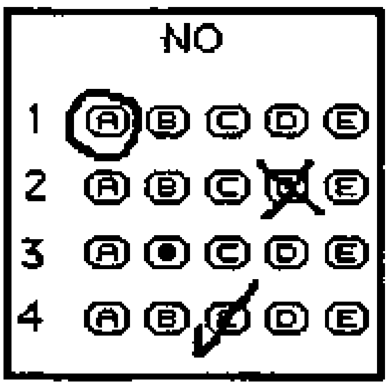
1. Use HB pencil ONLY. DO NOT use ink or ball point.
2. Print your name on the answer sheet in the space provided.
3. Fill the oval by BOY if you are a boy or GIRL if you are a girl.
4. In the four boxes under CENTRE write your centre number.
   In the three boxes under STUDENT write your examination number. In the column of numbers below each box, fill the oval that has the same number that you entered in the box.
   Fill the ovals with heavy black marks that fill the oval:



5. When you are told to begin, work as fast and as accurately as you can. If you cannot answer a question, do not spend too much time on it; go to the next question and come back to it later.
6. You may do rough work on the test paper or on a sheet of blank paper. DO NOT use the answer sheet for rough work.
7. Several possible answers are given for each question. Select the answer you think is the best and fill the oval for that answer on your answer sheet.
8. Be sure to fill the ovals like this:



Erase completely answers that you wish to change.
Do not make any stray marks on your answer sheet.
If more than one oval is filled for a question it will be marked wrong.
Be sure the oval you fill on your answer sheet is for the question you are working on in the test paper.
DO NOT mark the ovals like this:



If you do, your answers will be marked wrong.
9. Sample questions are given to help you. Read them carefully before doing the questions.

Sample Questions

Sample 1 If a drum-skin is tightened its note will

A. increase in pitch.
B. decrease in pitch.
C. sound louder.
D. sound quieter.

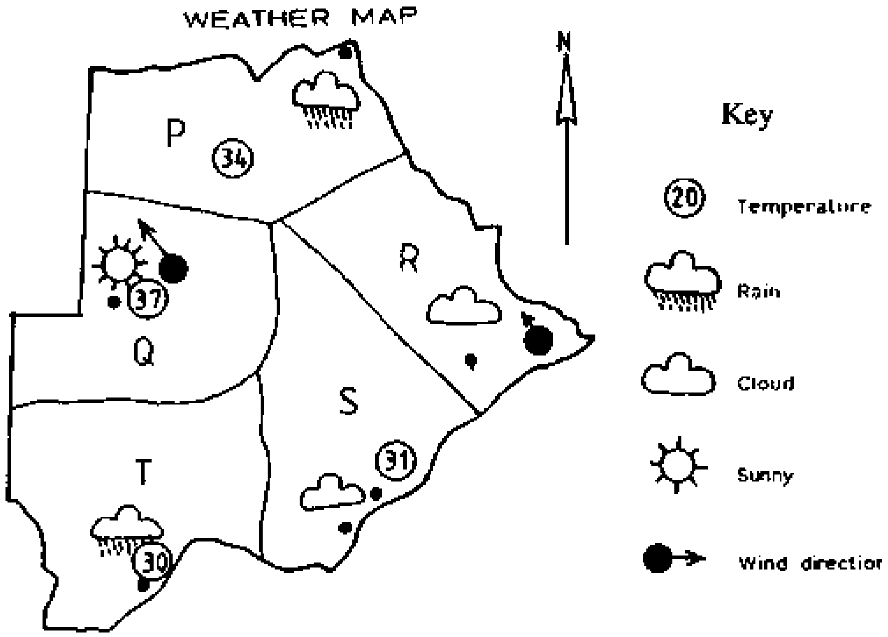
SAMPLE 1 ● Ⓑ Ⓒ Ⓓ Ⓔ

Sample 2 A man with a heavy cold finds his food tasteless because

A. the cold germs kill the taste of the food.
B. the cold germs numb the taste buds.
C. his blocked nose cuts out his sense of smell.
D. he has lost his appetite.

SAMPLE 2 Ⓐ Ⓑ ● Ⓓ Ⓔ

A group of Standard 7 pupils recorded what the weather had been like in regions P, Q, R, S and T on the map shown below. Use the information to answer questions 1 to 3.



1. In which of the following regions was it raining?

A P and Q
B R and S
C P and T
D S and T

2. In which direction was the wind blowing in regions Q and R?

A North-west
B South-east
C North east
D South-west

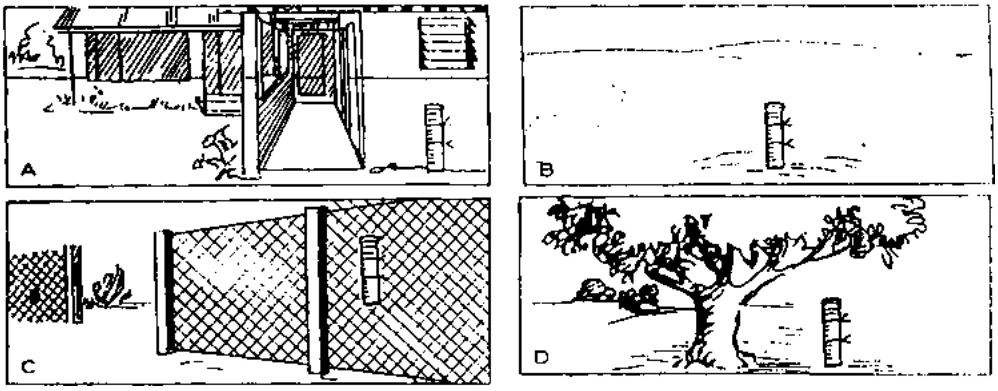
3. What was the weather like in region Q?

A Sunny and cloudy
B Sunny and windy
C Cloudy and windy
D Cloudy and hot

4. An anemometer is used to measure

A amount of rainfall.
B speed of wind.
C atmospheric pressure.
D temperature.

5. In which of the following diagrams is the rain gauge **correctly** placed?



6. Which of the following is a source of underground water?

A River
B Lake
C Dam
D Borehole

7. Evaporation takes place when

A steam turns to water.
B water turns to steam.
C water turns to ice.
D ice turns to steam.

8. Which water will a farmer who ploughs be most interested in when it rains?

A Water that runs off the surface of the soil.
B Water that is held around the soil particles.
C Water that runs off to the sea.
D Water that evaporates into the atmosphere.

Mpho heated some water in a container and recorded the temperature every two minutes as shown below. Heating was stopped after 28 minutes. Use the table to answer questions 9 to 11.

TIME (minutes)	0	2	4	6	8	10	12	14	16	18	20	22	24	26	28
TEMPERATURE (°C)	10	12	16	24	30	38	44	50	58	64	72	80	96	96	96

9. How long did it take for the water to heat up to 60 °C?

A 16 minutes
B Between 16 and 18 minutes
C Between 18 and 20 minutes
D 18 minutes

10. What was the temperature of the water at the beginning and end of heating?

	Starting temperature	End temperature
A	0 °C	96 °C
B	10 °C	86 °C
C	0 °C	100 °C
D	10 °C	96 °C

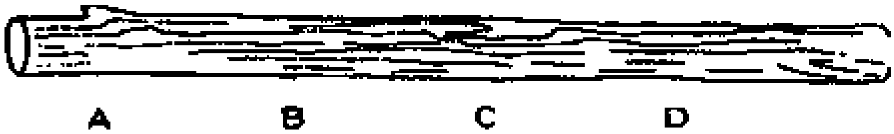
11. Which of the following reasons best explains why the temperature remained 96 °C between the 24th and 28th minute?

A The burner was not hot enough.
B The water had reached boiling point.
C All the water had evaporated.
D The thermometer was not working.

12. Which of the following organs is used to sense light?

A Skin
B Ear
C Eye
D Tongue

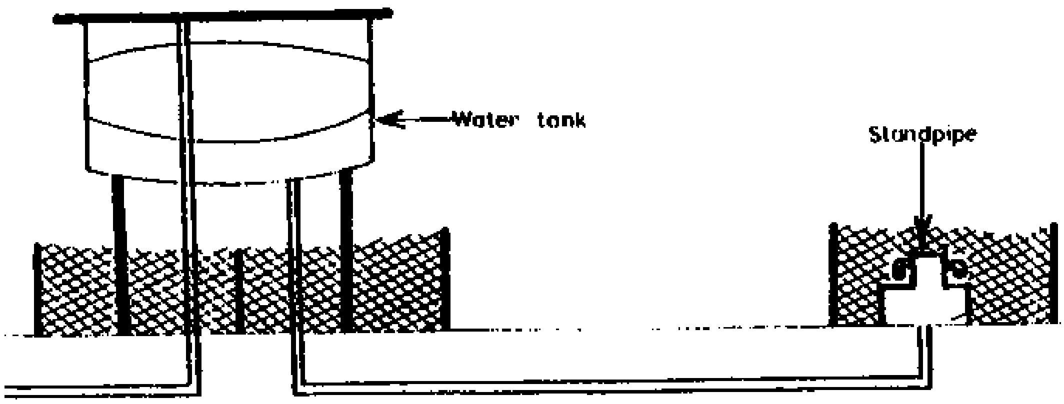
13. At which point in the diagram below would the stick break easily?



14. Which of the following activities **will help** in conserving soil?

A Burning wood
B Building houses
C Keeping many animals
D Digging terraces

The diagram shows a water system in a village. Use it to answer questions 15 and 16.



15. The water tank is covered to prevent

A the water from being contaminated.
B the water from evaporating.
C people from misusing the water.
D cattle from drinking the water

16. The water in the tank is purified by

A distillation.
B filtration.
C chlorination.
D sedimentation.

17. Wheelbarrows, scissors, hammers and spades are all examples of

A gears.
B inclined planes.
C pulleys
D levers.

Study the table below and answer questions 18, 19 and 20.

VERTEBRATE	**COVERING OF THE BODY**	**TYPES OF LIMBS**	**REPRODUCTION**	**BODY TEMPERATURE**
P	hair	arms and legs or four legs	young are born alive feed on milk	warm blooded
Q	feathers	wings and legs	eggs with hard shell	warm blooded
R	scales	legs	eggs, with leathery shell	cold blooded
S	damp skin	legs with webbed feet	eggs laid in water	cold blooded
T	thin scales	fins	eggs laid in water	cold blooded

18. Which of the following vertebrate groups have bodies covered with scales?

A P and R
B S and T
C R and T
D P and Q

19. Which of the following vertebrates are represented by the characteristics at P?

A Amphibians
B Reptiles
C Birds
D Mammals

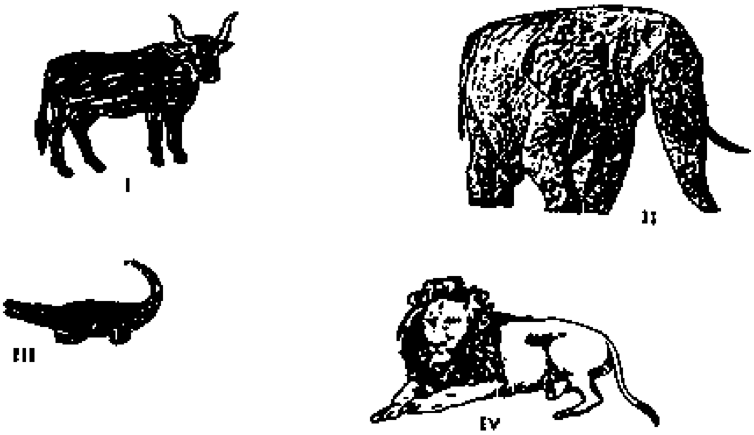
20. A frog is an example of a vertebrate represented by

A T.
B S.
C R.
D P.

21. When a substance is attracted to a magnet, it is said to be

A an insulator.
B magnetic.
C a conductor.
D non-magnetic.

Study the pictures of animals shown below, and answer question 22.



22. Which pair of animals shown below feeds on plants?

A III and II
B I and III
C IV and II
D I and II

23. Which of the following can be added to the soil to increase nutrients needed for plant growth?

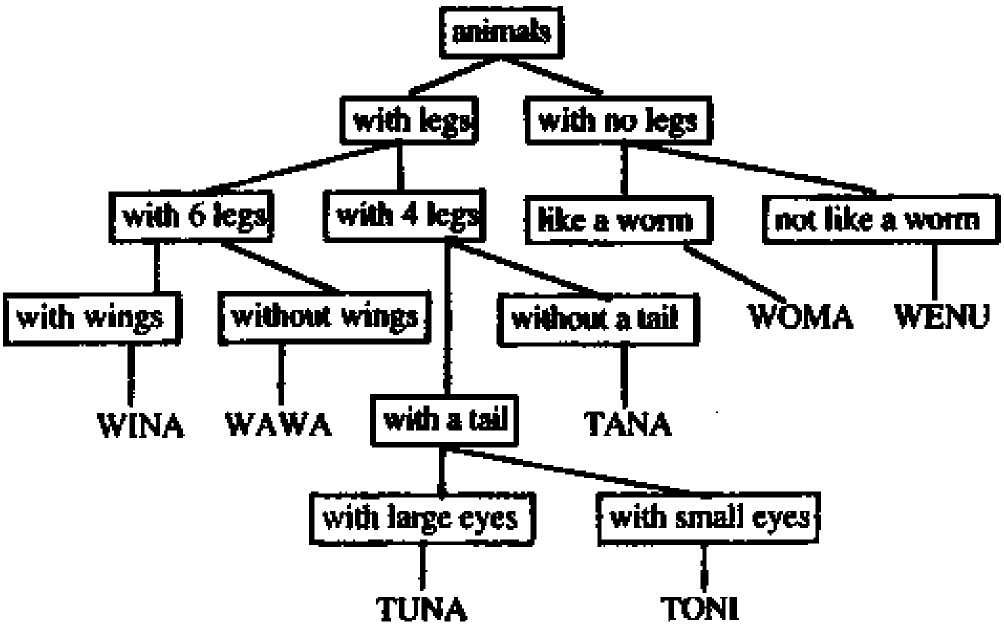
A Manure
B Plastic
C Sand
D Water

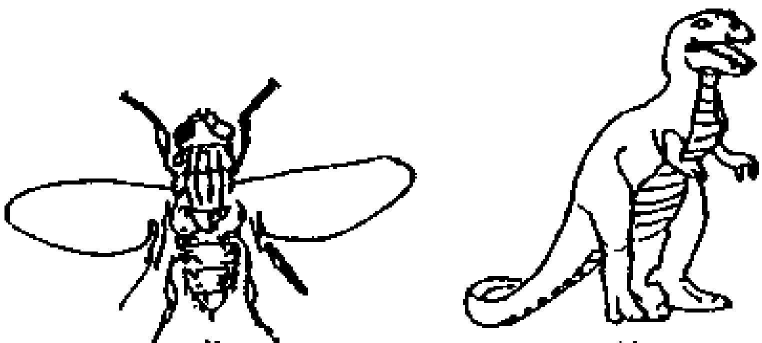
The diagram below shows parts of a plant. Use it to answer question 24.

24. The name of the part labelled I is

A leaf.
B fruit.
C flower.
D stem.

A class of pupils observed some animals in their environment. They classified them and invented names for them as shown below. Use it to answer questions 25 and 26.





X Y

25. What is the name of animal X?

A TANA
B WAWA
C TUNA
D WINA

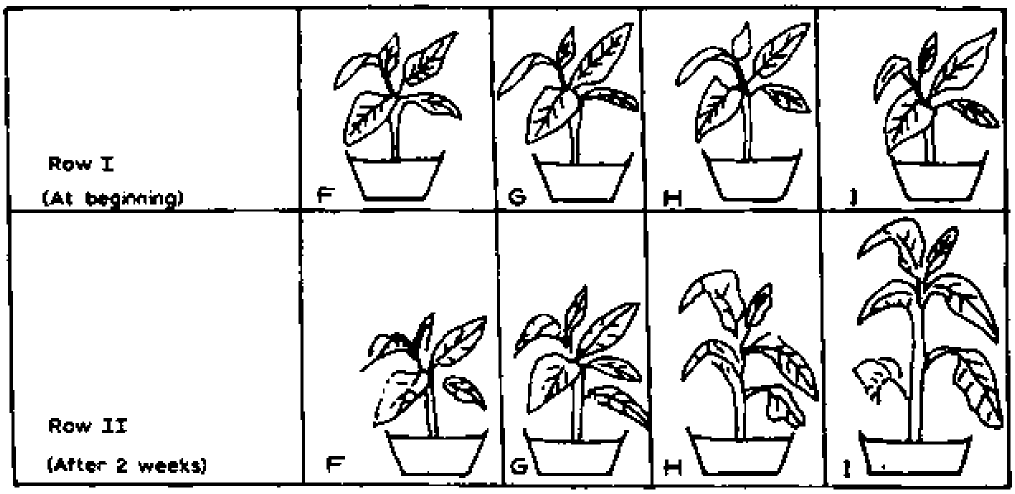
26. What is the name of animal Y?

A WAWA
B TANA
C TUNA
D WENU

27. Sound is heard when sound vibrations reach the

A eyes.
B nose.
C skin.
D ears.

Bontle grew plants in four different types of soil. She gave the plants the same amount of water and exposed them to the same amount of sunlight. Row I shows the plants at the beginning of the experiment and Row II shows the same plants after two weeks.

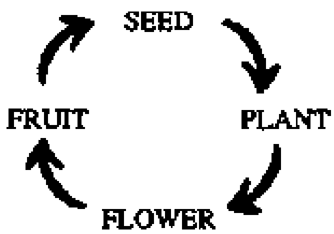


28. Which of the plants is likely to have been grown in loam soil?

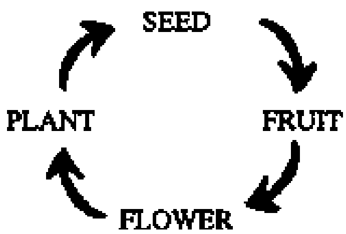
A F
B G
C H
D I

29. Which of these shows the correct order of the life-cycle of a flowering plant?

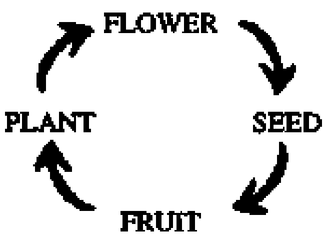
A



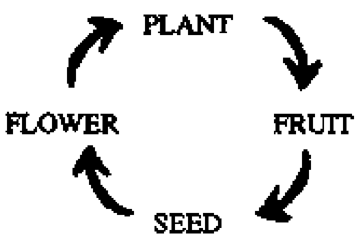
B



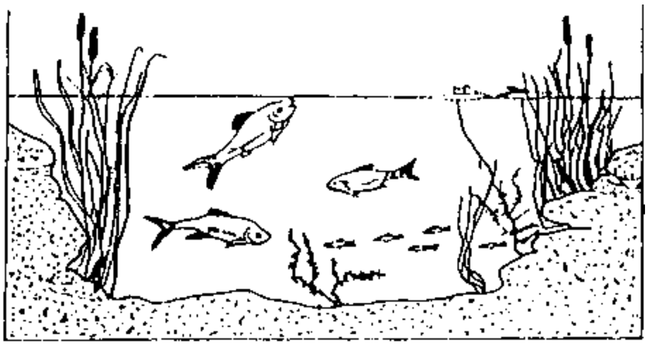
C



D



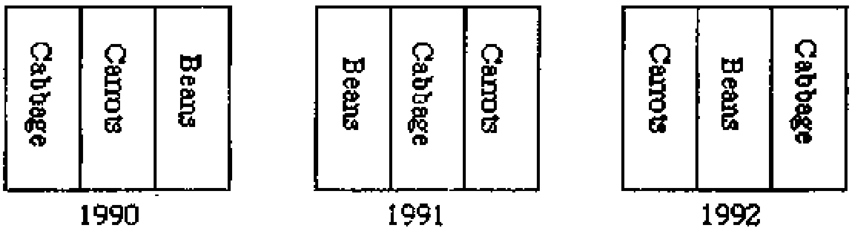
The diagram below shows an aquarium.



30. The water weed produces its own food. What is needed for this to take place?

A Movement
B Heat
C Sunlight
D Sound

31. The diagrams below show how plants were grown in a field for three years on the same plot.



What farming practice is most likely to have been carried out?

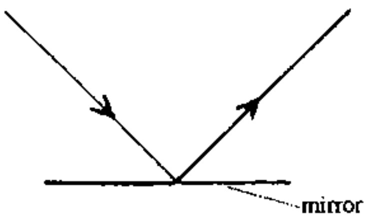
A Row planting
B Broadcasting
C Fallowing
D Crop rotation

32. Soil erosion can be prevented by

A ploughing down the slope.
B cutting down of trees.
C over stocking.
D ploughing across the slope.

33. What happens to light as it shines on the mirror as shown in the diagram below?

A It is reflected.
B It is refracted.
C It is absorbed.
D It is emitted.



The table below shows temperatures recorded in the morning and at midday for houses P, Q, R and S roofed with different material.

House	Temperature in the morning	Temperature at midday
P with iron roof	15 °C	37 °C
Q with clay tiles roof	18 °C	28 °C
R with grass roof	20 °C	27 °C
S with asbestos roof	18 °C	34 °C

34. Which house shows the greatest rise in temperature?

A P
B Q
C R
D S

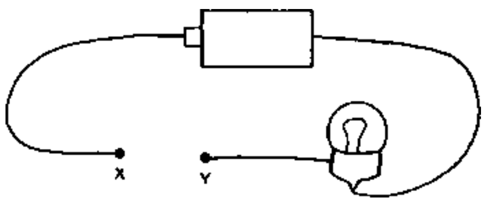
35. Which one of these instruments uses a string to produce sound?

A A guitar
B A drum
C A trumpet
D A flute

36. What would happen when the north pole of a magnet is brought near the north pole of a suspended magnet?

A They will attract.
B They will repel.
C Suspended magnet will lie in N-S direction.
D Suspended magnet will be demagnetised.

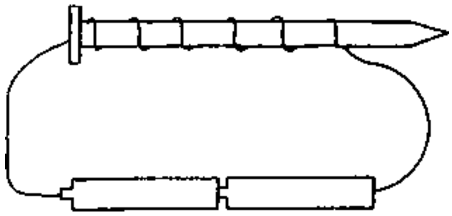
Dineo set an experiment shown in the diagram below to find substances through which electricity flows.



37. Which pair of substances would make the bulb light when they are connected between X and Y?

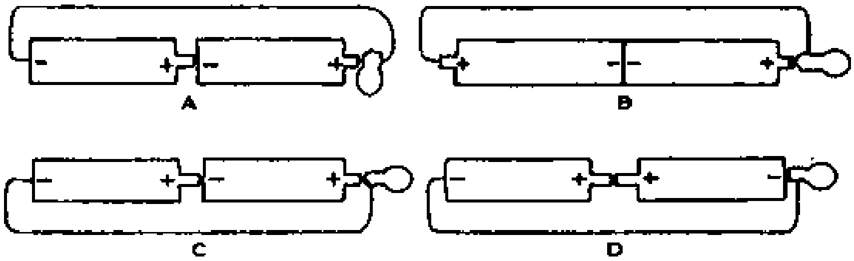
A Wood and paper
B Rubber and aluminium
C Glass and Plastic
D Iron and copper

38. What would happen when the number of coils is increased in the electromagnet shown below?



A The electromagnet would become weak.
B The nail would loose its magnetism.
C The electromagnet would become strong.
D The strength of the electromagnet would remain the same.

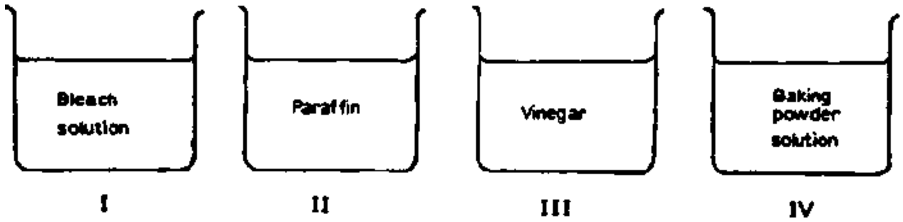
39. Which of the following connections would make the bulb light?



40. Which of these diseases is caused by lack of cleanliness?

A Scabies
B Syphilis
C Measles
D Malaria

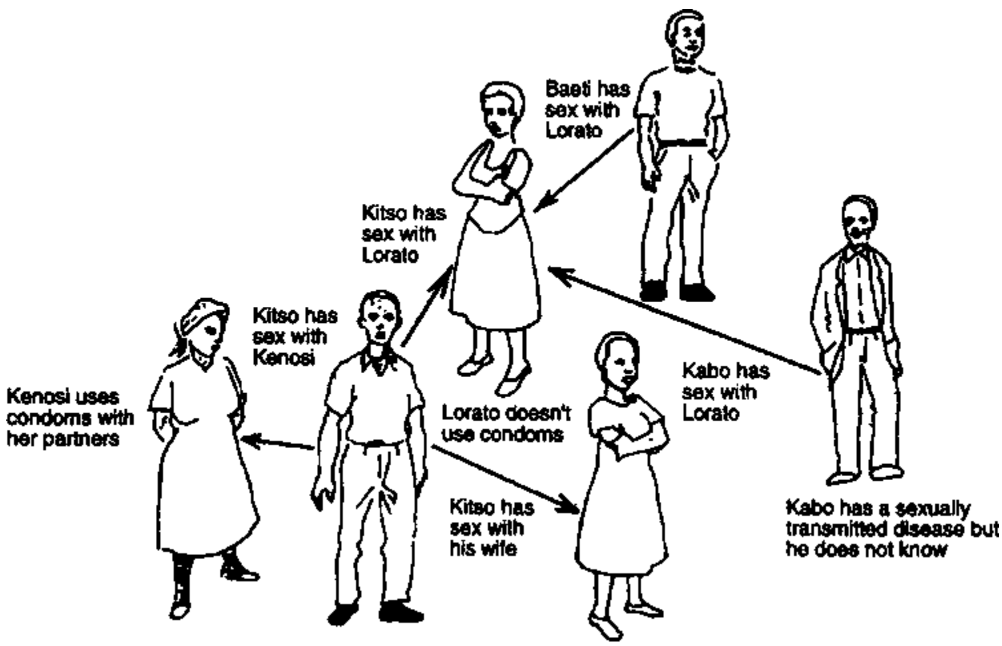
41. Which of the chemicals shown below are dangerous when swallowed?



A II and IV
B III and IV
C I and III
D I and II

42. Who is most likely to be free from a sexually transmitted disease?

A
B
C
D



43. Which of the following foods would make a balanced meal?

A Porridge, meat and cabbage
B Samp, bread and porridge
C Meat, eggs, and fish
D Spinach, pumpkin and cabbage

44. Which of the following changes takes place in a boy at puberty?

A He becomes fat.
B His voice deepens.
C His hips grow larger and round.
D He grows hairs in the ears.

The table below shows the causes of death from accidents in the home in one country. Use it to answer questions 45 and 46.

Cause of Death	**Age group in years**					**TOTAL**
	0-4	**5-14**	**15-64**	**65-74**	**75+**	
Falls	21	6	334	359	2092	2812
Poisoning	10	8	398	53	56	525
Burns	57	26	192	94	270	639
Drowning	20	3	21	12	17	73
TOTAL	108	43	945	518	2445	4049

45. What was the cause of most deaths?

A Burns
B Poisoning
C Falls
D Drowning

46. What age group had most accidents?

A 0-4 years
B 15-64 years
C 65-74 years
D 75+ years

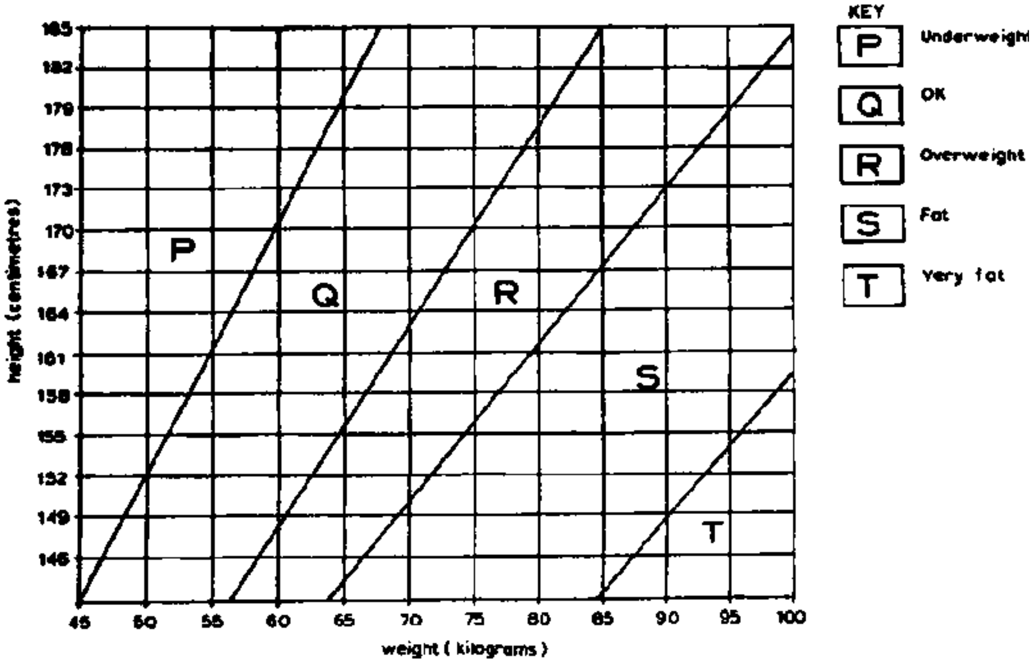
47. Which of the following methods of birth control can help to prevent pregnancy and spread of sexually transmitted diseases?

A Using birth control pills
B Using a loop
C Using a cream that kills sperms
D Using condoms

48. Which of the following drugs helps people to get well?

A Vaccine
B Alcohol
C Tobacco
D Medicine

The chart below is used to see if one is overweight, underweight or just the right weight. Use it to answer questions 49 and 50.



49. A person weighs 80 kilograms and is 176 centimetres tall. In which group is this person in?

A P
B Q
C R
D S

50. In which group is a person most likely NOT eating enough?

A P
B R
C S
D T

51. Smoking in young people may

A slow the growth of the body.
B make them grow taller.
C make them grow fat.
D deform their bones.

The diagram below shows some groups of foods.

W Carrots Spinach Tomatoes Oranges	**X** Sugar Potatoes Bread Rice
Y Eggs Beef Beans Chicken	**Z** Cheese Butter Groundnuts Margarine

52. Which foods would you eat for energy?

A W and X
B W and Y
C Z and X
D Z and Y

53. Which one of the following is part of the digestive system?

A Lungs
B Kidney
C Heart
D Small intestine

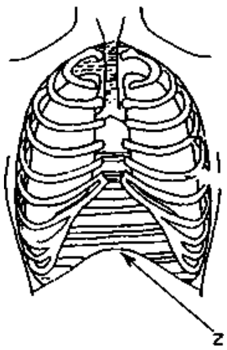
54. Which one of the following statements about smoking is NOT true?

A It is good for pregnant women.
B People who smoke cannot stop it easily.
C Smoking increases the chances of getting lung cancer.
D Smoking increases the risks of heart attack.

55. Which is the correct statement about the diseases cholera, typhoid and bilharzia?

A They can be prevented by vaccinating in children.
B People suffering from these usually get well after a few weeks.
C They are caused by lack of cleanliness of the body.
D Organisms causing them are spread by water with human waste.

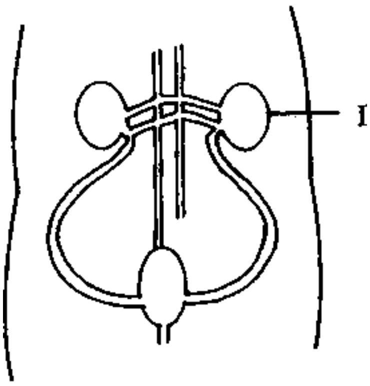
The diagram below shows parts of the breathing system.



56. The part labelled Z is the

A lung.
B rib.
C diaphragm.
D wind-pipe.

Study the diagram of the system shown below.



57. The part labelled I is the

A bladder.
B heart.
C kidney.
D ovary.

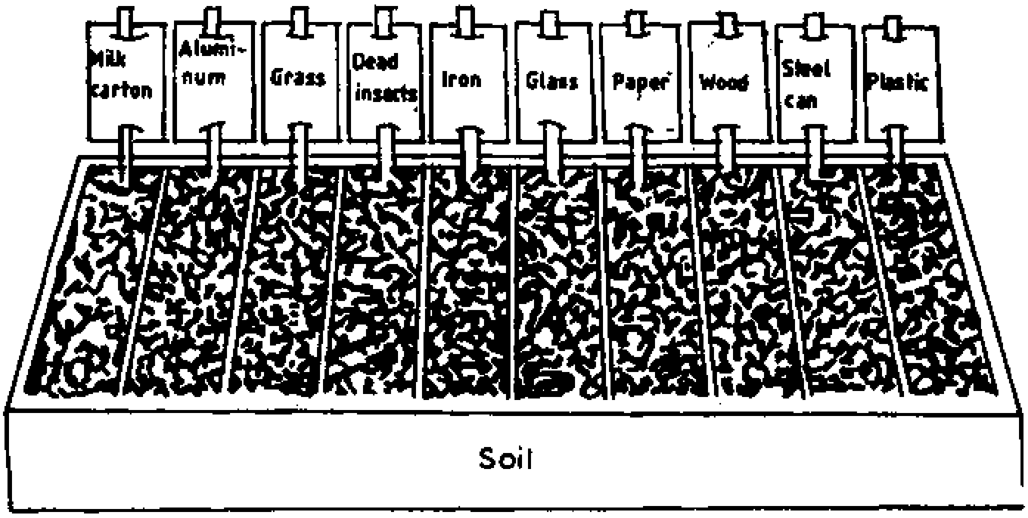
58. Stagnant water must not be kept near homes because organisms which spread ________ may breed in it.

A tuberculosis
B measles
C malaria
D scabies

59. Who is responsible for proper disposal of waste in towns and villages?

A Health Inspector
B Family Welfare Educator
C Police Officer
D Medical Officer

A group of students set an experiment shown in the diagram below. Each material shown on the labels was buried in the soil.



60. Which of the materials are going to be decomposed?

A Aluminium can, dead insects, wood, iron
B Paper, plastic, iron, steel can
C Grass, plastic, milk carton, aluminium can
D Grass, dead insects, paper and wood

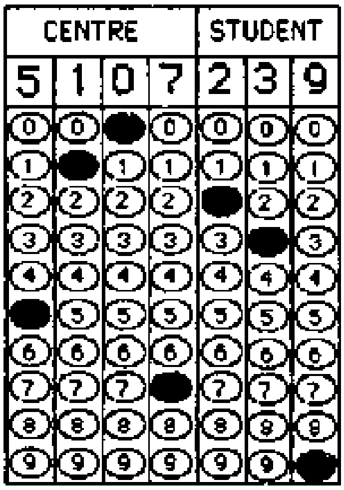
3.1.4. 1993 Primary School Leaving Examination/Science Paper

REPUBLIC OF BOTSWANA
1993 PRIMARY SCHOOL LEAVING EXAMINATION

SCIENCE **TIME: 60 MINUTES**

Directions

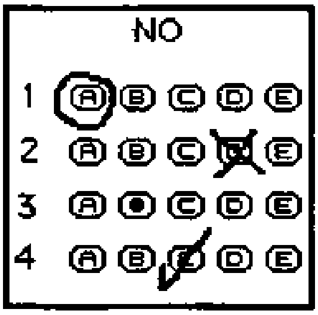
1. Use HB pencil ONLY. DO NOT use ink or ball point.
2. Print your name on the answer sheet in the space provided.
3. Fill the oval by BOY if you are a boy or GIRL if you are a girl.
4. In the four boxes under CENTRE write your centre number.
   In the three boxes under STUDENT write your examination number. In the column of numbers below each box, fill the oval that has the same number that you entered in the box. Fill the ovals with heavy black marks that fill the oval:



5. When you are told to begin, work as fast and as accurately as you can. If you cannot answer a question, do not spend too much time on it; go to the next question and come back to it later.
6. You may do rough work on the test paper or on a sheet of blank paper. DO NOT use the answer sheet for rough work.
7. Several possible answers are given for each question. Select the answer you think is the best and fill the oval for that answer on your answer sheet.
8. Be sure to fill the ovals like this:

   Erase completely answers that you wish to change.
   Do not make any stray marks on your answer sheet.
   If more than one oval is filled for a question it will be marked wrong.
   Be sure the oval you fill on your answer sheet is for the question you are working on in the test paper.

DO NOT mark the ovals like this:



If you do, your answers will be marked wrong.

9. Sample questions are given to help you. Read them carefully before doing the questions.

Sample Questions

Sample 1 If a drum-skin is tightened its note will

A. increase in pitch.
B. decrease in pitch.
C. sound louder.
D. sound quieter.

SAMPLE 1

Sample 2 A man with a heavy cold finds his food tasteless because

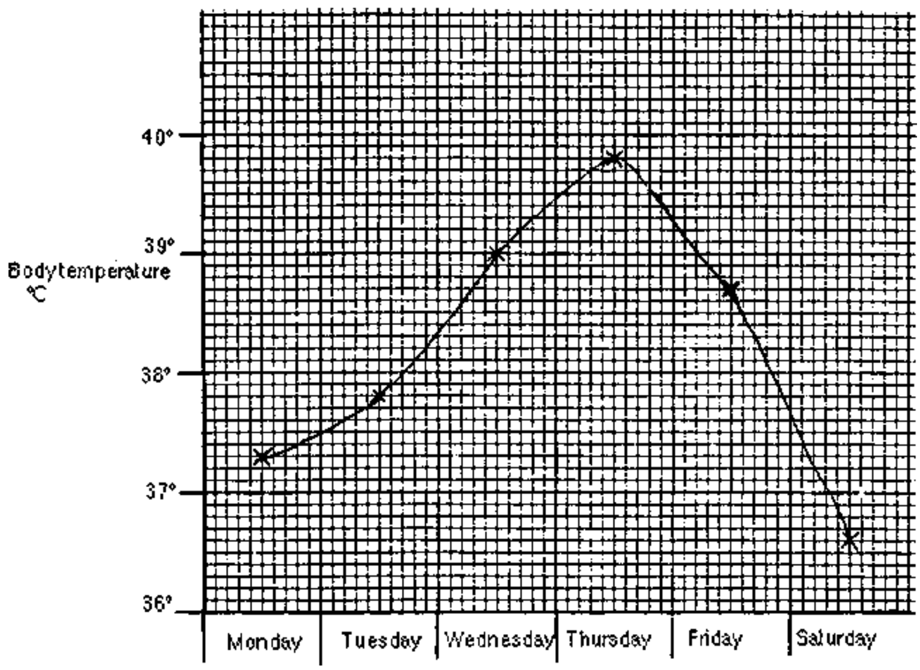
A. the cold germs kill the taste of the food.
B. the cold germs numb the taste buds.
C. his blocked nose cuts out his sense of smell.
D. he has lost his appetite.

SAMPLE 2

DO NOT TURN OVER THE PAGE UNTIL YOU ARE TOLD TO DO SO

<u>Questions 1 and 2</u>

Mpho was sick for a week. The graph below shows his body temperature recordings.



1. What was Mpho's temperature on Monday?

A 37,3 °C
B 37,5 °C
C 37,6 °C
D 38,7 °C

2. On what day was Mpho's temperature 36,6 °C?

A Monday
B Tuesday
C Thursday
D Saturday

3. What type of animal is a snake?

A A mammal
B An amphibian
C A reptile
D A fish

4. The best food for a baby is

A cow's milk.
B goat's milk.
C mother's milk.
D milk powder.

5. Which of these will melt when heated?

A Paper
B Cotton
C Leather
D Plastic

6. To which part of a plant are insects mostly attracted?

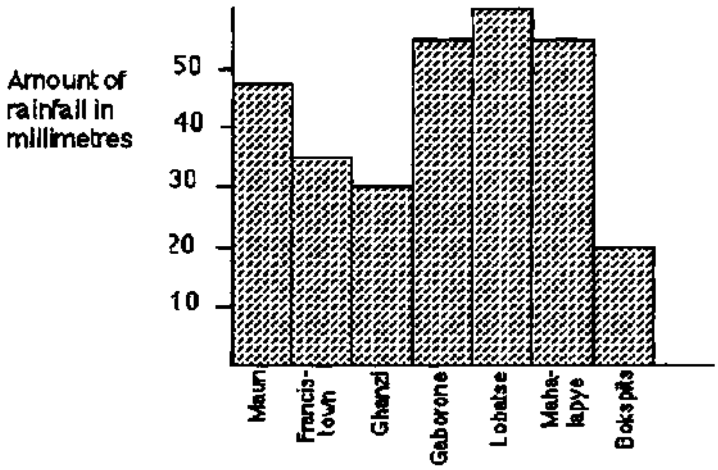
A Flower
B Leaf
C Stem
D Root

7. Plants kept in the dark become thin and yellowish because they lack

A air.
B sunlight.
C manure.
D water.

Questions 8 and 9

The graph below shows rainfall recordings for some places in Botswana for a day in January.



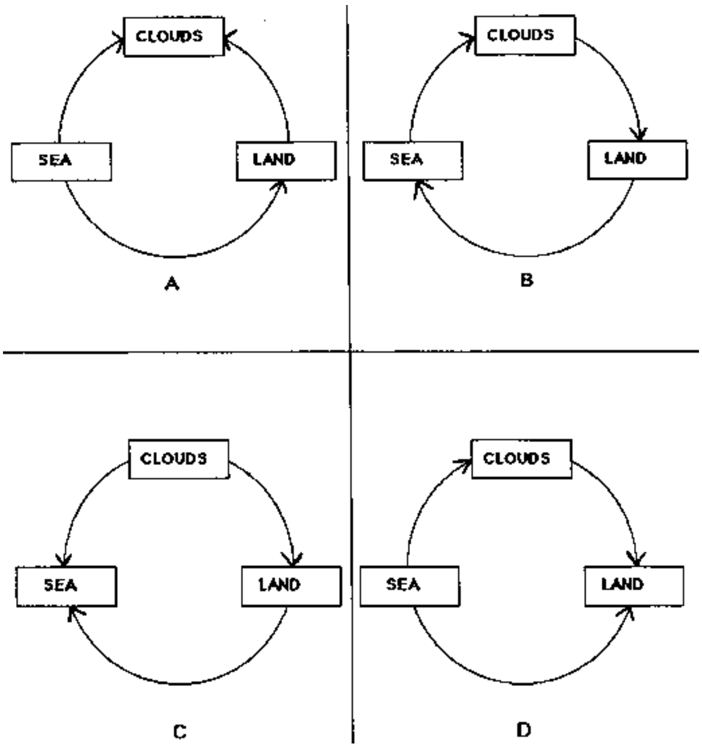
8. The place with the least amount of rainfall recorded is

A Lobatse.
B Ghanzi.
C Bokspits.
D Francistown.

9. Which place had more rain than Gaborone?

A Francistown
B Maun
C Mahalapye
D Lobatse

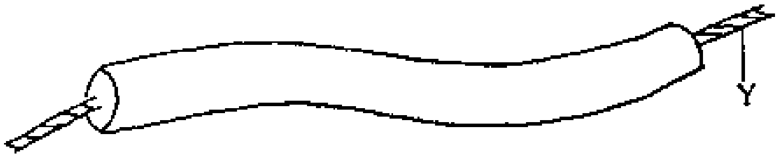
10. Select the diagram that correctly shows the water cycle.



11. Which of the following types of soil is the most fertile?

A Clay
B Sand
C Loam
D Gravel

12. The picture below shows part of a wire to be connected to the "live" pin of an electric three-pin plug.



Which of the following materials can be used to make part **Y**?

A Rubber
B Plastic
C Copper
D Wood

13. Which organ pumps blood to all parts of the body?

A Brain
B Kidney
C Liver
D Heart

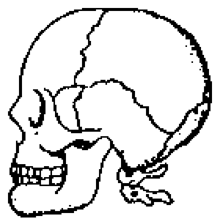
14. The largest cause of death among smokers is

A heart attack.
B tuberculosis.
C lung cancer.
D cancer of the liver.

15. What are infectious diseases? They are diseases which

A can easily be passed on from person to person.
B are caused by a shortage of a particular food.
C cannot be cured.
D only infect young people.

16. The following diagram shows part of a human skeleton.



Which of the following is a function of this part? It protects the

A heart.
B brain.
C heart and lungs.
D brain and lungs.

17. The most likely way to get a sexually transmitted disease is by

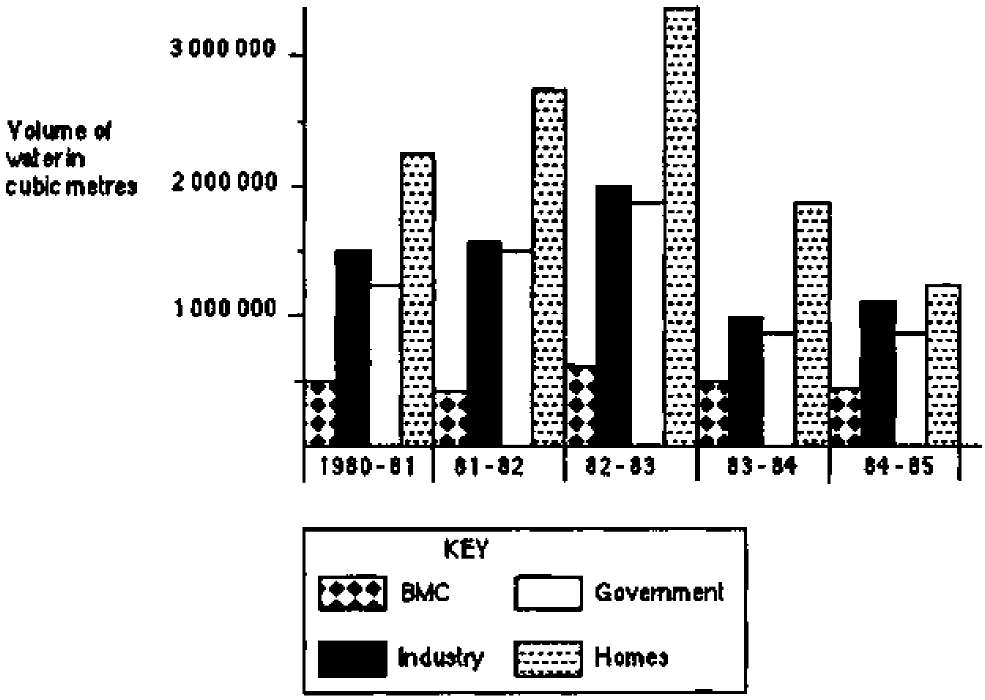
A sharing toilets used by infected people.
B kissing or touching another person.
C having sexual intercourse with an infected person.
D sharing cups and plates with other people.

18. Which of the following objects **changes movement** energy to **sound energy**?

A Lamp
B Battery
C Guitar
D Match stick

Questions 19 and 20

The graph below shows the volume of water used in Botswana from 1980 to 1985.



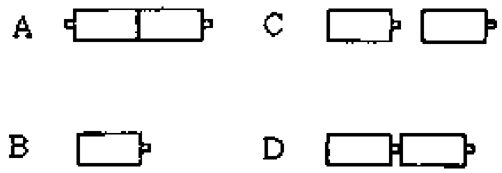
19. The largest use of water during 1984-85 was in

A BMC.
B industry.
C government.
D homes.

20. How much water was used at BMC in 1980-81?

A 500 000 m^3
B 1 000 000 m^3
C 1 500 000 m^3
D 2 250 000 m^3

21. Select the diagram that represents a battery.



22. The season that has longer nights and shorter days is

A summer.
B autumn.
C winter.
D spring.

Questions 23 to 27

Choose diseases from the list below to answer questions 23 to 27.

A Bilharzia
B Malaria
C Scabies
D Diarrhoea

23. For which of the diseases above should patients be given an oral rehydration drink?

24. Which of the diseases above is caused by a blood fluke?

25. Which of the diseases above is the commonest among children under 5 years in Botswana?

26. Which of the diseases above is spread by mosquitoes?

27. Which of the diseases can be prevented by regular washing of the body?

28. If the south pole of a magnet is brought near the north pole of another magnet, the two magnets will

A remain at rest.
B attract one another.
C repel one another.
D point in the north-south direction.

29. Which of the following substances will dissolve in water?

A Chalk dust
B Sand
C Sugar
D Bread flour

30. Which of the following parts of the body is the hardest?

A Skin
B Hair
C Muscle
D Bone

31. Which of the following does not make a healthy mother?

A Having babies every year
B Spacing children
C Having fewer children
D Breast feeding her babies

32. What instrument is used to measure humidity?

A Hygrometer
B Rain gauge
C Speedometer
D Anemometer

33. The purest form of natural water is

A river water.
B pond water.
C well water.
D rain water

34. Which of the following are all agents of soil erosion?

A Water, wind and animals
B Animals, plants and wind
C Wind, water and plants
D Animals, water and plants

35. The part of the human eye through which light passes to the inside is called the

A iris.
B pupil.
C cornea.
D retina.

36. Which of the following forms of energy do we need to cook our food?

A Electrical energy
B Heat energy
C Light energy
D Solar energy

37. Which of the following statements is true about plants?

A All leaves have the same shape.
B Green plants can make their own food without sunlight.
C The stem holds fruits and flowers.
D The root holds plants firmly to the ground.

38. Which of the following statements best describes soil erosion?

A It is the breaking down of rocks to form soil.
B It is the layers that make up the soil.
C It is the removal of mineral salts from the soil.
D It is the removal of topsoil.

39. Which of the following factors does not control the weather?

A Pressure

B Week day
C Sun
D Humidity

40. The most likely reason for having windows on two opposite sides of a room is to

A make the house look beautiful.
B allow people to escape if there is a fire.
C allow movement of air for ventilation.
D enable one window to be closed while the other is open.

41. In which of the following conditions will wet clothes dry fastest?

A In moving, hot air
B In moving, damp air
C In still, hot air
D In still, cool air

42. What source of energy does a solar heater use?

A Moonlight
B Sunlight
C Electricity
D Gas

43. Four groups of pupils A, B, C and D collected some small animals and classified them as follows:

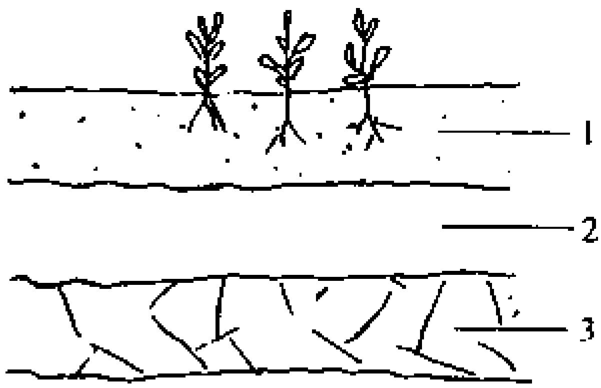
Group	**Body parts**	**Jointed legs**	**Wings**
A	3	6	1 or 2 pairs
B	2	6	1 pair
C	2	8	0
D	3	8	2 pairs

One of the animals collected was a spider. Which group could have collected the spider?

44. Maize, cooking oil, honey, sugar and butter are all good examples of

A energy-giving foods.
B foods dangerous to health.
C protective foods.
D body-building foods.

45. The diagram below shows a soil profile.



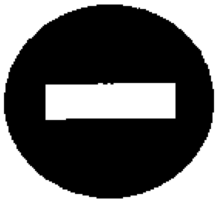
What is layer 3?

A Topsoil
B Subsoil
C Parent rock
D Sandy soil

46. Which of the following is used for preventing disease?

A Nicotine
B Aspirin
C Alcohol
D Vaccine

47. What does the road sign shown below mean?

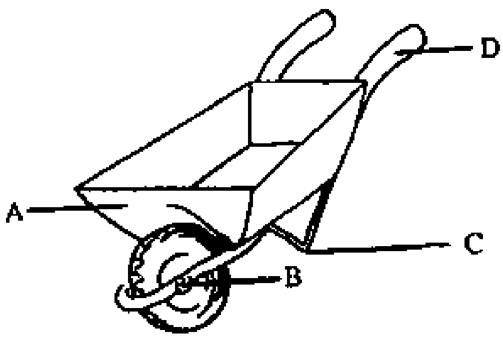


A Road crossing with another.
B For pedestrian crossing.
C One-way road.
D No entry.

48. In which direction does a compass needle point?

A North
B South
C East
D West

49. The diagram below shows a lever.



Which of the parts labelled A, B, C or D is the pivot?

50. What do plants get from humus?

A Mineral salts
B Chlorophyll
C Oxygen
D Water

51. Tebogo added water to soil in a tin. She observed bubbles coming out. This is because

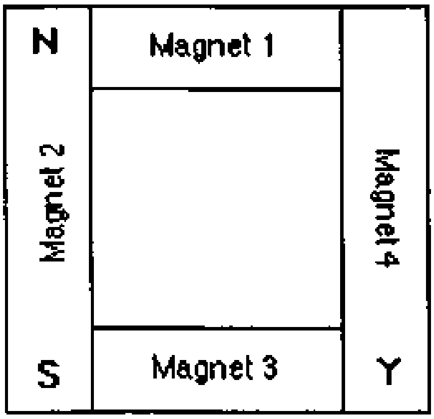
A soil breathes air.

B water has air.
C soil has air.
D bacteria in the soil produce air.

52. Which of the following statements about AIDS is false?

A AIDS affects men, women and children.
B A person with AIDS can look perfectly healthy.
C AIDS is spread through shaking hands.
D AIDS is caused by a virus.

53. Badiri wanted to make a square using four bar magnets as shown in the diagram below.

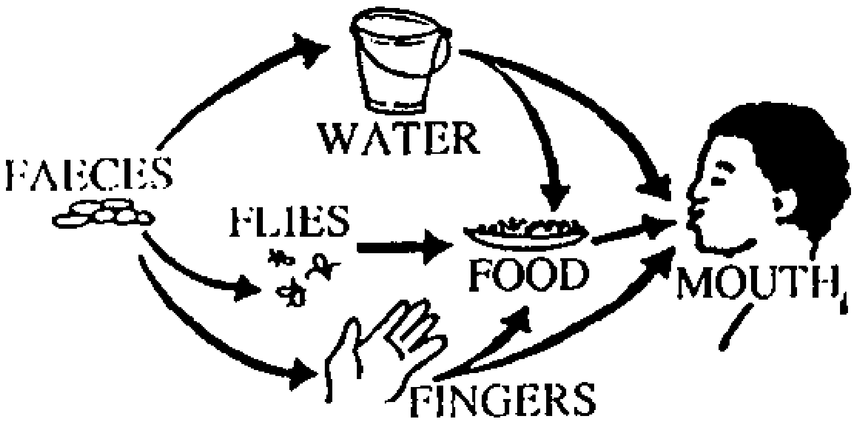


What should pole Y be for him to succeed?

A North
B South
C West
D Neutral

Questions 54 and 55

The diagram below shows how infections can be spread because of poor hygiene.



54. Which of the following paths of infection is NOT represented in the diagram?

A Faeces ⇒ soil ⇒ food ⇒ mouth
B Faeces ⇒ skin ⇒ mouth
C Faeces ⇒ flies ⇒ food ⇒ mouth
D Faeces ⇒ water ⇒ mouth

55. Which of the following diseases is likely to be spread by the water?

A Polio
B Measles
C Cholera
D Whooping cough

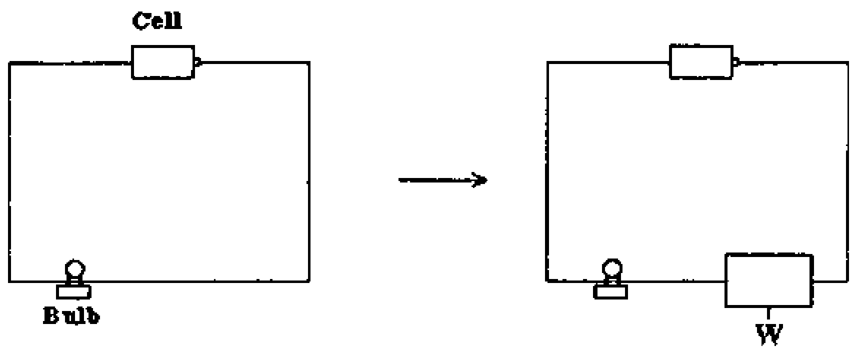
56. Which of the following is NOT looked after by the Council Health Services?

A Planting vegetables
B Food hygiene
C Preventing spread of disease
D Rubbish disposal

57. Which of the following will cause physical weathering of rocks?

A Water, temperature change and oxygen
B Water, wind and oxygen
C Wind, temperature change and oxygen
D Water, temperature change and wind

58. A student set up the following circuit and observed that the bulb lit normally. He connected a mystery box, W, to the circuit and observed that the bulb lit more brightly.



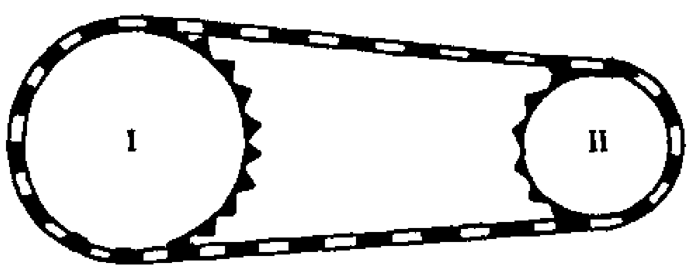
What does the mystery box contain?

A another bulb
B a piece of wire
C another cell
D a strip of plastic

59. How does heat travel from the sun to the earth?

A Radiation
B Reflection
C Convection
D Conduction

60. The diagram below shows toothed gear wheels connected by a chain.



If gear **I** is turned clockwise, gear **II** will turn

A clockwise.
B anticlockwise.
C sideways.
D upwards.

3.2. Kenya

3.2.1. Overview

End of Primary School Examination

1, Title of examination:	Kenya Certificate of Primary Education (KCPE)
2. Amount of fees charged:	≈ US$ 4.5
3. Examination after years in primary school (6, 7, 8 years):	8 yrs
4. Children's entry age in primary school:	6 yrs
5. Number of pupils sitting examination in 1994:	395,765
6. Examination subjects offered:	14 subjects, 7 compulsory papers: • English • Kiswahili • Mathematics • Science & Agriculture • Art & Craft, Music • Business Education & Home Economics • GHC (Geography, History, Civics), Religious Education (Christian or Islamic or Hindu)
7. Language of examination:	English (except for Kiswahili paper)
8. Institution setting the examination questions:	Kenya National Examinations Council
9. Have there been any reforms in the examination questions?	Yes
When? (year)	1985
What kind?	There was a shift from simple recall questions to higher-order questions.
10. Stages of development of examination questions (please describe):	• Invitation of setters • Setting of questions • Pre-moderation of questions • Final moderation

11. Type of examination questions and distribution of different kind of questions.	All are multiple-choice questions with: 26% recall questions 33% comprehension 24% application 17% higher abilities
12. Is continuous assessment incorporated in the final examination?	Yes [ ] No [x]
13. Are examination items pretested?	Yes [ ] No [x] The set KCPE papers are not pretested because of technical problems (inadequate time, costs involved, security).
14. Which professional groups are involved in setting the examination questions?	• Primary school teachers • Tutors of TTCs • Examination Officers
15. Are the same professionals who set the examination questions involved in marking papers?	Yes [x] No [ ]
16. How are examination results used for improving teaching in primary schools?	Primary school teachers change their teaching strategies to improve performance in examination.
17. To what other uses are the examination results put?	• Selection • Certification
18. Main problem with Primary School Leaving Examinations?	Assessment of practical skills

3.2.2. Writing of Test Items for the Primary School Leaving Examination in Kenya

by Philip M. Kitui, Kenya National Examinations Council

Background

The primary education course in Kenya takes eight years. The Kenya Certificate of Primary Education examination was administered for the first time in November 1985 by the Council to primary school leavers who had completed the first cycle of the 8.4.4. Education System. The examination consists of seven compulsory papers and tests each of the pupils in 14 subjects namely, English, Kiswahili, Mathematics, Science, Agriculture, History, Civics, Geography, Music, Craft, Home Science, Art, Business Education and either Christian Religious Education, Islamic Religious Education or Hindu Religious Education. Over the last years about 400,000 candidates took the examination annually.

Objectives of the KCPE Examination

The objectives of the KCPE examination are:

1) To rank candidates according to their achievement in all the subjects offered in the examination. This ranking facilitates fair selection for further education.

2) To award certificates to persons who have completed primary education. Every candidate who sits the KCPE examination is awarded a certificate in which his/her attainment in each of the subjects he/she sat is indicated by means of a letter grade and a standard score.

3) To generate data on candidates' performance that can be used in the evaluation of the curriculum and effectiveness of instruction in the primary schools. For the KCPE examination to facilitate a fair allocation of the limited opportunities for further education and training to over 400,000 candidates, it has to be objective. Thus it must satisfy the psychometric criteria for a good test, namely: validity, reliability and efficiency. Administration of the test should also be cost-effective. Hence the Kenya National Examinations Council uses objective items of the multiple-choice type for most of the papers. Each item has four options, one of which is the key. In addition to an objective paper, each of the two language subjects, English and Kiswahili, is tested by means of a composition.

For the practical subjects like Science, Agriculture and Home Science, questions testing practical skills are part of the written test.

However, there is a school-based practical assessment of these subjects and other subjects of the school curriculum conducted by the Ministry of Education for the purpose of awarding specially revamped primary school leaving certificates. School-based assessment was started in 1984 as a Government policy. This approach is superior and has the support of modern thinking on certification. The modern approach is dichotomous, the examination certificate being supported by a profile from the school. In our case, the school leaving certificate is a basis for this approach and needs to be strengthened.

The KCPE examination papers for each subject are based on national syllabi developed by the Kenya Institute of Education. These, syllabi specify both the objectives of the learning activities and the content and skills to be learned. In so doing, they set the levels of competence expected of a learner who completes the course in any subject.

Development of the KCPE Examination Papers

For each of the subjects it examines, the Kenya National Examinations Council has employed a tests and measurement specialist who is also an expert in the subject. This person not only plans the work and schedules necessary for the development of tests but also provides guidance in the area of tests and measurements to contracted professional people appointed by the Council to perform the functions of setters and moderators. The development of a test paper for the KCPE examination is carried out through the following stages:

Stage 1: The Council identifies and appoints six professional educators as setters for the paper. For each subject, persons identified must

(1) have had practical experience in either teaching at the primary school level or in the development of the primary school curriculum for the subject;

(2) be trained teachers who are competent in the subject;

(3) be men and women of proven integrity;

(4) be conversant with the technicalities of writing multiple-choice test items;

(5) not be preparing candidates for the KCPE examination.

Stage 2: The subject specialist and the setters prepare a table of specifications for the test. The specifications are the blueprint for the test. They show the syllabus content and cognitive skills to be tested, the number of questions for each type of content and cognitive skill. Drawing up this table enables the setters to identify a representative sample of content for the test as well as spread the skills to be tested so that the test as a whole can discriminate effectively between candidates of different levels of achievement.

Stage 3: The setters divide up the work of writing test items on various units of content and skills. The council tests and measurement specialist goes over the expected qualities of test items and reminds the setters of the precautions they must take to safeguard security of the drafts they will work on. In the course of writing items, the setters meet to discuss the items they have come up with. During the discussions poor items are discarded and shredded while advice is given on items that must be improved upon. In the end, the setters put together a draft question paper which they submit to the Council through the tests and measurement specialist. The draft is then kept in a secure place to await moderation.

Stage 4: Moderation of the draft test items is done by a group of 10 experts. They include the six setters and four other experts identified on the basis of the criteria used for identifying the setters. The moderation meeting is chaired by a senior tests and measurement specialist. It may take two to five full working days depending on the quality of items produced by the team of setters. During the period of moderation, some of the questions may be replaced while others will be re-worded.

Stage 5: The tests and measurement specialist, who is also secretary to the moderation committee for the subject, writes a neat draft of the paper and ensures that all the necessary diagrams, graphs and pictures are drawn in their final form and labelled correctly. The specialist proofreads the paper as it is typeset and printed and advises on necessary corrections. For the English Composition and Kiswahili Insha papers only one setter is commissioned for the setting. The team of moderators for each of these two papers goes over the drafts with as much thoroughness as for papers consisting of multiple-choice questions. However, they take less time on their work because they moderate only one composition/Insha.

The skills required for writing test items can only be acquired through intensive practical training. The item writer needs to be familiar with the types and varieties of test items and with their possibilities and limitations. The Kenya National Examination Council mounts item-writers' workshops regularly to train item writers for its examinations. This is a practice that should be encouraged and supported financially by national examining boards, and local and international organisations. The financial support should incorporate training-of-trainers at such internationally recognized testing centres as the Educational Testing Service of the United States of America and the local Examinations Syndicate of the United Kingdom.

3.2.3. KCPE 1994/Science and Agriculture Paper

THE KENYA NATIONAL EXAMINATIONS COUNCIL

KCPE 1994

SCIENCE AND AGRICULTURE

Time: 2 hours

READ THESE INSTRUCTIONS CAREFULLY

1. You have been given this question booklet and a separate answer sheet. The question booklet contains 60 questions.

2. Do any necessary rough work in this booklet.

3. When you have chosen your answer, mark it on the **ANSWER SHEET,** not in this question booklet.

HOW TO USE THE ANSWER SHEET

4. Use only an ordinary pencil.

5. Make sure that you have written on the answer sheet:

YOUR INDEX NUMBER

YOUR NAME
NAME OF YOUR SCHOOL

6. By shading the correct numbered ellipses (small oval shapes) mark your full Index Number (i.e. School Code Number and three-figure Candidate's Number) in the grid near the top of the answer sheet.

7. Do not make any marks outside the ellipses.

8. Keep the sheet as clean as possible and **DO NOT FOLD IT.**

9. For each of the questions 1-60 four answers are given. The answers are lettered A, B, C, D. In each case only **ONE** of the answers is correct. Choose the correct answer.

10. On the answer sheet, show the correct answer by shading the ellipse in which the letter chosen is written.

Example

In the **Question Booklet:**

16. The pressure exerted by a liquid depends on its

A. volume
B. depth
C. surface area
D. mass.

The correct answer is **'B'.**

On the **Answer Sheet:**

16 (A) ● (C) (D)
17 (A) (B) (C) (D)
18 (A) (B) (C) (D)
19 (A) (B) (C) (D)
20 (A) (B) (C) (D)

In the set of ellipses numbered 16, the ellipse with B in it is shaded.

11. Your shading MUST be within the ellipse. Make your shading as **DARK** as possible.

12. For each question ONLY ONE ellipse is to be shaded in each set of four ellipses.

This Question Paper consists of 8 printed pages.

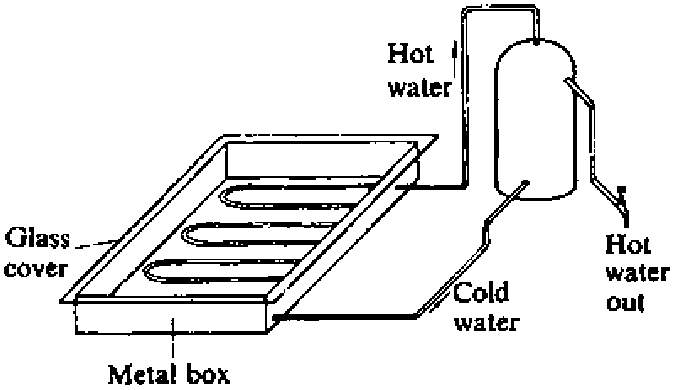
SCIENCE

1. A charcoal burner was used to boil water and the steam produced was used to turn a turbine.

Which one of the following shows the correct order of the energy changes that took place from the time the charcoal was lit to the time the turbine turned?

A. Chemical heat mechanical.
B. Heat chemical mechanical.
C. Chemical mechanical heat.
D. Heat mechanical chemical.

2. The diagram below represents a solar heater.



Which of the following would make the water heat up faster?

A. Painting the pipe black and the inside of the metal box white.
B. Painting the glass cover white and the inside of the metal box black.
C. Painting the pipe black and reducing the number of coils.
D. Painting both the pipe and the inside of the metal box black.

3. The purpose of a fuse in a circuit is to

A. break the circuit when necessary
B. reduce the current
C. switch the current on and off
D. complete the circuit.

4. Which one of the following mixtures can be separated by decanting?

A. Sand and water.
B. Sand and sugar.
C. Salt and water.
D. Salt and iron filings.

5. Which one of the following is **NOT** a correct method of determining whether a piece of metal is a magnet or not?

A. Repulsion between the metal and a magnet.
B. Attraction between the metal and a magnet.
C. Attraction between the metal and a pin.
D. Suspending the piece of metal in air to observe the direction it points to.

6. Standard seven pupils carried out an investigation on mixing liquids. They used four liquids **P**, **Q**, **R** and **S** and made the following observations:

Liquid **P** mixed with liquid **Q**
Liquid **P** mixed with liquid **R**
Liquid **Q** mixed with liquid **R**
Liquids **P**, **Q**, **R** did not mix with liquid **S**.

They then poured all the four liquids into a transparent bottle and shook the bottle.

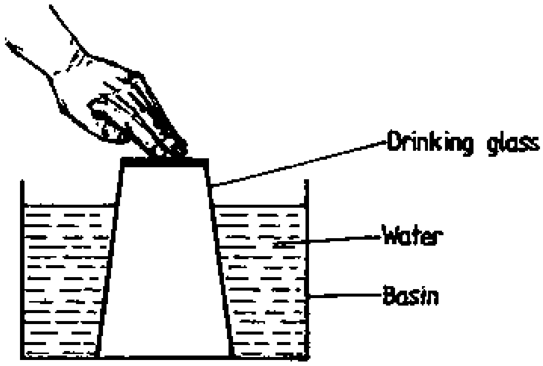
The number of layers that were formed is

A. one
B. two
C. three
D. four.

7. Which one of the following gases makes approximately one fifth of air by volume?

A. Nitrogen.
B. Carbon dioxide.
C. Oxygen.
D. Water vapour.

8. A drinking glass was inverted over water in a basin and pushed down as shown in the diagram below.



Water did not enter the glass because

A. air occupies space
B. water is denser than air
C. the glass is upside down
D. water cannot move upwards.

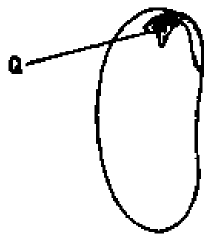
9. The correct unit for expressing density is

A. g
B. g/cm
C. g/cm^2
D. g/cm^3.

10. A boat sinks deeper in a fresh water lake than in sea water. This happens because sea water differs from lake water in

A. mass
B. volume
C. density
D. weight.

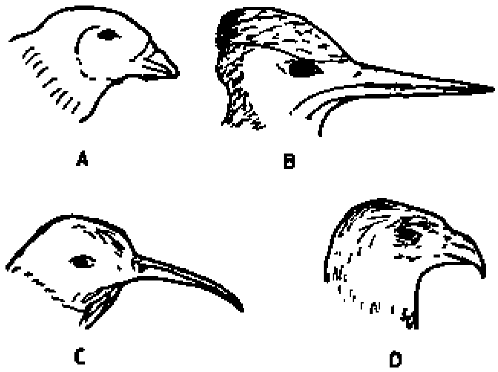
11. A section through a bean seed is shown in the diagram below.



The part labelled **Q** is the

A. hilum
B. plumule
C. radicle
D. cotyledon.

12. Which one of the following diagrams represents the beak of a flesh eating bird?



13. Which one of the following parts of a flower is correctly matched with its function?

	Part	Function
A.	Stigma	Produces pollen grains.
B.	Petals	Attract insects.
C.	Anther	Receives pollen grains.
D.	Style	Holds the anther.

14. Use the information below to answer the question that follows.

Frogs eat grasshoppers.
Grasshoppers eat grass.
Snakes eat frogs.

From this information, which one of the following is the correct food chain?

A. Frogs ⇒ grasshoppers ⇒ grass ⇒ snakes.
B. Snakes ⇒ frogs ⇒ grasshoppers ⇒ grass.
C. Grass ⇒ grasshoppers ⇒ frogs ⇒ snakes.
D. Grass ⇒ grasshoppers ⇒ snakes ⇒ frogs.

15. Which one of the following seeds is NOT correctly matched with its agent of dispersal?

	Seed	Agent
A.	Pawpaw	Animal.
B.	Coconut	Water.
C.	Black jack	Animal.
D.	Castor	Wind.

16. Which one of the following parts of an insectivorous plant is adapted for trapping insects?

A. Flower.
B. Leaf.
C. Stem.
D. Fruit.

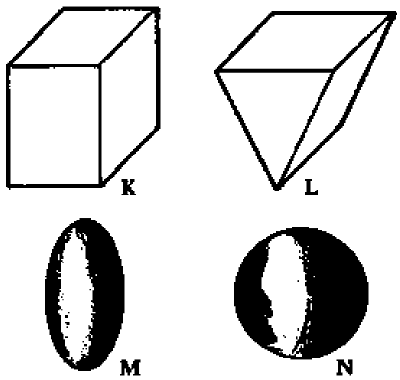
17. The correct life cycle of a mosquito is

A. adult larva pupa egg
B. egg pupa larva adult
C. adult pupa larva egg
D. egg larva pupa adult.

18. The thick layer of fat under the skin of a whale is for

A. keeping the skin of the whale oily
B. making the whale heavier
C. keeping the body of the whale warm
D. making the whale float in water.

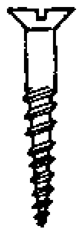
19. Mary cut four pieces from a yam whose shapes are as shown in the diagrams below.



She then held each piece by the top and pushed it downwards in a jar containing water. Which one of the pieces would Mary find easier to push down?

A. **K.**
B. **L.**
C. **M.**
D. **N.**

20. The diagram below represents a simple machine.



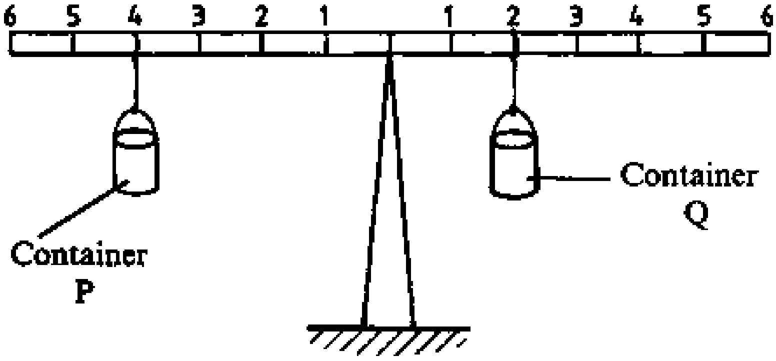
Which one of the following simple machines is of the same type as the one shown in the diagram?

A. Gear wheel.
B. Crow bar.
C. Winch.
D. Inclined plane.

21. In which of the following **pairs** do both machines have the fulcrum between the load and the effort?

A. Bottle opener, wheel barrow.
B. Seesaw, pliers.
C. Hammer, nut cracker.
D. Pair of scissors, fishing rod.

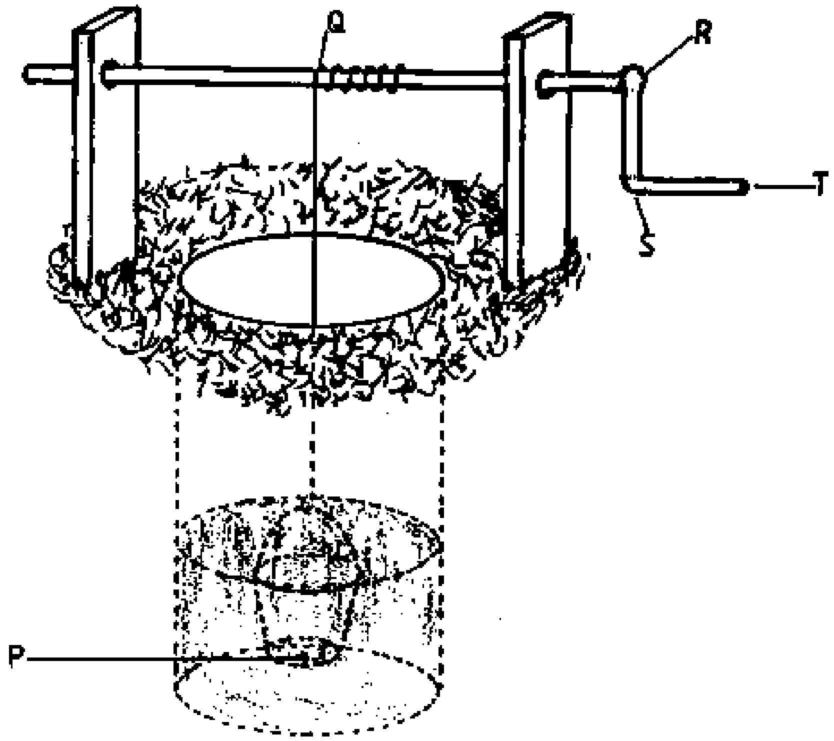
22. Two identical containers **P** and **Q** containing water were balanced on a beam. The set up is as shown in the diagram below.



Which one of the following statements about the set up is **CORRECT?**

A. Container **P** contains as much water as **Q**.
B. Container **P** contains a quarter as much water as **Q**
C. Container **P** contains half as much water as **Q**.
D. Container **Q** contains half as much water as **P**.

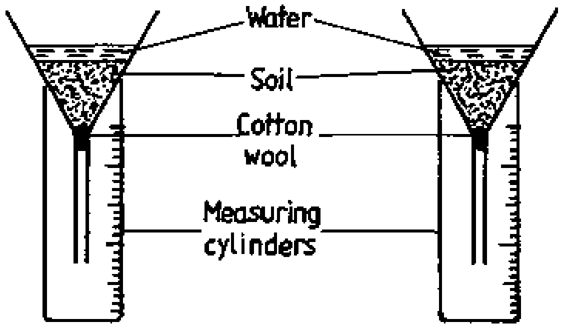
23. The diagram below represents a simple machine that can be used to raise water from a well.



Which one of the following is the effort distance?

A. PQ.
B. QR.
C. RS.
D. ST.

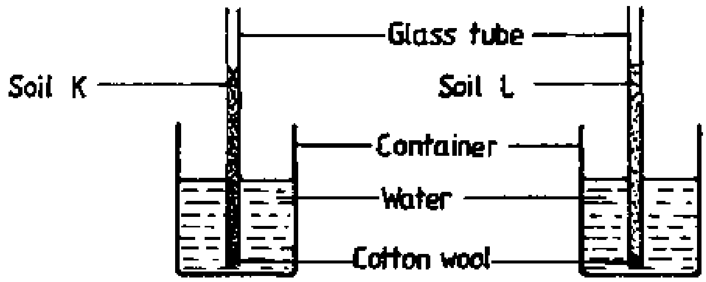
24. An experiment was set up as shown in the diagrams below.



The experiment was to investigate

A. water retention by different types of soil
B. capillarity in different types of soil
C. amount of air in different types of soil
D. amount of humus in different types of soil.

25. The set-ups shown in the diagram below were used to investigate how water moves up in different types of soil.



Which one of the following need **NOT** be the same in both set-ups?

A. Size of containers.
B. Size of glass tubes.
C. Amount of cotton wool in each glass tube.
D. Amount of soil in each glass tube.

26. When the arrow of a wind vane points to the east, the wind must be blowing from

A. South to North
B. West to East
C. North to South
D. East to West.

27. The rotation of the earth on its axis causes

A. day and night
B. phases of the moon
C. high and low tides
D. seasons.

28. Which one of the following materials **DOES NOT** pollute the environment?

A. Sawdust.
B. Broken pieces of glass.
C. Plastic paper bags.
D. Metal cans.

29. Cancer of the lungs may be caused by excessive

A. chewing of khat *(miraa)*
B. sniffing of glue
C. smoking of cigarettes
D. drinking of beer.

30. Which one of the following drugs is **NOT** extracted from plants?

A. Bhang.
B. Mandrax.
C. Cocaine.
D. Heroin.

AGRICULTURE

31. Why is it recommended to transplant seedlings late in the afternoon?

A. To give a farmer time to prepare the field in the morning.
B. To avoid withering of seedlings due to strong heat.
C. To ensure that the ground is warm enough for the seedlings.
D. To allow the farmer to work when the day is cool.

32. During a visit to a local farm, Standard VII pupils found one cow lying down and unable to rise up. The cow died later. What would have been the **best** way of disposing of the dead cow?

A. Throwing it away from the farm.
B. Selling it to a local butcher.
C. Skinning it and boiling the meat for pets.
D. Burying it deep in the ground.

33. Which one of the following is the correct tool for pruning small coffee branches?

A. Handsaw.
B. Sickle.
C. Secateurs.
D. Hacksaw.

34. The purpose of placing litter on the floor of a brooder is to

A. make the floor comfortable
B. keep the floor clean
C. keep the floor dry
D. keep the floor free from pests.

35. Which one of the following practices is carried out in order to produce clean eggs in a deep litter system of poultry rearing?

A. Supplying green vegetable matter to the layers.
B. Providing oyster shells to the layers.
C. Giving a balanced diet to the layers.
D. Collecting the eggs frequently.

36. Why is it necessary to reduce green vegetable material feeds and to increase grains in the diet of rabbits during the last month before marketing?

A. To fatten the rabbits.
B. To reduce the cost of feeding.
C. To improve the food intake.
D. To maintain the weight of rabbits.

37. Why is it advisable to reduce watering and to remove overhead shade gradually from a nursery one week before transplanting seedlings?

A. To allow seedlings to form the green colour.
B. To control pests in the nursery.
C. To control diseases in the nursery.
D. To make seedlings get used to the field conditions.

38. A farmer wishes to borrow a loan from the Agricultural Finance Corporation to improve his farm. Which one of the following would be required by the Agricultural Finance Corporation before the loan is processed?

A. Security offered by the farmer.
B. Records of the farmer's educational background.
C. Market for the farm produce.
D. Map showing the layout of the farm.

39. Which one of the following is an advantage of zero-grazing?

A. It requires less skill to manage.
B. There is less feed wastage.
C. It is cheap to start.
D. It requires less labour.

40. To discourage bees from abandoning a bee hive during a dry season, it is necessary to

A. shift the bee hive close to a water point
B. move the bee hive to a sheltered place
C. provide a sugar solution close to the bee hive
D. leave the bee hive undisturbed.

41. Before handling newly born rabbits, it is advisable to rub the doe's bedding materials on the hands to avoid

A. the likelihood of introducing infection to the newly born rabbits
B. the likelihood of rejection of newly born rabbits by the doe
C. disturbing and making the doe aggressive
D. interference with the growth of the newly born rabbits.

42. Which one of the following is used as the planting material by farmers in sugar cane production?

A. Cuttings.
B. Splits.
C. Suckers.
D. Seeds.

43. Why is it necessary for farmers to leave strips of unploughed land between ploughed portions during seedbed preparation?

A. To keep crop remains after harvesting.
B. To provide grass for grazing.
C. To control insect pests.
D. To control soil erosion.

44. A farmer kept 200 layers from which she collected 165 eggs one day and 155 eggs the following day. Calculate the laying percentage of the layers for the two days.

A. 37.5%
B. 50.0%
C. 60.0%
D. 80.0%

45. Which one of the following crop pests is correctly matched with the part of crop that the pests damage?

	Pests	*Part of crop*
A.	Weevils	Stem
B.	Aphids	Root
C.	Armyworms	Leaves
D.	Cutworms	Flowers

46. The following list shows records for Soy farm as at 31st December, 1993.

Cash in bank	Sh. 5,000
Loan from AFC	Sh. 45,000
Value of cattle on the farm	Sh. 78,000
Value of buildings on the farm	Sh. 210,000
Money to be paid to KGGCU	Sh. 15,000
Value of farm land	Sh. 350,000

Calculate the value of the assets of Soy farm.

A. Sh. 643,000
B. Sh. 763,000
C. Sh. 778,000
D. Sh. 823,000.

47. After finishing school Robi was given a piece of land by her father for which she acquired a title deed. She grows tomatoes and kales on the land. What kind of land ownership is this?

A. Owner operator.
B. Tenancy.
C. Landlordism.
D. Communal ownership.

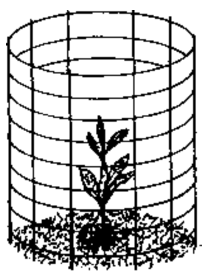
48. Small scale dairy farmers in Mwambao location are finding it difficult to sell their milk, to acquire cattle feeds and to manage their cattle. Which one of the following actions is the most appropriate for the farmers to take?

A. Attend adult education classes.
B. Form a co-operative society.
C. Sell milk at the local market.
D. Buy a lorry for milk transportation.

49. Which one of the following practices would be most suitable for improving soil fertility on a flat farm land?

A. Application of manures.
B. Controlling soil erosion.
C. Application of mulch.
D. Draining away excess water.

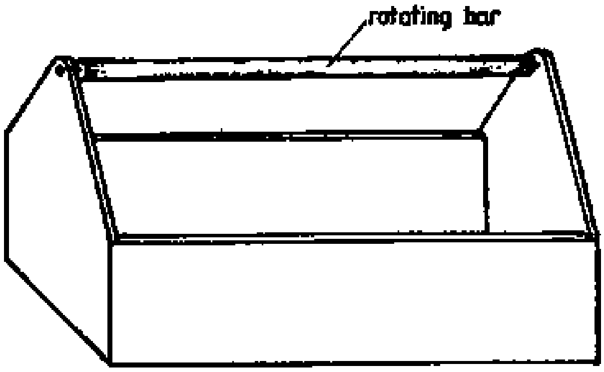
50. Below is an illustration of a tree seedling with a structure around it.



The reason for erecting such a structure around a seedling is to

A. provide shade from strong sunlight
B. make the seedling grow upright
C. protect the seedling from attack by animals
D. protect the seedling from strong wind.

51. The diagram below represents a wooden chicken feed trough.



What is the use of the rotating bar?

A. To prevent chickens from competing for the feed.
B. To prevent chickens from perching on the trough.
C. To provide a resting place for chickens after feeding.
D. To divide the trough into two feeding sides.

52. Standard V pupils collected different types of soils from their home areas for experiments. One of the soil samples was found to have the following characteristics:

(i) *has very fine soil particles*
(ii) *retains more water than all the others*
(iii) *makes thinner and longer ribbons than all the others*

Which one of the following types of soils has the characteristics listed above?

A. Clay soil.
B. Loam soil.
C. Sandy soil.
D. Sandy loam.

53. Which one of the following should a calf be fed on during the first three days of its life?

A. Calf pellets.
B. Dairy meal.
C. Whole milk.
D. Colostrum.

54. 4-K Club pupils made nursery beds that were 150 cm wide. Their teacher advised them to reduce the widths to 100 cm. Why was it advisable to reduce the widths of the nursery beds?

A. To keep the cost of watering low.
B. To enable pupils to work without stepping on the beds.
C. To be able to make many nursery beds in an area.
D. To be able to produce healthy seedlings.

55. A farmer kept maize in a raised, well ventilated and properly roofed store. Later she found the maize rotting. What was the most likely cause for the rotting?

A. Damage to the maize by pests.
B. Wet weather conditions.
C. High moisture content of maize.
D. High temperature in the store.

56. In which type of record should a farmer enter the details of the quantity of farm produce sold and the amount of money obtained from the sale?

A. Production records.
B. Field operation records.
C. Inventory records.
D. Marketing records.

57. A livestock officer went to a farm to examine a sick cow. In which structure should the cow be put during examination?

A. A pen.
B. A shed.
C. A crush.
D. A hutch.

58. Which one of the following tools requires sharpening as a maintenance practice?

A. Trowel.
B. Chisel.
C. Hacksaw.
D. Fork *jembe.*

59. Which one of the following is a symptom of coccidiosis in livestock?

A. Blood stained diarrhoea.
B. Swollen lymph glands.
C. Wounds in the mouth.
D. Difficulty in breathing.

60. A local agricultural extension officer advised a farmer to include a legume crop in her crop rotation system. The main reason for including a legume is to

A. provide feed for livestock
B. improve the soil structure
C. increase nitrogen content in the soil
D. provide cover for the soil.

3.2.4. KCPE 1993/Science and Agriculture Paper

THE KENYA NATIONAL EXAMINATIONS COUNCIL

KCPE 1993

SCIENCE AND AGRICULTURE

Time: 2 hours

READ THESE INSTRUCTIONS CAREFULLY

1. You have been given this question booklet and a separate answer sheet. The question booklet contains 60 questions.

2. Do any necessary rough work in this booklet.

3. When you have chosen your answer, mark it on the **ANSWER SHEET,** not in this question booklet.

HOW TO USE THE ANSWER SHEET

4. Use only an ordinary pencil.

5. Make sure that you have written on the answer sheet:

   YOUR INDEX NUMBER
   YOUR NAME
   NAME OF YOUR SCHOOL

6. By shading the correct numbered ellipses (small oval shapes) mark your full Index Number (i.e. School Code Number and three-figure Candidate's Number) in the grid near the top of the answer sheet.

7. Do not make any marks outside the ellipses.

8. Keep the sheet as clean as possible and **DO NOT FOLD IT.**

9. For each of the questions 1-60 four answers are given. The answers are lettered A, B, C, D. In each case only **ONE** of the answers is correct. Choose the correct answer.

10. On the answer sheet, show the correct answer by shading the ellipse in which the letter chosen is written.

Example

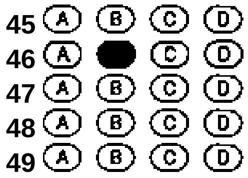
In the **Question Booklet:**

46. Which one of the following services is provided by the Kenya Grain Growers Co-operative Union?

A. Provides employment to farmers.
B. Sells inputs to farmers.
C. Organises agricultural shows.
D. Banks money for farmers.

The correct answer is 'B'.

On the **Answer Sheet:**



In the set of ellipses numbered 46, the ellipse with B in it is shaded.

11. Your shading MUST be within the ellipse. Make your shading as **DARK** as possible.

12. For each question, ONLY ONE ellipse is to be shaded in each set of four ellipses.

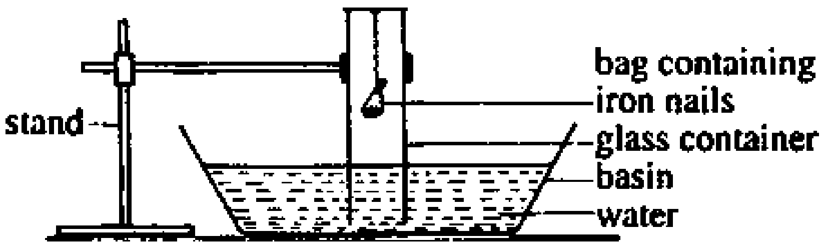
This Question Paper consists of 9 printed pages and 3 blank pages.

SCIENCE

1. The pressure exerted by a liquid depends on its

A. volume
B. mass
C. depth
D. surface area.

2. A small porous bag containing wet iron nails was fixed onto the bottom of a glass container. The glass container was then inverted over water in a basin as shown in the diagram below.



Which one of the following is most likely to happen if the set up is left for a few days?

A. Level of water in the basin will rise.
B. Level of water in the glass container will rise.
C. Weight of the iron nails will decrease.
D. Air bubbles will escape from the glass through the water.

3. The shape of a rubber sheet which was tied round the mouth of a bottle appeared as shown in diagram I. After immersing the bottle in cold water, the shape of the rubber sheet appeared as in diagram II.

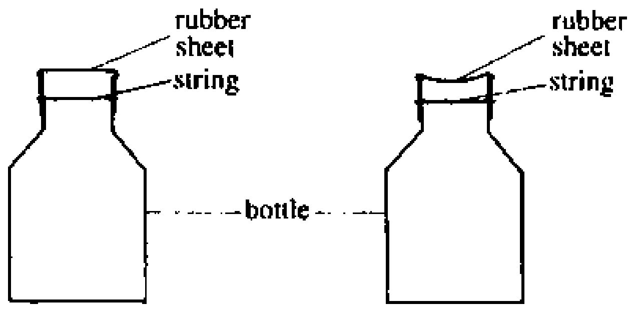


Diagram I Diagram II

The shape of the rubber sheet changed because

A. the rubber sheet absorbed air
B. air in the bottle expanded
C. air escaped through the rubber sheet
D. pressure in the bottle decreased.

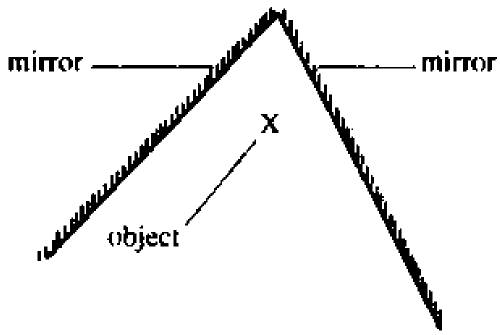
4. Four groups of pupils **P**, **Q**, **R** and **S** wanted to compare rates of evaporation of different liquids. The materials set up by each group were as follows:

P Identical containers with different amounts of liquids.
Q Identical containers with equal amounts of liquids.
R Different sizes of containers with equal amounts of liquids.
S Different sizes of containers with different amounts of liquids.

Which one of the groups of pupils set up the materials **CORRECTLY**?

A. **P**
B. **Q**
C. **R**
D. **S**

5. Two mirrors were placed as shown in the diagram below.



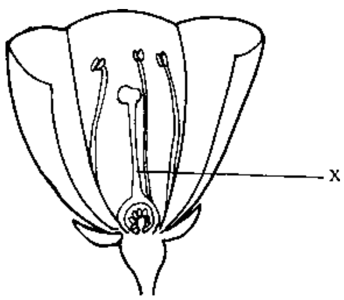
If an object is placed at point X, which one of the following would be TRUE?

A. Many images will be formed.
B. The image formed will be smaller than the object.
C. Only one image will be formed.
D. The image formed will be upside down.

6. A kerosene stove was used to boil water to produce steam for turning a model turbine. Which one of the following shows the correct order of energy changes that took place?

A. Heat chemical mechanical.
B. Chemical heat mechanical.
C. Chemical mechanical heat.
D. Heat mechanical chemical.

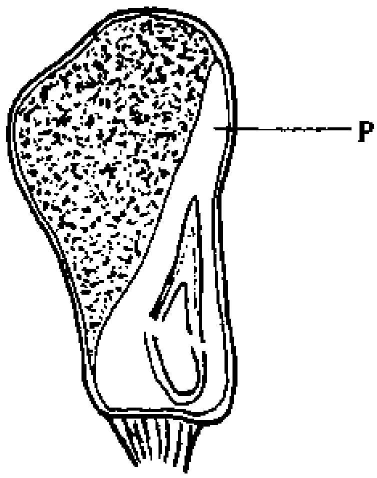
7. The diagram below represents a flower opened to show inner parts.



The part marked X is the

A. stamen
B. filament
C. stigma
D. style.

8. A section through a maize grain is shown in the diagram below.



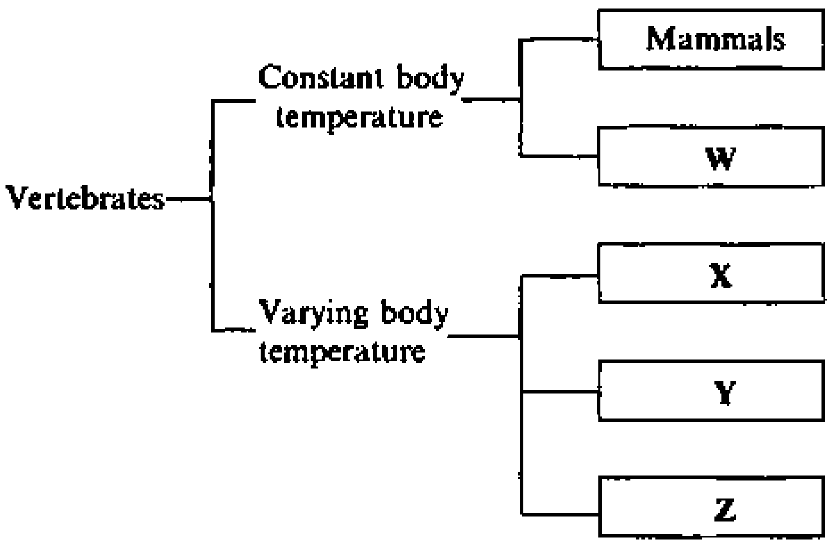
The part marked **P** is the

A. radicle
B. hilum
C. cotyledon
D. plumule.

9. Which one of the following animals is CORRECTLY MATCHED with its adaptation?

	Animal	Adaptation
A.	Hawk	Long beak.
B.	Frog	Scales.
C.	Praying mantis	Colour.
D.	Ant-bear	Teeth.

10. The chart below shows a simple classification of vertebrates.



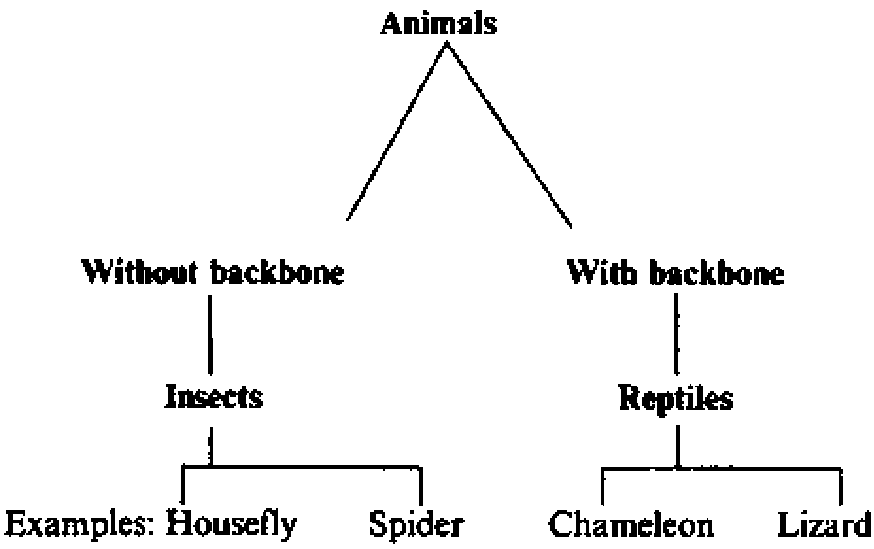
Which one of the following groups of vertebrates does **W** represent?

A. Reptiles.
B. Amphibians.
C. Fish.
D. Birds.

11. Which one of the following is a function of the pancreas? It

A. absorbs digested food.
B. produces digestive juice.
C. absorbs water.
D. stores digested food.

12. A pupil classified some animals as shown in the chart below:



Which of the folowing animals was NOT classified correctly?

A. Housefly.
B. Spider.
C. Chameleon.
D. Lizard.

13. When the heart of a mammal contracts, blood in the left ventricle is forced out

A. through the aorta
B. through the pulmonary artery
C. through the pulmonary vein
D. into the left auricle.

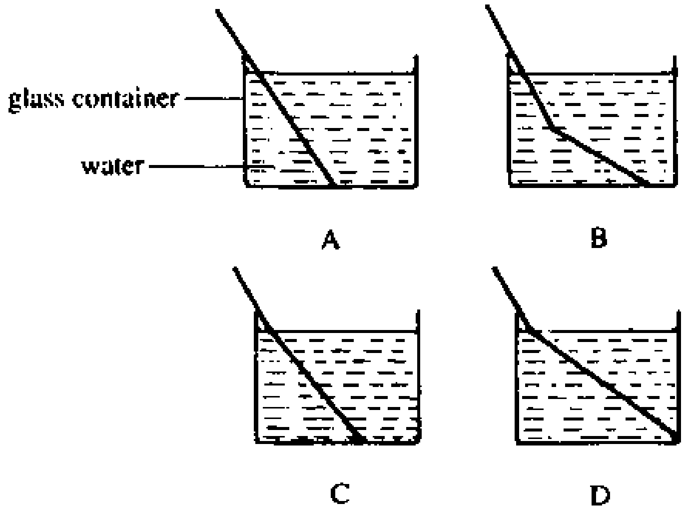
14. A fruit of a certain plant is shown in the diagram below.

The fruit is mainly dispersed by

A. wind
B. animals
C. explosive mechanism
D. water.

15. Kijita dipped a ruler in water in a glass container.

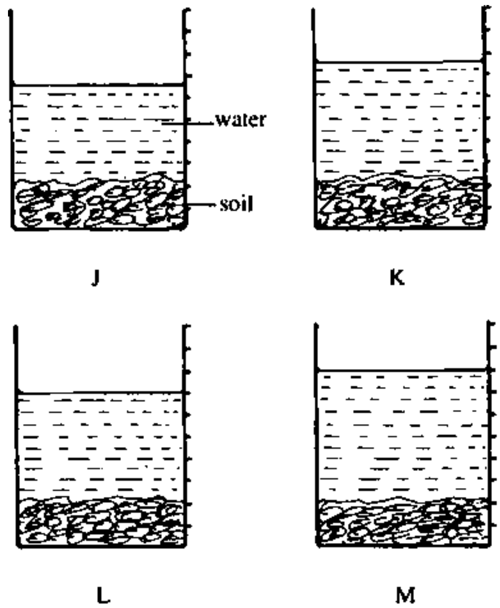
Which of the following diagrams shows how the ruler appeared when viewed from the side of the glass?



16. Which one of the following properties of soil does **NOT** depend on the size of its particles?

A. Colour.
B. Water retention.
C. Drainage.
D. Texture.

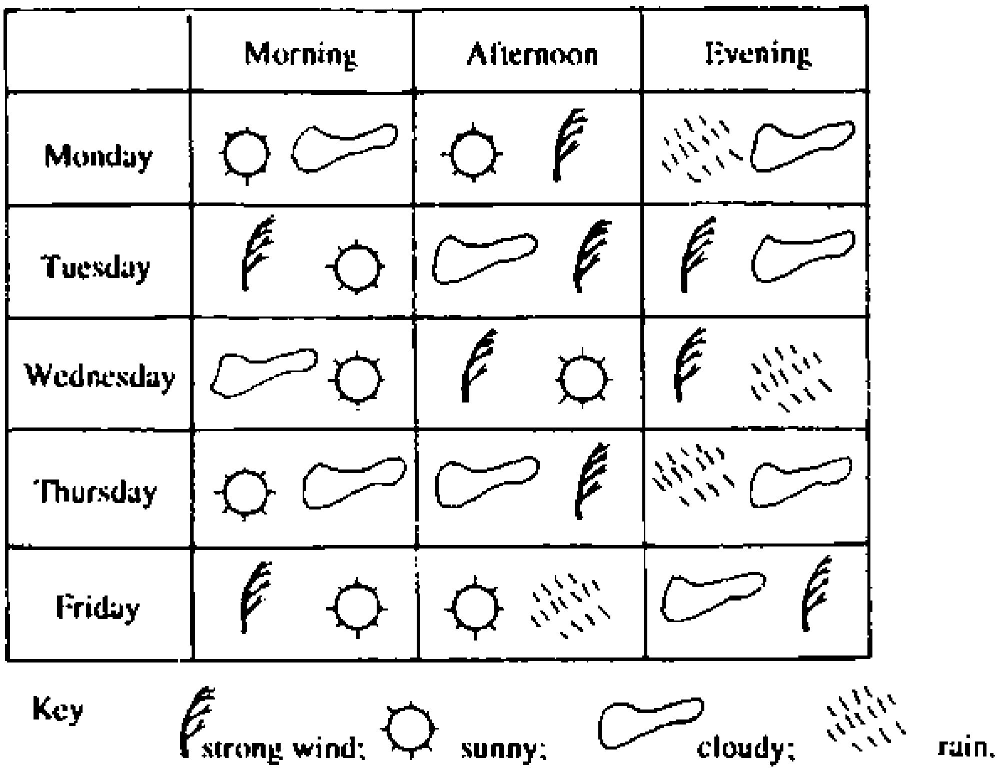
17. Equal amounts of different types of soils **J, K, L** and **M** were put into four identical glass containers. Equal volumes of water were then added to each container. After all the air had escaped from the soil in each container, the levels of water in the containers were as shown in the diagrams below.



Which one of the following conclusions about the soils is correct?

A. Soil **L** had more air spaces between its particles than soil **K**.
B. Soil **M** had the most air spaces between its particles.
C. Soil **K** had less air spaces between its particles than soil **M**.
D. Soil **J** had the least air spaces between its particles.

18. The chart below shows a record of weather made by pupils in Standard Five for a week.



Which one of the following statements about the weather chart above is **correct**?

A. It only rained after strong winds blew earlier in the day.
B. It was cloudy in all the afternoons.
C. It was sunny everyday in the morning and windy everyday in the afternoon.
D. Strong winds blew in the mornings on more days than in the evenings.

19. As Katinda was walking from home to school early in the morning, she saw her shadow on her right hand side and the school directly ahead of her.

In which direction was the school from where she was?

A. East.
B. West.
C. North.
D. South.

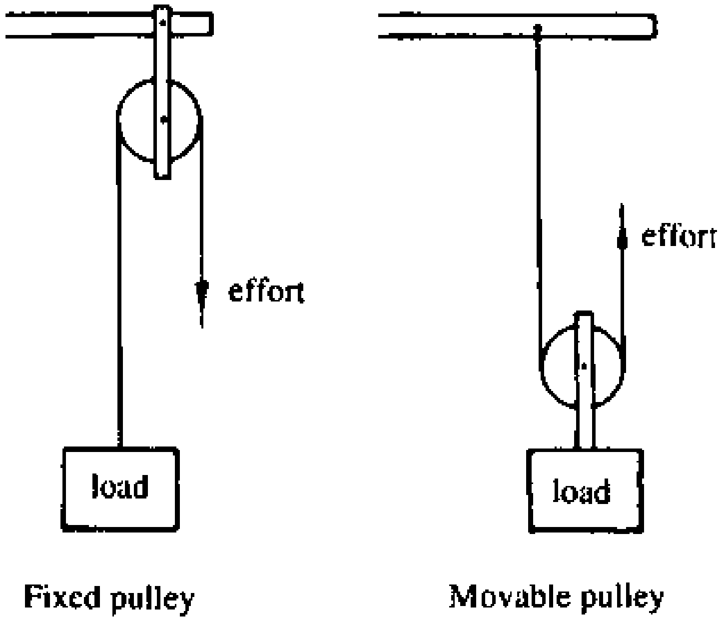
20. Amina was instructed by the doctor to lake two teaspoonfuls of some medicine after every six hours for five days. She forgot the instructions and look four teaspoonfuls of the medicine at once. After realising her mistake, Amina should have

A. sought immediate advice from a doctor
B. taken the medicine only after the next twelve hours
C. drunk plenty of water to dilute the medicine
D. continued taking the medicine correctly as instructed.

21. Cirrhosis is a disease of the liver which is commonly caused by excessive

A. drinking of beer
B. smoking of tobacco
C. chewing of *miraa*
D. inhaling of cobbler's glue.

22. Movable and fixed pulley arrangements shown in the diagram below were used separately to lift a load by a distance of one metre.



Which one of the following shows the correct distances moved by the effort in each case?

	Fixed pulley	Movable pulley
A.	1 m	1 m.
B.	2 m	1 m.
C.	1 m	2 m.
D.	2 m	2 m.

23. Which one of the following practices does **NOT** pollute the environment?

A. Spilling used oil in a forest away from homes.
B. Spraying some oil in a lake to kill mosquito lavae.
C. Dumping vegetable remains in a farm near homes.
D. Dumping factory wastes into a river that flows into the sea.

24. The chart below shows a feeding relationship in a certain habitat.

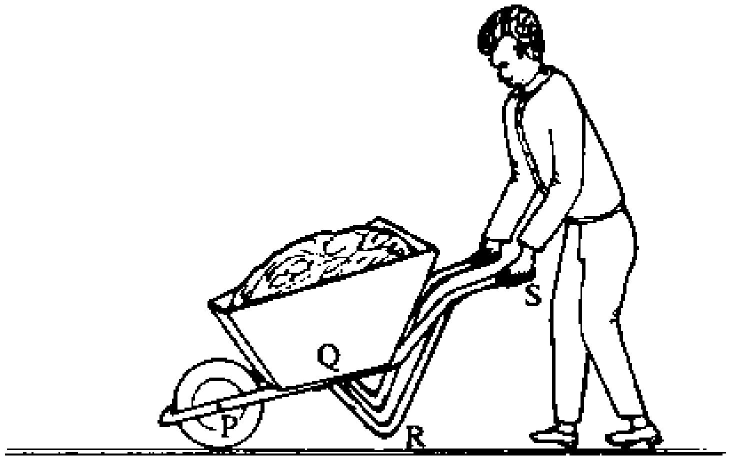
Grass $\Rightarrow$ Insects $\Rightarrow$ Lizards $\Rightarrow$ Snakes.

Note: The arrow points to the eater.

If a disease killed all the lizards, which one of the following would be the immediate effect?

	Grass	Insects	Snakes
A.	Decrease	increase	decrease.
B.	Increase	increase	decrease.
C.	Decrease	decrease	decrease.
D.	Increase	decrease	decrease.

25. The diagram below shows a loaded wheelbarrow being pushed.



Which one of the following represents the effort distance?

A. QS.
B. PS.
C. QR.
D. PR.

26. Juma sat on the seesaw at point **P** while John sat at point **Q**. The seesaw tilted lifting John up.

Which one of the following should John do in order to balance with Juma?

A. Move nearer the fulcrum.
B. Remain at **Q** and press the seesaw downwards.
C. Move the fulcrum closer to himself.
D. Move further away from the fulcrum.

27. In which one of the following activities does a man need to reduce friction?

A. Walking downhill.
B. Writing on a piece of paper.
C. Sliding a carton of milk across a table.
D. Picking bottles from a crate.

28. A transparent plastic container was filled with water. Two small holes were then made, one on the lid and the other at the bottom. It was noticed that when both holes were open, water flowed out through the bottom hole. When the top hole was closed, the flow of water stopped. The flow of water stopped because

A. water in the container is denser than air
B. pressure in water is greatest at the bottom
C. air pressure in the container increased
D. pressure exerted by the water is equal to the air pressure at the bottom hole.

29. A little amount of water in a tin can was heated and the water allowed to boil for sometime. The tin was closed firmly and cold water poured on it. The can collapsed suddenly. This happened because

A. pressure outside the tin can increased
B. pressure inside the tin can increased
C. the contraction of tin can was sudden

D. pressure inside the tin can decreased.

30. A small piece of glass was cut off from a large shee of glass. Which one of the following properties o glass does **NOT** change after the cutting?

A. Mass.
B. Weight.
C. Volume.
D. Density.

AGRICULTURE

31. Which one of the following sheep breeds is kept for wool production?

A. Maasai.
B. Merino.
C. Blackhead Persian.
D. Dorper.

32. Which one of the following sets of characteristics apply to a dairy cow?

A. Early maturity and block shaped body.
B. Thick neck and high fertility.
C. Short legs and strong back.
D. Well developed udder and wedge shaped body.

33. Which one of the following parasites **CANNOT** be controlled by rotational grazing?

A. Ticks.
B. Tapeworms.
C. Tsetse flies.
D. Liver flukes.

34. A farmer noticed that one of his cows was eating objects such as clothes and soil.

What action should the farmer take to correct this behaviour?

A. Give the cow more feed.
B. Give the cow feed rich in proteins.
C. Separate the cow from others.
D. Give the cow mineral salts.

35. The diseases below attack the animals shown against them.

Disease	**Animals attacked**
Anthrax	cattle, sheep, goats
Foot and mouth	pigs, sheep, cattle, goats
Nagana	camels, pigs, sheep, goats, cattle
Coccidiosis	chickens, rabbits, sheep.

Which of the following animals are attacked by **all** of the above diseases?

A. Cattle.
B. Goats.
C. Sheep.
D. Pigs.

36. Which one of the following characteristics can be used to identify a hen that has stopped laying when culling poultry?

A. Bright and alert eyes.
B. Large and warm comb.
C. Large and moist vent.
D. Dry comb and hard abdomen.

37. The reason for smearing grease on wires that suspend Kenya Top-bar hive is to prevent

A. ants from reaching the hive
B. the wire from rusting
C. rats from reaching the hive
D. birds from resting on the wire.

38. A farmer built a house for his chickens to stay in at night and provided watering points for the chickens in the farm.

What system of poultry rearing was the farmer practising?

A. Free range.
B. Deep litter.
C. Battery cage.
D. Fold.

39. Which one of the following statements describes the term **mixed farming?**

A. Growing cereal and leguminous crops together.
B. Rearing livestock and growing crops on the same farm.
C. Rearing livestock and keeping poultry on the same farm.
D. Growing vegetables and cash crops together.

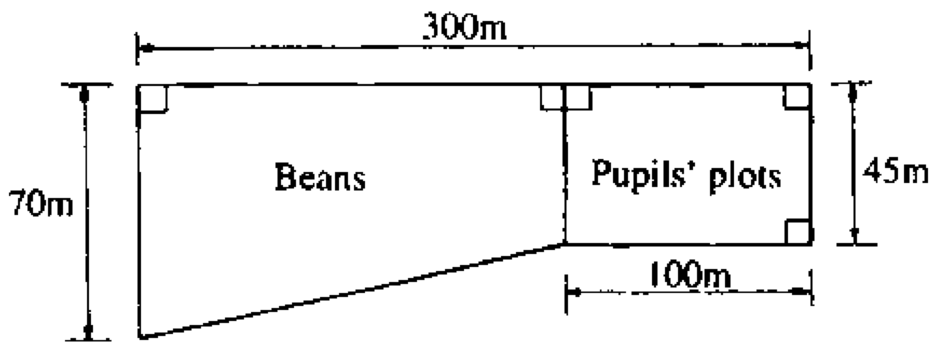
40. How do plants help to control soil erosion?

A. By their leaves preventing rain water from reaching the ground.
B. By their roots holding the soil particles together firmly.
C. By their leaves preventing sun's heat from reaching the soil.
D. By preventing moving water from passing between them.

41. What is the purpose of constructing a shade over seedlings in a nursery bed?

A. To conserve soil moisture.
B. To make seedlings grow taller.
C. To improve soil fertility.
D. To prevent rain water from reaching the seedlings.

42. The sketch map given below represents a school farm.



Calculate the area of the plot planted with beans in hectares.

A. 1.15 ha.

B. 1.35 ha.
C. 1.40 ha.
D. 2.10 ha.

43. A farmer noticed that his maize at flowering stage had holes on the leaves and stems.

Which one of the following pests is likely to have caused the damage?

A. Aphids.
B. Armyworms.
C. Weevils.
D. Stalkborers.

44. Which one of the following is an oil crop?

A. Pawpaw.
B. Peas.
C. Sun-flower.
D. Wheat.

45. Tomato plants are staked in order to

A. allow for easy pruning.
B. keep the fruits off the ground.
C. allow uniform ripening of fruits.
D. prevent the fruits from being damaged by insects.

46. Which one of the following entries should **NOT** be entered under Input records?

A. Foods given to poultry.
B. Fertilizers used for planting.
C. Eggs sold to the market.
D. Pesticides applied to crops.

47. Mrs. Juma kept the following information in the records for her dairy cattle:

Dates when cows are served
Dates when cows are due to calve down
Sexes of calves born
Breeds of bulls used for service

In which one of the activities below would the above information be most useful to Mrs. Juma in managing her farm?

A. Marketing her dairy products.
B. Selecting suitable animals for breeding.
C. Detecting the health of her livestock.
D. Buying the required materials for her livestock.

48. The price of groundnuts at Mur Malanga market on one Tuesday was Shs. 65.00 per kg before mid-day, and Shs. 85.00 per kg after mid-day.

What is likely to have caused the increase in price?

A. Less quantity of groundnuts supplied in the morning and few buyers present.
B. Large quantity of groundnuts supplied in the afternoon and few buyers present.
C. Less quantity of groundnuts supplied in the afternoon and many buyers present.
D. Large quantity of groundnuts supplied in the morning and few buyers present.

49. In the month of June 1992, a farmer kept the following records:

1st June sold eggs for Shs. 900.00
4th June bought layers mash for Shs. 1,080.00
8th June sold carrots for Shs. 1,000.00
16th June sold cabbages for Shs. 2,400.00
20th June bought fertilizers for Shs. 1,000.00
30th June bought fungicides for Shs. 300.00

What profit or loss did the farmer make during the month of June 1992?

A. A profit of Shs. 1920.00.
B. A loss of Shs. 2380.00.
C. A profit of Shs. 4300.00.
D. A loss of Shs. 6680.00.

50. Which one of the following organisations provides loans for farming?

A. 4-K Clubs.
B. Agricultural Society of Kenya.
C. Young Farmers Clubs.
D. Agricultural Finance Corporation.

51. In which one of the following land tenure systems does a farmer have full right to the use of land?

A. Tenancy.
B. Communal ownership.
C. Individual owner operator.
D. Co-operative.

52. Which one of the sets of tools and equipment listed below is the most appropriate to use when constructing a wooden chicken feed trough?

A. Handsaw, claw hammer, try square and tape measure.
B. Spirit level, try square, tape measure, and handsaw.
C. Ball pein hammer, *panga*, try square and spirit level.
D. Try square, *panga,* tape measure and handsaw.

53. Which one of the following tools is most suitable for preparing a seedbed from a hard piece of ground that has couch grass?

A. Garden fork.
B. *Jembe.*
C. Mattock.
D. Fork *jembe.*

54. What maintenance practices should be carried out on garden tools to prevent rusting during long storage?

A. Clean, dry and apply oil on tools before storage.
B. Clean, dry and sharpen tools before storage.
C. Wash the tools and replace worn out parts.
D. Wash the tools and repair broken parts.

55. Which one of the places described below is suitable for siting a bee hive?

A. An open place near flowering plants.
B. A place far from a grazing field and far from a water source for bees.

C. A sheltered place close to a water source for bees.
D. A sheltered place close to a homestead.

56. Matera Primary School pupils have observed for a number of years that their maize crops get damaged by being blown down by strong winds.

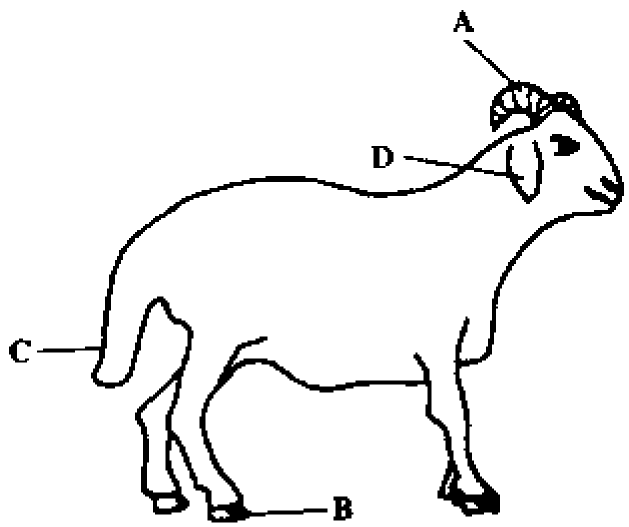
What action should they take to control the problem in future?

A. Apply more fertilizers to their maize crops.
B. Grow a short maize variety.
C. Intercrop maize with beans.
D. Plant trees around their maize plot.

57. Which one of the following sets of practices contains safety measures which should be "observed when applying insecticides?

A. Wearing protective clothing and using insecticides of correct concentration.
B. Using the right type of insecticide and spraying against the direction of wind.
C. Wearing protective clothing and using highly concentrated insecticides.
D. Pouring the remaining insecticides on the grass and cleaning the equipment after use.

58. Below is an illustration of a sheep. Which one of the parts labelled is usually docked?



59. Which one of the following planting materials is used to establish a crop of bananas?

A. Tubers.
B. Suckers.
C. Bulbils.
D. Cuttings.

60. Why should compost materials be turned three to four limes during the preparation of compost manure?

A. To reduce the smell of compost materials.
B. To encourage uniform rotting of compost materials.
C. To allow fast water penetration in the compost heap.
D. To check if the compost heap is ready for use.

3.3. Lesotho

3.3.1. Overview

End of Primary School Examination

1. Title of examination:	Primary School Leaving Examination
2. Amount of fees charged:	≈ US$2
3. Examination after years in primary school (6, 7, 8 years):	7 yrs
4. Children's entry age in primary school:	6 yrs
5. Number of pupils sitting examination in 1994:	31,396
6. Examination subjects offered:	8 subjects in 5 papers: • Mathematics • English • Sesotho • Social Studies • Science (Science, Home Economics, Agriculture, Health Education)
7. Language of examination:	English (except for Sesotho paper)
8. Institution setting the examination questions:	N.C.D.C. (National Curriculum Development Centre) and Primary Examination Office for printing
9. Have there been any reforms in the examination questions?	No, but syllabi for primary schools were revised 1994 and are on trial in selected schools countrywide.
10. Stages of development of examination questions (please describe):	• Item writing workshop for Primary School Leaving Examination by selected teachers with the assistance of subject specialists from National Curriculum Development Centre. The workshop is conducted by the Examination Office with the assistance of the Office of Evaluation, Research and Testing. • Editing and proofreading of developed items by Evaluation, Research and Testing Division. Final proofreading by subject specialists. • Banking of good items by Evaluation, Research and Testing Division. • Two papers per subject produced by Evaluation, Research and Testing Division and printing of papers by Examination Office. • Pre-testing on selected sample by the Inspectorate. • Scoring of answer sheets on computer and item analysis coordinated by the Inspectorate.

11. Type of examination questions and distribution of different kind of questions.	Multiple-choice in English, Sesotho, Science, Mathematics and Social Studies; mainly recall questions; essay writing: English and Sesotho.
12. Is continuous assessment incorporated in the final examination?	Yes [ ] No [x]
13. Are examination items pretested?	Yes [x] No [ ]
14. Which professional groups are involved in setting the examination questions?	• Primary school teachers • School inspectors • Primary Examination officers • Curriculum developers
15. Are the same professionals who set the examination questions involved in marking papers?	Yes [ ] No [x]
If no, who marks the papers (state)?	District Education Offices select teachers for marking of English and Sesotho essays and letters.
16. How are examination results used for improving teaching in primary schools?	The District offices, National Curriculum Development Centre and Examination office produce a report which is sent to schools, curriculum developers and Ministry of Education for the purpose of improving teaching in primary schools. Examination results are used together with the report by the three bodies mentioned above. Evaluation, Research and Testing Division conducts an analysis of items used by NCDC to improve items, and teachers to improve teaching.
17. To what other uses are the examination results put?	The examination results are also used for selection into secondary schools.
18. Main problem with Primary School Leaving Examinations?	• Distribution of examination papers is difficult because some places are not easy to reach. • Security of papers is not guaranteed. • Production of scanner sheets.

3.3.2. Item Writing for Primary School Leaving Examination in Lesotho

National Curriculum Development Centre (N.C.D.C.)

Introduction

During last week of October the Primary School Leaving Examination (PSLE) is administered countrywide. The time table which has been given to the head-teachers is followed to the letter. Five subjects are tested, namely: English, Sesotho, Mathematics, Science and Social Studies. These subjects are normally scheduled to be administered in four days. The language subjects Sesotho and English have three papers each. The first paper requires a composition on one of the two given topics. The second paper deals with composing a letter, and the third paper contains multiple-choice questions on comprehension and usage of the language. The other three subjects test the candidates by applying multiple-choice items.

In 1993 about 31,887 students enrolled for PSLE but the actual number of students who sat for PSLE were 31,979 of which 8,725 got the first division (1st class), 8,644 got the second class and 11,665 got third class. Only 1,742 students failed, while the total number of passes was 29,034 (90.8% of candidates who sat for PSLE).

The Development of the Item Bank

In 1987 it was decided that an item bank should be built up for the PSLE. The banked items would be pre-tested and statistically analysed. The Evaluation and Testing (E&T) Division of the National Curriculum Development Centre (NCDC) was then assigned the task of developing and building up the bank.

Step 1

The E&T Division consults with different subject divisions which in turn nominate a number of teachers (normally five per subject area) to attend the item writing workshop. It was felt that the contribution made by teachers towards this exercise would be more appropriate.

The criteria used are as follows:

(a) Subject panel members: This criteria has the disadvantage of not giving many different teachers a chance to gain an idea of proper item writing.

(b) Resource teachers: The aim here is that when the teachers get back to their respective regions they will share whatever knowledge they have gained on good item writing with their colleagues.

(c) Teachers from different localities throughout the country: The idea is the same as above; teachers would spread the message to teachers in their schools and neighbouring schools on how to write good items.

The subject divisions are encouraged to mix their nominees; e.g. out of five people, at most two teachers should already have attended the workshop while the other three teachers should be new to the exercise. The aim is that the experienced teachers give a lead to the inexperienced teachers.

Step 2

The item writing workshop normally runs for five days. On the first day and the first half of the second day teachers are introduced to the item writing circle as well as given tips on how to write good items. They are also given examples of items which are considered to be good or to be poor.

Teachers start writing items from the second half of the second day up to the fourth day. On the fifth day, teachers are normally given a chance to go through their work to convince themselves that they have produced what is required. From the very first day of the workshop, the representatives of the subject divisions work with the E&T group to guide teachers. Since teachers work in different groups according to the subjects they write items for, each representative of subject divisions works with his/her subject group.

Step 3

The following step after the item writing workshop is that of editing the items written by teachers. This exercise is done by the E&T group. Immediately after editing, the test papers are compiled using the edited items. When the papers are ready, the E&T Division passes them over to the respective subject divisions where the items are edited further. After the second editing the E&T Division produces final test papers ready for printing.

For each subject, two test papers are produced (papers A and B). The purpose of having two papers is to increase the chances of having many good items during pretesting (those items that show good statistical characteristics when analyzed).

Step 4

The test papers are taken for printing at this stage. The printing is done by the Instructional Materials Resource Centre (I.M.R.C.) unit, which also falls under the Ministry of Education (MOE).

During the printing of the test papers the E&T Division together with the Primary Examinations Office (PEO) selects a sample of schools in which pre-testing will take place.

The criteria for selecting schools takes a number of factors into consideration:

- The size of the district (the number of schools per district).

  The locality of the school within the district (e.g. rural, urban, foothills or mountains).

- Denomination of the proprietor (more than 95% of the primary schools in the country belong to churches).

- The performance of the school at PSLE level (e.g. very high, average or very low).

The schools are then warned a month in advance about the pretest visits.

Step 5

At this stage the E&T group together with the PEO administers the pre-test exercise. This exercise takes a full month (4 weeks), and it is done in September, when pupils are just ready to sit for their PSLE. Each test paper must be taken by at least 200 pupils. The tests taken at each school are chosen at random. One school takes two sittings. That is, either two or four different tests per school, depending on the size of the school.

Step 6

The pre-testing involves only the objective type of tests. Thus, the computer answer cards are used and scored by computers. The scoring is done by the Education Statistics Unit of the MOE.

The scoring computer has been fed with a programme which has been derived from the Kuder-Richardson Formula 20 (KR20) formula, which allows it to produce item analysis immediately after scoring the cards.

Step 7

The item analysis comes out in such a way that the E&T Division can easily decide whether an item should be banked, revised or trashed altogether. The items that are banked are those which show good statistical characteristics, and these are the items that would be put in the PSLE papers.

Step 8

When the PSLE papers have to be produced the E&T Division consults with each subject division to decide on the items that should be included in the papers. For this exercise the subject divisions are encouraged to use a table of specification (test blueprint) so that they can avoid bias.

When the items have been decided upon by the subject divisions, the E&T Division compiles the test papers, which in turn are proofread by the respective subject divisions. The camera-ready copies are then produced by the E&T Division and handed over to the PEO. It is the responsibility of the Primary Education Office to see that the test papers are printed, parcelled and sent to schools under very tight security. The PEO gets full help from the District Education Offices in order to perform these duties.

Step 9

The administration of the examinations is done by invigilators, who also have to send the candidates' papers to the relevant centres. The invigilators normally are teachers of class 6 and they should neither be headteachers nor should they be class 7 teachers as well. This is simply because these two categories of teachers have to be there when the examinations are being administered in their schools. The selection procedure takes place each year in September and at that very same time the test booklets are sent to schools; their safety is left with the head of the school. The invigilators are given a one-day training on how to conduct the PSLE and are also given each a PSLE administrators manual.

Step 10

After the PSLE results have been processed the item analysis of the objective tests is produced and sent to the E&T Division which decides on which items should be banked, revised or discarded.

Step 11

The District Education Offices are required to send comments to the E&T Division after marking the essays and letters. The required comments should have been made by markers, and they should be on points which they feel teachers should lay more emphasis on when teaching. The subject divisions also comment on problems concerning classroom teaching. They perform this exercise with the help of the E&T Division, on the basis of item analysis produced from the test papers. The E&T Division then produces a report based on all those comments and sends it to the schools.

Subjective Tests

Most of the steps outlined above prepare the objective tests candidates take. The subjective tests, that is, essays and letters for the languages, are not pre-tested. However, the topics are recommended by the teachers during the item writing workshop. The respective subject divisions are consulted by the E&T Division for them to decide on the topics which should be included in the PSLE papers.

Conclusion

PSLE is the only instrument on which to test and measure the ability and the extent of instruction at primary level. It is the only means that assesses countrywide the amount of skills, knowledge, and attitudes acquired in seven years of the learners' exposure to classroom instruction. It is still a way of selecting students who should proceed with higher education (post primary education).

However the Evaluation Research and Testing Division of the National Curriculum Development Centre presently explores a different way of assessment, whereby at the end of classes 3 and 6 students' achievements in Maths, English and Sesotho will be checked. The time and exposure given to the item writing during the workshops with teachers is too short. It is possible that some teachers write poor items because they may not have grasped some of the concepts. There has never been a chance to make a follow-up on teachers to ensure that they do share whatever they have gained with their colleagues.

3.3.3. Primary School Leaving Examination, Standard 7, 1994/Science Paper

KINGDOM OF LESOTHO
MINISTRY OF EDUCATION
PRIMARY SCHOOL LEAVING EXAMINATION
STANDARD 7
OCTOBER 1994
SCIENCE

(Time: 1 hour 30 minutes) (Marks: 70)

GENERAL INSTRUCTIONS

1. **Use only PENCIL on your answer sheet.**

2. When you have chosen the answer to a question, shade in the letter space **COMPLETELY** for that answer on the answer sheet.

Example: 

3. If you wish to change any answer you have chosen, use a rubber to rub out the **mark COMPLETELY** and then make a new mark. If you do not rub out completely the machine may mark the answer wrong.

4. Examples have been given to help you. Read them carefully before you start doing the questions.

SAMPLE QUESTIONS

I. Food should always be covered to keep away ________________.

A) smell
B) flies
C) people
D) rats

The correct answer is "B". You would shade in the space for B on your answer sheet.

II. Milk is a ___________.

A) crystal
B) solid
C) liquid
D) gas

The correct answer is "C". You would shade in the space for C on your answer **sheet.**

1. Which sense does Mpho use to tell that there is some nicely cooked food?

A) sight
B) touch
C) hearing
D) smell

2. Which sense is used to tell that water is cold or hot?

A) Touch
B) Smell
C) Taste
D) Hearing

3. Where does the moon get its light from?

A) Earth
B) Itself
C) Sun
D) Star

4. What can be done to the plough wheels that make a lot of noise?

A) wash the wheels
B) oil the wheels
C) spray the wheels with water
D) punch the wheels

5. Which of the following substances dissolves in water?

A) sand
B) sugar
C) wheat-meal
D) maize meal

6. Which of the following will help in pollinating roses?

A) Sheep
B) Birds
C) Bees
D) Man

7. Which one of the following animals is covered with scale?

A) Horse
B) Cow
C) Hen
D) Tortoise

8. How does a fish move? It _____.

A) swims
B) climbs
C) hops
D) runs

9. Fish uses __________ for breathing.

A) gills
B) stomata
C) lungs
D) pores

10. __________ soil has big particles.

A) clay
B) sand

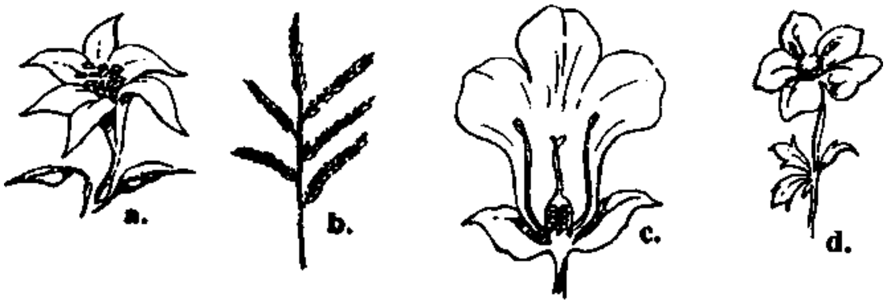
C) loam
D) aluvial

11. What kind of soil holds water for a long time?

A) loam
B) sand
C) clay
D) gravel

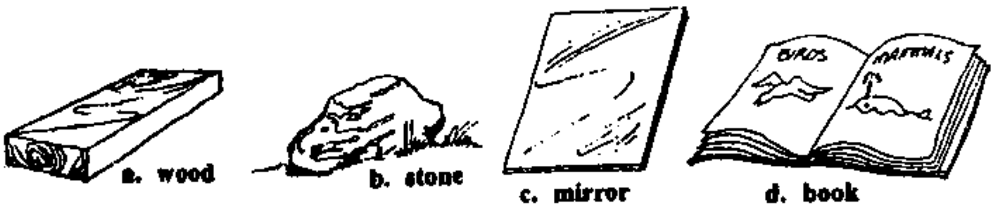
12. Which of the following flowers is a maize flower?

A) d
B) a
C) c
D) b



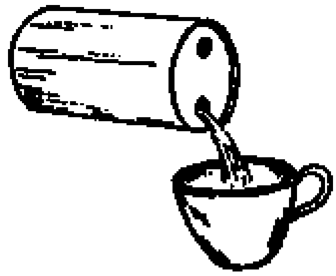
13. Which one of the diagrams below will reflect the rays of the sun when directed to it?

A) b
B) a
C) c
D) d



14. See the picture below. What will help the milk go out of the container?

A) Air pressure
B) Tea
C) Cup
D) Jar

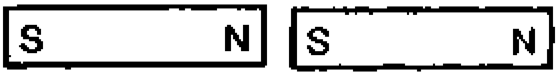


15. What happens to the wax when a candle burns? It _________.

A) expands
B) becomes black
C) becomes yellow
D) melts

16. In the diagram below what will happen to the magnets? They will _______ each other.

A) repel
B) attract
C) miss
D) change



17. Tau rubs a ruler on his head and after some few seconds the ruler was able to attract pieces of papers. This shows that a ruler becomes a ________.

A) magnet
B) permanent magnet
C) radiator
D) temporary magnet

18. How does a scorpion respond when being touched?

A) runs away
B) raises its sting
C) fights
D) stays still

19. Which part do plants use for breathing?

A) stem
B) flowers
C) leaves
D) roots

20. Which machine can you use to cut through a large piece of wood?

A) Axe
B) Knife
C) Nail
D) Hoe

21. How did Mphatlalatsane derive its name? It appears _________.

A) in the middle of the day
B) before sun set
C) before sun rise
D) after sun set

22. Which one of the following shows a complete life cycle of a grasshopper?

A) pupa, egg, adult and larva
B) adult, larva, egg and pupa
C) larva, pupa, adult and egg
D) egg, larva, pupa and adult

23. Which one of the following animals lives partly in water and on land?

A) frog
B) rat
C) hare
D) cat

24. Which of these is a wild animal?

A) Cat
B) Hare
C) Lamb
D) Cow

25. __________floats in water.

A) Pumpkin
B) Stone
C) Egg
D) Feather

26. What can you use to find the perimeter of the leaf?

A) a ruler
B) a string
C) a tape measure
D) foot steps

27. A bean pod disperses by _____________.

A) itself
B) wind
C) animals
D) water

28. Which of the following lists has a list of living things only?

A) paper, plastic, rose
B) horse, stone, soil
C) man, cat, carrot
D) house, bag, boy

29. When bicarbonate of soda is mixed with vinegar it will ________.

A) melt
B) make bubbles
C) change colour
D) evaporates

30. Which agent will help in breaking down rocks into small particles?

A) paper
B) road
C) water
D) insects

31. Tseli is ill and she goes to the clinic to see the doctor. The doctor uses ________ thermometer to measure her body temparature.

A) clinical

B) mercury
C) alcohol
D) scale

32. Which is a non-living object?

A) cat
B) tree
C) boy
D) stone

33. One has to wear dark clothes in Winter because they ________.

A) reflect light
B) absorb heat
C) are beautiful
D) lose heat

34. A flame needs _________ in order to keep burning.

A) carbon
B) water vapour
C) nitrogen
D) oxygen

35. The wearing away of soil by wind and water is called ______.

A) convection
B) conservation
C) erosion
D) migration

36. Which animal sleeps in winter?

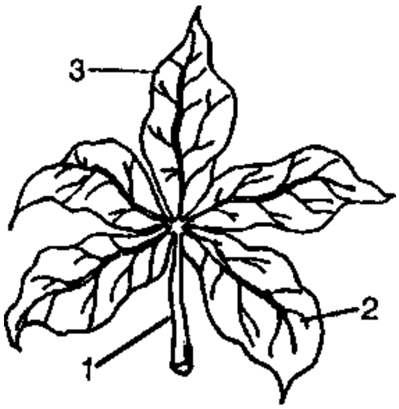
A) snake
B) rabbit
C) rat
D) dog

37. The chameleon takes the colour of the place where it lives in order to _______.

A) move quickly
B) smell its food
C) protect itself
D) see other animals properly

38. The part of the leaf marked 2 is called the __________.

A) vein
B) edge
C) midrib
D) stalk



39. Sand cannot dissolve in water. It is said to be _________ in water.

A) inseparable
B) insoluble
C) soluble
D) insolvent

40. A clinical thermometer is an instrument used for measuring body_____________

A) the time of day
B) air pressure
C) rainfall
D) temperature

41. We can prevent soil erosion on sloping ground by _________ the slope.

A) ploughing furrows across
B) frequently grazing animals on
C) ploughing up and down
D) burning vegetation on

42. Water and wind easily carry away top soil when the ground is ________________.

A) warm and fertilized
B) stony and wet
C) planted with trees
D) bare and dry

43. Soil erosion can be most effectively reduced on sloping fields by __________.

A) a drainage system
B) contour ploughing
C) bustard trenching
D) shift cultivation

44. Which one of the following practices is a means of preventing soil erosion?

A) Ploughing up and down the slope
B) Winter ploughing
C) Planting grass and trees
D) Cutting grass

45. A field crop which contains oil is _________.

A) sorghum
B) maize
C) sunflower
D) wheat

46. Most of my wheat crops did not form grain but produced powder of _________ effects.

A) pneumonia
B) rust
C) blight
D) mildew

47. Plants get their minerals from the ___________.

A) gravel
B) air

C) clouds
D) soil

48. Lesotho is advised to construct __________ for irrigating fields during drought.

A) dams
B) boreholes
C) tanks
D) reserviors

49. After washing garden tools one must apply ________ on them to prevent rust.

A) grease
B) vaseline
C) fat
D) dripping

50. Field crop which grow well in the highlands of Lesotho are __________.

A) sorghum and sunflower
B) maize and letils
C) wheat and peas
D) barley and beans

51. We can keep our bodies fit and strong by ___________.

A) keeping our bodies clean
B) drinking a lot of water
C) eating a lot of fatty foods
D) Exercising regularly

52. Teboho does not eat carrots. Which disease is he likely to suffer from?

A) Bleeding gums
B) Poor eye sight
C) Weak blood cells
D) Poor growth of bones

53. Drugs and alcohol are dangerous to our bodies because they ___________.

A) affect our brains and minds
B) destroy our muscles
C) cause breathing problems
D) weaken our bones

54. A prepared mixture of sugar, salt and water can be used for treating a child suffering from ___________.

A) whooping cough
B) sore throat
C) diarrhoea
D) Toothache

55. Daily exercises helps you to be ___________.

A) injured
B) healthy
C) tired
D) sleepy

56. We wash hands before eating to prevent spread of __________.

A) fleas
B) flies
C) lice
D) germs

57. Before crossing the road, one must look __________.

A) tright and down
B) up and down
C) right and left
D) left and up

58. If a child has headache, give him/her _______ to stop pain.

A) sweets
B) cool-drink
C) jam
D) paracetamol

59. Loss of ________ is example of physical disability.

A) limb
B) hearing
C) vision
D) memory

60. Cleaning of ears with a matchstick may damage the ear _______.

A) drum
B) bone
C) tube
D) flap

61. Which one of these vegetables is in the same food group as meat?

A) tomatoes
B) potatoes
C) cabbage
D) beans

62. Meat and other foods decay quickly in the __________.

A) winter
B) spring
C) summer
D) autumn

63. _________ brush should be used to clean a plain wooden floor.

A) Shoe
B) Scrubbing
C) Hair
D) Clothes

64. To find out the length of the material one of these is used.

A) Tape measure
B) Scissors

C) Thimble
D) Cord

65. Mention one article that can be made of wool.

A) blouse
B) jersey
C) stockings
D) shirt

66. Paint stains are removed with ____________.

A) paraffin
B) solution of salt
C) sour milk
D) vinegar

67. Which is the balanced meal among these?

A) potatoes, samp, tea
B) potatoes, meat, samp
C) soft porridge, tea, meat
D) meat, vegetable salad, rice

68. Why do you use soap when washing clothes? To remove ___________.

A) lice
B) colour of a cloth
C) dirt properly
D) bugs

69. When we clean leather shoes we need __________.

A) rags and oil
B) polish and brushes
C) polish and rags
D) oil and brushes

70. Which stain is removed by soaking a cloth in cold water with a little salt added?

A) grease
B) ink
C) milk
D) blood

3.3.4. Primary School Leaving Examination, Standard 7, 1993/Science Paper

KINGDOM OF LESOTHO
MINISTRY OF EDUCATION
PRIMARY SCHOOL LEAVING EXAMINATION
STANDARD 7
OCTOBER 1993
SCIENCE

(Time: 1 hour 30 minutes) (Marks: 70)

GENERAL INSTRUCTIONS

1. **Use only PENCIL on your answer card.**

2. When you have chosen the answer to a question, shade in the letter space **COMPLETELY** for that answer on the answer card.

Example: 

3. If you wish to change any answer you have chosen, use a rubber to rub out the mark **COMPLETELY** and then make a new mark. If you do not rub out completely the machine may mark the answer wrong.

4. Examples have been given to help you. Read them carefully before you start doing the questions.

SAMPLE QUESTIONS

I. Food should always be covered to keep away ________________.

A) smell
B) flies
C) people
D) rats

The correct answer is "B". You would shade in the space for B on your answer card.

II. Milk is a___________.

A) crystal
B) solid
C) liquid
D) gas

The correct answer is "C". You would shade in the space for C on your answer card.

1. On very cold winter mornings Thabang cannot get water from a well or a tap because the water has changed to __________.

A) snow
B) dew
C) frost
D) ice

2. You can make your wheelbarrow move easier by ___________ it.

A) oiling
B) carrying
C) watering
D) filling

3. Lineo's mother uses a cloth to hold a hot saucepan. The cloth is a __________ conductor of heat.

A) cold
B) bad
C) good
D) hot

4. The yellow dust that insects carry from plant to plant is called _________.

A) stamen
B) sepal
C) pollen
D) pistil

5. A flame needs _________ in order to keep burning.

A) oxygen
B) water vapour
C) nitrogen
D) carbon

6. The wearing away of soil by wind and water is called ______.

A) migration
B) conservation
C) convection
D) erosion

7. A/An _________ makes it easier to get a heavy barrel onto a table.

A) wedge
B) lever
C) inclined plane
D) pulley

8. Hot plates on stoves are made of metal because metal ______.

A) is a bad conductor of heat
B) is a good conductor of heat
C) will stay cool
D) will burn easily

9. Which animal sleeps in winter?

A) dog
B) rabbit
C) rat
D) snake

10. The chameleon takes the colour of the place where it lives in order to _______.

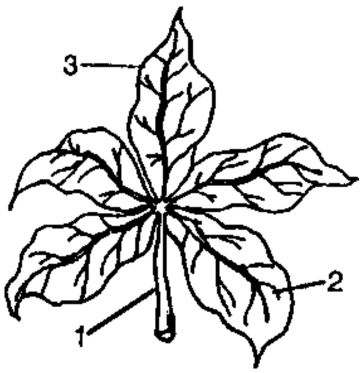
A) protect itself
B) smell its food
C) move quickly
D) see other animals properly

11. Air is a mixture of _________________________.

A) salts
B) water
C) gases
D) liquids

12. The part of the leaf marked 2 is called the _______________.

A) edge
B) vein
C) midrib
D) stalk



13. Sand cannot dissolve in water. It is said to be _________________ in water.

A) insolvent
B) inseparable
C) soluble
D) insoluble

14. A clinical thermometer is an instrument used for measuring ________________.

A) air pressure
B) body temperature
C) rainfall
D) the time of day

15. The path of electricity is called a ___________.

A) switch
B) cell
C) circuit
D) terminal

16. Which of the following is an electric appliance?

A) Torch
B) Rain gauge
C) Barometer
D) Thermometer

17. Light travels in ____________ lines.

A) dotted
B) straight
C) curved
D) broken

18. When a magnet is freely suspended it will always face __________.

A) East-South
B) South-East
C) West-North
D) North-South

19. Drops of water seen on leaves of plants in the morning are called _________.

A) rain
B) mist
C) dew
D) snow

20. Which sense does Mpho use to tell that there is some nicely cooked food?

A) smell
B) touch
C) hearing
D) sight

21. Which sense is used to tell that water is cold or hot?

A) Touch
B) Smell
C) Taste
D) Hearing

22. Where does the moon get its light from?

A) Earth
B) Itself
C) Sun
D) Star

23. What can be done to the plough wheels that make a lot of noise?

A) punch the wheels
B) wash the wheels
C) spray the wheels with water
D) oil the wheels

24. Which of the following substances dissolves in water?

A) sand
B) sugar
C) wheat-meal
D) maize meal

25. Which of the following will help in pollinating roses?

A) Bees
B) Birds

C) Sheep
D) Man

26. Which of these soils is good for smearing (ho lila) when mixed with cow dung?

A) Sand
B) Loam
C) Clay
D) Glavel

27. What do we call animals with backbone?

A) Reptiles
B) Invertebrates
C) Mammals
D) Vertebrates

28. Which one of the following animals is covered with scale?

A) Hen
B) Cow
C) Tortoise
D) Horse

29. How does a fish move? It _____.

A) climbs
B) swims
C) hops
D) runs

30. How does a scorpion respond when being touched?

A) raises its sting
B) runs away
C) fights
D) stays still

31. __________ soil has big particles.

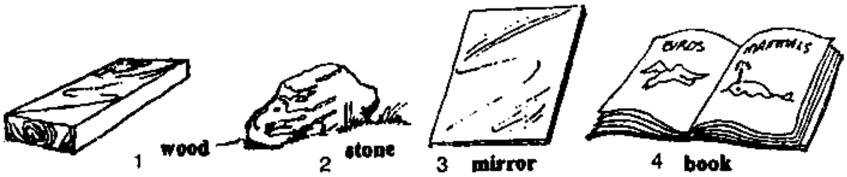
A) loam
B) clay
C) sand
D) alluvial

32. What will happen to a paper clip when put next to a magnet? It will be ___________ a magnet.

A) bend by
B) repelled from
C) stretched by
D) attracted to

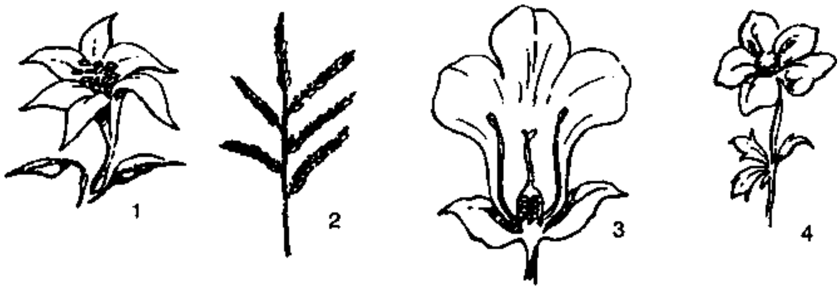
33. Which one of the diagrams below will reflect the rays of the sun when directed to it?

A) 1
B) 3
C) 2
D) 4



34. Which of the following flowers is a maize flower?

A) 3
B) 1
C) 2
D) 4

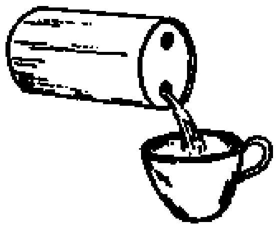


35. What kind of soil holds water for a long time?

A) gravel
B) sand
C) loam
D) clay

36. See the picture below. What will help the milk go out of the container?

A) Air pressure
B) Tea
C) Cup
D) Jar



37. Maize in the diagrams below was grown at the same time on different types of soil. On what type of soil was maize '1' grown?

A) gravel
B) clay
C) loam
D) sand

38. What happens to the wax when a candle burns? It _________.

A) expands
B) becomes black
C) becomes yellow
D) melts

39. Name an instrument used for measuring temperature.

A) Thermometer
B) Rain gauge
C) Syringe
D) Telescope

40. Which sense do we use to identify paraffin?

A) Taste
B) Smell
C) Sight
D) Touch

41. __________ disease attacks dairy cows.

A) Lice and mites
B) Boat
C) Mastitis
D) Bots

42. A good way to prevent wind erosion is to ___________.

A) plant trees
B) graze goats
C) build dams
D) make contours

43. Good top soil with plenty of ___________ produce the best plants.

A) sand
B) compost
C) air pockets
D) snow

44. We can prevent soil erosion on sloping ground by _________ the slope.

A) burning vegetation on
B) frequently grazing animals on
C) ploughing up and down
D) ploughing furrows across

45. in order to feed the soil after we have cultivated it, we can use ______________.

A) fertilisers
B) rocks
C) water
D) dust particles

46. _________ insect pest attacks cabbage.

A) Millipede

B) Blight
C) Aphis
D) Centipede

47. _______ is used for leveling the soil.

A) Digging fork
B) Rake
C) Spade
D) Hoe

48. Garden tools should be stored in a ________.

A) fenced place
B) shady place
C) cold place
D) dry place

49. _________ is a root crop.

A) Spinach
B) Cabbage
C) Potatoe
D) Egg plant

50. The milk turns sour because of ________.

A) mastitis
B) bacteria
C) black quarter
D) boat

51. We can keep our bodies fit and strong by

A) Exercising regularly
B) drinking a lot of water
C) eating a lot of fatty foods
D) keeping our bodies clean

52. If the temperature of your body is 37° C, you are probably _____________.

A) overheated
B) sick
C) fainting
D) healthy

53. Animals and man use the _________ stored in food to help them do work.

A) taste
B) energy
C) colour
D) weight

54. ________ contain some substances which are harmful to the health of an individual.

A) Coffee
B) Drinks
C) Sweets
D) Drugs

55. In order to kill germs, water should be _______ before drinking.

A) boiled
B) filtered
C) covered
D) served

56. The insect which carries disease germs to uncovered food is __________.

A) louse
B) bee
C) house fly
D) beetle

57. In order to avoid accidents at night, one should wear _________ clothes when walking near the road.

A) bright
B) warm
C) black
D) tight

58. The disease likely to be caused by smoking is called __________.

A) lyphoid
B) lung cancer
C) polio
D) cholera

59. One of the following diseases is a lung disease.

A) Kwashiorkor
B) Marasmus
C) Tuberculosis (TB)
D) Diarrhoea

60. Which of the following sentences about tight fitting clothes is true?

A) They help stale air around the body to escape.
B) It is healthier to wear them.
C) They are more confortable.
D) They prevent the flow of blood through the skin.

61. The embroidery below shows a __________ stitch

A) feather
B) blanket
C) decorative
D) chain

62. For cutting cloths we should use a ____________.

A) thimble
B) pair of scissors
C) tape measure
D) needle

63. Mother's milk is a perfect food for ________.

A) babies
B) grandmothers
C) grandfathers
D) girls

64. These are the good sources of energy.

A) peas, cabbage, carrots
B) apples, bananas, oranges
C) bread, samp, sugar
D) bread, apples, carrots

65. To protect our bodies from heat and cold, we have to wear _____.

A) clothes
B) sacks
C) leaves
D) shoes

66. The best water for washing clothes is ________ water.

A) hard
B) greasy
C) muddy
D) warm

67. Which animals kill rats and mice in the store rooms?

A) Dogs
B) Cats
C) Hens
D) Pigs

68. _________ are a good source of vitamin C.

A) Eggs
B) Cakes
C) Oranges
D) Onions

69. When frying an egg one should use __________.

A) vinegar
B) water
C) fat
D) sauce

70. Which article is best for cleaning classroom chalk board.

A) hand
B) broom
C) grass
D) duster

3.4. Malawi

3.4.1. Overview

End of Primary School Examination

1. Tide of examination:	Primary School Leaving Certificate Examination (PSLCE)
2. Amount of fees charged:	Nil
3. Examination after years in primary school (6, 7, 8 years):	8 yrs
4. Children's entry age in primary school:	6 yrs
5. Number of pupils sitting examination in 1994:	103,833
6. Examination subjects offered:	11 subjects in 8 papers: • English • Arithmetic • General Knowledge (Geography, History, Civics) • Chichewa • Agriculture • Science & Health Education • Home Science • Needle Craft The last three subjects are optional. Candidates are required to choose anyone. In practice boys opt for Science & Health Education, girls choose between Home Science and Needle Craft. Each candidate therefore covers 6 subjects which all must be passed to qualify for the PSLCE. **Note:** From 1995 on the former 11 examination subjects are offered in 7 papers: • English (Paper I Composition, Paper II Grammar, Structure, Comprehension) • Chichewa (Paper I Composition, Paper II Grammar, Comprehension) • Arithmetic • General Paper (History, Geography, Civics) • Science (incl. Agriculture and Health Education) • Home Economics • Needle Craft The papers in subjects 1-4 are compulsory. One additional optional paper out of 5-7 is further needed.
7. Language of examination:	English (except for the national/local language paper)

8. Institution setting the examination questions:	Malawi National Examinations Board (MANEB)
9. Have there been any reforms in the examination questions?	Yes
When? (year) **What kind?**	1991 and 1995 Deliberate introduction of items testing higher cognitive skills (1991). Introduction of Multiple-Choice Test Items (1995).
10. Stages of development of examination questions (please describe):	• Appointment of chief examiners or setters. • Drafting of examination papers. • Typing of drafted examination papers. • Moderation of examination papers by panels. • Typing and proofreading of final examination papers.
11. Type of examination questions and distribution of different kind of questions.	No multiple-choice questions but mostly structured and essays. Composition: 50% recall, 50% application and higher order. However, note the changes since 1995.
12. Is continuous assessment incorporated in the final examination?	Yes [ ] No [x]
13. Are examination items pretested?	Yes [ ] No [x]
14. Which professional groups are involved in setting the examination questions?	• Secondary school teachers • School inspectors • Tutors of TTCs • Curriculum developers
15. Are the same professionals who set the examination questions involved in marking papers?	Yes [x] but in the capacity of team leaders, the markers being primary school teachers. No [ ]
16. How are examination results used for improving teaching in primary schools?	Chief examiners' reports which analyse examination are issued to schools.
17. To what other uses are the examination results put?	For selection to secondary school.
18. Main problem with Primary School Leaving Examinations?	Very competitive, to the extent that they guide the curriculum and promote cheating especially in the schools. There is also the problem of repetition at standard 8.

3.4.2. Innovations in Primary School Leaving Certificate Examinations (PSLCE) in Malawi and Overview of the 1993 Results

by Jacob Mwanza, Malawi National Examinations Board

Introduction

A consultancy report in 1987 by H.C.A. Somerset had pointed out that PSLCE and Junior Certificate Examinations (JCE), and PSLCE in particular, tended to test simple factual recall at the expense of more important cognitive skills such as comprehension, application and reasoning. Recall type of questions were found to be predominant especially in Science, History, Geography, and Agriculture. Further, candidates are usually asked to recall a single isolated fact: a name, a date or a place. Questions which probe understanding of causes or reasons are much less common. The questions ask »who«, »when«, »what« or »where«, rather than »why« or »how« (Somerset 1987).

These findings were confirmed by a research study in 1988 carried out by the Malawi National Examinations Board (MANEB). This study also indicated that sampling of content tended to be unbalanced in some subjects of the PSLCE.

Somerset gives the following examples picked from past examination papers to illustrate his point:

1. Mention the <u>four</u> types of bollworm that attack cotton.

2. Name the branch of Agriculture that a farmer practises when he grows

a) Cabbages.
b) Bluegum or Eucalyptus.
c) Millet or Maize.
d) Hibiscus flowers.

(1986 Agriculture)

3. Name the type of ship that carries

a) oil.
b) people.

4. Name two ways by which people in USA earn their living.

5. Which two countries in Africa are leading producers of copper?

6. Mention the two types of coffee grown in Tanzania.

Partly in the light of these findings, a contract for a Test Development Specialist (TDS) was arranged by the Malawi National Examinations Board (MANEB) in conjunction with the Ministry of Education and Culture (MOEC). The contract was managed by the British Council and funded by the World Bank through the 5th Education Sector Credit for the period 10 March 1989 to 10 March 1991.

Among the TDS's terms of reference were the following:

Purpose: Improve the Malawi Examination Systems

Main Duties:

- be responsible for the development of examinations at the Primary School Leaving

Certificate Examination, Junior Certificate Examination and Malawi School Certificate of Education levels;

- be responsible for curriculum development and construction and developing essay and objective examinations. Besides he will be responsible for pre-testing the items in Secondary Schools, Primary Schools and Teachers' Colleges;

- organise and conduct item writing workshops;

- train examiners in both essay and objective tests;

- establish and construct the blueprint for use by the examiners in both essay and objective tests;

- help determine the skills to be tested in each subject area. That is, determine the percentage of each skill to be tested in each subject area.

Primary School Examinations

Malawi has an 8-4-4 education system, which implies that pupils spend at least eight years in primary school before they can go to secondary school, if at all.

PSLCE have undergone major improvements in Malawi. In 1989 a workshop for chief examiners and moderators was held. The workshop exposed participants to principles of examining and to ways of devising questions which test higher cognitive abilities.

In five subjects which had tested mainly recall - Agriculture, General Paper (Geography, History and Civics), Science and Health Education, Home Economics, and Needle Craft - complete papers were eventually produced by workshop participants and MANEB staff.

Prior to pre-testing the papers, sets of specimen papers were issued to schools in May 1990 with notice that changes in examination questions would be effected for the first time in July 1991. Another innovation was the conversion of all the papers to answer booklet form. This enables candidates to write their answers in spaces next to the questions on the paper. It has the advantage of being easier for candidates to handle and for examiners to mark, and of reducing the amount of loose paper which MANEB has to issue to schools.

In July 1990 the papers were pre-tested. A sampling framework was devised by finding the pass rate in the 1989 examinations for each of the 24 districts in the country and then choosing a school from each district of an appropriate size with a pass rate similar to that of its district. Each school was asked to enter candidates for two out of the three subjects Agriculture, General Paper, and Science/Health Education, according to an overlapping pair design. The subjects Home Economics and Needle Craft were also pretested in those of the sample schools which offered them as options. Arithmetic, Chichewa and English were not pre-tested as the style of questioning in the new papers differed little from that in use.

Candidates' Performance in Pre-Tests

Pre-test papers were marked by chief and senior examiners during July and August 1990. At the end of marking, the examiners were interviewed for their impressions of how the questions had behaved. In general, their impressions were favourable with none thinking that the papers were far too difficult for the candidates.

The subsequent statistical item analysis confirmed the examiners' impressions. Also the marks which the candidates were given on the pre-test papers compared favourably with those on the real PSLCE although all pre-test papers were found to be more difficult, but not by such a wide margin.

The new-format examination has been in operation since 1991 and what needs to be done is to follow it up and reinforce it, preferably by holding workshops for examiners to review the results of the first new examinations and for teachers to ensure that the aims of the reforms are understood.

Use of Multiple-Choice Items for PSLCE

MANEB has been encouraged by the World Bank to use multiple-choice items in some subjects of the PSLCE. With increasing numbers of candidates, this would speed up marking and increase the reliability of the examinations. Multiple-choice testing is not new to Malawi at the primary school level. It was in use until about 20 years ago, when it was abolished, probably because of its restrictive effect on the development of pupils' power of expression. Plans, however, are under way for the introduction of multiple-choice testing of the 1995 PSLCE. During the months of June and July 1992, MANEB pre-tested multiple-choice papers at a sample of schools throughout the country in Science and Health Education, Agriculture and General Paper.

The 1993 Primary School Leaving Certificate Examinations

In 1993 the total numbers of pupils in class 8 was 96,434 and of these 63,771 were boys and 32,663 were girls, or 66.13% boys and 33.87% girls which means education is more accessible to boys than to girls. The number of pupils who passed the examination was 60,418 which represents a percentage pass of 62.65. The number of boys who passed the examination was 42,341 (66.40%) and the number of girls was 18,077 (55.34%). The table below compares the performance of boys and girls within the 28 education districts in Malawi.

Table I: Performance of Boys and Girls within the 28 Education Districts in the 1993 PSLCE

District	Total Entry (Girls)	No. of Girls Passing	Total Entry (Boys)	No. of Boys Passing
Chitipa	1,164	716 (61.5%)	2,406	1,725 (71.70%)
Karonga	774	562 (72.61%)	1,793	1,317 (73.45%)
Nkhata Bay	938	592 (63.11%)	2,055	1,452 (70.66%)
Rumphi	1,210	733 (60.58%)	2,101	1,440 (68.54%)
Mzimba	3,332	1,760 (52.82%)	6,679	4,206 (62.97%)
Kasungu	1,107	796 (71.91%)	2,068	1,562 (75.53%)
Nkhotakota	626	391 (62.46%)	1,406	978 (69.56%)
Ntchisi	588	376 (63.95%)	946	672 (71.04%)
Dowa	990	608 (61.41%)	2,273	1,602 (70.48%)
Salima	577	394 (68.28%)	1,520	1,168 (76.84%)
Lilongwe	1,936	1,158 (59.81%)	3,954	2,828 (71.83%)
Mchinji	623	392 (62.92%)	1,309	1,002 (76.55%)
Dedza	838	374 (44.63%)	1,788	1,123 (62.81%)
Ntcheu	1,203	622 (51.70%)	2,277	1,430 (62.85%)
Mangochi	791	459 (58.03%)	2,011	1,415 (70.36%)
Machinga	1,047	517 (49.38%)	2,040	1,296 (63.53%)
Zomba	1,586	687 (43.32%)	3,366	2,087 (62.00%)
Chiradzulu	1,029	489 (47.52%)	1,784	1,084 (60.76%)
Blantyre	1,199	477 (39.78%)	2,279	1,206 (52.92%)
Thyolo	1,403	793 (56.52%)	2,770	2,770 (73.39%)
Mulanje	1,874	885 (47.23%)	3,643	2,332 (64.04%)
Chikwawa	561	275 (49.02%)	1,696	955 (56.31%)
Nsanje	407	301 (73.96%)	1,061	849 (80.02%)
Mwanza	409	261 (63.81%)	794	525 (66.12%)
Blantyre City	3,258	1,204 (36.96%)	4,765	2,406 (50.49%)
Lilongwe City	1,872	1,281 (68.43%)	3,019	2,183 (72.31%)
Mzuzu City	625	506 (80.96%)	879	706 (80.32%)
Zomba Urban	667	454 (68.07%)	1,039	716 (68.91%)

What is clearly discernible from the table I is that, except for Mzuzu City, girls' performance

(% pass) was lower in all districts than that of boys in the 1993 PSLCE. The underachievement of girls is scantly documented in Malawi although it is common knowledge that girls do not perform as well as boys. But the fact that girls achieved less than boys nationwide in this examination (perhaps the trend is the same in earlier years) should be cause of concern. What is strange too about these results is that the percentage pass of both girls and boys is lowest in the biggest City of Blantyre (39.96% girls and 50.49% boys). Research in Malawi on the secondary school leaving examinations indicates that urban schools do better than rural schools, especially in science subjects. One would have expected a similar result at the primary school level.

Malawi is divided into three administrative regions, the Northern region, Central region and the Southern region. Although the country is so divided for administrative reasons, there are marked differences between the regions. The Northern region, for example, has one dominant language which is different from the one largely spoken in the South and Centre; and the people's customs in the Centre and South are, generally, different. There are, of course, other differences within the regions e.g. prevalence of several dialects and customs, but generally differences are more marked between regions. Nationwide all schools take the same examination on similar days and times. Because of the influence of such factors as catchment area, test bias, etc. on achievement, it becomes important to study pupils' achievement in different localities and hence attempt to see whether pass rates in different regions of the country are the same or not and why, if different, especially where the examination is the same.

Some research at the school leaving level indicates differential student achievement between the regions in some subjects. Table II shows that the percentage of pupils who passed the 1993 PSLCE in the Southern region of both girls and boys is lower than that of the Centre and North.

Table II: % Pass by Region for Boys and Girls

Region	% Pass Girls	% Pass Boys
South	47.80	62.04
Centre	61.70	70.81
North	60.54	68.16

The percentage of girls passing the 1993 PSLCE is lower than that of boys in all the regions and is lowest in the Southern region. The differences in the pass rates of girls in the North and Centre were marginal and so were the differences in the pass rates for the boys in the same regions. The reasons for these anomalies/similarities can only be entangled through indepth research.

Table III: Examination Statistics (means, standard deviations, medians and modes)

Subject	$\overline{X}$	SD	Mode	Median Mark
Science and Health Education	56.76	20.17	70	59
Arithmetic	57.92	23.50	73	60
General Paper	59.43	20.01	74	62
Agriculture	61.41	19.00	75	63
English	61.12	19.04	70	63
Needle Craft	71.67	11.94	76	73
Housecraft	73.47	12.47	75	75
Chichewa	75.19	12.27	78	77

The statistics on table III indicate that Science and Health Education was most difficult in the 1993 PSLCE followed by Arithmetic and General Paper (note the low means, large SDs and low median marks). The easiest subject was Chichewa (the national language) then Housecraft followed by Needle Craft. English and Agriculture were of the same difficulty. Arithmetic had the largest standard deviation implying that the dispersion of scores was widest while Needle Craft had the lowest followed by Chichewa and Housecraft. Arranged in order of difficulty with the most difficult first, they rank as follows:

1. Science & Health Education
2. Arithmetic
3. General Paper
4. Agriculture
5. English
6. Needle Craft
7. Housecraft
8. Chichewa

Science subjects therefore, except Agriculture, were the most difficult (i.e. Science and Health Education - $\overline{X}$ = 56.76 and Arithmetic - $\overline{X}$ = 57.92). This is not a surprising result. Our schools have problems imparting scientific knowledge either because of poor tuition, student anxiety or some other unknown factors.

These discussions, however, should be treated with caution not only because they are based on aggregated data but also because pupil background factors as well as school factors have not been accounted for in the analyses.

Note: From 1995 on the PSLCE has been changed in format and method. With the exception of the language paper in Chichewa and English who are each split into two papers (Composition and Multiple-Choice answers) all other papers use multiple-choice questions only.

3.4.3. 1995 Primary School Leaving Certificate Examinations/Science Incorporated Paper

THE MALAWI NATIONAL EXAMINATIONS BOARD

1995 PRIMARY SCHOOL LEAVING CERTIFICATE EXAMINATION

SCIENCE INCORPORATED

Subject Number: P192

Tuesday, 18 July

Time Allowed: 1 ½ hours
1.30 - 3.00 pm

Name of Candidate:____

Name of School: ____

Examination Number: ____

INSTRUCTIONS

1. **This paper contains 12 pages. Please check.**

2. Answer **all** questions. Write your answers on the separate **answer sheet** provided.

3. There are 70 questions in this paper.

4. **IMPORTANT**

Please hand over your computer answer sheet to the Invigilator: **DO NOT FOLD THE COMPUTER ANSWER SHEET.**

Because of the recent changes we have included the 1995 examination paper, now called

SCIENCE INCORPORATED.

EXAMINATION NO.:____________

Section A (25 marks)

AGRICULTURE

1. To which branch of Agriculture does the growing of cauliflower belong?

   A. Floriculture
   B. Olericulture
   C. Aboriculture
   D. Silviculture

2. Which of the following practices can control rosette in groundnuts?

   (1) early planting
   (2) correct plant spacing
   (3) planting resistant varieties

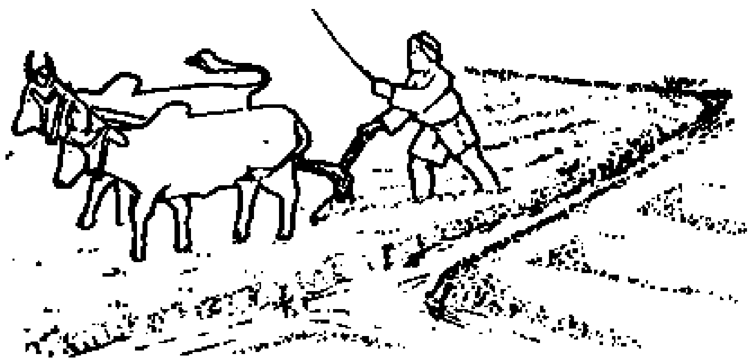
   A. (1) and (2) only
   B. (1) and (3) only
   C. (2) and (3) only
   D. (1), (2) and (3)

3. One advantage that indigenous cattle have over cattle introduced into this country from temperate countries is that indigenous cattle

   A. grow faster.
   B. are more tolerant to drought.
   C. have longer horns.
   D. produce more milk.

4. Which centre of early civilization used the source of power shown in **Figure 1** below?

   A. Egypt
   B. India
   C. Mesopotamia
   D. China



5. In an experiment, pupils applied 15 kg of UREA fertilizer to a one hectare plot of maize. In another hectare plot of maize they applied 15 kg of CAN fertilizer. In both plots all recommended production practices were followed. What might have been the objective of the experiment?

   A. to find out the type of fertilizer that gives the best yield
   B. to find out the amount of fertilizer that gives the best yield
   C. to find out if following recommended production practices improves yield
   D. to find out if application of fertilizer is necessary in maize growing

6. Why is it advisable to grow different types of crops on a farm?

A. to earn more money during marketing
B. to reduce the danger of total crop failure in times of low rainfall
C. to have enough to eat and surplus to sell to others
D. to be self reliant on crop production

7. Which of the following are advantages of crop rotation?

(1) It helps to maintain soil fertility.
(2) It helps to reduce labour.
(3) It helps to control diseases and pests.

A. (1) and (2) only
B. (2) and (3) only
C. (1) and (3) only
D. (1), (2) and (3)

8. Name the cheapest system of keeping chickens.

A. deep litter system
B. semi-intensive system
C. free range system
D. battery cage system

9.

STATEMENT		**REASON**
Pruning is one of the recommended practices in tree growing	**BECAUSE**	it protects trees from diseases and pests.

A. The statement is true but the reason is false.

B. The statement is false but the reason is a true fact.

C. Both the statement and reason are true and the reason is a correct explanation of the statement.

D. Both the statement and the reason are true but the reason is not a correct explanation of the statement.

10. A farmer bought 10 bags of fertilizer at K30 each, maize seed at K20 and paid K40 for labour. He harvested 20 bags of maize which he sold at K25 each. How much profit did he make?

A. K500
B. K220
C. K180
D. K140

11. **Figure 2** is a diagram of a cow.

Which of the following things can be made from the part of a cow labelled X?

A. brushes
B. buttons
C. shoes
D. bags

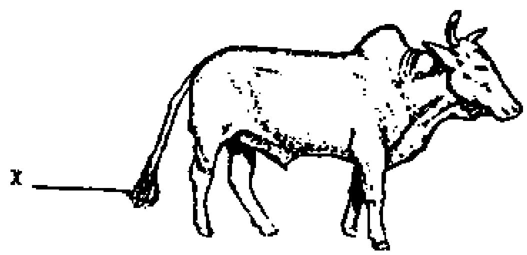


Figure 2

12. Which of the following practices can prevent egg-eating in a flock of layers kept in a deep litter system?

(1) allowing adequate ventilation in the room
(2) debeaking the layers
(3) providing more calcium in the feed

A. (1) and (2) only
B. (1) and (3) only
C. (2) and (3) only
D. (1), (2) and (3)

13. What should a fish farmer do if he observes black foul looking water in his fish pond?

A. He should stop feeding the fish.
B. He should harvest the fish.
C. He should apply fertilizer to the pond.
D. He should supply the fish with more food.

14. If Chitembana groundnut seed costs K4.20 per kilogram, and the seedrate for Chitembana groundnuts is 100 kg per hectare. What would be the cost of seed for 500 square metres? (1 hectare = 10,000 m^2).

A. K21
B. K210
C. K420
D. K2100

15. Which of the following fruits is **not** correctly matched with its method of propagation?

A. oranges	budding
B. pawpaw	seeds
C. apples	grafting
D. banana	layering

16. In animal husbandry the purpose of vaccinating animals is to

A. eradicate animal parasites.
B. control outbreak of diseases.
C. control internal parasites.
D. ensure high quality breeds.

17. Commercial farming is **best** described as the production of

A. hybrid crops and animals.
B. crops and animals to satisfy one's needs.
C. crops and animals for sale-
D. crops mainly for food and animals mainly for sale.

18. Which of the following is a list of storage pests only?

A. stalk borer, beetles, giant loopers
B. armyworm, locust, mealy bug
C. weevil, moth, rat
D. moth, aphids, mite

19. Name a natural resource which plants need to manufacture their food and is also a source of Vitamin D.

A. air
B. sunlight
C. water
D. soil

20. The **best** time to apply farmyard manure and compost manure in a maize garden i

A. when maize is about to tassel.
B. when maize is about knee high.
C. soon after germination.
D. before planting.

21. In an experiment pupils put some soil in a glass jar. They poured some water into the jar. The soil and water were shaken together. The mixture was allowed to settle. The diagram in **Figure** 3 below shows the components seen through the glass.

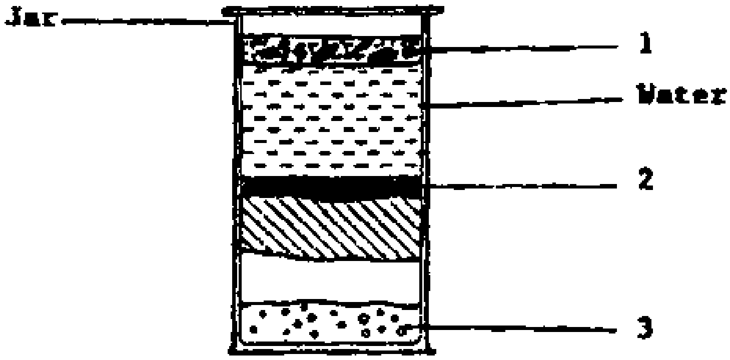

Figure 3

The numbered layers are likely to be

	1	2	3
A.	floating organic matter	sand	gravel
B.	gravel	floating organic matter	sand
C.	floating organic matter	clay	gravel
D.	silt	gravel	floating organic matter

22. Soil erosion may be prevented by

A. ridging across the slope.
B. practicing mixed farming.
C. early land preparation.
D. burning crops attacked by diseases.

23. Which of the following explains how early planting of maize gives high yields?

(1) The growing plants make full use of rainfall and plant food.

(2) The farmer has enough time to do other things apart from caring for maize.

(3) The plants escape some of the attacks by diseases and pests.

A. (1) and (2) only
B. (1) and (3) only
C. (2) and (3) only
D. (1), (2) and (3)

24. One of the methods of controlling foot and mouth disease of cattle is by

A. dipping the animals regularly.
B. vaccinating all the animals.
C. vaccinating the infected animals.
D. providing adequate spacing for the animals.

25. The diagrams in **Figure 4** below show some examples of vegetables.

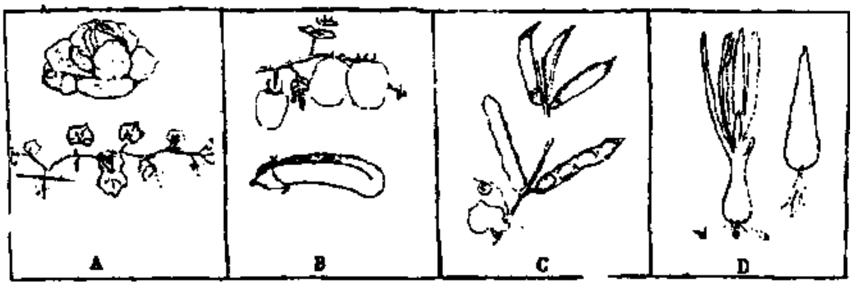

Figure 4

Which is a leguminous group?

Section B

SCIENCE (30 marks)

26. **Two** necessary conditions for a rainbow to form are

A. sunlight and humidity.
B. sunlight and raindrops.
C. clouds and sunlight.
D. raindrops and clouds.

Figure 5 is a **chart** showing recordings of wind direction. Use it to answer questions **27** and **28**.

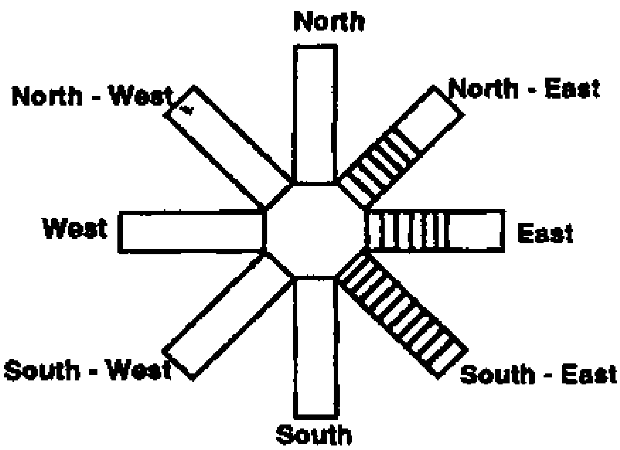

Figure 5

27. What is the name of this chart?

A. wind rose
B. wind vane
C. wind gauge (anemometer)
D. windsock

28. According to the chart, from which direction does the wind mostly come?

A. North-East
B. East
C. South-East
D. South

29. Which of the following liquids will conduct electricity?

(1) salt solution
(2) sugar solution
(3) soap solution

A. (1) and (2) only
B. (1) and (3) only)
C. (2) and (3) only
D. (1), (2) and (3

Study the **table** below and use it to answer questions **30** and **31**.

Planet	Distance from the Sun	Time for one trip round the sun
X	58 million kilometres	88 days
Venus	108 million kilometres	225 days
Earth	150 million kilometres	1 year
Jupiter	780 million kilometres	12 years
Uranus	2870 million kilometres	84 years
Neptune	4500 million kilometres	165 years

30. What is the name of the planet represented by letter X?

A. Mercury
B. Pluto
C. Saturn
D. Mars

31. There is another planet not shown in the table. It is 1430 million kilometres from the sun. About how long will it take this planet to make one trip round the sun?

A. 10 years
B. 30 years
C. 100 years
D. 250 years

32. The diagrams in **Figure 6** show simple electric circuits. When a bulb and battery are connected by wires as shown in **Figure 6a** the bulb lights.

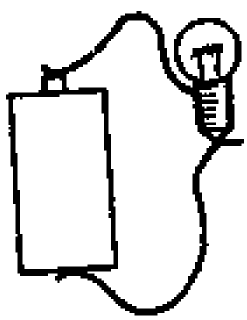

Figure 6a

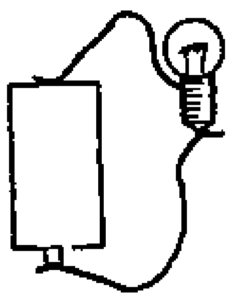

Figure 6b

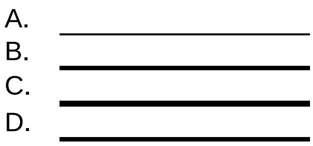
What would happen if the battery is reversed as in **Figure 6b**?

A. The bulb will be brighter than in **Figure 6a**.
B. The bulb will be less bright than in **Figure 6a**.
C. The bulb will light as bright as in **Figure 6a**.
D. The bulb will not light.

33. A guitar has strings arranged as shown below. The strings are equally tight.

Which string will produce the lowest sound when plucked?



34.

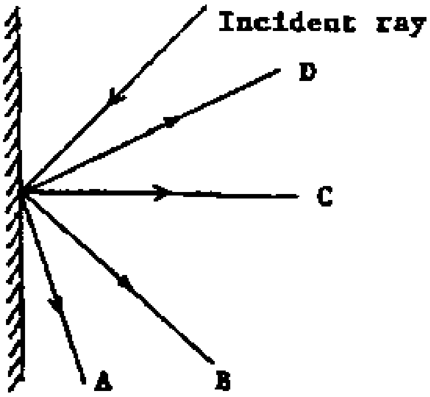


Figure 7

The diagram in **Figure 7** above shows an incident ray of light and four other rays labelled **A**, **B**, **C** and **D**. Which of the four rays is reflected from the incident ray?

35. Why are telephone wires tied loosely between telephone poles?

A. to allow the smooth passing of sound
B. to give room for the contraction and expansion of wire
C. to give room for vibrations inside the wire
D. to avoid wire breakage when a pole falls

The diagram in **Figure 8** shows how matter changes from one state to another due to heating or cooling. Use it to answer questions **36** and **37**.

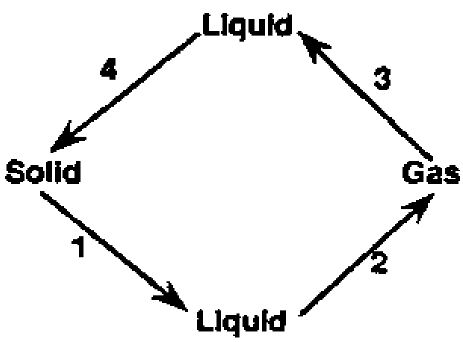

Figure 8

36. Which number represents the process of evaporation?

A. 1
B. 2
C. 3
D. 4

37. Which **two** numbers represent change of state resulting from cooling of the substance?

A. 1 and 2
B. 2 and 3
C. 3 and 4
D. 1 and 4

38. Where in a plant does most transpiration take place?

A. leaves
B. roots
C. stems
D. Flowers

39. The diagram in **Figure 9** below shows a balance with a 2 kg mass placed at 6 cm away from the balancing point.

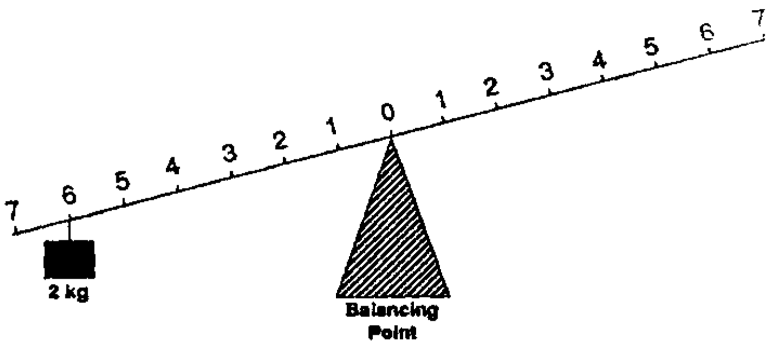

Figure 9

Where on the other side would you place a 4 kg mass in order to balance?

A. 2 cm away from the balancing point
B. 3 cm away from the balancing point
C. 4 cm away from the balancing point
D. 6 cm away from the balancing point

Study the diagram of a food web in **Figure 10** below and use it to answer questions **40** and **41**.

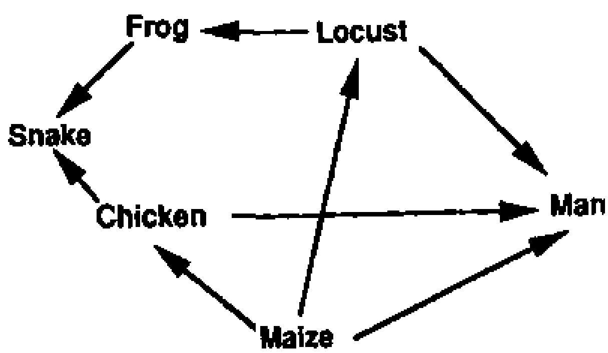

Figure 10

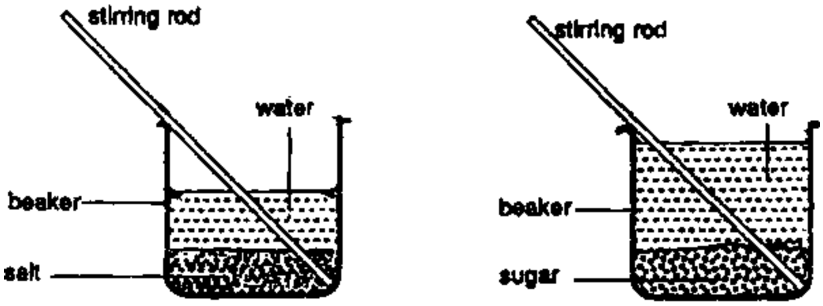
40. Name the producer.

A. maize
B. man
C. locust
D. Chicken

41. Which of the following food chains is correctly represented in the food web?

A. locust ⇒ maize ⇒ man ⇒ frog
B maize ⇒ chicken ⇒ locust ⇒ man
C. locust ⇒ chicken ⇒ snake ⇒ frog
D. maize ⇒ locust ⇒ frog ⇒ snake

42. Mary wanted to find out if sugar dissolves in water just as quickly as salt. She put two spoonfuls of sugar in a glass of water. She also put two spoonfuls of salt in another glass of water as shown in **Figure 11.** She stirred the two solutions slowly and timed how long it took the sugar and salt to disappear.



What should Mary have done to get accurate results?

A. She should have used equal volumes of water.
B. She should have used the same container.
C. She should have used hot water.
D. She should have stirred quickly.

43. In a simple cell, zinc and copper plates are called

A. positive poles.
B. negative poles.
C. electrolytes.
D. electrodes.

44. In **Figure 12** below are drawings of two measuring cylinders. **Cylinder 1** contains water as shown. When a stone is dropped in it the water level rises to a level as shown in **cylinder 2.** (1 ml = 1 cm^3)

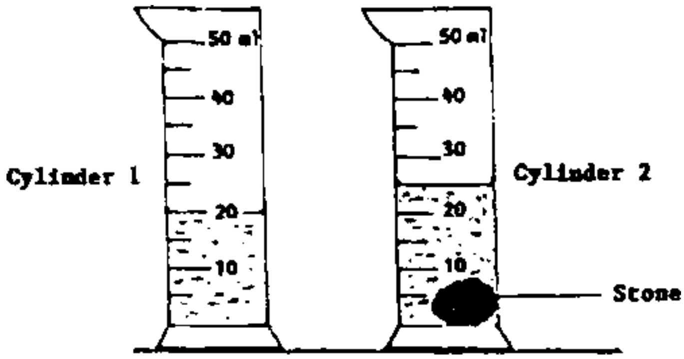


Figure 12

What is the volume of the stone?

A. 1 cm^3
B. 5 cm^3
C. 20 cm^3
D. 25 cm^3

45. The diagram in **Figure 13** below shows a column of water trapped in a glass tube.

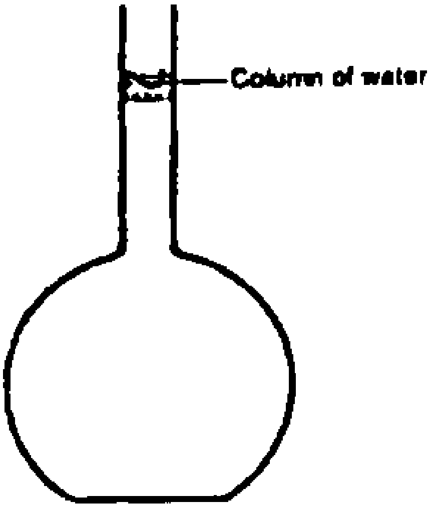

Figure 13

Why does the column of water rise on gentle heating?

A. Air inside the glass tube expands more than water.
B. Air can take the place of liquids when there is heat.
C. The heat pushes the column of water up.
D. Air expands when heated and pushes the water column up.

46. **Figure 14** shows four types of non-flowering plants labelled **A**, **B**, **C** and **D**.

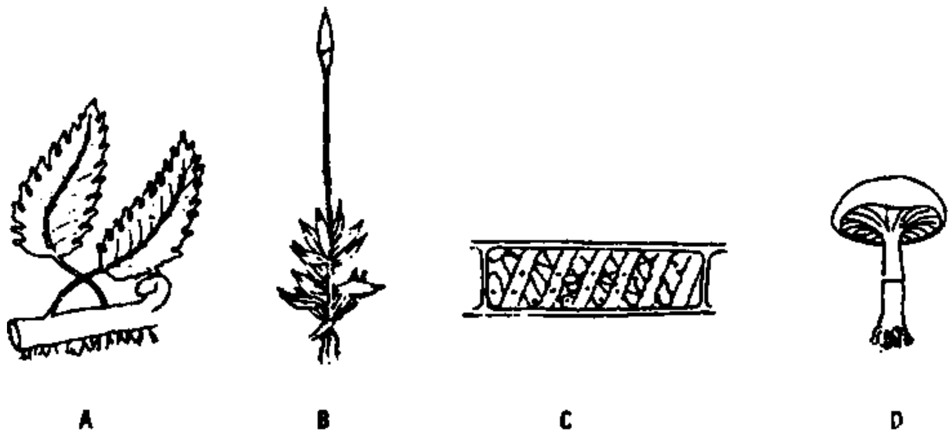

Figure 14

Which **one** does **not** manufacture its own food?

47. Substances which allow light to pass through are said to be

A. luminous.
B. spectrum.
C. transparent.
D. opaque.

Figure 15 is a diagram of a water cycle. Study it and answer questions **48** and **49.**

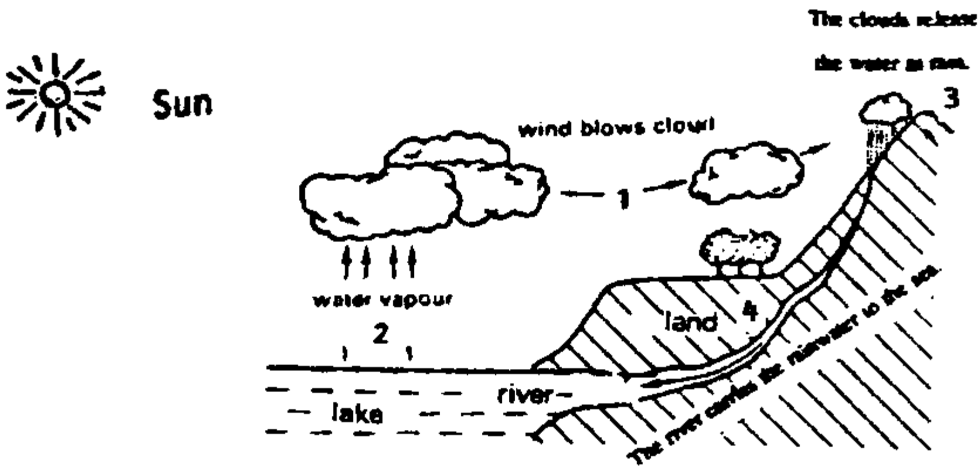

Figure 15

48. What is the importance of the sun in the cycle?

A. It is required in rainbow formation.
B. It provides heat which causes water to evaporate.
C. It is necessary in the formation of clouds.
D. It makes the water vapour to condense.

49. Which of the following is the correct order for the cyc

A. 1 ⇒ 2 ⇒ 3 ⇒ 4
B. 2 ⇒ 1 ⇒ 3 ⇒ 4
C. 4 ⇒ 1 ⇒ 2 ⇒ 3
D. 4 ⇒ 3 ⇒ 2 ⇒ 1

50. Which of the following is **not** a mammal?

A. whale
B. pigeon
C. bat
D. cow

51.

Figure 16

When the sun, the moon and the earth are in line as shown in **Figure 16** above, which of the following happens?

A. An eclipse of the sun happens.
B. An eclipse of the moon happens.
C. An eclipse of the earth happens.
D. A lunar-solar eclipse happens.

52. The rotten remains of dead animals and plants in the soil are called

A. loam
B. clay.
C. humus.
D. sand.

53. The diagrams in **Figure 17** below show two beakers filled with two different liquids, X and Y.

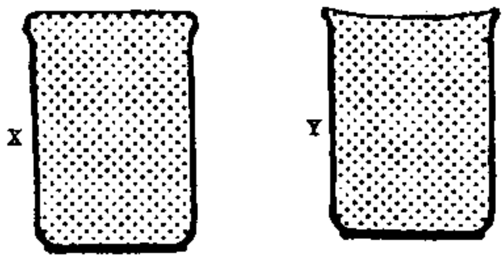

Figure 17

Which of the following statements about the two liquids are true?

(1) Particles of **X** hold each other more strongly than particles of **Y**.
(2) particles of **Y** hold each other more strongly than particles of **X**.
(3) **X** has a bigger drop size than **Y**.
(4) **Y** has a bigger drop size than **X**.

A. (1) and (2) only
B. (1) and (3) only
C. (1) and (4) only
D. (2) and (4) only

Figure 18 below shows the path of food through the body. Study it and use it to answer questions **54** and **55**.

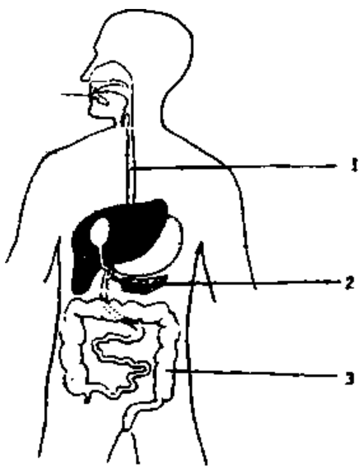

Figure 18

54. The parts labelled **1** and **3** are

	1	3
A.	gullet	stomach
B.	gullet	large intestines
C.	small intestines	large intestines
D.	email intestines	stomach

55. Name a fluid produced in the part labelled 2.

A. pancreatic juice
B. bile
C. saliva
D. gastric juice

Section C (15 marks)

HEALTH EDUCATION

56. Which of the following diseases can be caused by careless disposal of human excreta?

A. malaria
B. common cold
C. dysentery
D. Marasmus

57. The first aid to be given to a person bitten by a dog is to

A. tie with a cloth just above the bitten part.
B. wash the bitten part with soap and water.
C. cover up the wound with a dressing.
D. take the patient to the hospital.

58. **Figure 19** is a bar chart showing the relationship between smoking habits and the number of lung cancer patients. Use it to answer questions **58** and **59**.

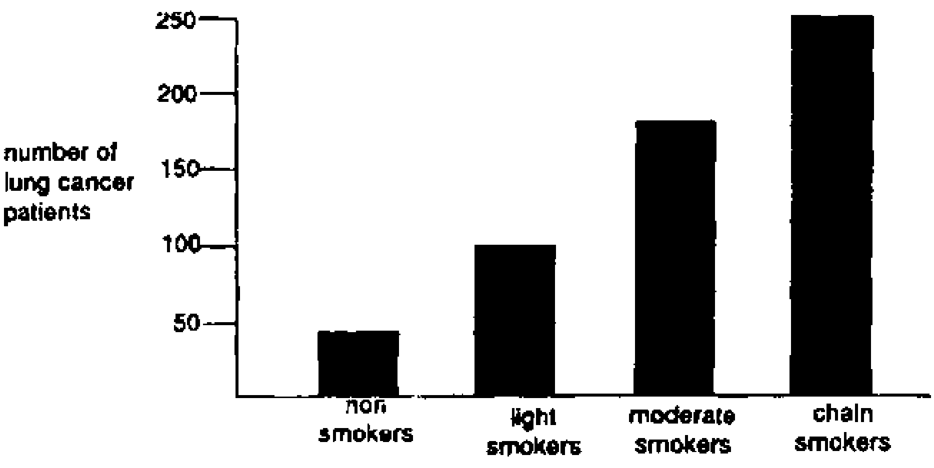

Figure 19

Which group has the lowest danger of suffering from lung cancer?

A. chain smokers
B. moderate smokers
C. light smokers
D. non-smokers

59. Which of the following statements is true?

A. Only smokers can suffer from lung cancer.
B. Smoking increases the danger of suffering from lung cancer.
C. Both smokers and non-smokers have equal chance of suffering from lung cancer.
D. Non-smokers can never suffer from lung cancer.

60. At the water works why is alum added to water?

A. to filter the water
B. to stick together pieces of mud
C. to kill germs
D. to dissolve unwanted particles

61. One of the advantages of the under-five clinic is that it allows

A. babies to eat balanced meals.
B. expectant mothers to learn baby care.
C. babies to be vaccinated against childhood diseases.
D. mothers to discuss baby care.

62. How is the malarial parasite transmitted to a new host?

A. through body contact
B. through breathing
C. through eating poorly cooked food
D. through mosquito bite

63. Which of the following tissues join bones to muscles?

A. cartilage
B. fat
C. ligament
D. tendon

64. The part of the ear that carries messages from the ear to the brain is the

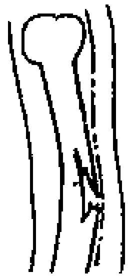
A. eardrum.
B. eustacian tube.
C. auditory nerve.
D. optic nerve.

65. **One** of the causes of anaemia is the deficiency of

A. mineral iron.
B. mineral calcium.
C. vitamin C.
D. vitamin D.

66. What kind of fracture is shown in **Figure 20** below?

Figure 20



A. complicated fracture
B. simple fracture
C. compound fracture
D. greenstick fracture

67. The immunity that one gets after antibodies have been injected into the body is called

A. inborn immunity.
B. acquired active immunity.
C. acquired passive immunity.
D. natural immunity.

68. Which of the following happens when we do **not** do exercises?

A. We become lonely.
B. We get tired easily.
C. We become weak.
D. Our bones become soft.

69. At lunch Chifundo ate **nsima,** cabbage, an orange and cassava. The meal was not a balanced diet because it did not contain

A. proteins..
B. vitamins.
C. carbohydrates.
D. mineral salts.

70. Study the diagram in **Figure 21** below and answer the question that follows.

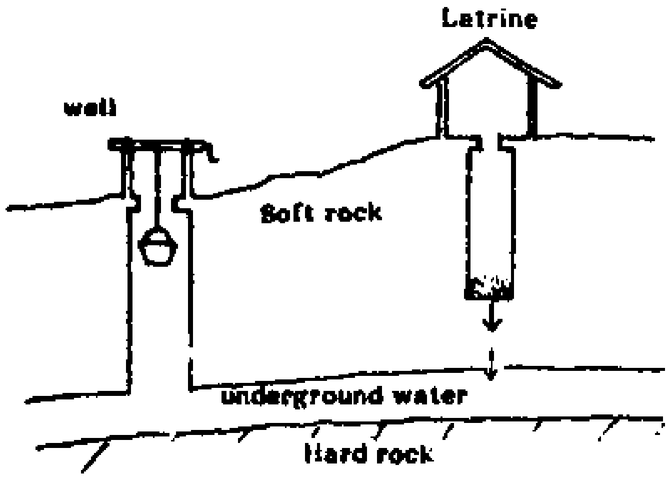


Figure 21

What is wrong with this set-up?

A. The well can be contaminated.
B. The latrine can fall into the well.
C. The wind can blow bad smell from the latrine to the well.
D. The latrine can be used by too many people coming to draw water.

END OF QUESTION PAPER

3.4.4. 1994 Primary School Leaving Certificate Examinations/Science and Health Incorporated Paper

THE MALAWI NATIONAL EXAMINATIONS BOARD

1994 PRIMARY SCHOOL LEAVING CERTIFICATE EXAMINATION

SCIENCE AND HEALTH EDUCATION

(100 marks)

Subject Number: P191

Wednesday, 13 July

Time Allowed: 2 hours
1.30 - 3.30 pm

Instructions:

1. **This paper contains 16 pages. Please check.**

2. Write the name of the **District** where you are writing the examination, **Centre Number** and your **Examination Number** on every sheet in the spaces provided.

3. Answer **all** questions. Write your answers in the spaces provided.

4. If you find any question too difficult, leave it and return to it later if you have time.

5. If you have any questions about these instructions, ask them now. You may not ask questions once the examination has begun.

DISTRICT	**CENTRE NO.**	**EXAMINATION NO.**
________________	________________	________________

1994 **P191**

SCIENCE

1. a. What do we call water when it is in solid form?

____ **(1 mark)**

b. Figure 1 is a diagram showing a saucer and a cup containing equal volumes of water.

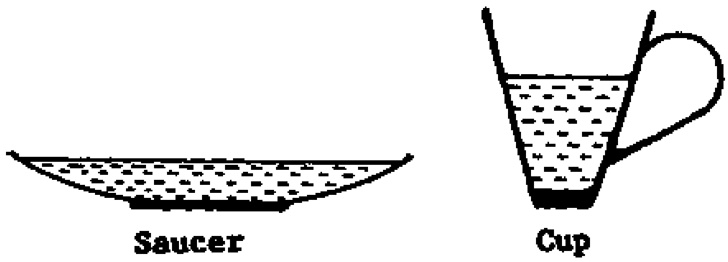

Figure 1

Suggest a reason why the water will evaporate faster from the saucer than from the cup.

____ **(1 mark)**

2. Figure 2 is a diagram showing the result of mixing paraffin, water and cooking oil (covo) labelled **A**, **B** and **C** but not necessarily in that order.

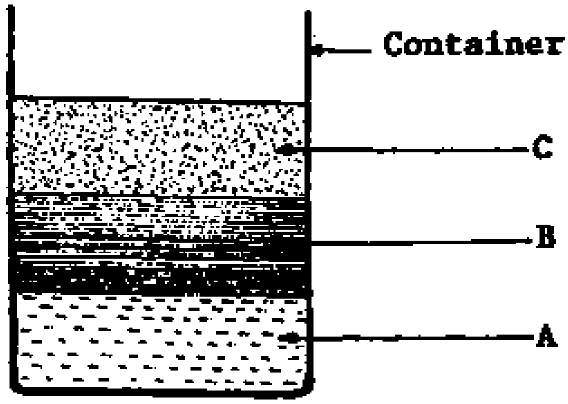

Figure 2

a. Which of these, **A**, **B** or **C** is paraffin?

____ **(1 mark)**

b. Give a reason for your answer to 2a.

____
____ **(1 mark)**

3. If an axe with a wooden handle is left lying in the sun for some hours, the axe feels hot while the handle feels warm.

Suggest a reason for this difference.

____
____ **(1 mark)**

4. a. (i) Mention **one** type of mosquito.

____ **(1 mark)**

(ii) What disease is transmitted by the type of mosquito you have mentioned in 4a (i)?

____ **(1 mark)**

b. Give any **two** ways in which the number of mosquitoes in a given area can be reduced.

____
____
____
____ **(2 marks)**

c. What does an ant lion eat?

____ **(1 mark)**

5. **Figure 3** is a diagram showing an empty plastic bottle **A** and the same bottle **B** when it is squeezed.

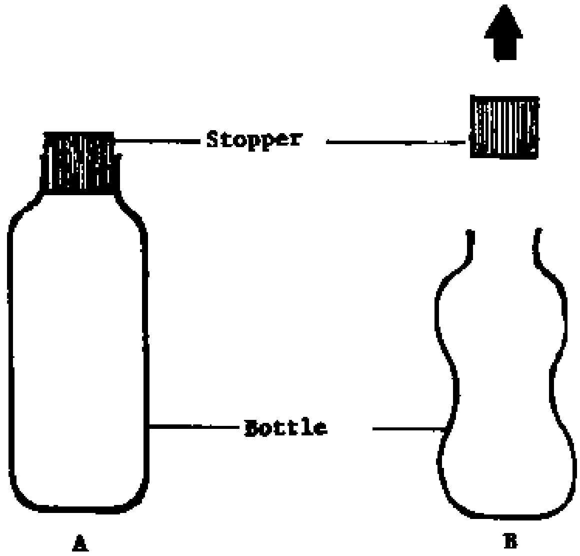

Figure 3

Why does the stopper in bottle B go out?

____
____ **(2 marks)**

6. a. State **two** conditions that are necessary for the multiplication of bacteria.

____ **(2 marks)**

b. In what **two** ways are bacteria important to man?

____
____
____
____ **(2 marks)**

7. a. What is the centre of the solar system?

____
____ **(1 mark)**

b. Name the type of movement the earth makes which results into day and night.

____ **(1 mark)**

c. Explain why the new moon is not visible.

____ **(1 mark)**

d. Give **one reason** why life is impossible on the moon.

____
____ **(1 mark)**

8. **Figure 4** is a diagram showing an Irish potato tuber that is beginning to grow:

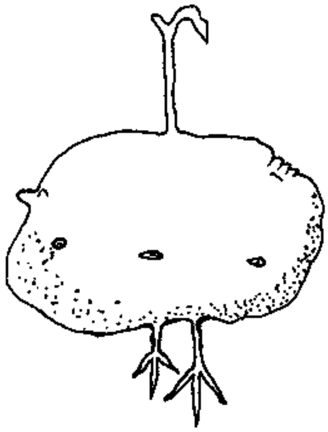

Figure 4

a. Name **two** features which show that the tuber is a stem.

____
____ **(2 marks)**

b. What is the function of this type of stem?

____ **(1 mark)**

9. a. Name the **two** parts which make up a stamen of a flower.

____
____ **(2 marks)**

b. Maize is usually cross pollinated.

(i) What is cross pollination?

____
____ **(1 mark)**

(ii) How are the chances of self pollination reduced in a maize plant?

____
____ **(1 mark)**

10. a. What feature makes the toes of the hind legs of a frog similar to those of a duck?

____ **(1 mark)**

b. What is the function of the feature you have mentioned in 10a?

____ **(1 mark)**

11. The image of an object on the film in a pin-hole camera is upside down. What property of light does this show?

____ **(1 mark)**

12. a. State **two** ways in which sounds differ.

____

____ **(2 marks)**

b. **Figure 5** is a diagram of one of the musical instruments played in Malawi.

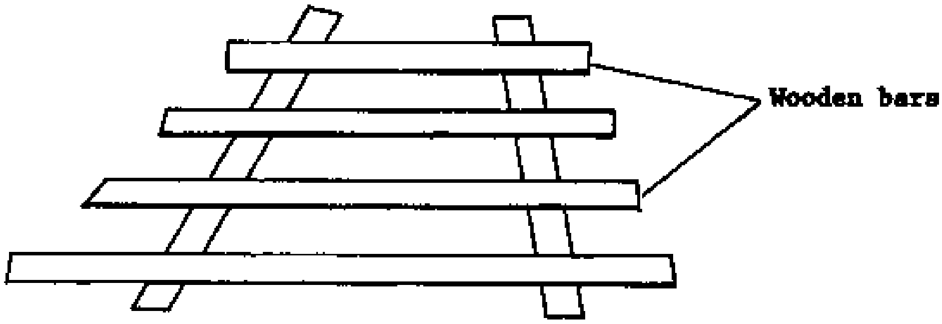

Figure 5

(i) What is the name of the instrument?

____ **(1 mark)**

(ii) How is this instrument played?

____ **(1 mark)**

13. a. Explain why mineral salts are easily washed away in sandy soil.

____

____ **(1 mark)**

b. Mention **one** way in which earthworms are useful in the soil.

____ **(1 mark)**

14. The **table** below shows readings on a wet and dry bulb thermometer taken from Monday to Friday.

	Mon	**Tue**	**Wed**	**Thur**	**Frid**
Dry Bulb	30°C	27°C	28°C	30°C	30.5°C
Wet Bulb	25°C	26°C	27.5°C	24.5°C	24°C

a. On which day was humidity lowest?

____ **(1 mark)**

b. (i) On which day did it likely rain?

____ **(1 mark)**

(ii) Give a reason for your answer to 14b (i).

____ **(1 mark)**

15. Figure 6 is a diagram showing how living things depend on each other for food.

Figure 6

a. Complete the diagram by filling in the blank box. (1 mark)

b. What would happen to:

(i) the grasshoppers if all the frogs disappeared?

____ **(1 mark)**

(ii) the organism you have mentioned in 15a if all the frogs disappeared?

____ **(1 mark)**

c. Give a reason for your answer to 15b (ii).

____
____ **(2 marks)**

16. a. Mention **two** plants which can be grown using a stem.

____
____ **(2 marks)**

b. How does water from the ground get to all parts of the plant?

____
____ **(2 marks)**

17. **Figure 7** is a diagram showing a balancing beam.

4 bottle-tops of the same weight were placed on **side A**
3 cm away from the centre.

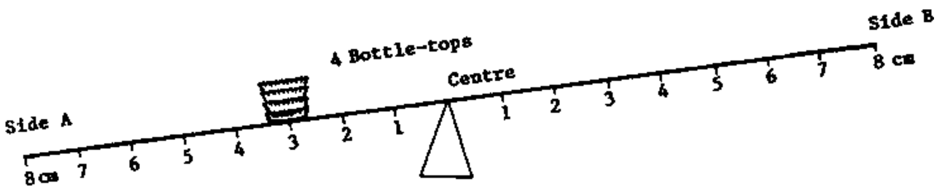

Figure 7

On **side B**, where would you put 2 bottle-tops of the same weight as those on **side A** in order to balance the beam? Show your work.

____
____
____
____
____ **(3 marks)**

18. A pupil is given the materials shown in **figure 8** below.

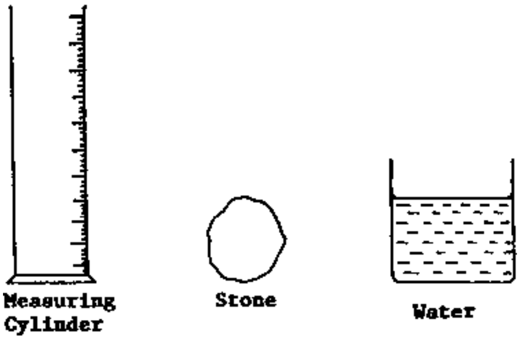

Figure 8

Explain how the pupil would use the measuring cylinder and the water to measure the volume of the stone.

____ **(3 marks)**

19. **Figure 9** is a diagram showing beaks of two different birds.

Figure 9

a. Suggest the type of food each one of them feeds on.

(i) **A** feeds on _______________________________________ **(1 mark)**

(ii) **B** feeds on _______________________________________ **(1 mark)**

b. Give reasons for your answer to 19a (i) and (ii).

(i) **A** ____
____ **(1 mark)**

(ii) B ____
____ **(1 mark)**

20. **Figure 10** is a diagram showing a ray of light striking a glass containing water.

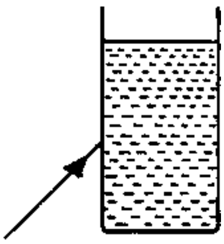

Figure 10

Complete the diagram to show how the ray passes through the water and comes out on the other side of the glass. **(2 marks)**

HEALTH EDUCATION

21. a. What do you call a place where two or more bones meet?

____ **(1 mark)**

b. Mention **one** common injury that can occur where two or more bones meet.

____ **(1 mark)**

c. State **one** sign of the injury you have mentioned in 21b.

____ **(1 mark)**

22. a. Study the following list of food items:

cassava, fish, beans, pineapples, rice and mangoes.

Choose any **three** food items from the above list which make a balanced meal.

____ **(2 marks)**

b. How does each of the **three** food items you have chosen in 22a help to make a balanced meal?

(i) ____

(ii) ____

(iii) ____ **(3 marks)**

23. a. A patient with diarrhoea should be given plenty of water to which some substances are added.

Mention the **two** substances.

(i) ____

(ii) ____ **(2 marks)**

b. Give **one** reason why a patient with diarrhoea should be given such a drink.

____
____ **(1 mark)**

24. State why it is necessary to

a. prevent things from entering our eyes.

____
____ **(1 mark)**

b. have our eyes checked by an eye specialist regularly.

____
____ **(1 mark)**

25. **Figure 11** is a diagram showing a road sign.

Figure 11

a. What is the meaning of this road sign?

____ **(1 mark)**

b. **Figure 12** is a diagram showing two roads crossing.

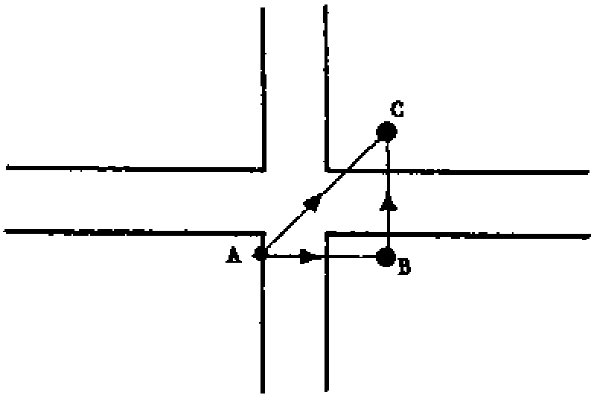

Figure 12

(i) You want to go to **C** from **A** on a busy day. Which path is safer, **A** to **C** direct, or **A** to **B** and then to **C**?

____ **(1 mark)**

(ii) Give a reason for your choice.

____
____ **(1 mark)**

26. a. State **two** reasons why it is more important to breathe through the nose than through the mouth.

____ **(2 marks)**

b. (i) Write **one** possible cause of nose bleeding.

____ **(1 mark)**

(ii) What first aid would you give to a patient with nose bleeding?

____
____
____
____ **(2 marks)**

27. a. What is immunisation?

(1 mark)

b. Mention **one** way in which immunisation is done.

(1 mark)

c. State **one** disease that can be prevented by immunisation.

(1 mark)

28. Figure 13 is a flow diagram which can be used by a family to make river water safe for drinking.

RIVER WATER → FILTERED → X → STORED IN A CONTAINER

Figure 13

a. Why is the water filtered?

(1 mark)

b. Why is the water still not safe for drinking after being filtered?

(1 mark)

c. (i) What process is carried out at **X**?

(1 mark)

(ii) Explain why the process carried out at **X** is important.

(1 mark)

d. How is the water protected from contamination when stored in the container?

(1 mark)

29. a. Give **two** differences in behaviour between a person who is drunk and one who is not drunk.

Drunk	**Not Drunk**
(i)	
(ii)	

(2 marks)

b. Give **two** reasons why it is important to avoid smoking indian hemp (chamba).

(i)

(ii) **(2 marks)**

30. a. State **two** ways in which a person can get infected by rabies.

(i) ____

(ii) ____ **(2 marks)**

b. Give **two** ways in which dogs can be protected from diseases.

(i) ____

(ii) ____ **(2 marks)**

31. a. Name any **one** organisation which deals with Public Health in Malawi.

____ **(1 mark)**

b. Mention **two** parts of the human body where bilharzia parasites feed and lay their eggs.

(i) ____

(ii) ____ **(2 marks)**

END OF QUESTION PAPER

3.4.5. 1994 Primary School Leaving Certificate Examinations/Agriculture Incorporated Paper

THE MALAWI NATIONAL EXAMINATIONS BOARD

1994 PRIMARY SCHOOL LEAVING CERTIFICATE EXAMINATION

AGRICULTURE

Subject Number: P012

Tuesday, 12 July (100 marks) **Time Allowed: 2 hours**
1.30 - 3.30 pm

Instructions:

1. **This paper contains 15 pages. Please check.**

2. Write your **District Name**, **Centre Number**, and **Examination Number** In the spaces at the **top of every page.**

3. Answer **all** questions in the spaces provided.

4. The marks for each question are indicated in the brackets.

5. If you find any question too difficult, leave it and return to it later.

6. If time allows, check your answers.

7. If you have any questions about these instructions, ask them now. You may not ask questions once the examination has begun.

Answer **all** questions

(Each question carries 4 marks)

1. The diagram below shows a fruit crop.

a. Name the fruit crop.

____ **(1 mark)**

b. Name the planting material for the crop shown in the diagram.

____ **(1 mark)**

c. Give any **two** varieties of the fruit crop.

(i) ____ **(1 mark)**

(ii) ____ **(1 mark)**

2. a. How do cattle get infected by liverfluke?

____ **(1 mark)**

b. What effect does liverfluke have on cattle?

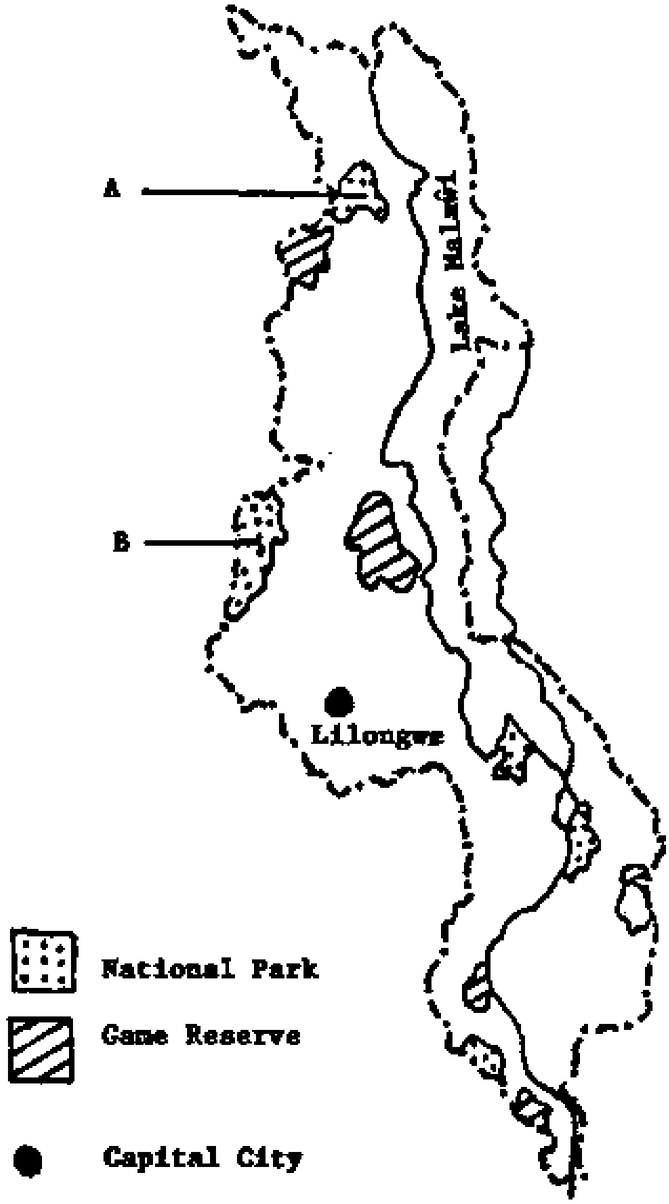
____ **(1 mark)**

c State any **two** methods of controlling liverfluke.

(i) ____
____ **(1 mark)**

(ii) ____
____ **(1 mark)**

The map below shows the national parks and game reserves of Malawi.



a. Name the National Parks labelled **A** and **B.**

A ____ **(1 mark)**

B ____ **(1 mark)**

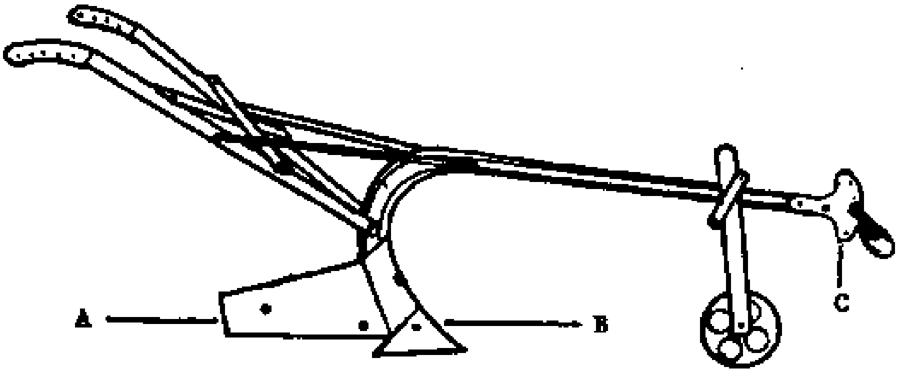
b. Name any **one** animal which is commonly found in **B.**

____ **(1 mark)**

c. State any **one** method of conserving wild life in a National Park.

____ **(1 mark)**

4. The diagram below shows a farm implement.



a. Name the farm implement.

____ **(1 mark)**

b. Identify the parts labelled **A** and **B.**

A ____ **(1 mark)**

B ____ **(1 mark)**

c. What is the function of the part labelled **C**?

____ **(1 mark)**

5. a. Name any **two** varieties of oranges grown in Malawi.

(i) ____ **(1 mark)**

(ii) ____ **(1 mark)**

b. Name the most serious disease of oranges.

____ **(1 mark)**

c. How can the named disease be controlled?

____ **(1 mark)**

7. The diagram below shows a method of harvesting maize.

a. Name the method.

____ **(1 mark)**

b. State **two** advantages of this method of harvesting maize,

(i) ____
____ **(1 mark)**

(ii) ____
____ **(1 mark)**

c. State **one** disadvantage of this method of harvesting maize.

____
____ **(1 mark)**

a. Name **one** tool that is recommended for transplanting vegetable seedlings.

____ **(1 mark)**

b. What is the recommended spacing for large headed cabbage varieties?

____ **(1 mark)**

c. State **two** ways of controlling aphids in cabbage.

(i) ____ **(1 mark)**

(ii) ____ **(1 mark)**

8. a. State any **two** reasons why farmers keep farm records.

(i) ____ **(1 mark)**

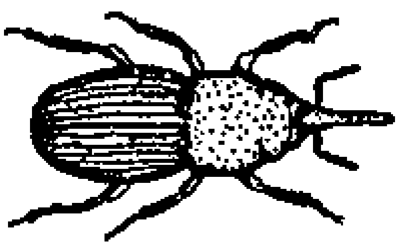
(ii) ____ **(1 mark)**

b. Explain the **two** main types of farm records.

(i) ____ **(1 mark)**

(ii) ____ **(1 mark)**

9. The diagram below shows a crop pest.



a. Identify the pest.

____ **(1 mark)**

b. Name the crop attacked by the pest.

____ **(1 mark)**

c. State the damage caused by the pest.

____
____ **(1 mark)**

d. How can the pest be controlled?

____
____ **(1 mark)**

10. a. What are natural resources?

____
____ **(1 mark)**

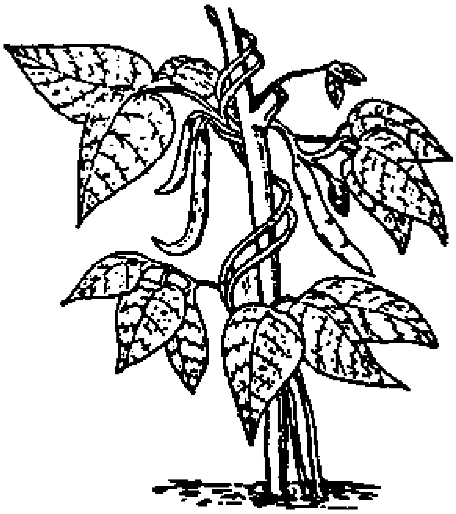
b. How can the following natural resources be conserved?

(i) Soil ____ **(1 mark)**

(ii) Vegetable ____ **(1 mark)**

(iii) Water ______________________________________ **(1 mark)**

11. The diagram below shows a vegetable crop.



a. Name the crop.

____ **(1 mark)**

b. To which group of vegetables does it belong?

____ **(1 mark)**

c. Give a reason why the crop does not require Nitrogen fertilizer.

____ **(1 mark)**

d. How would you control aphid attack in the named crop?

____ **(1 mark)**

12. The table below shows characteristics of soil.

Soil Characteristics	**Soil A**	**Soil B**	**Soil C**
Texture	Very fine	Course	Fine to course
Aeration	Poor	Good	Moderately good
Water holding	Very high	Low	Medium
Nutrient holding capacity	Very high	Low	Medium

a. Identify soils **A** and **B.**

(i) **A** ____ **(1 mark)**

(ii) **B** ____ **(1 mark)**

b. Which of the **three** soils **A**, **B** and **C** is most suitable for the growing of maize?

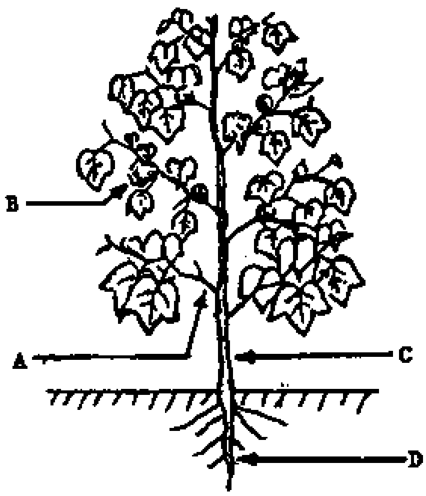
____ **(1 mark)**

c. How would you improve the water holding capacity of soil **B**?

____

____ **(1 mark)**

13. The diagram below shows parts of a cotton plant.



a. Name the parts labelled **A** and **B.**

A ____ **(1 mark)**

B ____ **(1 mark)**

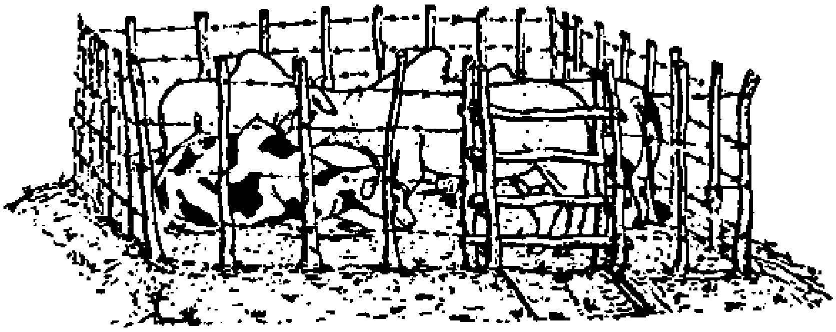
b. What is the function of the part labelled **C**?

____ **(1 mark)**

c. Identify the type of root system labelled **D**.

____ **(1 mark)**

14. The diagram below shows a type of cattle khola.



a. Name the type of khola.

____ **(1 mark)**

b. Give any **two** disadvantages of such type of khola.

(i) ____
____ **(1 mark)**

(ii) ____
____ **(1 mark)**

c. State **one** way of improving this type of khola.

____ **(1 mark)**

15. a. Define the term experiment.

____ **(1 mark)**

b. Give **one** reason why field experiments are important in agriculture.

____
____ **(1 mark)**

c. What is fertilizer trial?

____
____
____
____ **(2 mark)**

6. Explain how the following environmental factors influence agriculture production:

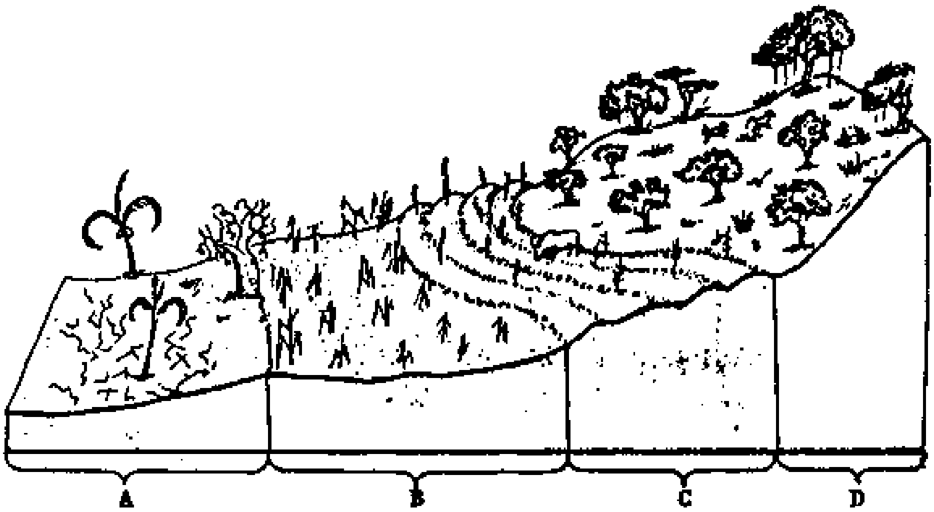
a. Rainfall

____
____
____
____ **(2 marks)**

b. Temperature

____
____
____
____ **(2 marks)**

17. The diagram below illustrates groups of class of land.



a. Name the groups of classes labelled **A** and **C**.

A ____ **(1 mark)**

C ____ **(1 mark)**

b. State the most suitable use for each of the groups of classes of land labelled **B** and **D**.

(i) **B** ____ **(1 mark)**

(ii) **D**____ **(1 mark)**

18. Name **one** tool or implement used in each of the following centres of civilization:

a. China

____ **(1 mark)**

b. Egypt

____ **(1 mark)**

c. India

____ **(1 mark)**

d. Mesopotamia

____ **(1 mark)**

19. a. Mention **two** types of fish suitable for pond breeding.

(i) ____ **(1 mark)**

(ii) ____ **(1 mark)**

b. Give **one** reason why manure is applied to fish ponds.

____ **(1 mark)**

c. Give **one** reason why farmers are encouraged to grow fish in ponds.

____ **(1 mark)**

20. a. Name any **two** types of goats based on function.

(i) ____ **(1 mark)**

(ii) ____ **(1 mark)**

b. Explain any **one** principle of goat management.

____
____
____
____ **(2 marks)**

21. The diagrams below show some common tools on farms in Malawi.

A

B

a. Name the tools labelled **A** and **B.**

A ____ **(1 mark)**

B ____ **(1 mark)**

b. Give **one** use of each tool.

A ____ **(1 mark)**

B ____ **(1 nark)**

22. State **two** advantages and **two** disadvantages of deep litter system of keeping poultry.

a. advantages:

(i) ____
____ **(1 mark)**

(ii) ____
____ **(1 mark)**

b. disadvantages:

(i) ____
____ **(1 mark)**

(ii) ____
____ **(1 mark)**

23. A farmer sows Malimba groundnuts at one seed per hole, 10 cm apart in a single row on ridges which are 90 cm apart.

a. Calculate the plant population per hectare. Show your working.

____
____
____
____
____
____
____
____ **(2 marks)**

b. State **two** ways in which high plant population reduces yield.

(i) ____
____ **(1 mark)**

(ii) ____
____ **(1 mark)**

24. State any **four** reasons for the rapid agricultural development in Malawi after independence.

a. ____
____

b. ____
____

c. ____
____

d. ____
____ **(4 marks)**

25. A farmer has 1.5 hectares of land on which to plant hybrid maize. The recommended seed rate is 25 kg per hectare.

a. How much seed should he buy? Show your working.

____
____
____
____
____
____
____
____ **(2 marks)**

b. How much fertilizer should he buy if the recommended rate is 100 kg of urea per hectare? Show your working.

____
____
____
____
____
____
____
____ **(2 marks)**

END OF QUESTION PAPER

Note: This paper contains 15 papers

3.5. Namibia

3.5.1. Overview

End of School Examination

1. Title of examination:	Junior Secondary Certificate (JSC)
2. Amount of fees charged:	≈ US$6
3. Examination after years in school (6, 7, 8 years):	10 yrs
4. Children's entry age in primary school:	6 yrs
5. Number of pupils sitting examination in 1994:	15,000 - 20,000
6. Examination subjects offered:	9
7. Language of examination:	English
8. Institution setting the examination questions:	Examinations Directorate
9. Have there been any reforms in the examination questions?	Yes
When? (year)	1992
What kind?	Increase the number of multiple-choice items. Change from only recall to other domains as well. Make more use of diagrams. Include more continued assessment and start making use of projects.
10. Stages of development of examination questions(please describe):	• Make sure all people know the syllabus. • Invite people to the item-writing workshop (to be nominated by the regional offices). • Put up a specification grid. • Divide in groups. Groups work on various topics. Every member of the group writes items (15-20 each) according to the specification grid. • Workshop co-ordinated by curriculum expert or examination expert. • Groups exchange items, moderate, improve or reject. • Items stored in bank. • Examination expert/curriculum expert finalizing examination paper.
11. Type of examination questions and distribution of different kind of questions	30% multiple-choice 5% closed type 5% matching 60% structured

12. Is continuous assessment incorporated in the final examination?	Yes [x] No [ ]
If yes, to what extent?	It varies from 33%-50%.
13. Are examination items pretested?	Yes [ ] No [x] 4 pilot schools will write a full Junior Secondary Certificate examination used for pre-testing purposes.
14. Which professional groups are involved in setting the examination questions?	• Secondary school teachers • School inspectors (subject advisors) • Examination and curriculum experts
15. Are the same professionals who set the examination questions involved in marking papers?	Yes [x] No [ ] They are involved in item-writing and marking, however, not responsible for final examination papers' design.
16. How are examination results used for improving teaching?	Every year an examinators' report and moderators' report is sent to schools after examinations, giving hints and recommendations on how to improve answering items and teaching.
17. To what other uses are the examination results put?	• Junior Secondary Certificate • Entering into IGCSE (International General Certificate of Secondary Education) (selection) • Monitoring education, teachers' performance, curriculum.
18. Main problem with School Leaving Examinations?	• Lack of experts in multiple-choice item-writing. • Lack of experts in continued assessment. • Lack of resources.

Note: The introduction of an end of primary school examination is planned for 1999. The following statements concern the existing Junior Secondary Certificate only.

3.5.2. Curriculum Development and Examinations in Namibia

by Jacobus A. Myburgh, Directorate of Curriculum Research and Development, and Cavin M. Nyambe, Directorate of Examinations

Curriculum Development since Independence

Namibia gained its independence in March 1990 after 105 years under foreign rule, thereby becoming the last country in Africa to be de-colonialized. Namibia is a vast, sparsely populated country on the South Atlantic coast. It is bordered by Botswana and Zimbabwe in the East, South Africa in the South and Angola and Zambia in the North. The capital is Windhoek. Namibia occupies an area of 82,4296 sqkm and is mainly arid or semi-arid, with the Namib Desert, the oldest in the world, extending along the entire coastline. In the North Eastern Caprivi Region the annual rainfall is, however, approximately 600 mm per annum. We have a population of 1.5 million with a population density of 1.5 persons per square kilometre. There are eleven ethnic groups. A variety of 18 different languages and dialects are spoken. The official language is English.

450,000 pupils enrolled in Namibia's schools for 1992. The distribution in the different school phases are as follows.

Grade	1 - 3 (junior primary)	204,350
	4 - 7 (senior primary)	156,825
	8 - 10 (junior secondary)	75,013
	11 - 12 (senior secondary)	13,269

Following independence it was decided by the Ministry of Education and Culture to embark upon a major reform process. Reform was initiated in junior secondary education. Local and international experts were given the task of redrafting the curricula for grades 8-10. The change-over to the new curriculum coincided with the change-over to English as the medium of instruction.

Learners in the Junior Secondary School (grades 8, 9 and 10) are now following the Namibian Junior Secondary Curriculum. The first national, external examination for grade 10 took place in 1993. There are, however, a number of project schools testing the new curriculum and allowing us to gain experience so as to enable us to make the necessary changes, if any, to the curriculum.

The Senior Secondary School introduced the internationally recognized IGCSE curriculum in 1994. The reform of primary school education has also been initiated and the new Broad Curriculum has been finalized. Curriculum panels have developed new syllabi for all the subjects.

Changes in Examinations

Examinations can be looked at in two ways as they can be internal which is school-based and external which is done at national level. The examinations are controlled by the Directorate of Examinations in Namibia.

(1) Primary School Leaving Examination (Grade 1-7)

Before independence, Namibia was divided into eleven ethnic groups, thus each group or region had full control over its internal examination. Question setting, marking and writing of progress reports was school-based. Promotion schedules which show all marks recorded for the year were approved by the regional inspectors. In some regions semi-external papers were set by different examiners in the region for grade 7.

Namibia does not offer any external examination after the primary phase. The mode of examination undertaken is school-based assessment, which is mainly under the control of the Regional Directors, Head-teachers and Subject Teachers. The examination is used for promotion and selection to the next grade or class. It is the responsibility of each school to draw up its own examination question papers and all other related materials. It is difficult to establish a national standard as the examination is not done at national level. The Ministry is preparing to introduce a school leaving certificate after Grade 7 in the near future. Experts from the Curriculum division and Examination division are engaged in the drafting of syllabi for Grade 5, 6 and 7.

(2) Junior Secondary School Leaving Examination

There is more emphasis put in this section. After the first two years (Grades 8 and 9) an internal examination is done by the school. At the end of the last part of the year (Grade 10) an external examination at national level is written by all schools registered. The Directorate of National Examinations and Assessment is responsible for control and administration. The New Broad Curriculum was implemented in 1991 on which a new national examination was written in November 1993. Examiners and markers are appointed at national level. Marking is centrally done, therefore it is easier to work out all the statistical information needed. It is a subject examination where a learner is graded on positive achievement. A certificate is awarded for every subject graded. The grade symbols are as follows: A, B, C, D, E, F, G, and UN (ungraded).

Learners are to do the following six compulsory subjects:

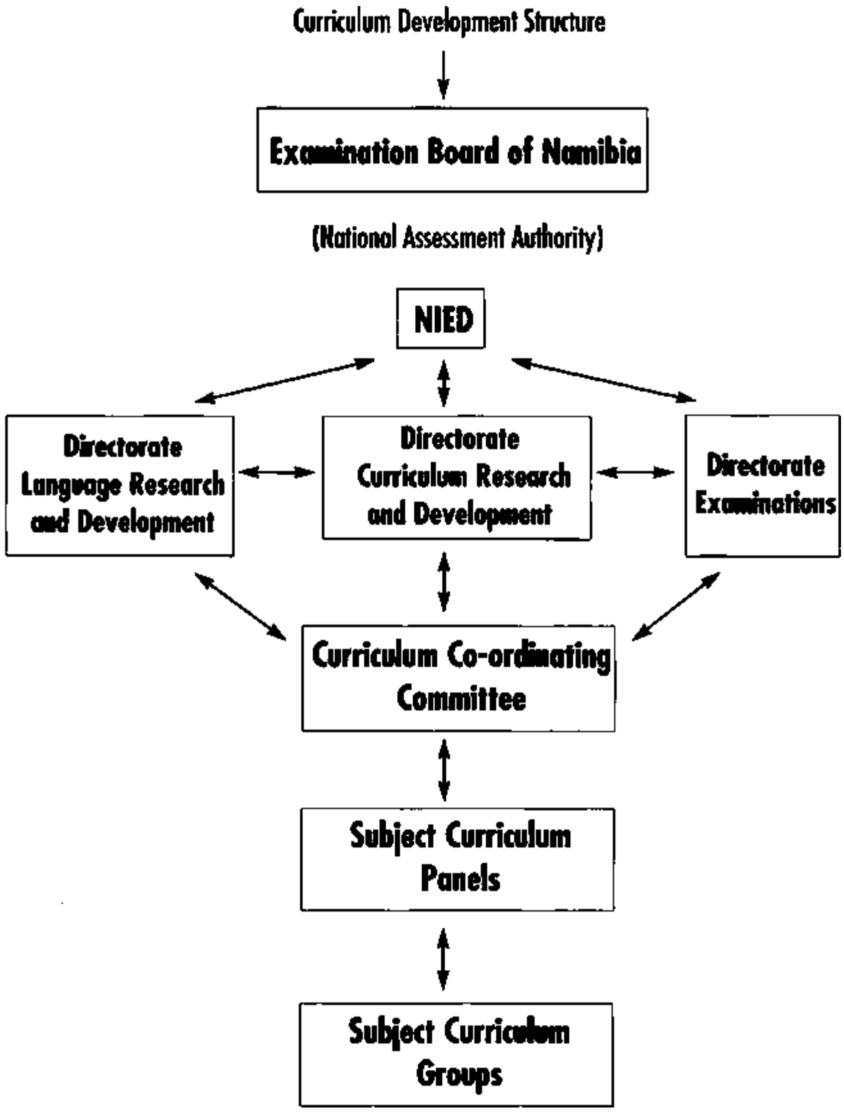
- English
- Mathematics
- Physical Science
- Life Science
- Geography
- History

There are options from the following subjects:

- Accounting
- Business Management
- Agricultural Production & Farming Technology
- Technical Subjects
- Music
- School Art, and many others.

A points system is used for the best six subjects as an entrance to IGCSE or HIGCSE.

Learners are expected to complete the Junior Secondary School between the age of 15-16 years.



NIED = National Institute for Educational Development

3.5.3. Agricultural Production and Farming Technology: Scheme of Assessment. Terminal Examination 1992

Paper 1

Section A: (45 minutes) 20 Multiple questions. (1 mark each); 5 close type (fill in the missing word, 1 mark each); matching type (5 marks)

Total: 30 marks

Section B: (1 hour 30 minutes) compulsory short-answer and structured question with subdivisions weighted as follows:

1.	General Agriculture (section 1)	15 marks
2.	Crop Husbandry (section 2)	25 marks
3.	Animal Husbandry (section 3)	20 marks
4.	Farming Technology (section 4)	10 marks
	Total	70 marks

This will carry 50% while the continuous Assessment will also carry 50%. The final mark will be 100%.

Sample question from the Grade 10 Specimen paper for 1992 exams. (From the Draft)

Section A. Choose

1. What process involves loosening the soil before planting in order to obtain a deep, loose soil?

a. harrowing
b. levelling
* c. ploughing
d. ridging

2. What is the function of the epididymis?

a. To make sperm
b. To produce sperm
* c. To store sperm
d. To transport sperm

Fill in the missing words

3. (a) The water which is available to plants is known as.........?

(b)................is the production of crops and the rearing of livestock.

4. Choose from column B the correct word or phrase which suits the word in column A. Write the correct letter in the box provided.

Column A		Column B
1. mealie meal	☐	A. Enzyme

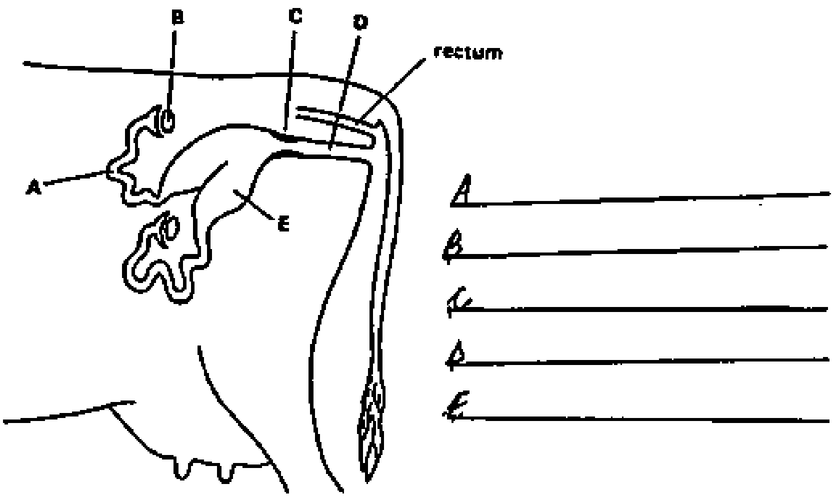
2. Groundnut cake	[ ]	B. Ovary
3. hand-hoe	[ ]	C. Testes
4. Spermatogenesis	[ ]	D. Carbohydrate-rich
5. Amylase	[ ]	E. Farm tool
	[ ]	F. Protein rich Concentrate
	[ ]	G. Roughage

<u>Section B</u>

1. State the function of the following parts of the ruminants digestive system.

   a. Teeth...............
   b. Rumen...............
   c. Small intestine......

The diagram shows the reproductive system of a ruminant. Label the parts labelled A, B, C, D and F.



3.6. South Africa

3.6.1. Independent Examinations Board.[1] Report on Standard 7 Pilot Programme. 1993 Examinations Programme

by D.R. Pitt

[1] **Note:** In South Africa the Independent Examinations Board, a NON-Governmental Organization, offers an end of primary school examination. Preparations and trials were conducted in 1992/93. Since 1994 Std. VII leavers of primary school can sit this examination. The draft syllabus and examination papers (General Science) from 1993 and 1995 are included.

Examining Panels

In 1993 the IEB Standard 7 Pilot Examinations Programme was expanded to include I examinations in Combined Science, History and Geography, and examinations in English First and Second Language and Mathematics. In English and Mathematics continuity was maintained, members of the panel in most cases being previous examiners. The new examinations were set by examining panels, the members being nominated by the user groups and the final selection made by the IEB. Apart from three members of the Mathematics panel of four, all examiners were drawn from teachers in IEB schools.

Participants

Approximately 5,000 candidates from 77 schools were entered for the 1993 examinations. The subject breakdown was as follows:

English First Language:	3,500
English Second Language:	1,550
Mathematics:	4,500
Combined Science:	3,893
History:	3,219
Geography:	3,026

The participating schools were affiliated to different education authorities, and came from these areas:

Eastern and Western Cape
Transkei
Natal and Kwa-Zulu
Leboa, Gazankulu and Venda
Northern Transvaal
Bophuthatswana
The Vaal Triangle
Orange Free State

The school entries varied in number from 6 to 199, and were diverse in composition, some being single sex and others co-educational.

Comment

1993 marks the end of the Pilot Project begun in May 1990. Most of the objectives then set out have been achieved. They were:

a. to gain expertise in the organization of a national examination and to build a cumulative record in English of the first IEB matriculation group of 1993;

b. to involve schools in all parts of South Africa affiliated to varying education autorities;

c. to involve teachers in every stage of the examining process;

d. to explore the viability of testing a wide range of pupils in one examination.

One of the most significant developments of the project has been the establishment and expansion of the user groups, and the teachers involved have found the contacts across the academic and geographical spectrum immensely exciting and valuable.

3.6.2. Independent Examinations Board. Standard 7 Examinations 1993 - Combined Science

by Rose Smuts

The enormous differences in syllabus content which exist from school to school severely limited the points of reference of the 1993 Combined Science examination.

The skills which were considered by the initial examinations committee as relevant to 14 year olds are not adequately learnt in many schools, viz. construction of graphs, experimental method etc. Therefore a description of content and skills to be examined was circulated to all participating schools in July for their information.

Examination Format of the final 1993 Combined Science Examination

This was successful in the following respects:

a. most candidates appeared to have sufficient time to complete the examination;

b. most candidates were able to answer some questions on the paper;

c. many teachers commented favourable on a **new approach** - »a breath of fresh air«; this was on the skills orientation of questions and the examination presentation;

e. the marks achieved by all candidates were realistic, taking into account the limitations.

This examination was unsuccessful in the following respects:

• the »academically advantaged« candidates from well established schools who wrote the examination in their home language found the paper too easy - some silly errors were still made by these candidates, but some of their marks were unrealistically high;

• the factual content was limited and candidates were able to score well without having to put in a realistic effort.

Comments on the Examination

Section A

1. Many candidates do not know how to answer a series of multiple-choice questions.

2. The diagrams, graphs and some tables of data, needed clearer presentation.

3. Many people have unrealistic expectations of 14 year old Std 7 pupils; pages must not be too crowded as this leads to confusion; the language used must be simple and clear; giving of instructions and provision of data or text, must be at a level which is accessible to all.

4. Terms (such as hypothesis) need clarification; perhaps the syllabus should specify the use of some special terms (in this example »Aim« is preferable).

5. Certain skills considered by some teachers to be fundamental are lacking in many candidates. The IEB needs to set up communications and assistance in these areas:

- understanding text which includes some terminology
- graphs - their construction and interpretation
- science methodology - simple experimental procedure
- understanding and application of units of measurement
- models and their application for teaching the »abstract«
- biological sectional views

6. The »New Syllabus for 1994«, available early in 1994, will identify skills which can be used in order effectively to »teach« certain areas of the syllabus; the Exemplar Booklet, available in February 1994 will have further examples of lesson plans, ideas for teaching, notes on how to get into graphs - their construction, application and interpretation, some examination questions, flow charts etc.

Section B

1. The open ended, creative-type questions were poorly answered; they were either misinterpreted or the answers given were too non-specific. Their wording needs clarification.

2. The graphs were disastrous; they were either left out altogether, or incorrectly drawn - the application of bar graphs as opposed to line graphs, needs further elaboration. Identification of the dependent and independent variable was confused.

3. Experimental design was poorly executed; clear concise descriptions of method need encouragement; identification of variables also needs elaboration.

4. Calculations of a simple nature (% calculation) were poorly handled. There is no realization of cross-curriculum application of knowledge in some candidates.

5. The examination questions need to be relevant to everyday examples or situations.

6. Difficulties with language/text appear to be the root cause of many problems.

7. Pupils are unfamiliar with some »basic« materials e.g. cottonwool etc.

3.6.3. Draft Syllabus for General (Combined) Science[1] 1994

Independent Examinations Board

[1] Implementation date: 1994. This document is of an interim nature, subject to revision. It will form part of a larger syllabus covering the whole of the junior secondary phase.

1. Introduction

The Independent Examination Board syllabus for General (or Combined) Science for the General Education Certificate is, at this stage, an interim syllabus designed for the examination of students (age 14 - plus: Standard Seven level) from the end of 1994.

Both the syllabus itself and the use of the name »General Science« are based on the current core syllabus. However, the IEB believes that a very different approach to the teaching of the subject will be encouraged by the setting of examination questions which focus on the aims and objectives outlined below.

The content of this syllabus has thus been reorganised in what is believed to be a more integrated and more meaningful way. The order of presenting the syllabus content is in no way finite and can be re-arranged by any inventive teacher, in order to suit his/her particular vision. An integrated approach is however strongly recommended as integrated questions will be used in the IEB examination.

The main sections of this syllabus are as follows:

- Aims
- General Objectives
- Specific Curriculum Objectives
- Assessment Specifications

2. Aims/Educational Purpose of the Course

The aims are the same for ALL students independent of background and/or future career prospects in the sciences. They are not listed in any order of priority. The course is based on the assumption that the examination will take place at the end of the compulsory phase of schooling, and that successful candidates will have demonstrated a good basic education in science serving as a foundation both for further learning and for life in general.

The aims are to enable students to acquire:

2.1 Some basic SCIENTIFIC KNOWLEDGE which will enable them to understand their world better, communicate better and/or pursue studies in science or science dependent courses, beyond the Std. 7 level.

2.2 Certain manual and thinking skills which are useful in solving scientific and/or everyday problems.

2.3 An awareness of what science is all about and of its importance in everyday life.

2.4 Certain useful attitudes about themselves, their safety, the processes of science and their environment.

3. General Objectives

These relate to the four main aims listed above.

3.1 Knowledge

At the end of the course students should be able to demonstrate KNOWLEDGE AND UNDERSTANDING of:

- some basic scientific concepts and their application to familiar and new situations;
- some facts and concepts concerning the environment;
- the use of appropriate (although basic) instruments for scientific experiments;
- simple scientific vocabulary and its usage.

Note: The Curriculum Objectives define the factual material that students need to recall and explain. Questions testing these objectives will often begin with one of the following words: define, state, describe, explain or outline.

3.2 Manual and Thinking Skills

A. HANDLING INFORMATION AND SOLVING PROBLEMS

Students should be able, in words or using other written forms of presentation (ie. symbolic, graphical & numerical) to:

1. locate, select, organise and present information from a variety of sources;

2. transpose information from one form to another;

3. manipulate simple numerical and other data;

4. use information to identify patterns, report trends and draw simple conclusions;

5. present reasoned explanations of phenomena, patterns and relationships;

6. make simple predictions and propose hypotheses, giving supporting evidence;

7. solve problems, including some of a quantitative nature.

B. EXPERIMENTAL SKILLS AND INVESTIGATIONS

Students should be able to:

1. use techniques, apparatus and materials (including the following of a sequence of instructions where appropriate);

2. make and record observations and measurements;

3. interpret and evaluate experimental observations and data;

4. plan and carry out simple investigations, evaluate methods and suggest possible improvements (including the selection of techniques, apparatus and materials).

3.3 Attitudes

Students should have acquired attitudes of:

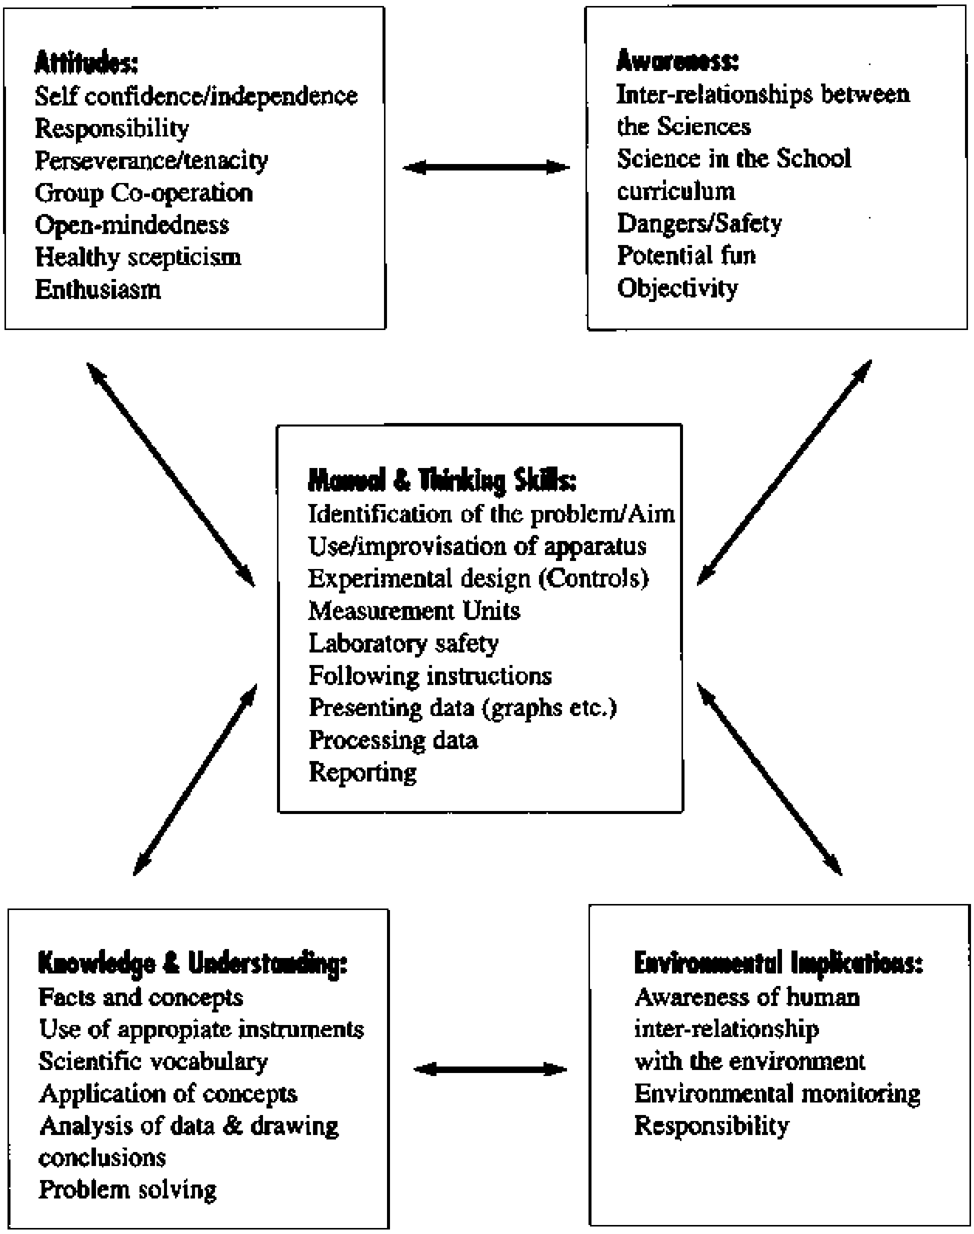
- self confidence and independence;
- responsibility for their own learning;
- perseverance and tenacity;
- tolerance for the views of others;
- co-operation when working in a group;
- open-mindedness towards alternative perspectives;
- a healthy scientific scepticism requiring justification;
- an enthusiasm for science.

3.4 Awareness

Students should demonstrate an awareness of:

- the inter-relationship of different disciplines of science;
- the relationship of science to other aspects of the school curriculum;
- the dangerous nature of certain substances and phenomena;
- the fun and enjoyment to be found in the science curriculum;
- the importance of objectivity in observation.

Note: Although the objectives 3.3 and 3.4 are difficult to measure in an external examination, they are considered as very important. Teachers should devise their own methods of assessing these summatively.



Summary of Inter-Relationships

4. Curriculum Objectives

It is important that the Physical Science and Biology content of this Standard 7 Syllabus should be presented in an integrated manner. To help accomplish this and to make it more meaningful, the syllabus has been re-ordered. Guidance has also been offered as to which thinking, process and manual skills can be used to enhance learning in each area of the syllabus.

The subject content is set out as a combination of the traditional Physics, Chemistry and Biology topics in an attempt to encourage teachers to use a more integrated approach in their teaching of these sciences. This does not mean that parallel teaching by a team of specialist teachers should not occur. Consultation, co-operation and cross-referencing are however recommended.

An explanatory booklet containing exemplars of course content will be made available to all participating schools early in 1994. This document should be read together with the syllabus.

Guidelines to the Examiner & all Teachers

1. The Curriculum Objectives outlined below are designed to provide guidance to as to what will be assessed; they are not meant to limit, in any way, the teaching programme of any particular school.

2. **Only the subject material contained within the first two Columns entitled »Topic Core and Core Extensions« are examinable as regards factual content, in detail.**

3. The »Supplement« section is optional; each teacher may decide whether or not to use material contained within this section. It is included in an attempt to provide guidance to the less experienced teacher. This section is printed in italics.

4. The »Skills & Teaching Suggestions« section in the exemplar booklet is likewise an aid to teachers. This section will, however, play a role in shaping the types of questions the IEB Combined Science Examination will contain. (Refer to the 1993 IEB Combined Science Examination in the IEB Combined Science Exemplar Booklet: available March 1994).

5. This Syllabus will form the basis of the IEB General [Combined] Science Examination. A list of topics to be examined externally by the IEB will be circularised each year.

6. The above-mentioned IEB Combined Science Exemplar Booklet contains:

- The 1993 IEB Combined Science Examination paper & marking memorandum;
- Hints on teaching aspects of the syllabus;
- A list of the thinking, process and manual skills students should be introduced to and ways of devising exercises which incorporate or illustrate these skills;
- Some sample lessons;
- Some sample tests or practical lesson suggestions, sample answers from students and their evaluation.
- This Exemplar Booklet will be upgraded and developed constantly; any teacher who has suitable material which could be included in this booklet, should be encouraged to submit it to:

The Deputy Director - Curriculum Development
Independent Examinations Board
PO Box 875

3.6.4. Independent Examinations Board. General Science Examination Paper 1995 (General Education Certificate)

EXAMINATION NUMBER ___________________

INDEPENDENT EXAMINATIONS BOARD

GENERAL EDUCATION CERTIFICATE
OCTOBER 1995

GENERAL SCIENCE EXAMINATION

Time: 1 ½ hours 100 marks

PLEASE READ THESE INSTRUCTIONS CAREFULLY

1. **Write your examination number in the space provided at the top of this page.**
2. This paper consists of 22 pages. Please check that your paper is complete.
3. Use the reading time to go through the examination paper carefully.
4. Write clearly and neatly.
5. Answer Questions 1-9 on the answer grid for multiple choice questions on Page 3.
6. Answer Questions 10-20 in the space provided on the question paper.

1-9	
10	
12	
13	
14	
15	
16	
17	
18	
19	
20	
TOTAL	

READ THE INSTRUCTIONS BELOW **BEFORE** YOU ANSWER QUESTIONS 1-9.

Questions 1-9 are MULTIPLE CHOICE questions.

INSTRUCTIONS

1. Read each question through carefully.

For each question, there are FOUR possible answers (A, B, C and D). Three of these answers are WRONG. Only **one** of these answers is CORRECT.

2. Choose which ONE of the four possible answers is correct.

3. Look at the letter (A, B, C or D) next to the CORRECT answer.

4. On the page called ANSWER GRID FOR MULTIPLE CHOICE QUESTIONS (Page 3), find the number of the question. Use a PENCIL to draw a LARGE cross through the LETTER of the answer which you think is correct.

5. You may draw only ONE cross on each line.

Example:

QUESTION 64

Pure water

A is a green solid
B is a liquid
C has a very strong smell
D conducts electricity very well.

The answer to Question 64 is B. Show this on the Answer Sheet as below:

64	A	~~B~~	C	D

ANSWER GRID FOR MULTIPLE CHOICE QUESTIONS

1	A	B	C	D
2	A	B	C	D
3	A	B	C	D
4	A	B	C	D
5	A	B	C	D
6	A	B	C	D
7	A	B	C	D
8	A	B	C	D

QUESTION 1

'AIDS is caused by a virus which can only live in blood, semen, and vaginal fluid.' People can catch AIDS by...

A using the same fork and knife as a person who has AIDS.
B having sex with a person who has AIDS.
C holding hands with a person who has AIDS.
D swimming with a person who has AIDS.

QUESTION 2

Iron sulphide is

A a MIXTURE which has properties of iron and properties of sulphur

B a MIXTURE of iron and sulphur with properties which are NOT the same as the properties of iron and sulphur

C a COMPOUND with the same properties as iron and sulphur

D a COMPOUND with properties very different to the properties of iron and sulphur

(2)

QUESTION 3

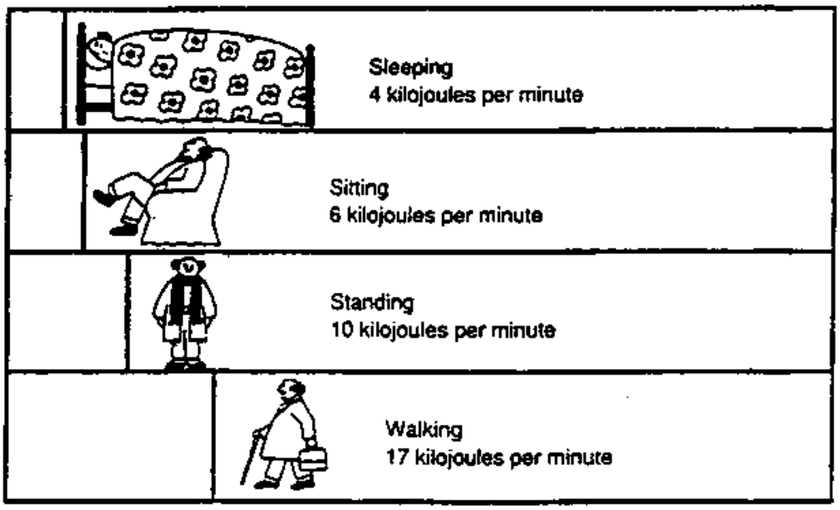
Which activity below uses the most glucose?

A

B

C

D

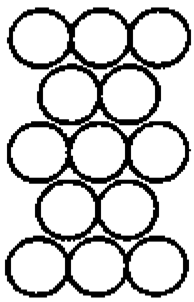


The amount of energy a 65 kg man needs in a minute

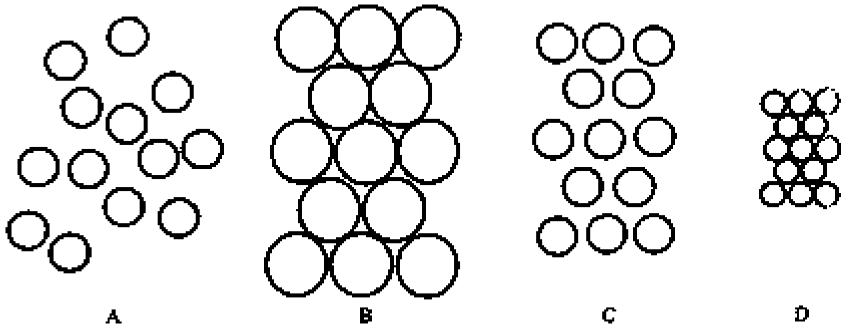
(2)

QUESTION 4

The diagram below represents the particles of which a metal teaspoon is made. The diagram shows how the particles are arranged on a very cold day.



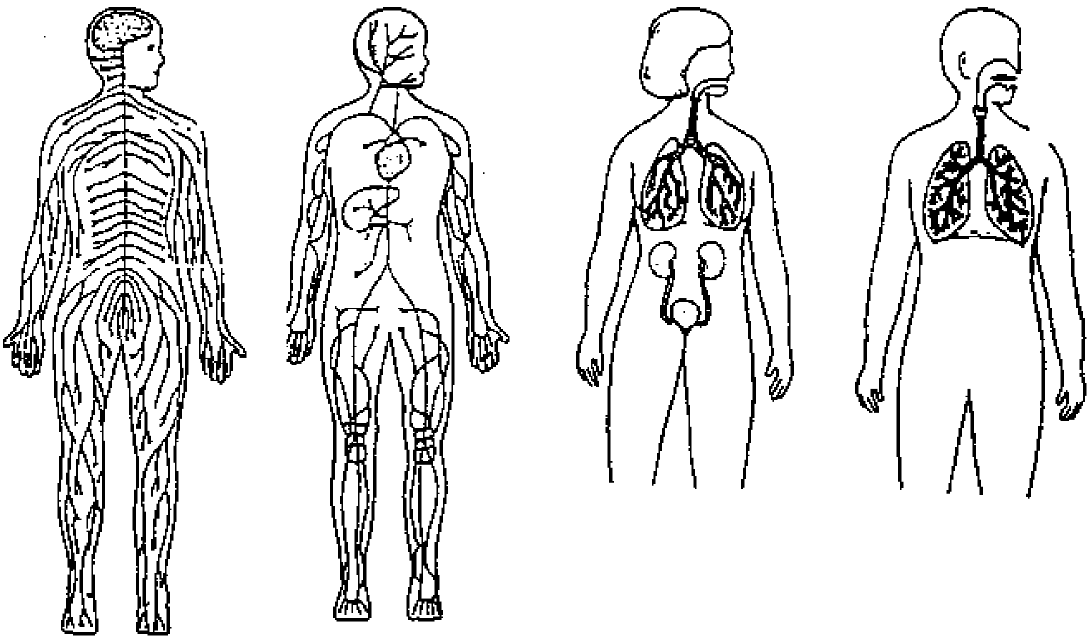
Which of the diagrams below represents the same particles after the teaspoon has been in boiling water for twenty minutes?



(2)

QUESTION 5

The following diagrams show different systems in the human body. Each system performs a life process. Choose the system that is involved in the transport of oxygen and nutrients throughout the body.



nerve system A

blood system B

excretory system C

breathing system D

(2)

QUESTION 6

We inhale and exhale air all the time.

Choose the correct answer from the choices below.

A Exhaled air contains less oxygen and less carbon-dioxide than inhaled air.
B Exhaled air contains less oxygen and more carbon-dioxide than inhaled air.
C Inhaled air contains less oxygen and more carbon-dioxide than exhaled air.
D Exhaled air contains more oxygen and more carbon-dioxide than inhaled air.

(2)

QUESTIONS 7 AND 8 BOTH REFER TO THE DRAWING PIN IN DIAGRAM 7.

QUESTION 7

The area of the head of a drawing pin is 100 times bigger than the area of the point of the drawing pin.

A boy presses the drawing pin onto a piece of wood with a force of 15 N as shown below:

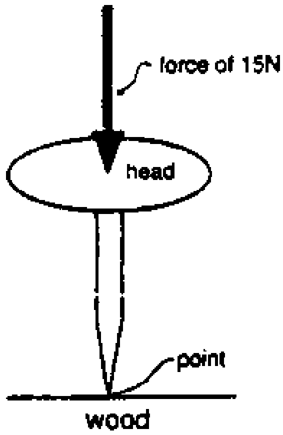


DIAGRAM 7

What force does the point of the drawing pin exert on the wood?

A 15 N
B 100 x 15 N
C $\frac{15\,N}{100}$
D The point exerts no force on the wood.

(2)

QUESTION 8

The statements below are about the **pressure** acting on the head of the drawing pin and the **pressure** acting at the point of the pin.

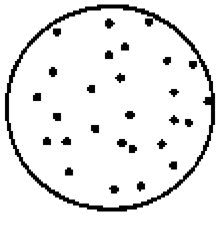
Which statement is correct?

A The pressure acting on the head of the pin is the same as the pressure acting at the point of the pin.
B The pressure acting at the point of the pin is greater than the pressure acting on the head of the pin.
C The pressure acting at the point of the pin is smaller than the pressure acting on the head of the pin.
D It is impossible to compare these pressures because the question does not give the area of the head or the area of the point of the pin.

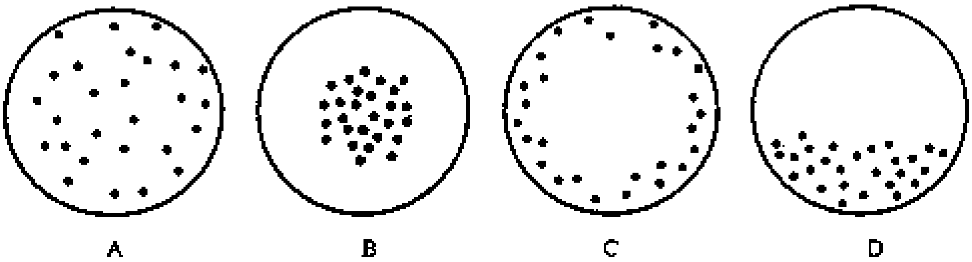
(2)

QUESTION 9

The picture below represents a **closed** container in which there are particles of the gas oxygen at room temperature.



Which of the diagrams below shows the arrangement of the same oxygen particles when we make the gas very cold? **(The oxygen does NOT turn into a liquid when we cool it.)**



(2)

18 marks

PLEASE ANSWER QUESTIONS 10-20 IN THE SPACES PROVIDED ON THE QUESTION PAPER.

QUESTION 10

Nitrogen reacts with hydrogen to form ammonia. Nitrogen, hydrogen and ammonia are gases at room temperature.

Diagram 10 below represents the particles of these three gases - nitrogen, hydrogen and ammonia.

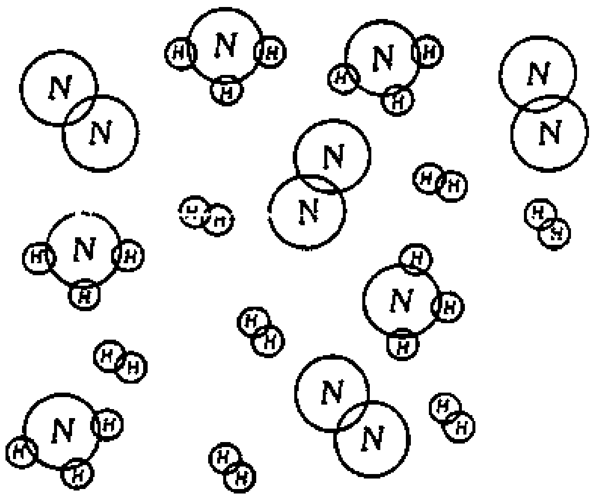


DIAGRAM 10

Use Diagram 10 to help you answer the questions below:

10.1 Is nitrogen an element or a compound?

____________________________________ (1)

10.2 Is ammonia an element or a compound?

____________________________________ (1)

10.3 Are the particles of nitrogen gas in Diagram 10 atoms or molecules?

____________________________________ (1)

10.4 Write the chemical formula for ammonia gas.

____________________________________ (2)

10.5 How many atoms of hydrogen are there in 6 molecules of ammonia?

____________________________________ (2)

10.6 Write the formula for 4 molecules of hydrogen gas.

____________________________________ (2)

9 marks

QUESTION 11

Look at Diagram 11 below.

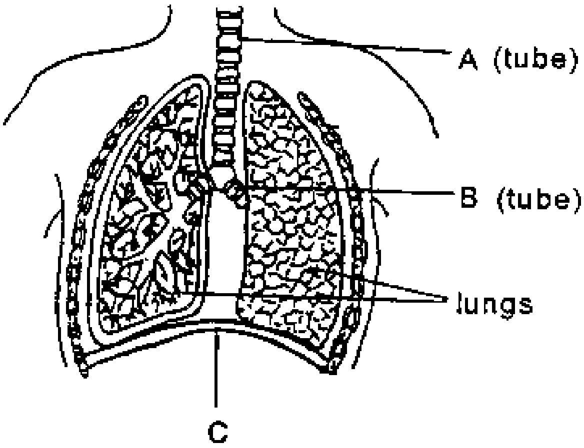

DIAGRAM 11

11.1 Give a label for each of the following structures:
A ____
B ____ (2)

11.2 Which letter points to a muscle? __________________________ (1)

11.3 Cross out the WRONG word or words in the following statements.
11.3.1 When C moves downwards, the volume of the chest cavity increases/decreases/stays the same. (1)
11.3.2 When C moves downwards, the air pressure inside the lungs increases/decreases/stays the same. (1)

5 marks

QUESTION 12

Diagram 12 below shows a long piece of wood (AB) with its one end (B). on the back of a truck.

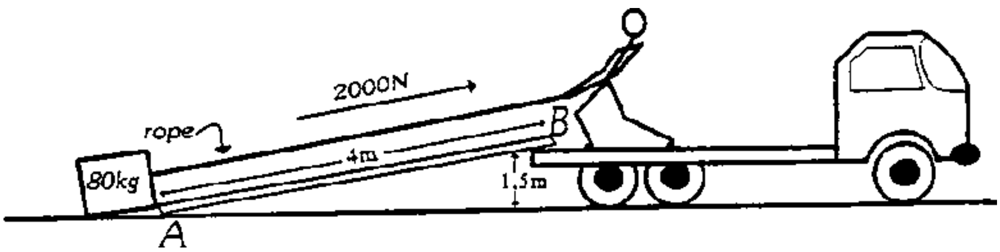

DIAGRAM 12

Allan uses a rope to pull a concrete block (of mass 80 kg) up the piece of wood onto the back of the truck. Allan pulls on the rope with a constant force of 2 000 N. The plank is 4m long. The back of the truck is 1,5m high.

12.1 How much **work** does Allan do to pull the block along the plank onto the truck? Use the formula

work = force x distance. (6)

____
____
____

12.2 Work out the weight of the concrete block.

(2)

____
____

8 marks

QUESTION 13

Diagram 13 below represents the human female reproductive system

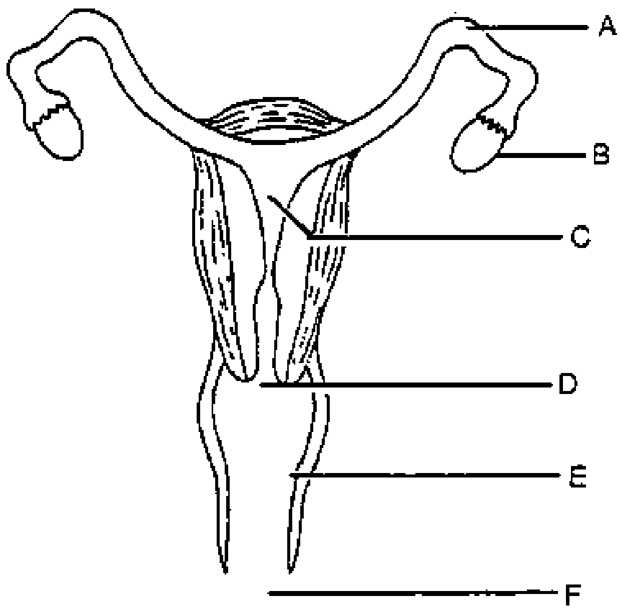

DIAGRAM 13

13.1 Match each statement in Column B to the correct word in Column A. Write the **number** of the correct statement in the space provided in Column A.

COLUMN A		COLUMN B
______CERVIX	1	The birth canal.
______VAGINA	2	The muscle which controls the opening of the womb.
______OVIDUCT	3	The organ in which eggs are made.
______OVARY	4	The place where fertilisation occurs.

(4)

13.2 Where should the contraceptive devices listed below be placed to prevent pregnancy? Use letters from Diagram 13 to answer.

IUD ______________
DIAPHRAGM ______________

(2)

6 marks

QUESTION 14

An engineer puts a long steel beam (XY) on top of two concrete pillars as in Diagram 14.1 below.

DIAGRAM 14.1

The engineer wants to find out how much the beam (XY) will bend (sag) when he hangs loads of different weight on the beam.

He hangs a load of known weight on the beam. He measures the sag (h) of the beam as shown in DIAGRAM 14.2 below.

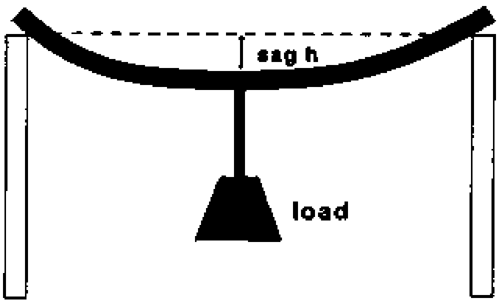

DIAGRAM 14.2

He measures the sag (h) for six different loads. He uses his results to plot a graph of Sag (in cm) on the y-axis against the Load (in N) on the x-axis. His graph is shown in Diagram 14.3.

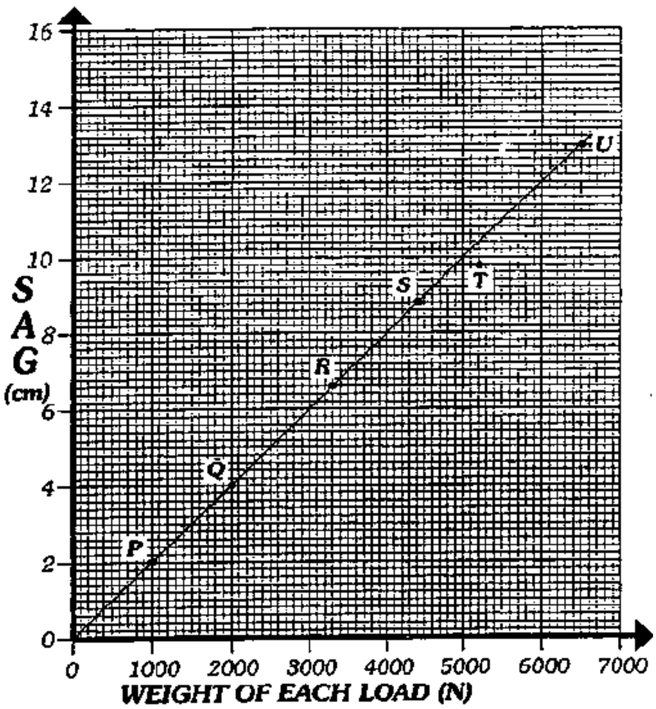

DIAGRAM 14.3

USE INFORMATION FROM THE GRAPH DIAGRAM 14.3 TO ANSWER THE QUESTIONS BELOW:

14.1 What is the weight (in N) of the load which will make the beam (XY) sag

(a) 4 cm? ____ (1)

(b) 7 cm? ____ (2)

14.2 How much (in cm) will the beam XY sag when a load of 4400 N hangs from its centre?

____ (2)

14.3 The engineer made a mistake when he measured how much beam (XY) sags with a load of 5200 N.

How much **should** beam XY sag when a load of 5200 N hangs from its centre?

____ (2)

14.4 The engineer tests another steel beam PQ. He puts the ends of PQ on top of two concrete pillars. PQ IS MUCH LONGER THAN XY, but it is the SAME thickness as XY. Will PQ sag more or less than XY under the same load?

____ (1)

8 marks

QUESTION 15

Use Diagram 15 to answer the questions below.

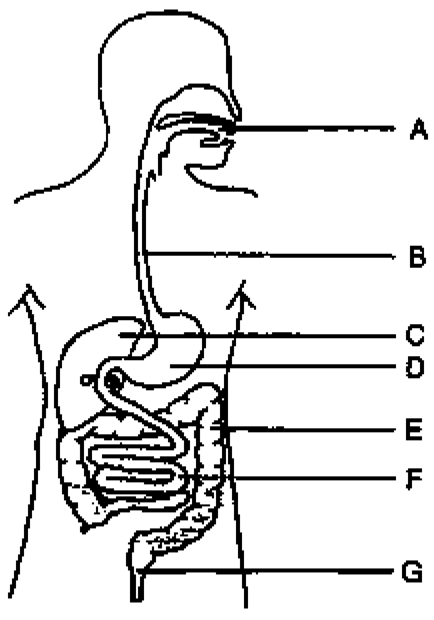

DIAGRAM 15

15.1 State **two places where** mechanical digestion takes place. (Use letters only)

____

____________________ (2)

15.2

15.2.1 Is digestive juice in D acid or alkaline?

____ (1)

15.2.2 What indicator could you use to check your answer to 15.2.1?

____ (1)

4 marks

QUESTION 16

In the space below draw and label a diagram of a cell from the human body eg. a cheek cell.

5 marks

QUESTION 17

When we push an object, we MAY do work on the object.

Table 17, on page 18 shows some things which may happen. In the table these things are called ACTIONS.

Read through Table 17 very carefully. For each ACTION (A, B, C and D), decide if work is done or if work is NOT being done. Fill in either YES or NO in the second column in TABLE 17.

17.1

	ACTION	IS WORK BEING DONE? Fill in YES or NO.
A	Fred pushes the wall as hard as he can. The wall does NOT move.	Does Fred do work on the wall? ______________________
B	Mary carries 6 very heavy books from the ground floor of a building up to the tenth floor of the building.	Does Mary do work on the books? ______________________
C	Four very strong poles hold up the roof of a house. The roof does NOT fall down.	Do the poles do work on the roof? ______________________
D	A ball falls towards the ground from a height of 1m.	Is work being done on the ball as it falls? ______________________

TABLE 17

(4)

17.2 Explain your answer to C in TABLE 17. Use words, 'distance', 'force' and 'work' in your explanation.

(3)

____
____
____
____

17.3 What kind of energy does the ball in D in Table 17 gain as it falls?

(1)

____

17.4 What kind of energy does the ball in D in Table 17 lose as it falls?

(1)

____

9 marks

QUESTION 18

Diagram 18.1 below shows some of the parts inside Mary's torch.

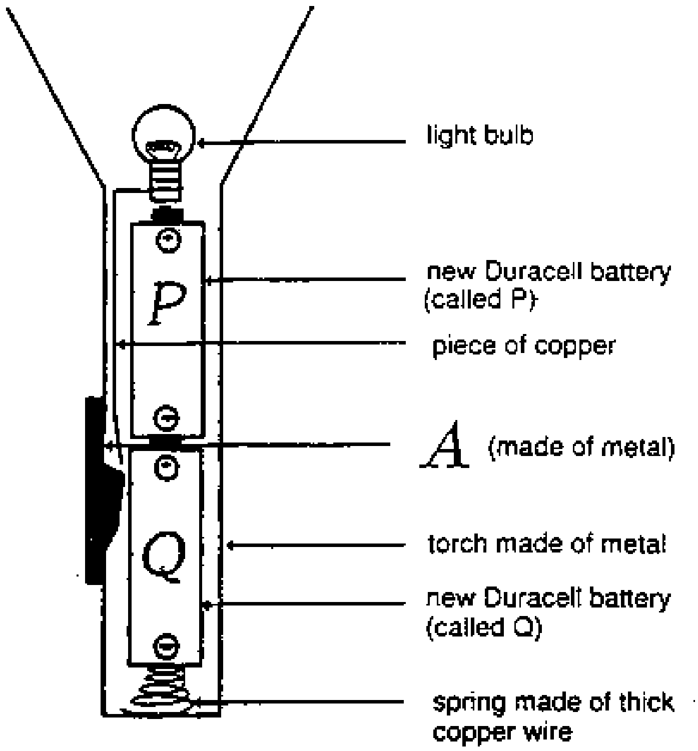

DIAGRAM 18.1

18.1 What will **happen** to the bulb in Mary's torch when she pushes A (in Diagram 18.1) **up?**

____ (1)

18.2 Draw an electrical circuit diagram to show EXACTLY how the parts in MARY'S TORCH in Diagram 18.1 are joined to each other. You MUST use the correct electrical symbols and you must put the following labels on your circuit diagram: Battery P, battery Q and part A. Label the + and - terminals on the Duracell batteries. The bulb in your circuit diagram must be turned off.

(6)

18.3 Marietjie has a new torch bulb and a new Duracell battery. She presses the bottom of the bulb hard against the bottom of the Duracell battery and holds it as shown in Diagram 18.3 below.

DIAGRAM 18.3

Marietjie's bulb does NOT light.

Draw a piece of copper wire in Diagram 18.3 which will make the bulb light. (2)

18.4 Tom has two light bulbs Bulb X and Bulb Y. Bulb X, has a thin filament. Bulb Y has a thick filament. The thick filament and the thin filament are the same length. See Diagram 18.4.

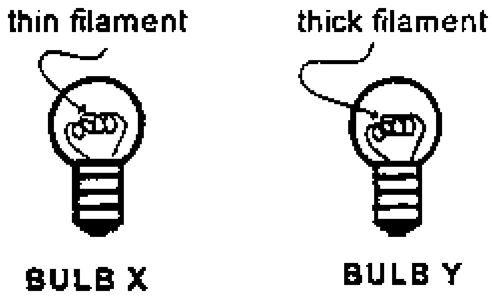

DIAGRAM 18.4

(a) Which bulb will carry more current if we put it into Mary's torch in Diagram 18.1?

Answer by writing Bulb X or Bulb Y.

____ (1).

(b) Explain your answer to 18.4 (a).

____
____
____ (2)

12 marks

QUESTION 19

Diagram 19 below shows the relative amounts of different nutrients in some common foods. The numbers alongside each bar are the percentages of each nutrient.

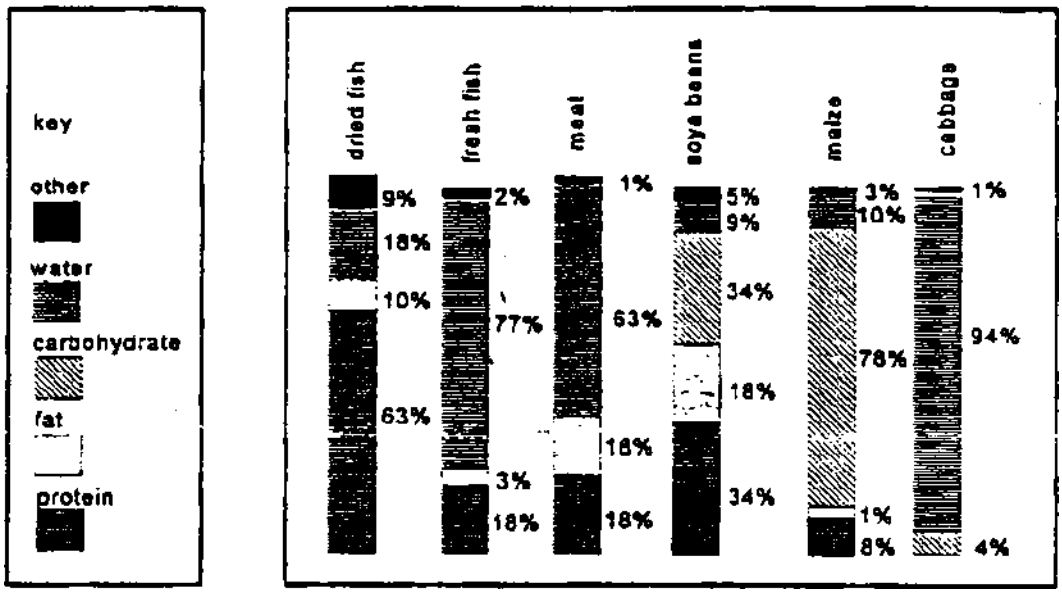

Diagram 19

19.1 Which food contains the highest percentage of carbohydrate?

____ (1)

19.2 Why does the body need carbohydrates?

____ (1)

19.3 Which food contains the lowest percentage of water?

____ (1)

19.4 Which food would you recommend for a child suffering from Kwashiorkor?

____ (1)

19.5

19.5.1 Which one of the above foods has the best balance of nutrients?

____ (1)

19.5.2 Explain how you made your choice in 19.5.1.

____ (2)

7 marks

QUESTION 20

Below is a diagram to show a leaf that has been cut in cross-section and is being looked at under a microscope.

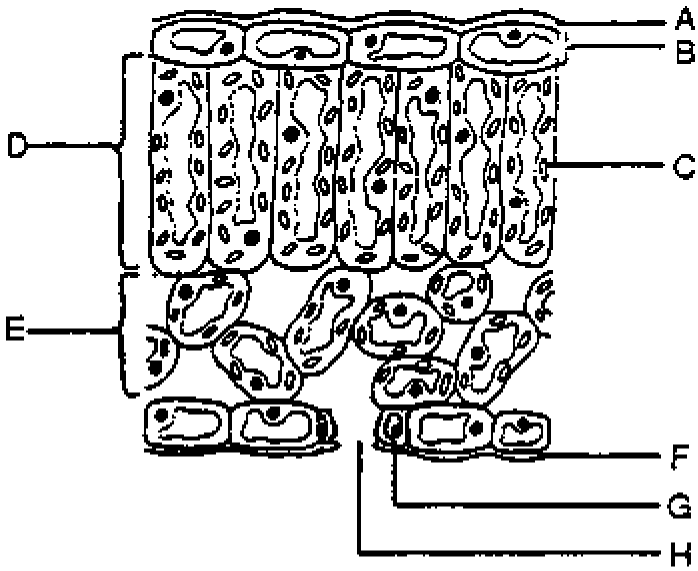

DIAGRAM 20

20.1 The leaf is an organ of a plant. It is made up of many different tissues. Choose TWO letters from the diagram that show two different kinds of tissues.

______ ______ (2)

20.2

20.2.1 Write down the letter of the tissue whose main function is photosynthesis.

______ (1)

20.2.2 Use information from Diagram 20 to explain how you made your choice in 20.2.1.

____
____
____ (3)

20.3 State the function of H.________________________________
____ (2)

20.4 What is the substance made in C, which turns iodine solution blue-black. (1)

____

9 marks

3.6.5. Independent Examinations Board. Combined Science Examination Paper 1993 (Standard 7 Examination)

INDEPENDENT EXAMINATIONS BOARD

STANDARD 7 EXAMINATION
SEPTEMBER 1993

COMBINED SCIENCE EXAMINATION

Time: 1¼ Hours 75 marks

PLEASE READ THESE INSTRUCTIONS CAREFULLY

1. Number your answers exactly as the questions are numbered.

2. It is in your interests to write legibly and to present your work neatly.

3. This examination consists of 2 sections:

Section A: **'Lucky Dip'** (40 marks)
Section B: **'The Air Around Us'** (35 marks)

4. **Answer ALL questions in both sections in the BLUE BOOKLET.**

5. This paper has been planned so that about one minute should be spent on each mark earned e.g. about 5 minutes should be spent on a question worth 5 marks.

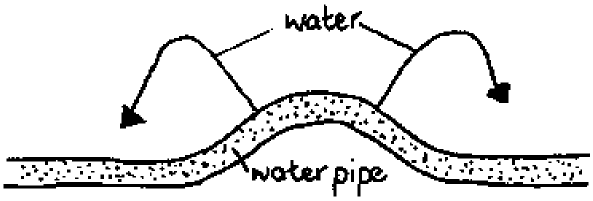
6. This paper consists of 24 pages: a white booklet (pages 1-11); and a blue booklet (pages 12-24). Please check that both booklets are complete.

SECTION A: "LUCKY-DIP" (40 marks)

Answer all questions in this section on the special answer sheet in the blue booklet.

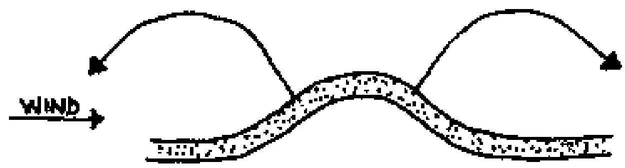
Questions 1 to 11 are all Multiple Choice Questions; just mark the appropriate letter (A, B, C or D) on the Answer Sheet, with a clear cross.

1. The diagram below represents water coming from 2 holes in a water pipe on a day with **NO wind blowing.**

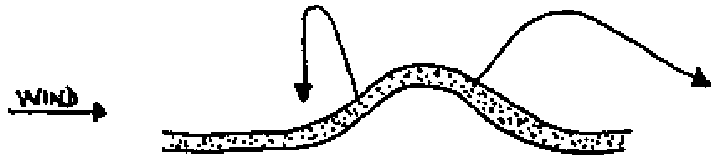


Now the wind blows in the direction that the arrows show. Choose the diagram which best shows how the water will move:

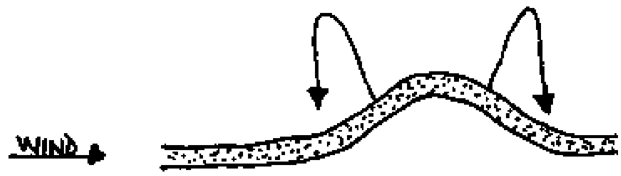
A



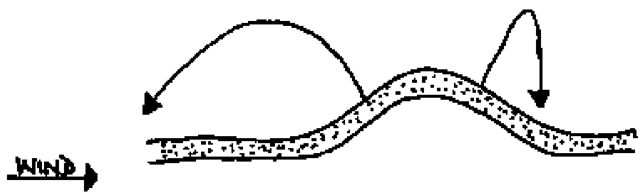
B



C

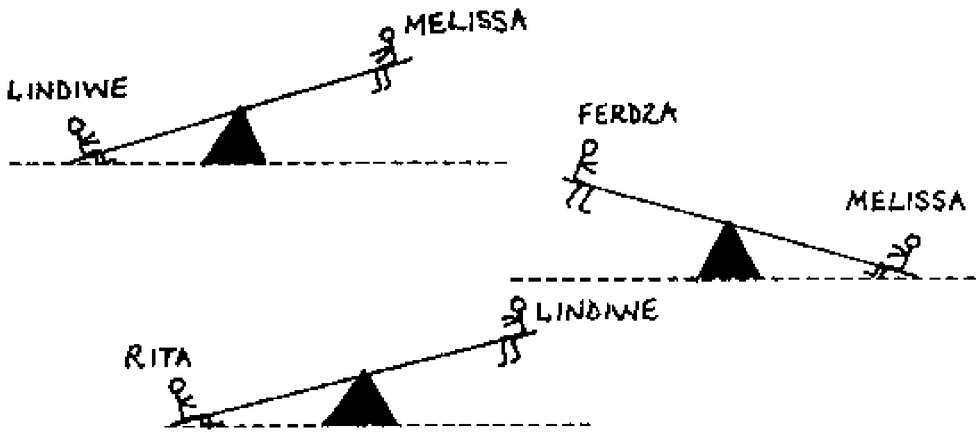


D



2. Four (4) children were playing on a see-saw and wanted to see who was the heaviest.

The diagrams below show what happened when they were sitting still:

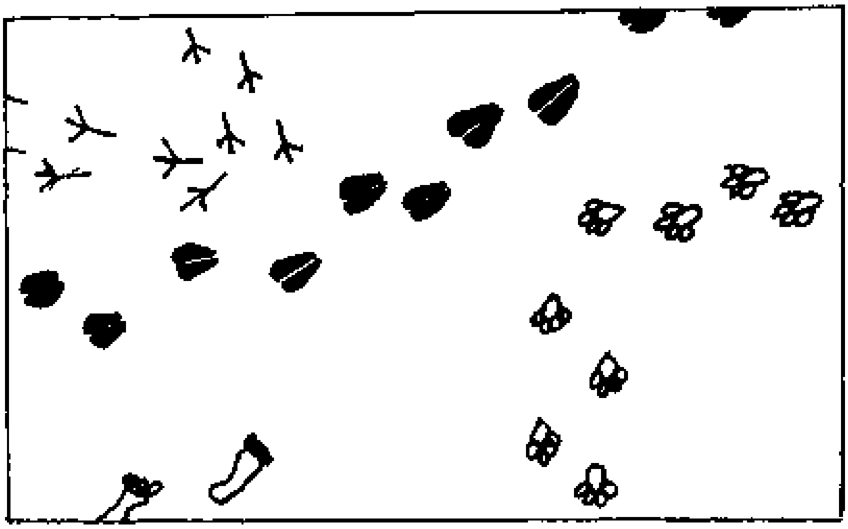


Which child was the heaviest?

A - Rita
B - Melissa
C - Lindiwe
D - Ferdza

(2)

3. A group of animals was feeding together on the farm; they were then disturbed and this is a sketch of the tracks in the sand they left:

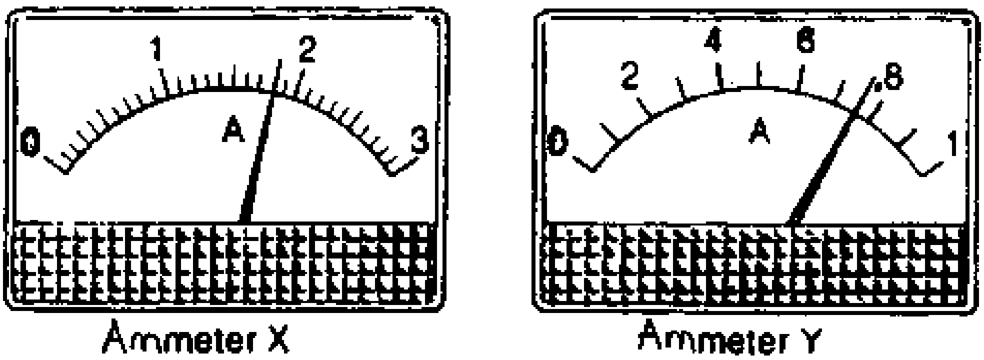


Which were the animals which produced the tracks above?

A - Hen, Cow, Elephant and Human
B - Human, Hen, Dog and Cow
C - Dog, Cow, Lion and Pigeon
D - Horse, Cow, Dog and Hen.

(2)

4. The reading on ammeter X is 1,8 A. What is the reading on ammeter Y?

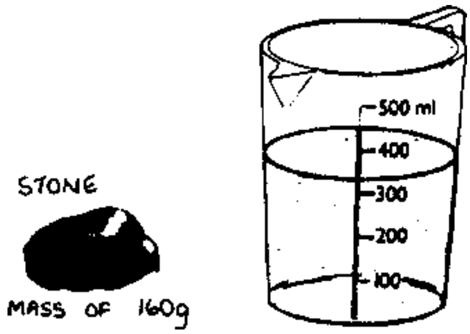


A - 6,75 A
B - 7,6 A
C - 0,72 A
D - 0,76 A

(2)

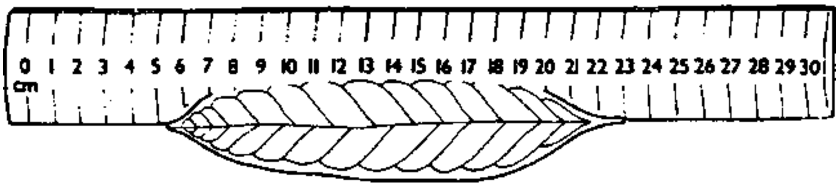
5. You put the stone in the jug of water. This makes the water rise to the 500ml mark. What is the **volume** of the stone? Choose A, B, C or D.

A - 160 g
B - 340 ml
C- 160 ml
D - 500 g



(2)

6. What is the length of the leaf?

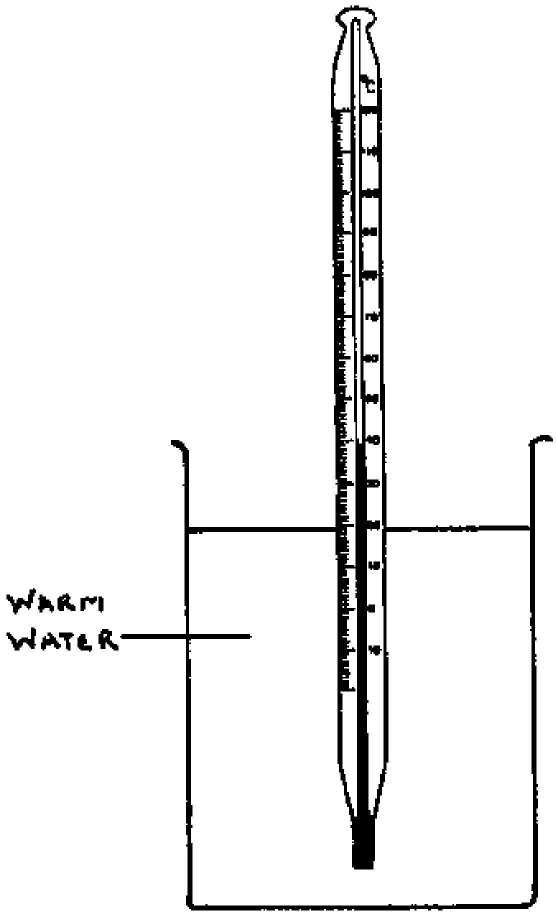


A - 23 cm
B - 17,7 cm
C - 16,4 cm
D - 21,5 cm

(2)

7. What is the temperature of the water?

A - 49° C
B - 41° C
C - 40° C
D - 39° C

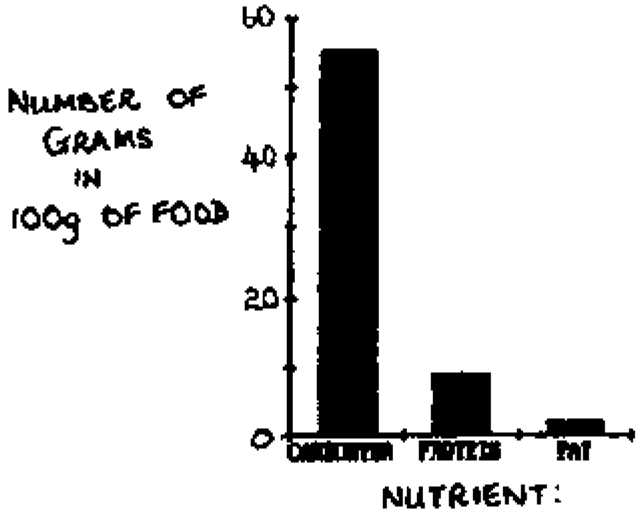


(2)

8. The table below gives the nutrients present in 100g of various foods:

FOOD:	NUMBER OF GRAMS OF NUTRIENTS IN 100g OF THAT FOOD		
	CARBOHYDRATES	PROTEIN	FAT
Wholemeal Bread:	46	10	3
Boiled Potatoes:	20	2	0
Potato Chips:	40	4	9
White Bread:	55	9	2

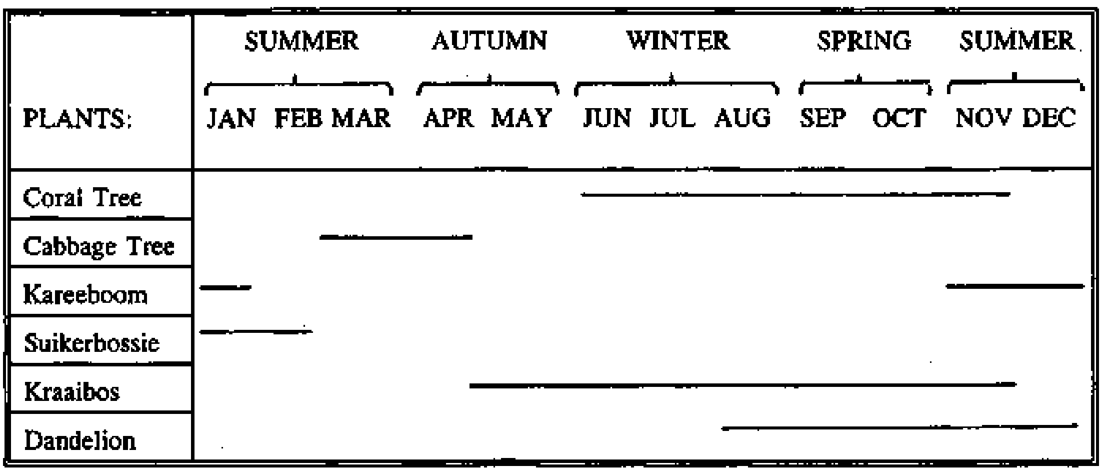
The following graph shows the differing amounts of the nutrients found in one of the foods; **which food does the graph represent?**



A - Wholemeal Bread
B - Boiled Potatoes
C - Potato Chips
D - White Bread

(2)

9. The table below shows some South African indigenous (natural) plants and it shows the months in which these plants produce flowers:



NOW ANSWER THESE QUESTIONS:

9. Which plant has flowers the longest?

A - Kareeboom
B - Suikerbossie
C - Dandelion
D - Kraaibos

(2)

10. Look at the plant you chose in your answer to (9) above. For how long does it produce flowers?

A - 7 months
B - 6 months
C - 8 months
D - 5 months

(2)

11. Which season has the most plants producing flowers?

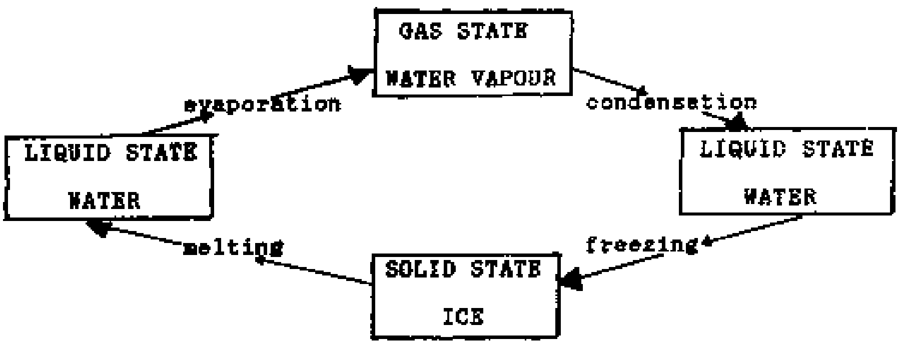
A - Spring
B - Summer
C - Autumn
D - Winter

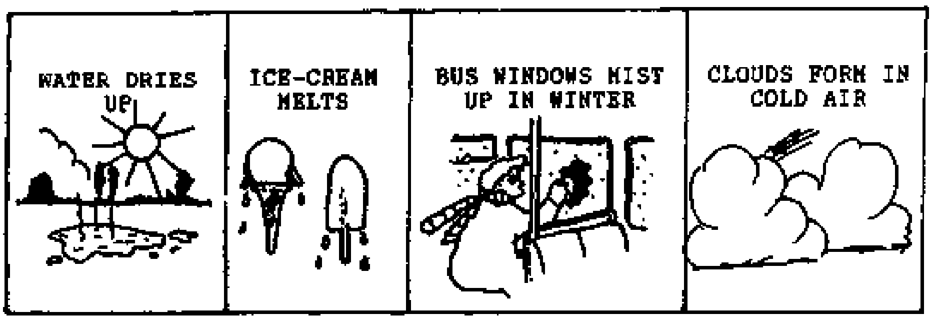
(2)

22 Marks

Questions 12 and 13 are to be answered in the blue booklet; use the lines and graph provided.

12. Study the following diagram and pictures, and answer the questions which follow:





12.1 Name the phase change (evaporation, melting, condensation or freezing) for each of the 4 diagrams.

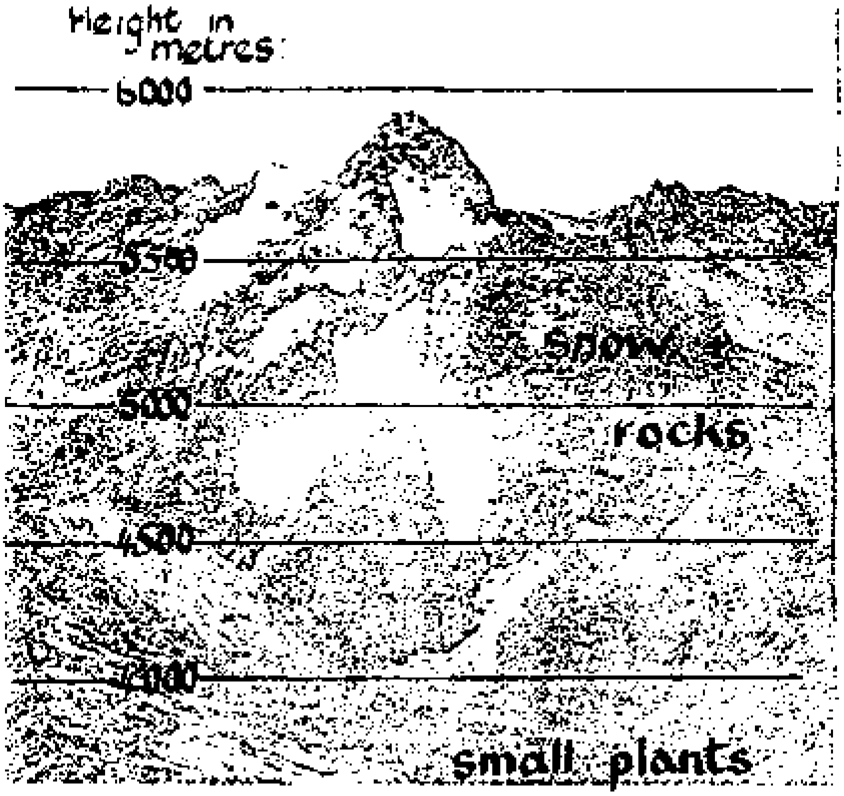
(4)

12.2 Give 2 more examples of substances changing phase.

(2)

13. Study the picture of Mount Kenya and the table of information below. Then answer Question 13.1 to 13.5.

This picture shows Mount Kenya. Altitudes have been drawn on the picture. (Altitude means the height above sea level)



Mount Kenya

Height above Sea Level:	Boiling Temperature of Water:	Atmospheric Pressure:
6000 m	80° C	47 kPa
4000 m	88° C	60 kPa
2000 m	93° C	77 kPa
Sea Level	100° C	100 kPa

13.1 To boil an egg very hard, the temperature of the boiling water must be higher than 88° C; if mountain climbers find that they cannot boil eggs hard, at what height would they be?

(1)

13.2 How high is the mountain? Look at the picture and give the most accurate answer you can.

(1)

13.3 Why would a mountain climber have difficulty breathing when he gets to the top of Mount Kenya?

(3)

(Support your answer by mentioning one observation from the picture of Mount Kenya).

13.4 Use the data from the table above to draw a graph (on the graph paper in the blue booklet) comparing Altitude and Boiling temperature of water.

(5)

Decide on a heading for this graph and write it on the line provided.

(1)

13.5 Use your graph to work out what the boiling temperature of water would be at 3000 metres (height above sea level). (Write your answer in the space provided in the blue booklet).

(1)

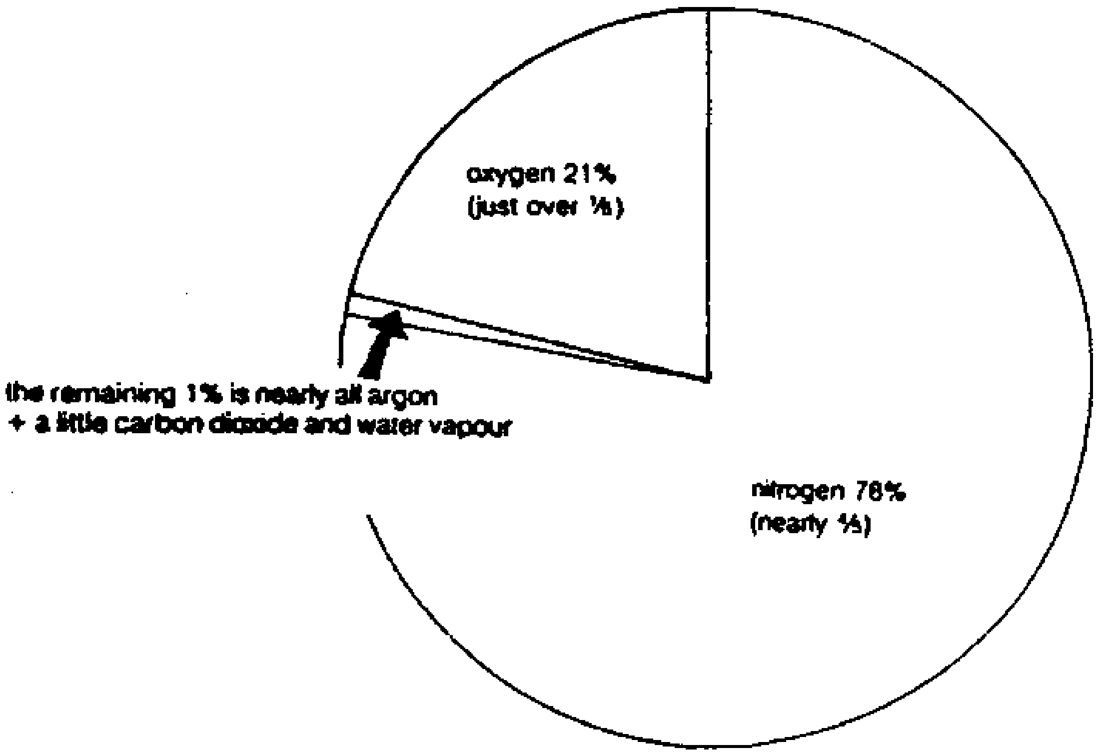
SECTION B: "THE AIR AROUND US" (35 marks)

Answer this section on the lines (and in the spaces) provided on this Question Paper.

READ THE FOLLOWING INFORMATION CAREFULLY AND THEN ANSWER THE QUESTIONS WHICH FOLLOW:

The following pie chart show the gases which make up "clean air" in our Earth's Atmosphere:

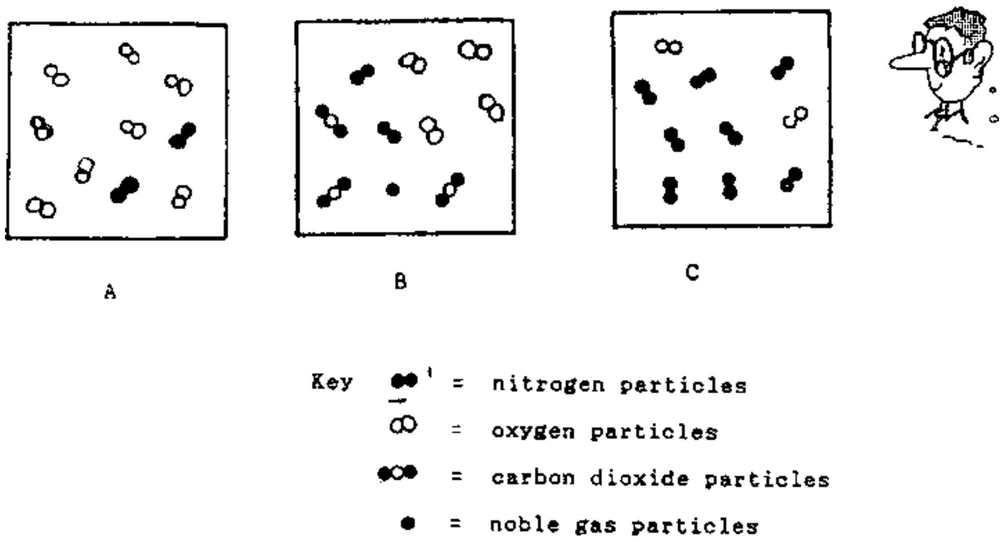


Sadly, much of the air we breathe in is **not** clean; it contains poisonous substances which we call **POLLUTANTS.**

Where do the pollutants come from? They come from factories, power stations and cars. In the past 100 years, all countries have become more industrialised. There are more factories and power stations which burn coal and oil. There are more and more cars on the roads; cars burn petrol and blow out waste gases into the air. The countries of the world burn almost a billion tonnes of coal, oil and gas each year.

NOW ANSWER THESE QUESTIONS:

1. Scientists believe that gases are made up of tiny particles which we cannot see with our eyes; try to imagine what gases look like if **you could** see these tiny particles - **they would look something like this:**



1.1 Which of the pictures above would best represent a small quantity of CLEAN AIR. (A, B OR C)?

____

(1)

1.2 Explain fully why you chose the above picture to represent clean air.

____
____
____

(3)

1.3 What does the word "**POLLUTANT**" mean?

____
____

(1)

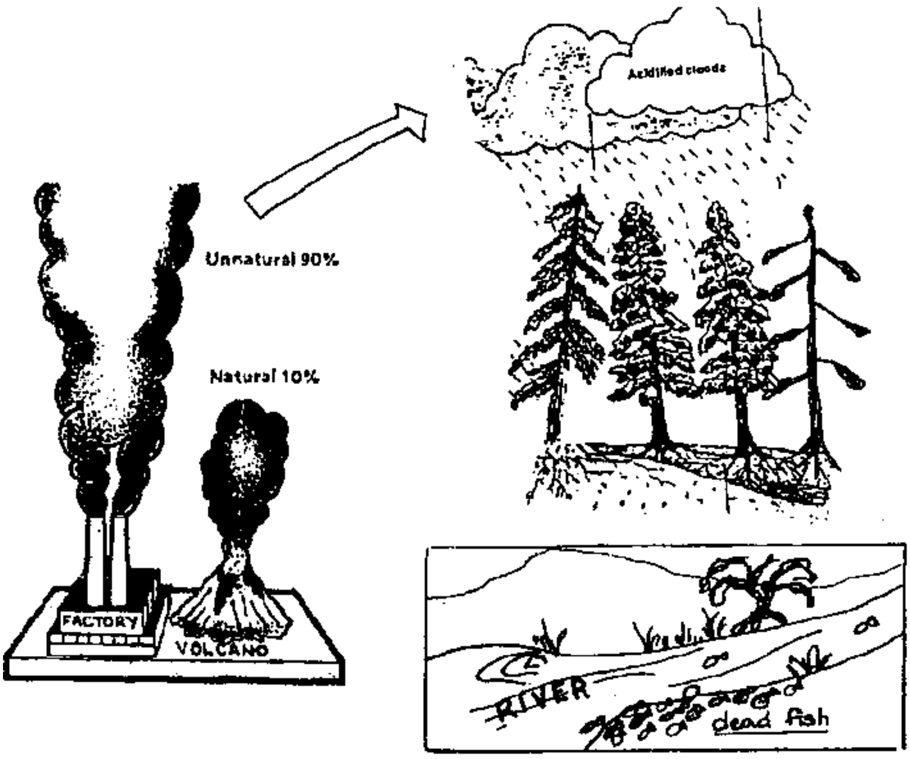
1.4 Explain why atmospheric pollution has increased over the years

____
____
____

(2)

7 Marks

2. Study the following diagram. The diagram summarises the effects of acid rain:



Acid Rain

In nature, volcanoes and lightning form sulphur dioxide and nitrogen oxide gases. Factories produce 9 times more sulphur dioxide and nitrogen oxide gases than nature produces. Nitrogen oxide and sulphur dioxide gases rise into the air. When they meet the moist air, the gases dissolve to produce sulphuric and nitric acids. The clouds become strongly acidified and these clouds produce acid rain.

QUESTIONS:

2.1 State two problems caused by acid rain which are shown on the diagram on page 16.

____

____

(2)

2.2 Where does the acid rain come from? What are its major sources?

____

____

(2)

2.3 Name two oxides that cause acid rain:

____

(2)

6 Marks

3. Some people think acid rain stops seeds germinating, but other people disagree. An experiment is a fair way to test an idea. You have been asked by your teacher to design a good experiment to investigate the effects of acid rain on the germination/growth of seeds. You can only use the apparatus and materials given below:

2 saucers/small dishes
cotton wool
tap water
an acid solution
a measuring cylinder
a packet of carrot seeds

3.1 Describe step by step the method you would use in doing this experiment:

____

____

____

____

____

____

____

____

____

(5)

3.2 Some students did a similar experiment with carrot seeds. They found that fewer seeds germinated in the acid solution than in the water. The following are some of the conclusions different students reached:

A. Acid rain affects the germination of all plant seeds.
B. Acid rain affects the germination of carrot seeds only.
C. The acid used in this experiment affected the germination of carrot seeds. Similarly, acid rain would affect the germination of carrot seeds.

3.2.1 Which one of these conclusions do you think is the best one?

____

(1)

3.2.2 Explain why you chose the above conclusion.

____
____
____
____
____
____

(3)

9 Marks

4. "AIR POLLUTION IS A BIG CHILD-KILLER"

Air pollution is a big factor in the deaths of many South African children under the age of five, claims the Medical Research Council.

Dr Von Schirnding, one of their researchers, said that:

"Outdoor pollution levels in Soweto, when last monitored in 1986, were found to be higher than the internationally acceptable standard and it is likely that the problem had worsened since."

She added that the domestic consumption of coal in Soweto remains high and that children in homes where coal stoves are used are inhaling sulphur dioxide and coal dust particles which could be damaging their health.

(Extract from an article printed in the Star, 22/8/1990)

Having read the above article, a group of students at the Lilian Ngoyi Secondary School decided to carry out a survey about the effects of air pollution on children in their own area.

The school is in Tembisa, a large township on the East Rand, close to an industrial area with many chemical factories.

The table below shows the results of their study:

POLLUTION FACTOR: This tells you how serious the air pollution is (e.g. Factor 1 - not too dirty; Factor 10 - very dirty)

Month:	Jan	Feb	Mar	Apr	May	June	July	Aug	Sept	Oct	Nov	Dec
Pollution Factor	3	3	3	4	7	9	9	10	8	5	4	2
Number of children with lung sickness	4000	4000	9000	10000	20000	25000	25000	30000	25000	12000	7000	3000

QUESTIONS

4.1 A hypothesis is an **idea or test question** which we can check scientifically. Suggest an hypothesis which could have been made by the students at the start of their research.

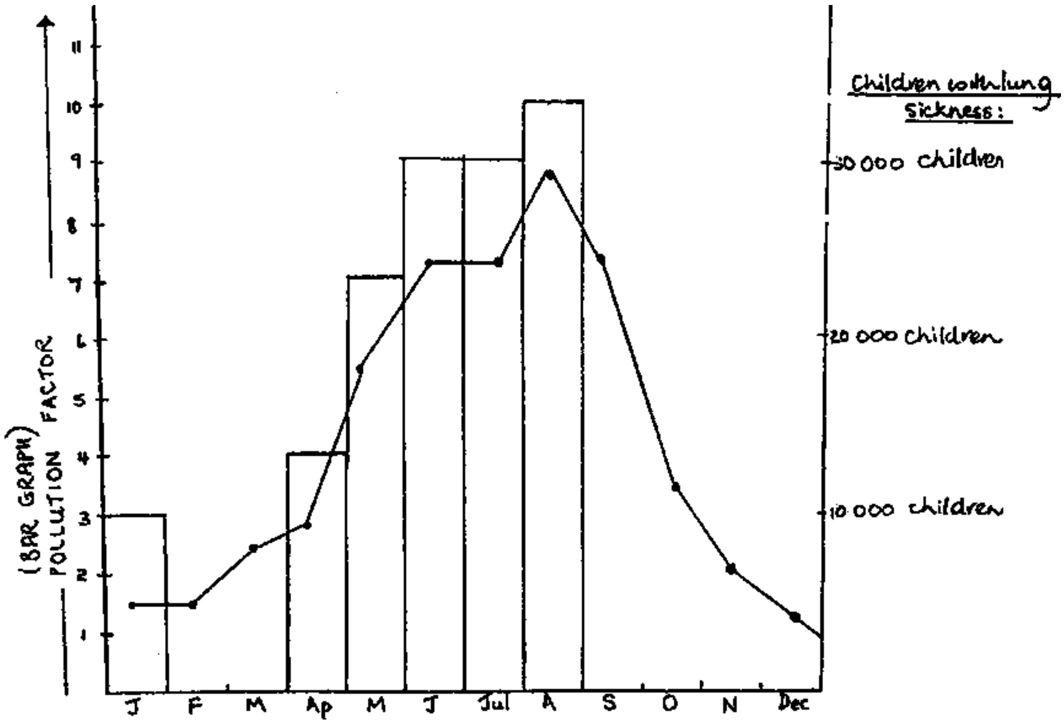
____

____

(2)

4.2 Using data from the table on the previous page complete the following ar graph (3)

[**Note:** This is 2 graphs; the Bar Graph shows how serious the pollution factor is. The line graph has been drawn on top of the Bar Graph - this shows how many children had lung sickness].



ATMOSPHERIC POLLUTION FACTOR IN TEMBISA IN 1991 (bar graph) associated with CHILDREN WITH LUNG SICKNESS (line graph)

4.3 Which month has the highest pollution factor?

____

(1)

4.4 Can you suggest a reason for the increased pollution factor during those months you named above?

____

____

(1)

4.5 If 50 000 children live in Tembisa, using data from the table of results, calculate the % of children with lung sickness when the pollution factor was 10.

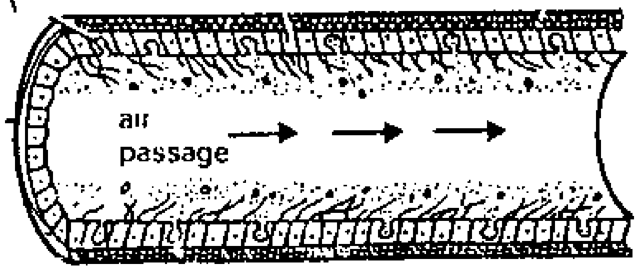
ANSWER:____

(2)

CALCULATION: ____

5. The following are diagrams of air tubes found in children's lungs:

A



B

This is how air tubes look when they have been cut open (dissected) - they are much smaller than shown in these pictures!

5.1 Complete the following table by writing in the main differences between the two tubes.

(2)

Air Tubes	Tube A	Tube B
Difference 1		
Difference 2		

5.2 Which of the above tubes (A or B) belongs to the sick child?

____

(1)

6. Suggest a way in which the pollution problems affecting the health of the children of Tembisa can be solved or improved.

____
____
____
____

(1)

TOTAL MARKS FOR SECTION B: 35 Marks

3.7. Swaziland

3.7.1. Overview

End of Primary School Examination

1.	**Title of examination:**	Swaziland Primary Certificate (SPC)
2.	**Amount of fees charged:**	≈ US$ 10
3.	**Examination after years in primary school (6, 7, 8 years):**	7 yrs
4.	**Children's entry age in primary school:**	6 yrs
5.	**Number of pupils sitting examination in 1994:**	17,888
6.	**Examination subjects offered:**	5 compulsory subjects in 9 papers: • Science (2 papers) • Mathematics (2 papers) • English (2 papers) • Siswati (2 papers) • Social Studies (1 paper) (incl. History, Geography, Civics) In addition 2 optional subjects are offered with one paper each: • Agriculture • Home Economics
7.	**Language of examination:**	English (except for Swazi language paper)
8.	**Institution setting the examination questions:**	Swaziland Examinations Council
9.	**Have there been any reforms in the examination questions?**	Yes
	When? (year)	1970
	What kind?	Science paper removed from a General Paper.
10.	**Stages of development of examination questions (please describe):**	• Setters' workshop is organized and they are trained through presentation. • Setters write items which are shredded at the workshop. • Shredded items are moderated and then compiled for pre-testing. • Pre-tested items are then analysed and some items may be removed. • Items are banked for use when required.

11.	**Type of examination questions and distribution of different kind of questions.**	Partly multiple-choice, partly structured questions.
12.	**Is continuous assessment incorporated in the final examination?**	Yes [ ] No [x]
13.	**Are examination items pretested?**	Yes [ ] No [x]
14.	**Which professional groups are involved in setting the examination questions?**	• Primary school teachers • School inspectors • Tutors of TTCs • University lecturers • Curriculum designers
15.	**Are the same professionals who set the examination questions involved in marking papers?**	Yes [x] No [ ]
16.	**How are examination results & used for improving teaching in**	Reports written at the end of the marking exercise: • help in-service specialists to organize regional workshops for the teachers on the major problematic areas; • help curriculum designers to review their teaching materials; • for administration purposes inspectors visit weak schools.
17.	**To what other uses are the examination results put?**	• Selection purposes. • Certification. • For administration to look into school situations.
18.	**Main problem with Primary School Leaving Examinations?**	• Distribution of examination papers. • Invigilation problems. • Security problems.

3.7.2. Examination and Continuous Assessment in Swaziland

by Jabulisile Fakudze/Valencia S. Simelane/Evart V. Dlamini

Classroom level examinations in primary schools in Swaziland are not administered on a consistent or systematic basis. Although teachers are expected to assess their students regularly this is determined by the individual teacher. The only tests provided to teachers are two or three questions inserted at the end of each unit of curriculum materials. Since a student's score in the teacher's record book is not based on a common measure, it is impossible to ascertain comparisons across classrooms or schools. The current system of classroom testing cannot be relied upon to provide meaningful hints for either instructional or management purposes.

External examinations are a key feature of the educational system in Swaziland. There are three such examinations:

- The Swaziland Primary Certificate Examination taken at the end of primary schooling (Grade 7)

• The Junior Certificate Examination taken at the end of Junior Secondary Education (Form 3) and

• The Cambridge Overseas Certificate Examination taken two years later (Form 5) at the end of Senior Secondary School.

All the examinations are subject examinations. Examinations are set on a series of curricular areas.

The Swaziland Examination Council is responsible for all aspects of the Primary and Junior Certificate Examination: registration of students, preparation of examination papers, printing and distribution of papers, appointment of supervisors (teachers in their own school, but not in their own subjects), appointment of markers, organization of meetings during the marking process, preparation and publication of the results.

The day-to-day running of the examinations is the responsibility of the Swaziland Examinations Council. It consists of eleven members made up of the Principal Secretary of the Ministry of Education, the Director of Education and representatives of headmasters, teachers, inspectors, and the University. It appoints moderators and examiners who set examination papers.

Science examiners and moderators are recommended by the science panel made up of the senior science inspector, Swaziland Science Teachers' Association members, training college lecturers, national curriculum designer, experienced teachers, University staff and science coordinators' representatives.

The chosen examiner and moderator sign a contract of two-three years with the Examination Council. The examiner then sets two papers. The first paper is a multiple-choice type, consisting of 40 questions which are answered in 1 1/2 hours. When setting, the examiner refers to the science syllabus, pupil's books, teachers' guides and other relevant materials. A table of specification is essential when setting the multiple-choice items. It is drawn up by writing unit topics covered from grade 4 to 7 in columns and essential skills in rows, e.g. facts, classification, observation, measurement, calculation etc. For each question set, a tick is put in the appropriate space. The ticks are added in rows and columns to ensure that the questions consist of evenly distributed unit topics and skills.

The second paper consists of six questions carrying 10 marks each. Again, to ensure that the questions cover the syllabus adequately, the questions are structured and mixed. That is, Question 1 a) could carry 6 marks on plant-related questions and part b) could carry 4 marks on animal-related questions. The candidates answer both question papers.

The examiner then hands over the question papers to the moderator. The moderator writes his general remarks about the papers. The moderator's report and papers (questions) are taken to the examiner. The examiner then makes any necessary changes and the papers are finally taken to the Examination Council for printing. Once printed the Exams Council takes the draft papers to the examiner. The examiner reads through all the pages signing each and every page. The draft is then taken to the Exams Council to be sent for printing again. If there were a number of mistakes in the first draft, the second draft is given to the examiner again for approval. The final draft is kept by the Exams Council for distribution to schools via the District Education Office.

Final examinations are supervised by appointed teachers in their own subject (but not in their own schools), retired teachers and in some cases church leaders.

The Examination Council appoints markers with the help of inspectors, about six from each of the four districts. The marking exercise is carried out in December two weeks before schools close. The examiner, together with the moderator, supervises the marking exercise. The markers, examiner and moderator, after this exercise, are paid by the Examination Council through funds generated by pupils' examination fees.

General analyses of performance in examinations are carried out and reports prepared on the basis of these analyses. In the past, more detailed item-analysis information was prepared for some subject areas on the machine scoring of answers. This, however, involved too many errors and had to be discontinued.

Overview of 1993 Results

About 16,789 students sat for the 1993 Swaziland Primary Certificate Examination, out of which 14,224 passed and 2,565 failed the examination. The pass rate was 84.72% which shows an increase of 0.4% from the 1992 pass rate.

Subject	A	B	C	D	E	F	PASS	%	FAIL	%
English	288	1714	3225	3657	5340	2565	14224	84.72	2565	15.28
Math	520	1473	2790	3400	6123	2484	14306	85.21	2484	14.79
Siswati	453	1363	3934	3682	5796	2269	14328	86.33	2269	13.67
Science	440	1443	3145	3808	5602	2251	14438	86.51	2251	13.49
Soc. Science	511	1518	2842	3639	5625	2654	14135	84.19	2654	15.81
Agric.	243	594	1232	1622	2520	1189	6211	83.93	1189	16.07
Home Ec.	259	683	1360	1549	2927	1082	6778	86.23	1082	13.77
Average								85.30		14.70

The main purpose of the Swaziland Primary Certificate Examination is to select pupils for Secondary Education. An examination is said to be good if it discriminates between lower and upper achievers. The marks are put in a normal curve, the mean is 50 and the standard deviation is 10. The marks are then run in a computer to produce standard scores (z-scores). The lower cut-off point is where z = 40. An »A« mark is obtained by a student who scores at least two standard deviations above the mean. Ideally one expects plus or minus 84% students to pass the examination.

This should give a picture of how students should pass. The overall performance is categorised into three.

- An aggregate of »C« or better is a first class,
- an aggregate of »D« is a second class pass,
- an aggregate of »E« (40-49%) is a third class pass.

A similar situation prevails at Secondary. At the Junior Certificate Examinations there is selection for O Level. The examinations are used as a screening instrument. The standard deviation at Junior Certificate is 15 and the mean is still 50, but the lowest cutoff point is still 40%.

The Science Results for 1992 and 1993

In 1992, 15,916 students registered for the science examination, 13,666 of these students passed, 2,250 failed. The passes can be classified as follows:

A	B	C	D	E
424	1307	2925	3760	5249

The numbers of failures also include pupils who did not sit for the examination due to various reasons, some died, others dropped because of pregnancy, others due to financial constraints. The pass rate was 85.86%.

In the 1993 examination there were 16,689 pupils who registered for Science and 14,438 passed. The passes can be classified as follows:

A	B	C	D	E
440	1443	3145	3808	5602

The passes indicate a pass rate of 86.51% which means that the passing percentage has increased by 0.65% when compared to the 1992 pass rate.

Continuous Assessment

The introduction of continuous assessment which is still at project stage was a logical development because it is related to curricula with clearly stated instructional objectives. Actually the introduction of continuous assessment is an important milestone in the development of the education system of the country. Not only will the assessment of the child's work be scientific and comprehensive but provision for remediation is also an integral aspect of the programme.

Continuous assessment is a component of a larger education project providing the technical assistance and resources needed to design and establish a comprehensive system for student's assessment at the primary level. This system ensures detailed feedback to teachers, headteachers, parents and the Ministry of Education (MOE) regarding student achievement in presently two subjects areas, English and Mathematics. Tests are developed at three levels:

1. Lesson level **-** by teacher
2. Unit level **-** by teachers
3. End of term level **-** by the National Curriculum Centre.

It is hoped that this programme will proceed through the first nine years of a Swazi student's education with greater efficiency and leading to reduced repetition and dropout rates and improving quality as evidenced by level of mastery of basic skills to practical real life situations.

Continuous Assessment as piloted in Swaziland is a comprehensive system for measuring students' achievement of the goals and objectives delineated in an educational system's curriculum. It is based on a testing technology called criterion-referenced testing (CRT) which is specifically designed to assess whether or not an individual has learned the skills or knowledge that were taught.

A critical feature of the CRT is the use of item specifications. Item specifications are detailed descriptions of the skills and knowledge to be measured, including allowable content, level of difficulty and test item format. Specifications are developed so that they are consistent with the curriculum.

Criterion-referenced tests are particularly useful for those concerned with monitoring, evaluating, and improving an educational system. They provide information at several levels, each of which has important decision-making implications. For example a test of mathematical skills can tell a teacher whether her instruction has been effective and can pinpoint those students who have not mastered particular skills. Using this information the teacher can decide whether to reteach the lesson or move to the next competency area and provide additional instruction only to those who did not learn the skill to a sufficient level of mastery.

Swaziland has only recently started continuous assessment implementation. However, this innovative approach is not without problems. The large numbers of primary school students and teachers' lack of understanding of the main features of assessment theory are the major constraints to implement continuous assessment successfully.

3.7.3 Swaziland Primary Certificate Examination 1994 - Science/Paper I & II

SWAZILAND MINISTRY OF EDUCATION
SWAZILAND PRIMARY CERTIFICATE
EXAMINATION, 1994
SCIENCE - PAPER I

THURSDAY, NOVEMBER 17th - 08:30 a.m. - 10:00 a.m.

TIME:	**1½ HOURS**	**TOTAL MARKS:**	**40**

CENTRE NUMBER:	

CANDIDATE'S NUMBER	

INSTRUCTIONS:

1. Answer all questions.

2. Each question has four (4) answers to choose from but only one of them is correct. Circle (0) the letter of the correct answers as shown in the example below.

3. Do not circle more than one answer. If you make a mistake cross (X) your first choice and then circle the answer you have finally chosen.

4. Use ink or ball pen.

Example

How many eyes does a frog have?

A. **2**
B. 4
C. 6
D. 8

1. Plants with tap roots live better in dry regions because their roots

A. store a lot of water.
B. reach water in great depths.
C. store a lot of food.
D. support the stems better.

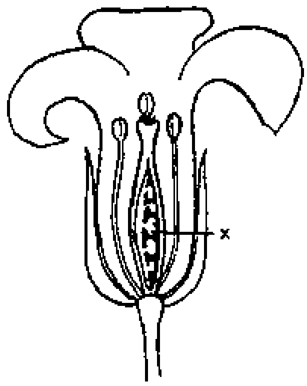
2. Dzambile's area is rainy, without toilets and has unprotected drinking water supply. People in her place are likely to suffer from

A. T.B.
B. diarrhoea.
C. measles.
D. polio.

3. The clouds that usually bring rain are known as

A. cumulus.
B. stratus.
C. cirrus.
D. nimbus.

4. The diagram shows parts of a flower. The part marked X is



A. an ovary.
B. an ovule.
C. a pistil.
D. a stamen.

5. Below are examples of matter except

A. sand.
B. light.
C. water.
D. trees.

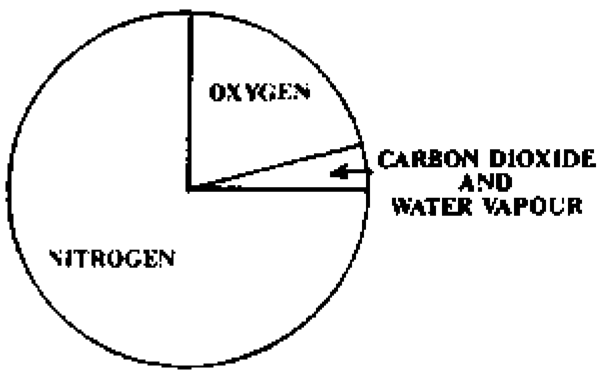
6. The presence of chlorophyll in plants is important for _______________ to take place.

A. respiration.
B. photosynthesis.
C. pollination.
D. transpiration.

7. Which of these is a sexually transmitted disease?

A. Tuberculosis.
B. Bilharzia.
C. Cholera.
D. AIDS.

8. According to the pie chart, which gas takes up more space in the atmosphere?

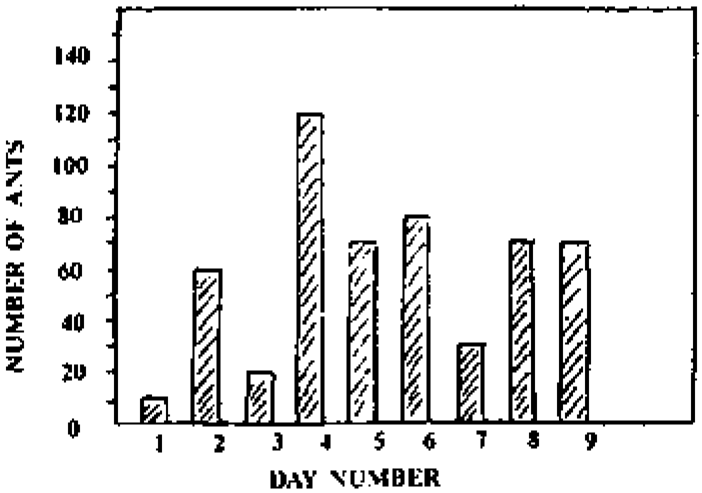


A. Oxygen.
B. Nitrogen.
C. Water vapour.
D. Carbon dioxide.

9. An object with no definite shape and volume is classified under

A. solids.
B. gases.
C. liquids.
D. none of the above.

10. Grade 7 pupils of Vulamehlo Primary School studied and counted ants on a 4 square metre piece of land. They kept the following record for 9 days.



Number of Ants on Different Days

On which days did they find less than 50 ants.

A. Days 1, 3 and 6.
B. Days 3, 5 and 6.
C. Days 1, 3 and 7.
D. Days 2, 4 and 5.

11. The eclipse seen during a cloudless day is known as

A. sunny eclipse.
B. lunar eclipse.
C. solar eclipse.
D. clear eclipse.

12. A large herd of cattle is kept in a small fenced grassy area for six months. Which of the following is **NOT** likely to happen?

A. Most vegetation will be eaten up.
B. Most cattle will be fat.
C. There will be signs of soil erosion.
D. There will be very few grasshoppers.

13. Three processes used in treating water in towns are

A. boiling, washing and irrigation.
B. settling, filtering and using chlorine.
C. mixing, dissolving and evaporating.
D. cleaning, sanding and building canals.

14. A broiler becomes an adult when it is

A. 6 weeks old.
B. 7 weeks old.
C. 8 weeks old.
D. 10 weeks old.

15. Twenty girls slept in a small air-tight room. The following morning, some of them felt very weak and tired. The reason for this condition was

A. the enjoyment of a good night's sleep.
B. tiredness caused by hard work the previous day.
C. the lack of oxygen due to overcrowding.
D. their laziness because they knew work must be done.

16. Many animals feed on grass and parts of trees. Therefore the plants are called

A. consumers.
B. producers.
C. good food.
D. tasty food.

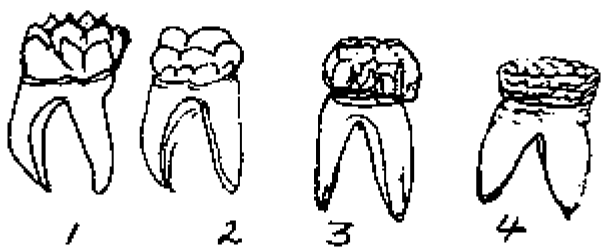
17. Which method of seed dispersal is demonstrated in the diagram. It is seed dispersal by

A. man.
B. animals.
C. wind.
D. water.

18. The main groups of rocks are

A. sedimentary, asbestos and coal.
B. sedimentary, metamorphic and asbestos.
C. sedimentary, coal and igneous.
D. sedimentary, igneous and metamorphic.

19. Look at the molars of animals shown in the diagram. Which molar belongs to a flesh eater?



A. 1.
B. 2.
C. 3.
D. 4.

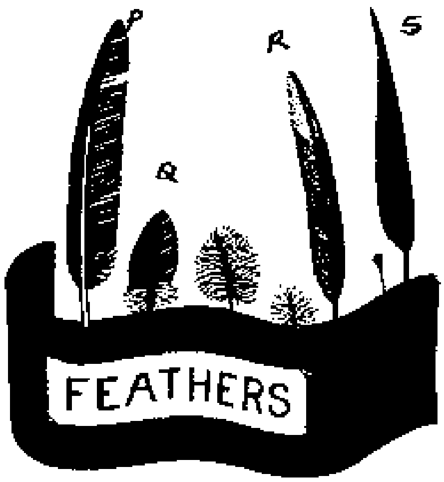
20. Wind speed is measured by a

A. thermometer.
B. barometer.
C. cup anemometer.
D. wind vane.

21. To make a sugar salt solution, dissolve (1) bottle cap of salt and (8) bottle caps of sugar in 1 litre of water. This measurement is

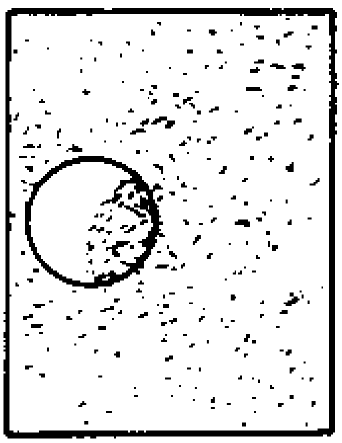
A. sometimes correct.
B. correct.
C. not correct.
D. correct for children only.

22. The (4)cm feather is



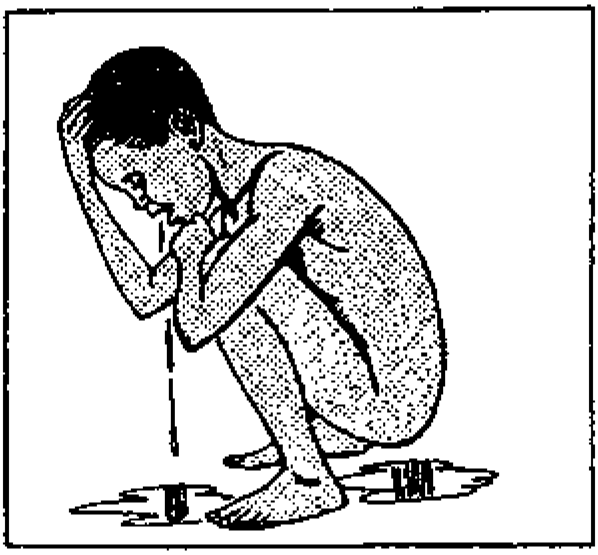
A. P.
B. Q.
C. R.
D. S.

23. It was full moon on a cloudless night when Thozo saw this shape of the moon. We call it



A. lunar eclipse.
B. new moon.
C. solar eclipse.
D. surprise moon.

24. Tentele could be suffering from

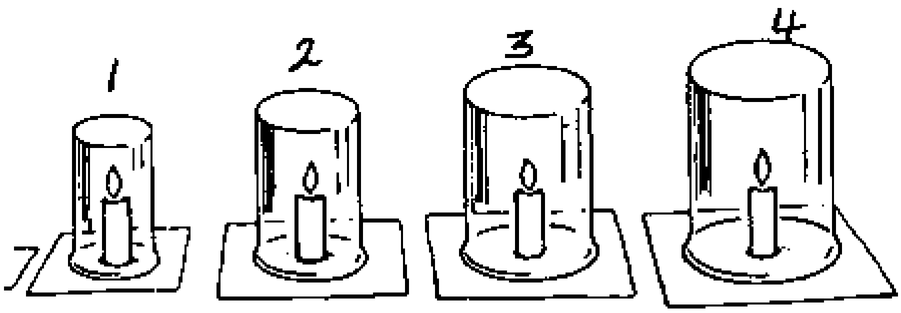


A. whooping cough.
B. headache.
C. cholera.
D. diarrhoea.

25. Some animals like man are omnivores. Which group of food is good for these animals.

A. Beef, chicken and rice.
B. Beef, porridge and lettuce.
C. Beef, pork and chicken.
D. Beef, cabbage and spinach.

26. Candles of the same length are covered with glass jars as shown in the diagram. Which candle will go out first?

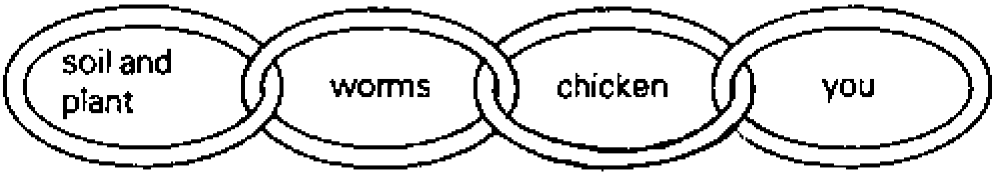


A. 1.
B. 2.
C. 3.
D. 4.

27. A stone weighs 9 grams. Which weights will balance this stone on the scale?

A. 3g 4g 3g.
B. 5g 3g 3g.
C. 4g 4g 3g.
D. 3g 3g 3g.

28. Which is the most important part of this food chain?

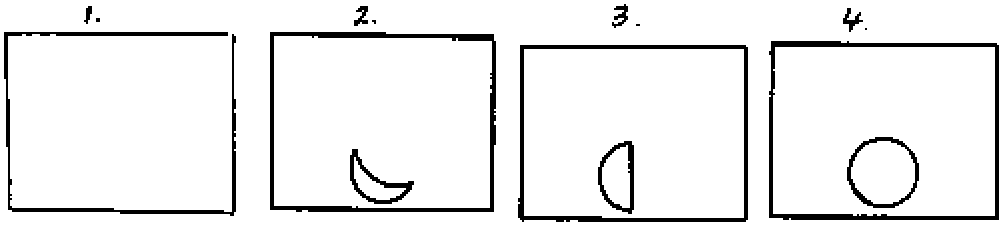


A. Soil and plant.
B. Worms.
C. Chicken.
D. You.

29. To kill bacteria and germs in water we need to add

A. salt.
B. chlorine.
C. ashes.
D. vinegar.

30. Which of the above drawings shows a new moon?



A. 1.
B. 2.
C. 3.
D. 4.

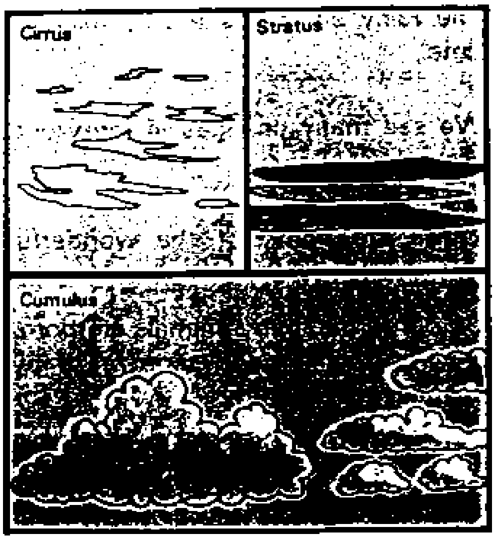
31. Breaking down of food into small pieces within the body is known as

A. respiration.
B. excretion.
C. digestion.
D. grinding.

32. Which statement explains the picture best?

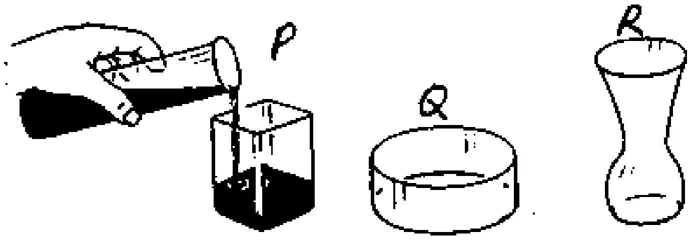
A. The boy is enjoying a good sleep.
B. The man is looking at a pencil.
C. The boy is sick.
D. The doctor is reading the sick boy's temperature.

33. Look at these clouds. Clouds which show clear and fine weather are



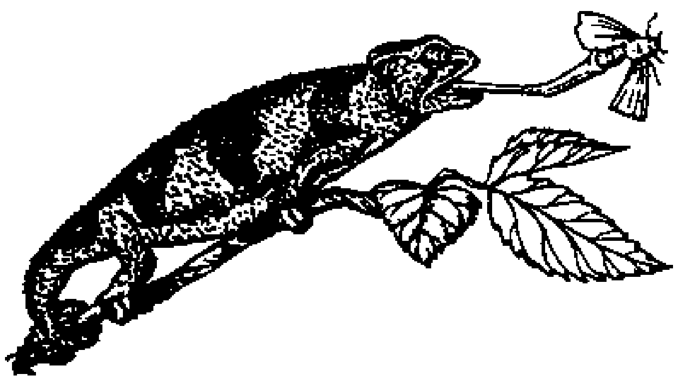
A. stratus.
B. cirrus.
C. cumulus.
D. none of these.

34. The same amount of water fills each of these containers. The container that holds more water is



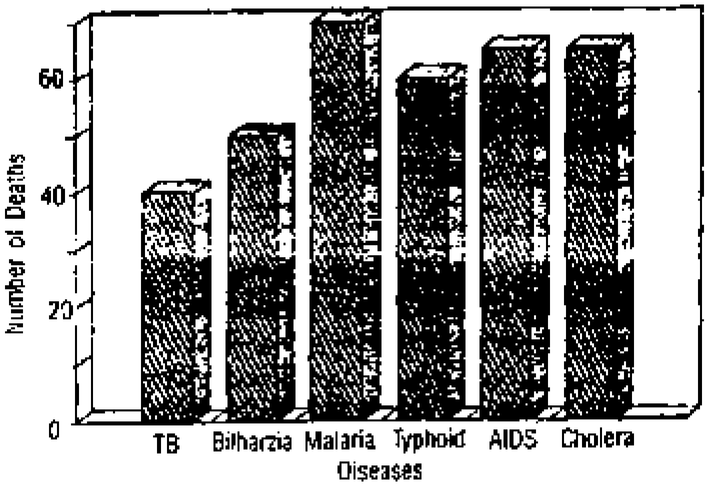
A. P.
B. Q.
C. R.
D. None of these.

35. Study the feeding habit of a chamelion shown on the diagram, This chamelion is.



A. a herbivore.
B. a carnivore.
C. an omnivore.
D. a scavenger.

36. Study the bar graph below which shows the number of people who died from various diseases in country X and answer the question that follows.



Deaths by Type of Disease

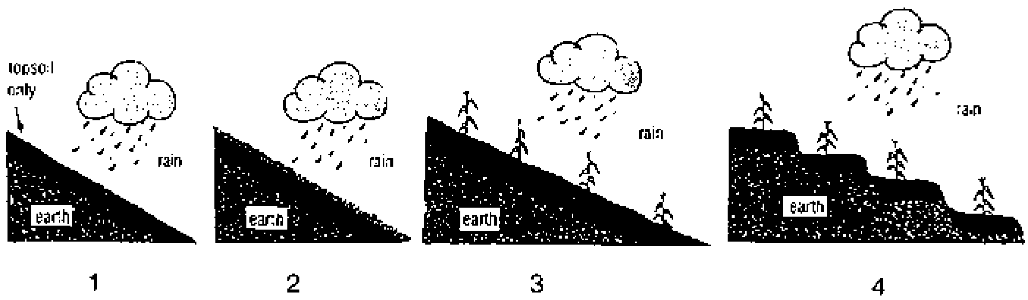
Which of the following is true according to the graph?

A. Cholera and Tuberculosis (TB) killed 120 people.
B. Cholera and Malaria killed 140 people.
C. Malaria and AIDS killed 135 people.
D. Bilharzia and Typhoid killed 120 people.

37. In the water cycle water changes

A. just once.
B. usually two times.
C. over and over.
D. four times.

38. Which piece of earth is likely to develop soil erosion faster?



A. 1.
B. 2.
C. 3.
D. 4.

39. Which of the following can transmit AIDS?

A. Playing together of boys and girls.
B. Swimming in the same pool with sick people.
C. Having sex with someone who has AIDS.
D. Eating with someone who has AIDS.

40. The best description of water is

A. that it is colourless.
B. that it has no definite shape.
C. that it has no smell.
D. all of the above.

SWAZILAND MINISTRY OF EDUCATION

SWAZILAND PRIMARY CERTIFICATE EXAMINATION FOR PRIMARY SCHOOLS, 1994

SCIENCE - PAPER II

FRIDAY, NOVEMBER 18th - 08:30 a.m. - 10:30 a.m.

TIME:	2 HOURS	TOTAL MARKS:	60

CENTRE NUMBER:	

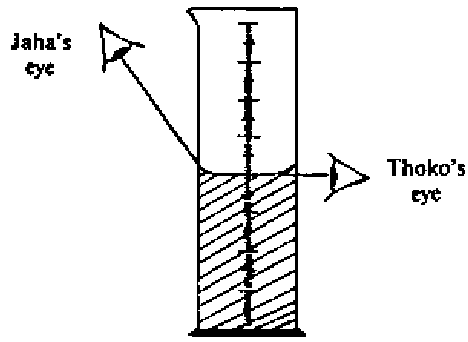
CANDIDATE'S NUMBER	

INSTRUCTIONS:

1. Answer all questions.
2. Write your examination number in the box above.

QUESTION 1

1. Jaha and Thoko read the volume of water in a measuring cylinder as shown below:



a) Who is likely to read the correct volume? _________________________ (1)
b) Give one reason for your answer in (a) _________________________ (1)

2. Write the following names of animals where they belong in the table, (lion, rabbit, mouse, man, grasshopper)

HERBIVORE	CARNIVORE	OMNIVORE

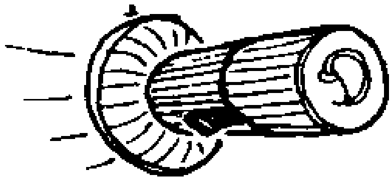
(5)

3. What are the three main food groups that make a balanced diet?

a) ____ (1)
b) ____ (1)
c) ____ (1)

(10)

QUESTION 2



1. The torch above uses electrical energy.

   a) Give two kinds of energy given by a torch.

   (i) ____
   (ii) ____ (2)

   b) Tona switched on the torch but there was no light. Write three possible reasons for this failure.

   i) ____

   ii) ____
   iii) ____ (3)
   iv) What produces electrical energy in a torch?
   ____ (1)

2. Raw water for the Matsapha Water Treatment Plant comes from Lusushwana river.

   a) What are the two substances used to purify this water?

   i) ____
   ii) ____ (2)

   b) Name two kinds of leaves.

   i) ____
   ii) ____ (2)

(10)

QUESTION 3

Look at the following picture very carefully and answer the questions on it.

a) The animal shown spreads disease-germs. What is it?

____ (1)

b) Write two good health habits to be used in this picture?

i) ____
ii) ____ (2)

c) Which two diseases could be spread by this animal?

i) ____
ii) ____ (2)

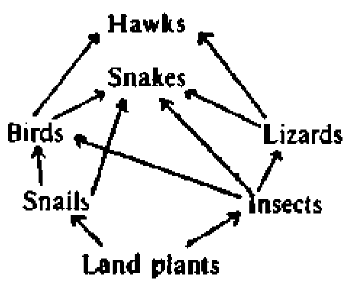
Complete the paragraph below using the following words. Each word is used only once, (loudly, AIDS, live, get, sex and five)

Dzikila was a bad school girl. She had _______________ boy friends and had _______________ with all of them. When the teacher explained about _______________, a disease that a person can _______________ by having sex with many people, she cried _________________

(5)

(10)

QUESTION 4



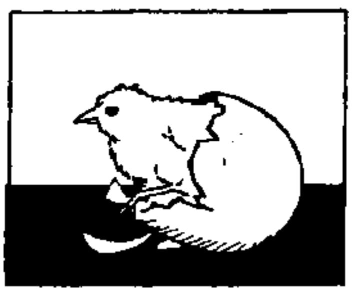
1. This diagram has many food chains. One of them is:

Land plant → snails → Birds → Snakes

Make three other food chains from this diagram?

a) ____ (2)
b) ____ (2)
c) ____ (2)
d) The producer in these food chains is _________________________ (1)

2. The drawing below shows a hatching chick.



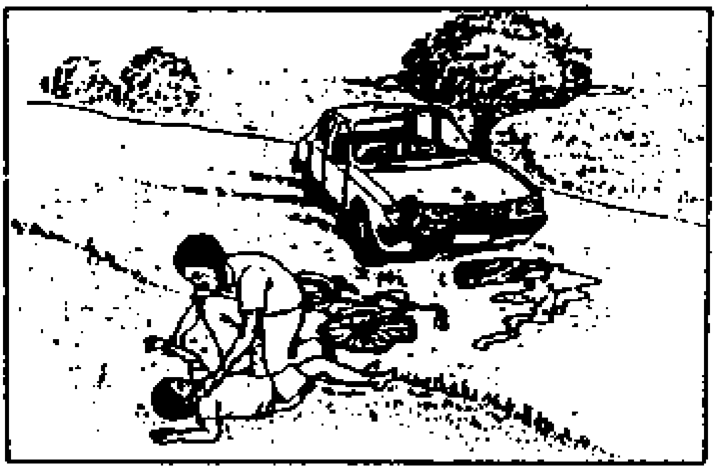
a) Fertilization in chickens takes place ___________________________ (1)
b) The time when the hen sits on its eggs is called the ______________________________ period (1)

3. Name one waste substance excreted through the skin ________________ (1)

(10)

QUESTION 5

1. Study the diagram below and answer the following questions.



a) What has happened in this diagram?
____ (1)
b) Write two good health habits that have not been kept.

i) ____
____ (2)
ii) ____
____ (2)

2.

a) What part of air does the fire need to keep burning?
____
b) Which part of the air that can be used to put the fire out?
____ (2)

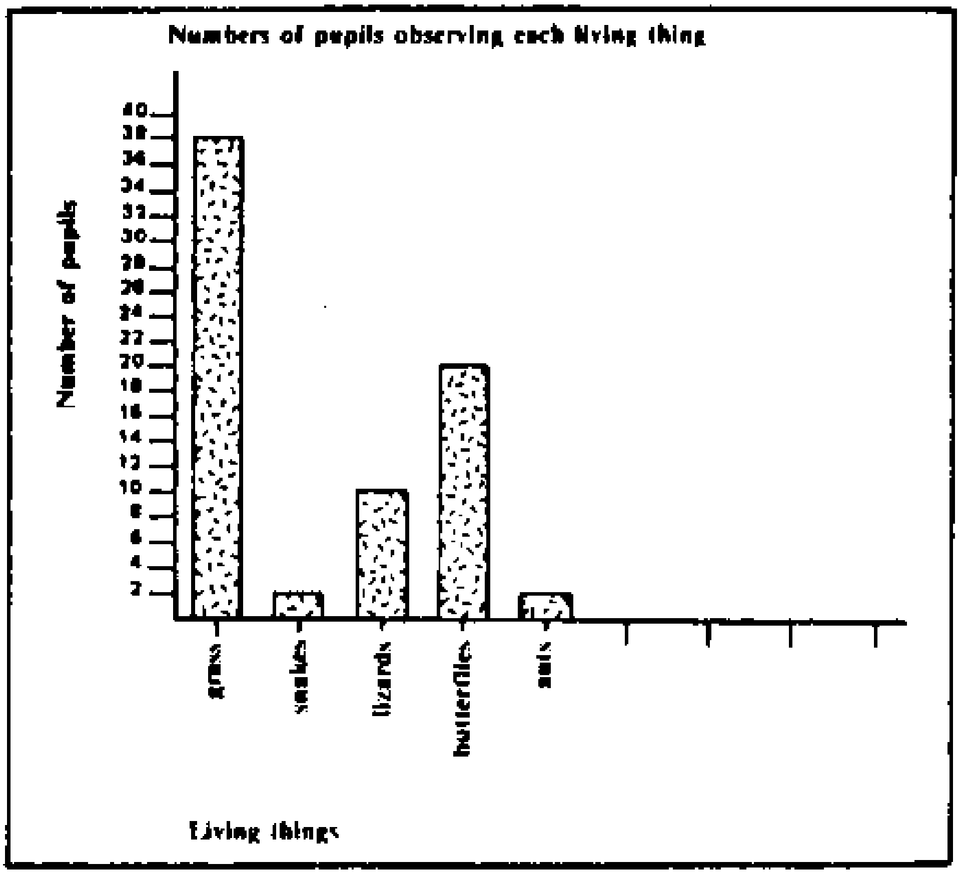
3. Write three functions of roots.

i) ____
ii) ____
iii) ____ (3)

(10)

QUESTION 6

1. Grade 6 pupils drew this bar graph after their field trip. Use it to answer questions (a) to (e) below.



a) What were the two kinds of living things observed?
____ (2)

b) Which animals were seen by few pupils?
____ (1)

c) Which animals were most common in this area?
____ (1)

d) How many pupils saw animals? Show how you got the answer.
____
____ (3)

e) Give two examples how living things depend on each other in this area

i) ____
ii) ____ (2)

The study of living things in their natural homes is called

____ (1)

(10)

3.7.4 Swaziland Primary Certificate Examination 1993 - Science/Paper I & II

SWAZILAND MINISTRY OF EDUCATION

SWAZILAND PRIMARY CERTIFICATE EXAMINATION, 1993

SCIENCE - PAPER I

TUESDAY, NOVEMBER 23rd - 08:30 a.m. - 10:00 a.m.

TIME:	**1½ HOURS**	**TOTAL MARKS:**	**60**

CENTRE NUMBER:	

CANDIDATE'S NUMBER	

INSTRUCTIONS:

1. Answer all questions.

2. Each question has four (4) answers to choose from but only one of them is correct. Circle (0) the letter of the correct answers as shown in the example below.

3. Do not circle more than one answer. If you make a mistake cross (X) your first choice and then circle the answer you have finally chosen.

4. Use ink or ball pen.

Example

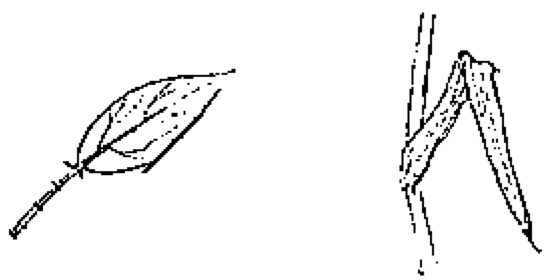
How many eyes does a frog have?

A. 4
(B.) 2
C. 3
D. None

1. Which of these is **not** a characteristic of living things?

A. Movement
B. Excretion
C. Photosynthesis
D. Respiration

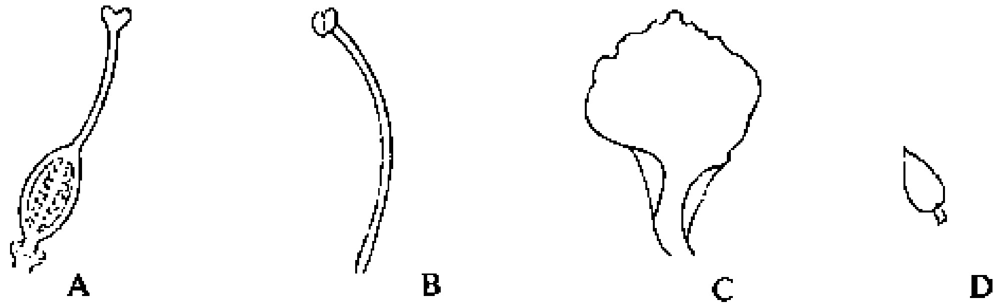
2. Study these two types of leaves below.



The difference between these leaves is that one

A. is edible and the other is not edible
B. has parallel veins and the other is net veined.
C. has been picked from a mango tree and the other has been picked from an orange tree.
D. one respires and the other does not.

3. Look at these parts of a flower and answer the question below.

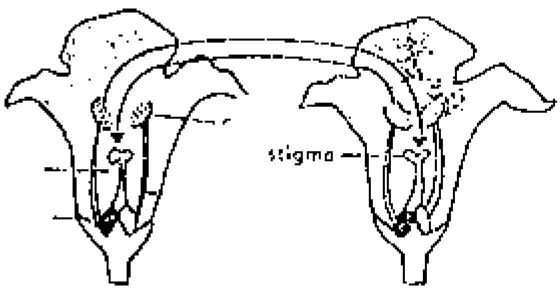


Which of these parts represents the male part of a flower?

4. Animals get more energy when they

A. sleep
B. breathe
C. eat
D. walk

5. Study this diagram and answer the question below.



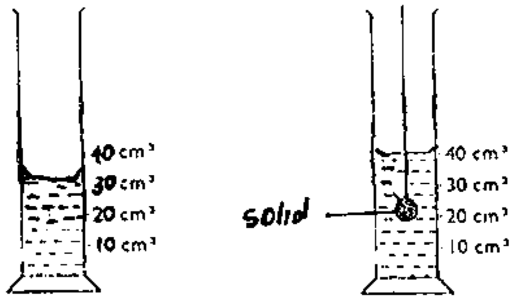
Describe the process that is taking place in this diagram.

A. Self Pollination
B. Cross Pollination
C. Seed dispersal
D. Fertilisation

6. The time taken by a simple pendulum to complete one swing depends on the

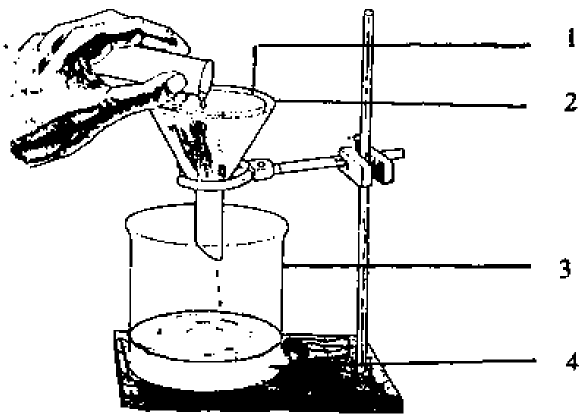
A. length of the pendulum
B. mass of its weight
C. shape of its weight
D. size of its weight

7. The volume of the solid below is



A. $10cm^3$
B. $30cm^3$
C. $40cm^3$
D. $55cm^3$

8. Look at the diagram below and answer questions 8 and 9.



The above diagram shows the process of

A. filtration
B. evaporation
C. condensation
D. distillation

9. Which number in the diagram shows a filtrate?

A. 1
B. 2
C. 3
D. 4

10. Which of the following is true about magnets?

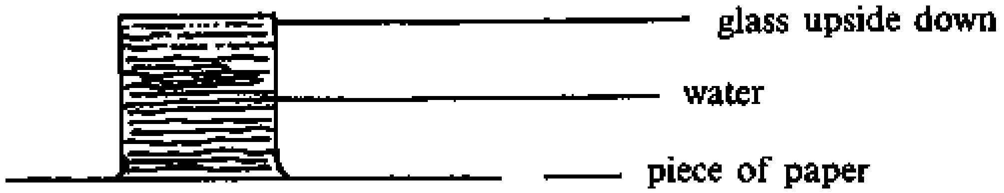
1. Like poles repel
2. Like poles attract
3. Unlike poles attract
4. Unlike poles repel

A. 1 and 3
B. 2 and 3
C. 1, 2 and 3
D. 2 and 4

11. An iron nail is not a magnet because it

A. will rust
B. does not attract another iron nail
C. can be attracted by a magnet
D. cannot be attracted by a magnet.

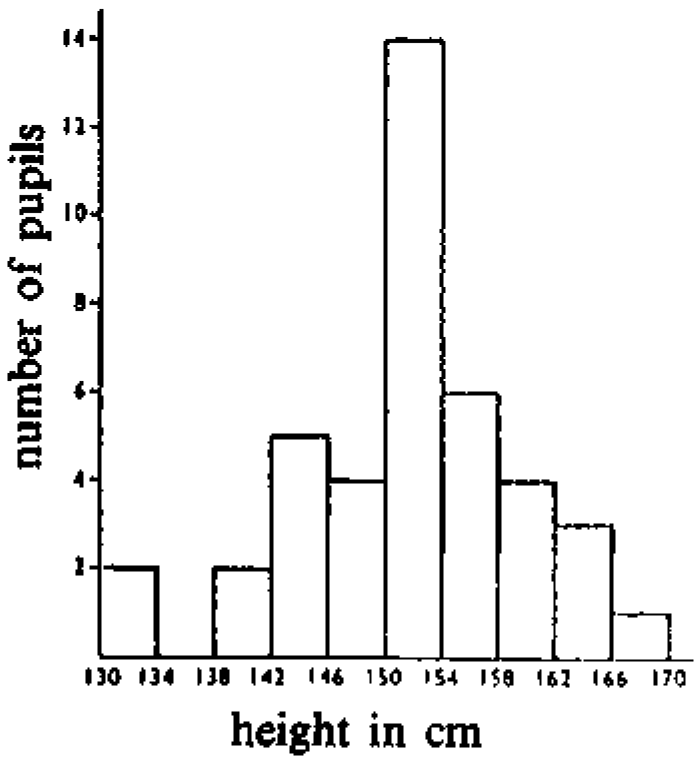
12. A piece of paper stays firmly under an overturned glass full of water that is held up without spilling any drop of water.



This is because

A. it is wet
B. the paper is smooth
C. it is sticky
D. of air pressure.

13. The graph below shows the heights of the pupils in a class.



How many pupils are taller than 154cms?

A. 3 pupils
B. 4 pupils
C. 6 pupils
D. 14 pupils

14. What type of food are the following; bread, rice, potatoes, sugar and wheat?

A. Vitamins
B. Proteins
C. Carbohydrates
D. Fats

15. Which of the following stages represents the correct order of the life cycle of an insect?

A. Pupa - adult - larva - egg
B. Egg - pupa - larva - adult
C. Pupa - larva - egg - adult
D. Egg - larva - pupa - adult

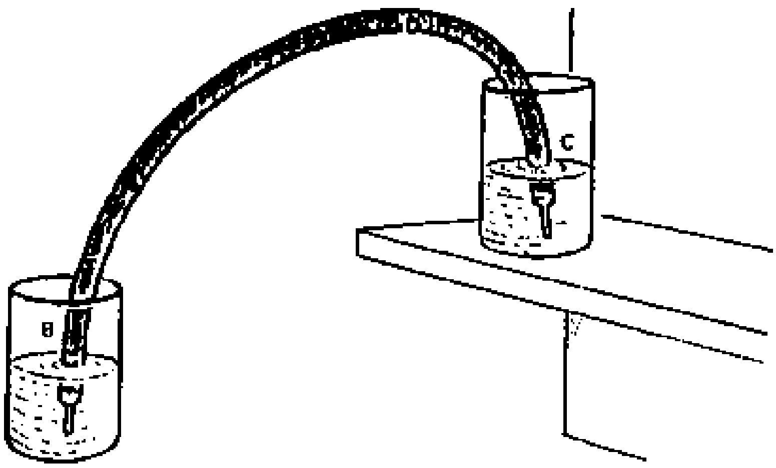
16. The smallest part of matter is

A. a compound
B. an atom
C. a mixture
D. an element

17. Pick out a non metal

A. Carbon
B. Iron
C. Copper
D. Gold

18. A siphon is used to suck out water from one container to another.



It works by

A. using the force of gravity
B. water pressure
C. air pressure
D. expansion of solids.

19. For photosynthesis to take place plants require certain conditions. Pick out one that is **not** necessary.

A. Sunlight
B. Oxygen
C. Carbon dioxide
D. Chlorophyll

20. All living things are made up of

A. meat
B. chlorophyll
C. organs
D. cells

21 Heat travels from one end of an iron rod to the other by

A. convection
B. absorption
C. conduction
D. radiation

22. Sabelo's cow died immediately after giving birth. What must he feed the calf with?

A. Growing mash
B. salt licks
C. milk
D. sugar solution

23 An example of a substance which is alkaline is

A. vinegar
B. lemon juice
C. soap solution
D. sugar solution

24. Water is commonly used as a

A. solute
B. solvent
C. solution
D. mixture

25. Mbokodvo is stung by a bee. Its sting is alkaline. Therefore he has to treat the wound with

A. water
B. soap solution
C. saliva
D. vinegar

26. Sometimes we feel uncomfortable after eating. This may be due to too much

A. water in the body
B. salt in the body
C. acid in the stomach
D. food in the stomach

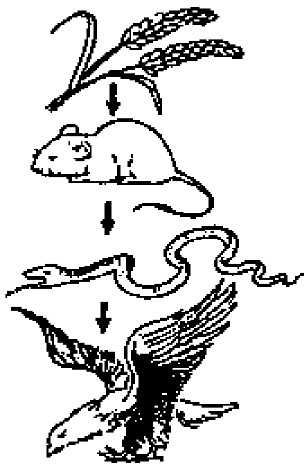
27. This kind of tooth is a

A. molar
B. incisor
C. canine
D. temporal tooth

28. The animal that feeds on both plants and animals is

A. a carnivore
B. a vulture
C. an omnivore
D. a herbivore

For questions 29 to 32 refer to the diagram below



29. This is an example of a

A. food cycle
B. food chain
C. food web
D. food way

30. The producer is a

A. mouse
B. plant
C. snake
D. eagle

31. The primary consumer is the

A. plant
B. snake
C. mouse
D. eagle

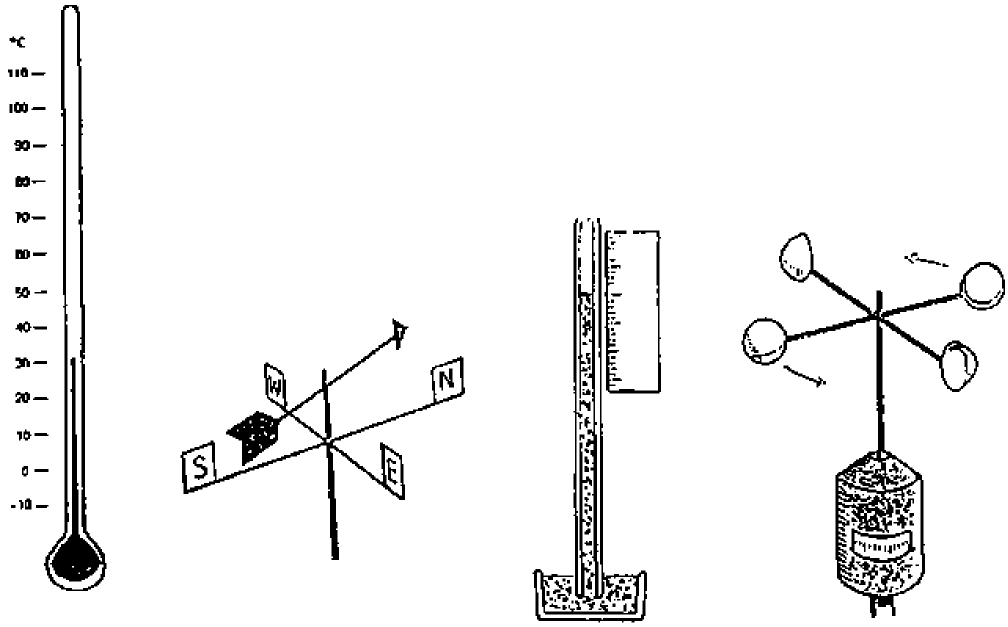
32 The secondary consumer is the

A. plant
B. mouse
C. snake
D. eagle

33. Which type of soil is best for growing plants?

A. Gravel
B. Clay
C. Sandy
D. Loam

34. Pick the instrument that is used to measure temperature.



A B C D

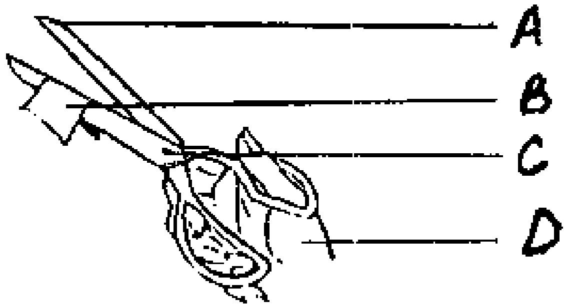
35. Lunga has a running nose, feels hot, and keeps coughing and sneezing. Probably she has

A. dysentery
B. AIDS
C. a common cold
D. diarrhoea

36. A chameleon survives better on land. What adaptations does it have to survive? It

A. can be easily seen
B. changes its colour to that similar to the place where it is.
C. can move very fast to run away from its enemies.
D. feeds on fruits.

37. This is an example of a simple machine. Find its fulcrum.



38. To keep fit one has to

A. read a lot
B. do some exercises
C. eat and sleep
D. consult a witch doctor.

39. Which one of the following factors is most needed by germinating seeds?

A. Water
B. Warmth
C. Soil
D. Light

40. If Nomsa has AIDS we should

A. not play with her
B. be afraid of her
C. treat her like one of us
D. not shake hands with her

SWAZILAND MINISTRY OF EDUCATION

SWAZILAND PRIMARY CERTIFICATE EXAMINATION FOR PRIMARY SCHOOLS, 1993

SCIENCE - PAPER II

WEDNESDAY, NOVEMBER 24th - 08:30 a.m. - 10:30 a.m.

TIME:	**2 HOURS**	**TOTAL MARKS:**	**60**

CENTRE NUMBER:	

CANDIDATE'S NUMBER	

INSTRUCTIONS:

1. Answer all questions.
2. Write answers in the spaces provided
3. Use ink or ball point pen

QUESTION 2

(a) Name three types of rocks.

____

____ (3)

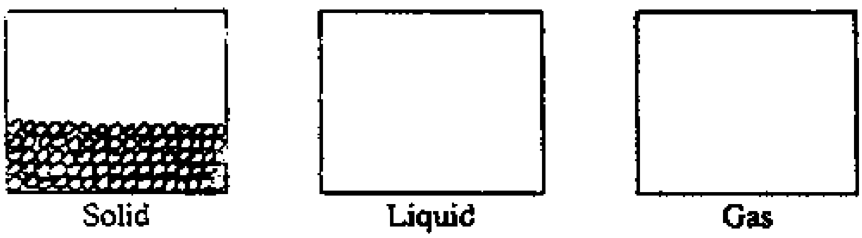
(b) Which type of rock is common in Swaziland?

____ (1)

(c) Give two uses of water

____ (2)

(d) i In the boxes provided draw the particles that show water in a liquid and gaseous state. The solid state has been done for you.



(2)

ii Give two conditions necessary for evaporation to take place.

____ (2)

(10)

C. Fill in the right word that describes the type of cloud from this list: cumulus, nimbus and cirrus.

DESCRIPTION OF CLOUDS	TYPE OF CLOUD
i Featherly, fibre-like	
ii Dark layers may contain rain	
iii Heaps separated by blue sky	

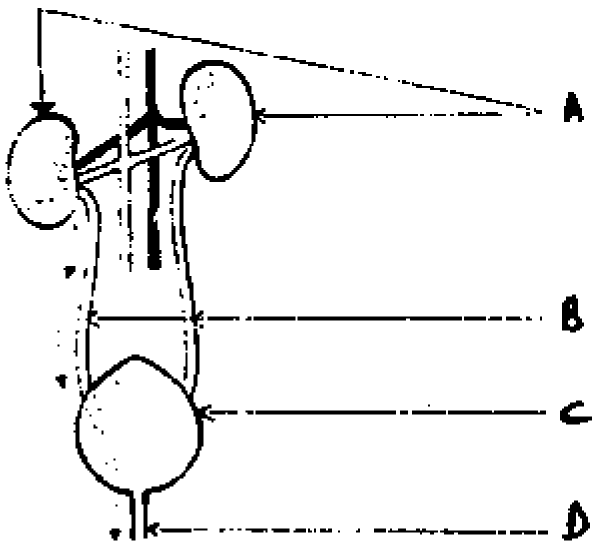
(3)

D. What do you call plants and animals that have decayed and added to the soil to make it fertile?_______________________________________(1)

(10)

QUESTION 4

(a) Study this diagram of the urinary system and label parts A, B, C and D.



(4)

(b) What is excretion?

____
____ (3)

(c) Name any two natural resources.

____ (2)

(d) What is excreted by the lungs?

____ (1)

(10)

QUESTION 6

a) Name two types of roots.

____

____ (2)

(b) State two main functions of roots.

____

____ (2)

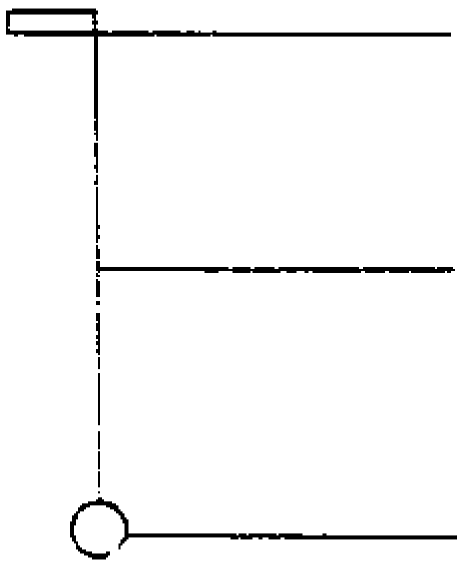
(c) A fully developed ovary is called a ______________________________ (1)

(d) Name two processes that take place in a leaf.

____

____ (2)

(e) Label these parts of a pendulum.



(3)

(10)

3.7.5. Swaziland Primary Certificate Examination 1994 - Agriculture Paper

MINISTRY OF EDUCATION
SWAZILAND PRIMARY CERTIFICATE
FINAL EXAMINATION 1994

AGRICULTURE

FRIDAY, NOVEMBER 18th - 11:00 a.m. - 12:30 p.m.

TIME:	1 HOUR 30 MINUTES	TOTAL MARKS:	100

CANDIDATE'S NUMBER:	

SCORE:	

SECTION I

Marks (30)

TEST INSTRUCTIONS FOR STUDENTS:

1. Read all questions carefully before you answer.
2. Five possible answers are given for each question, **ONLY ONE** is correct.
3. Choose the best answer and put a cross (x) over the letter on the **SEPARATE** answer sheet provided.

EXAMPLE:

How many legs does a chicken have?

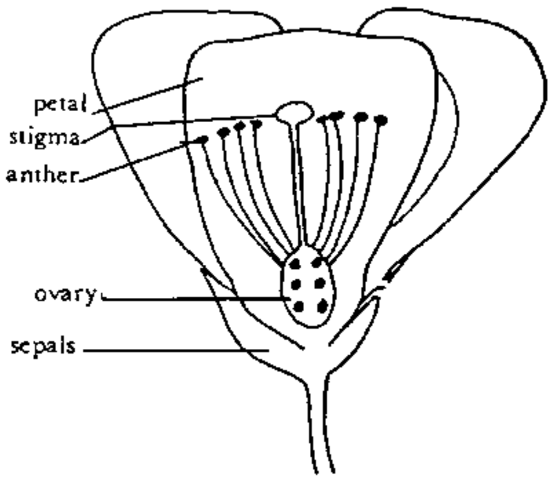
A. Four
B. Two
C. Thirty Two
D. Ten
E. Eight

SECTION I

1. Look carefully at the flower below. Then answer the question that follow.

Where do seeds develop?

A. Ovary
B. Petal
C. Anther
D. Sepal
E. Stigma



2. Where do cutworms damage a seedling?

A. At leaf level
B. At shoot level
C. At root level
D. Below the soil surface
E. At the soil surface

3. Which soil particles make the best soil structure?

A. Silt - Clay - Sand
B. Loam - Sand - Water
C. Sand - Air - Water
D. Air - Clay - Silt

4. What kind of soil is a "heavy soil"?

A. One with too much air
B. One with a 10kg weight
C. One with too much clay
D. One with a 100kg weight
E. One with too much water

5. Why do plants need water?

A. to spread their roots wide
B. to make their food
C. to die peacefully
D. to spread their leaves
E. to produce strong stems

6. A soil pH of 5.8 is good for which type of crops?

A. all legumes
B. all vegetables
C. all fruittrees
D. all trees
E. all grasses

7. Which is the most common problem of soil erosion in Swaziland?

A. muddy erosion
B. wind erosion
C. surface erosion
D. silt erosion
E. water erosion

8. What is the best way of controlling soil erosion?

A. Planting up and down the slope like they do in Malkerns
B. Overstocking
C. Grass burning
D. Cattle tracks
E. Keep the soil covered completely.

9. Which company below produces sugar?

A. Mpaka Coal Mine
B. Shiselweni Forest Company
C. Ubombo Ranches
D. Usuthu Pulp Company
E. Swaziland Fruit Canners

10. During a sugar-processing process, why is lime mixed with the juice?

A. to speed up the process
B. to stop the process
C. to remove unwanted materials
D. to make it less acidic
E. to make it taste better

11. Which climate do citrus trees grow best in?

A. a very cold climate
B. a semi-desert climate
C. a cold climate
D. a warm climate
E. a dry climate

12. Look carefully at the picture below. Then answer the questions below it.

Why does the pineapple worker cover her hands, feet and legs?

A. to protect herself from injury by the spines
B. to protect herself from injury by the sun
C. to protect herself from injury by the stem
D. to protect herself from injury by the pineapple fruit
E. to protect herself from broken bottles.

13. Spot a produce from cotton seed below.

A. jelly
B. grease
C. tar
D. oil
E. paraffin

14. Why are trees planted mostly in the Highveld?

A. Because it is hot
B. Because they need a lot of rain
C. Because it is cold
D. Because it is usually bright and sunny
E. Because it is dry

15. Which forest company in Swaziland produces gum mainly for mining?

A. Tonkwane Estates
B. Swaziland Plantations
C. Usuthu Forest
D. Bhunya
E. Shiselweni Forest

16. A ripe maize seed has a _________ patch

A. round
B. blue
C. square
D. red
E. black

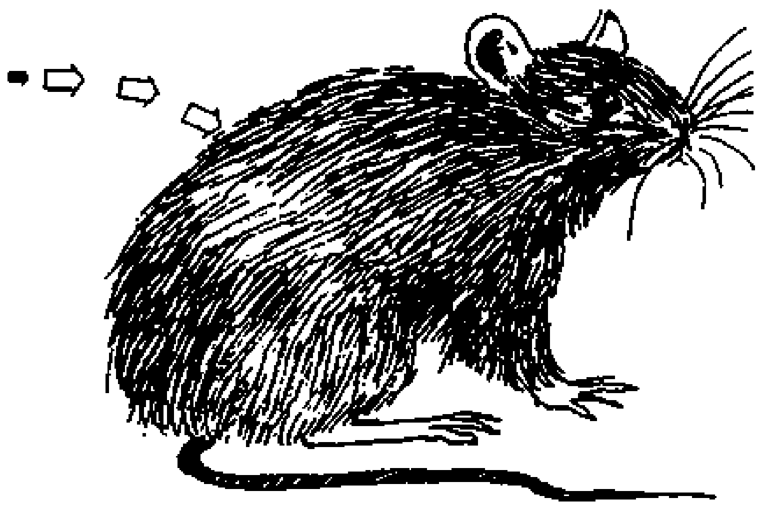
17. When are potatoes harvested?

A. One to two months after planting
B. When the tops are dry
C. When the flowers develop
D. 6 Months after planting
E. 3 months after planting

18. Drying crops before storing helps to reduce losses caused by __________

A. rats and mice
B. cattle and donkeys
C. parasites
D. pests and diseases
E. man

19. How can you protect your maize crib from



from damaging your maize cobs?

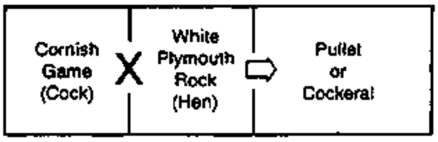
A. Kill them all
B. Guard the crops
C. Use DDT
D. Use jeyes fluid
E. Use rat baffles

20. Which, is a disadvantage of keeping chickens in an extensive system?

A. Low produce
B. Tasty meat
C. Healthy chickens
D. Good looking chickens
E. Fast growth

21. **Look carefully at the illustration on the right.**

Then answer the question.



Which is the parent stock in the illustration?

A. pullet and cockerel
B. Cock, cockerel and hen
C. White Plymouth hen and Cornish Game Cock
D. Both hen and cockerel
E. White Plymouth Rock

22. How can you recognize a chicken with Newcastle disease?

A. Feathers are rough
B. Wings become paralysed
C. The bird starts shivering
D. Diarrhoea with blood
E. Legs become paralysed

23. Why is ventilation important in a broiler house?

A. it helps to keep the birds cool
B. it provides heat to the chickens
C. it provides enough water to broilers
D. it prevents birds from getting water
E. it stops birds from getting air

24. Which of the following cattle breeds has an African origin?

A. Brahman
B. Jersey
C. Simmentaler
D. Afrikander
E. Friesian

25. Which of the following is a milk product?

A. Orange Marmalade
B. Quava juice
C. Margarine
D. Holsum
E. Yoghurt

26. Hay is made just _________ the grass flowers.

A. when
B. after
C. on
D. before
E. in

27. A large grazing area where cattle put on weight is a __________

A. paddock
B. breeding station
C. kraal
D. fattening ranch
E. Bull Exchange Scheme

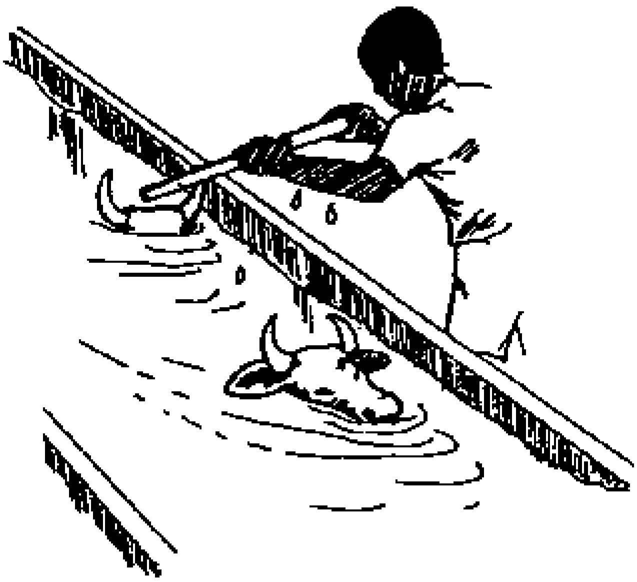
28. Which of the following diseases can be passed on from cattle to humans?

A. Mereks
B. Blackleg
C. Contagious abortion
D. Newcastle
E. Anthrax

29. A tick is a __________

A. harmful parasite
B. germ
C. helpful insect
D. virus
E. internal parasite

30. Cattle are being dipped by this method.



Why are they dipped?

A. to kill ticks
B. to make them as fat as possible
C. to remove their fur (hair)
D. to make them look nice
E. to feed ticks

SECTION II

Read all the questions carefully before you begin. Answer all questions on the spaces provided.

QUESTION 1

Use the following words to complete the food chain below. Use arrows where necessary.

Chicken, Man,	Grass, Grashopper,

(7)

QUESTION 2

Match the word / statements to the ones in the blocks on the right. Then **write only the letter** of the correct one on the space provided on the far right.

i) Burnt before harvesting	**A. Pumpkinfly**	____________
ii) Sunflower	**B. Rumevite**	____________
iii) Stocklick	**C. Sugarcane**	____________
iv) Keeps the chicks warm	**D. Backs of flower turn yellow and hard**	____________
v) Attacks flowers, and fruits fail to set	**E. Brooder**	____________

(5)

QUESTION 3

The chart below shows how a spinach plant grew from the 1st week of emergence to 12 weeks. The plant was measured once every week. **Study it carefully,** and then answer the questions below.

Week	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**
Height of plant (cm)	**5**	**8**	**9**	**10**	**10**	**10**	**15**	**18**	**22**	**30**	**38**	**47**

a) By how many centimetres did the spinach grow between week 1 and week 10.
____

b) By how much did it grow between week 4 and week 6?
____

c) What could be the reason for it maintaining the same height between week 4 and 6?
____ (6)

QUESTION 4

Fill in the missing words in the passage below. The words are provided for you above the passage.

Kill; Lime; Prepare; Air; Fork; Compost; Spade; Roots; Dig

To cultivate the land means to ___________________ it for planting.

We ___________________ the soil to ___________________ weeds; to mix ___________________, and ___________________ with it, to put ___________________ back into the soil, and make it easier for plant ___________________ to spread. Tools used to cultivate the soil are ___________________, hoe, ___________________ and rake.

(9)

QUESTION 5

What is another name for the grass "Eragrostis Curvula"?

____ (2)

QUESTION 6

Complete the crop rotation for year 4 below.

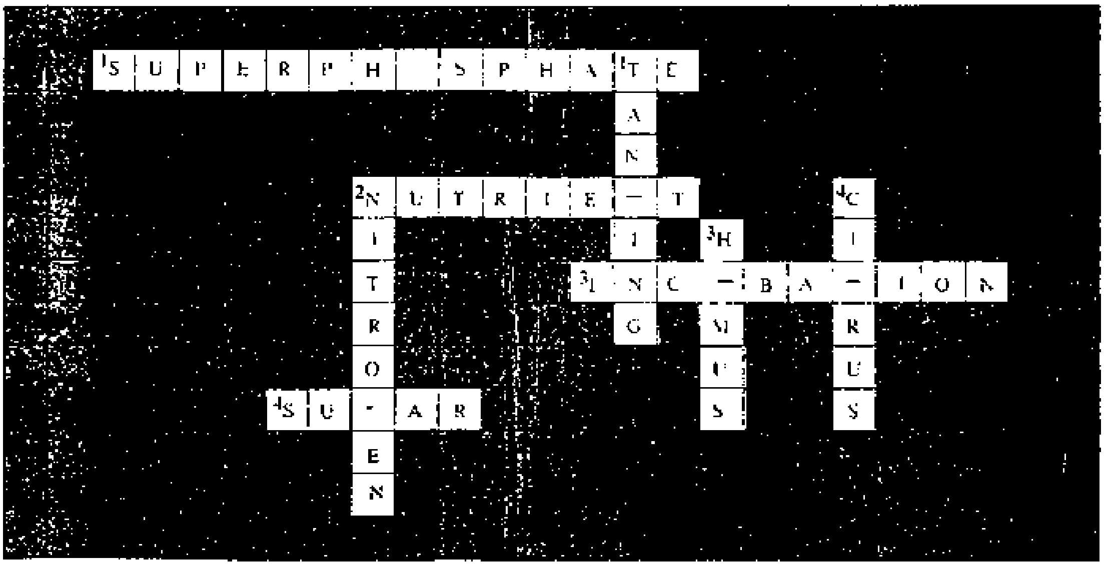
Plot	Year 1	Year 2	Year 3	Year 4
A	Grass	Beans	Maize	
B	Potatoes	Grass	Beans	
C	Maize	Potatoes	Grass	
D	Beans	Maize	Potatoes	

(4)

QUESTION 7: CROSS WORD PUZZLE

Use the statement that is meant by the phrase to solve the puzzle. Fill in the correct **letter** in the blank to complete the word.

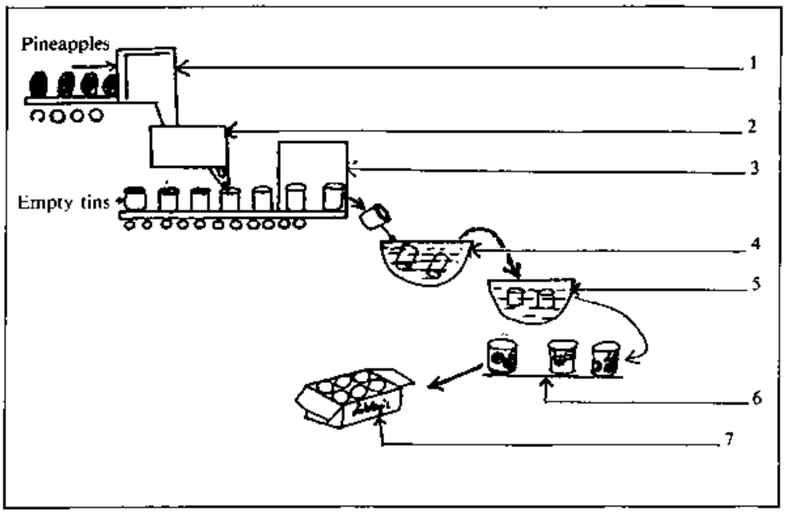
ACROSS	DOWN
1. A good fertilizer for tomatoes.	1. Treating skins for leather.
2. Potassium is an example of a major ________.	2. Increases leaf growth.
3. Hen sitting on eggs to warm them.	3. _________ is decayed plant and animal materials.
4. Export brings in the most money into Swaziland.	4. Oranges and Naartjies.



(9)

QUESTION 8

Look carefully at the illustration of a pineapple processing. Write in the missing stages 1 to 7.



(7)

QUESTION 9

This Prevocational Agriculture student from St. Phillips High School sold produce from his crop project at home

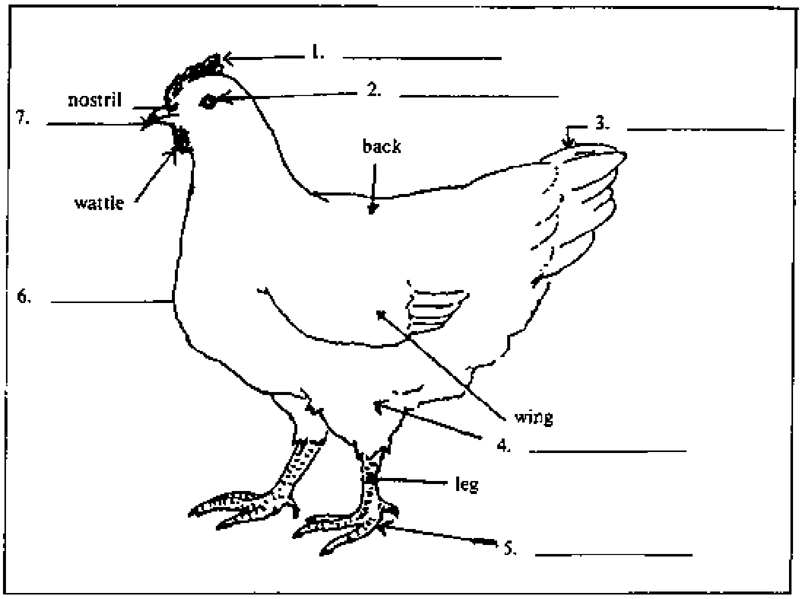
4 bales cotton sold for E202,00 per bale
3 bags sorghum for E40,00 per bag
2 Magogogo beans for E60,00 each

Item	E	c
TOTAL		
If he spend E528,00 buying all his inputs		
i) How much money did he make?		
ii) Which crop was sold for the lowest price per unit?		
iii) How much profit / loss did he make?		

(10)

QUESTION 10

On the picture of a chicken below **label the parts marked 1 to 7**



(7)

QUESTION 11

What did you do to keep the litter dry in your broiler house?

____
____ (2)

QUESTION 12

Why are Swaziland's cattle not very good for meat?

____
____ (2)

SECTION I

3.7.6. Swaziland Primary Certificate Examination 1993 - Agriculture Paper

MINISTRY OF EDUCATION

SWAZILAND PRIMARY CERTIFICATE
FINAL EXAMINATION 1993

AGRICULTURE

WEDNESDAY, NOVEMBER 24th - 11:00 a.m. - 12:30 p.m.

TIME:	1 HOUR 30 MINUTES	TOTAL MARKS:	100

CANDIDATE'S NUMBER:	

SCORE:	

SECTION I

TEST INSTRUCTIONS FOR STUDENTS:

1. Read all questions carefully before you answer.
2. Five possible answers are given for each question, **ONLY ONE** is correct.
3. Choose the best answer, then make a "cross **X**" on the correct letter on the answer sheet. The cross must fill the whole square.

EXAMPLE:

How many legs does a chicken have?

A. Four
B. Two
C. Thirty Two
D. Ten
E. Eight - (See answer sheet for your answer)

SECTION I

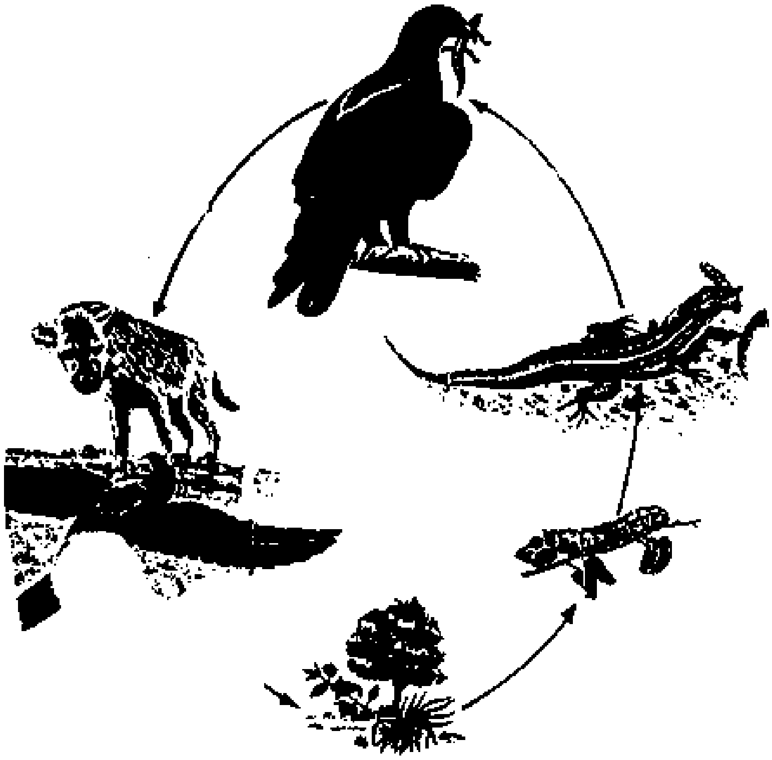
1. When you eat an onion bulb, what part of a plant do you eat?

A. fruit
B. stem
C. leaf
D. root
E. flower

2. Witchweed is an example of a ____________

A. pest
B. poisonous plant
C. parasite
D. poison
E. helpful plant

3. Look carefully at the picture. What is the right food chain for it?



A. Black eagle ⇒ plant ⇒ worm ⇒ lizard ⇒ hyena
B. Plant ⇒ lizard ⇒ worm ⇒ hyena ⇒ black eagle
C. Hyena ⇒ black eagle ⇒ worm ⇒ lizard ⇒ plant
D. Lizard ⇒ hyena ⇒ black eagle ⇒ plant ⇒ worm
E. Plant ⇒ worm ⇒ lizard ⇒ black eagle ⇒ hyena

4. A wet soil is damaged when you

A. stand on it
B. dig it
C. clean the area
D. prepare planting lines
E. make a seedbed

5. Breaking the soil clods down to the small pieces is the same as preparing ___________

A. a fine tilth
B. raking
C. digging it
D. topdressing
E. capping

6. If you grew beetroot at home, what was the space between the plants in a row?

A. 30cm
B. 10cm
C. 15cm
D. 5cm
E. 20cm

7. How deep should spinach seeds be planted?

A. 3.5cm
B. 1.2cm
C. 1.5cm
D. 2.5cm
E. 0.5cm

8. Which one is a function of a handfork?

A. harrowing
B. removing weeds
C. thinning
D. marking straight lines
E. digging

9. To prevent this disease in tomatoes, we used a dithane- copper oxychloride mixture. Which one is it?

A. rust
B. late blight
C. downey mildew
D. black rot
E. streak

10. How much dipterex 95% WP do you use to spray cabbages with 5 litres of water? (MB = matchbox)

A. 4MB
B. 3MB
C. 5MB
D. 2½MB
E. 3½MB

11. In clay soil, pore space is ____________

A. thin
B. flat
C. large
D. good
E. small

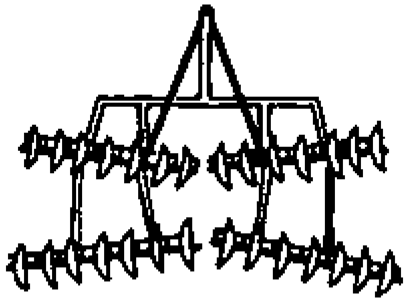
12. What does humus add to a soil?

A. water
B. air
C. soil pests
D. nutrients
E. poisons

13. Which of the following damages plant cover if it is done wrong?

A. mulching
B. grass burning
C. rotation of crops
D. cattle tracks
E. soil erosion

14. Look carefully at the picture of a tool. What is the use of the tool?



A. breaking down soil lumps
B. ploughing
C. marking straight rows
D. planting
E. weeding

15. From which part of a plant do new potato tubers grow?

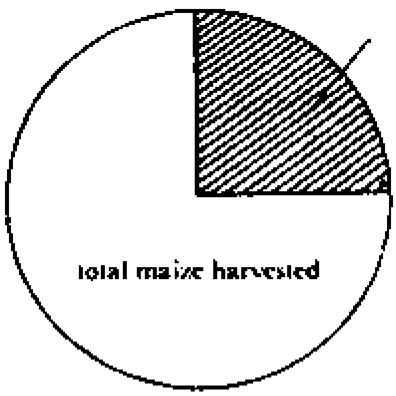
A. root
B. leaves
C. stem
D. flower
E. fruit

16. How long should sweetpotato cuttings be at planting?

A. 25cm
B. 40cm
C. 30cm
D. 20cm
E. 65cm

17. Look carefully at the diagram and answer the question. How much losses of crops due to poor storage in Swaziland?

A. 33%
B. 50%
C. 25%
D. 20%
E. 10%



18. When beans inside a pod are hard. What should be done to avoid damage to them?

A. thin them
B. stake them
C. water them
D. harvest them
E. dry them

19. If the nuts inside a pod rattle then they ____________

A. are still very wet
B. are just wet
C. are dry
D. are broken
E. are rotten

20. Which of the following is **not** a sign of harvesting sunflower?

A. when the tops have died
B. when the plant is dry
C. when seeds begin to fall down
D. when the back of the flower turns yellow
E. when the flower is yellow and hard

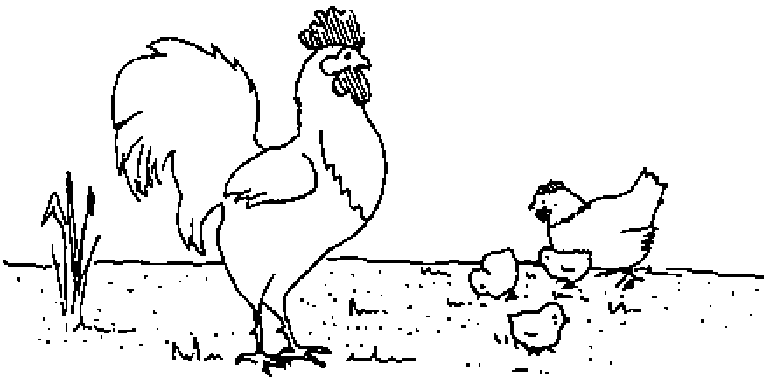
21. A sixth grade student at Nokwane Primary School obtained profit from the following crops last year.

E620,00 from 2 ha of pumpkin
E260,00 from 2 ha of groundnuts
E480,00 from 4 ha of dry beans
E1 500,00 from 2 ha of sugarcane

Which of the crops gave her the least profit per hectare?

A. sugarcane
B. groundnuts
C. pumpkins
D. dry beans
E. groundnuts and sugarcane

22. The picture below shows one way of keeping chickens. Name it.



A. deep litter
B. extensive
C. battery cages
D. semi - intensive
E. Intensive

23. Which of the following should **not** be used to prevent birds from pecking each other?

A. sump oil
B. tar
C. Jeyes fluid
D. Malathion
E. ash in oil

24. Broiler finishers is recommended for birds from:

A. One day to 4 weeks
B. 15 to 21 weeks
C. 6 to 4 weeks
D. 9 to 12 weeks
E. 4 to 10 weeks

25. How much feed per week would a chicken of 650gm (weight) need?

A. 490gm
B. 330gm
C. 560gm
D. 770gm
E. 210gm

26. What do we mean by "cattle industry"?

A. feast on meat
B. hooves
C. a cattle business
D. dairy animals
E. Brahman cattle

27. Overstocking of cattle causes

A. underweight animals
B. good milkers
C. long horns
D. fat animals
E. good draughters

28. During silage making, a plastic sheeting is placed over it. What is the main reason for this?

A. to avoid heat build up
B. to avoid rain and air
C. to avoid cold temperatures
D. to avoid oxygen build-up
E. to avoid carbon build-up

29. Where are cattle fattened?

A. abattoir
B. dipping tank
C. paddock
D. kraal
E. fattening ranch

30. Which is a symptom of black leg disease in cattle?

A. short shoulders
B. black shoulders
C. black legs
D. swollen shoulders
E. fat legs

SECTION II

70 MARKS

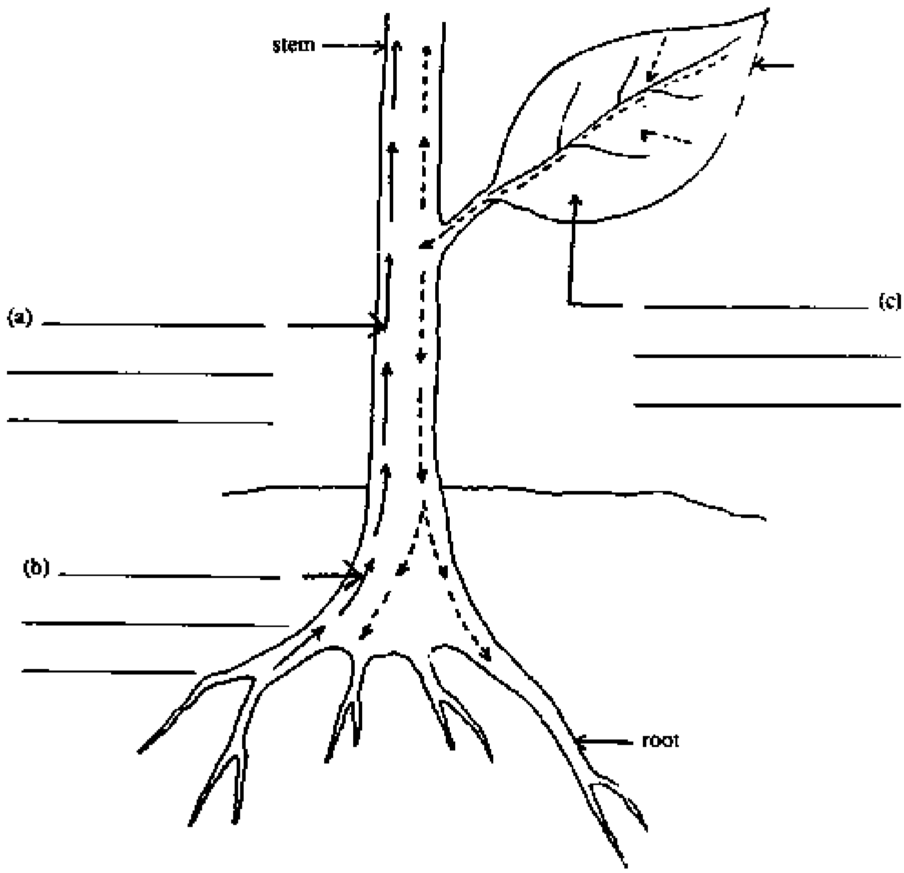
Read all the questions carefully before you begin Answer all questions on the spaces provided

QUESTION 1

Look carefully at the picture. What is happening at the parts marked (a), (b) and (c)?

(2 marks each)

(6)

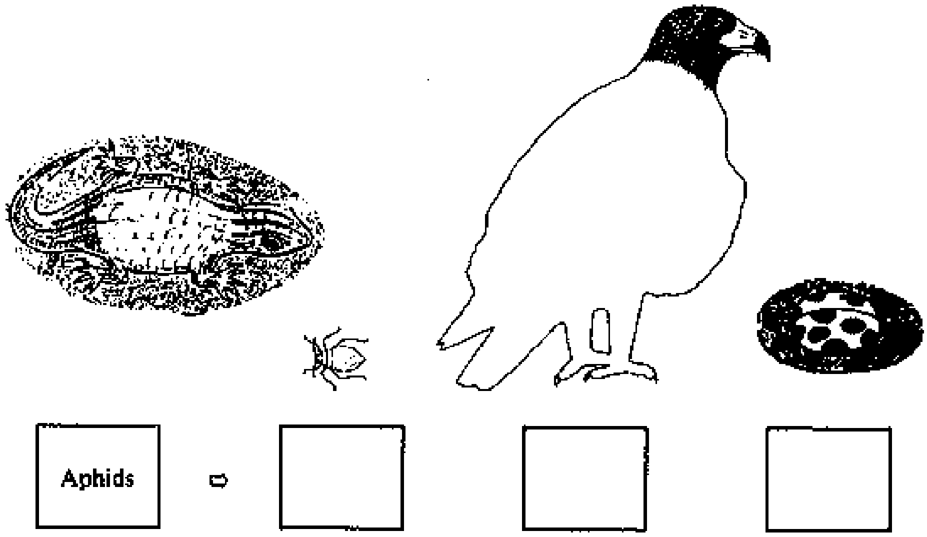


QUESTION 2

a) What is a food chain? ____

____ (2)

b) Look at the mixed pictures carefully. **Then complete the food chain below. Use names and arrows.** The first one has been done for you.



(10)

QUESTION 3

You used a set of tools for your practicals in the garden at school. Tell us, what did you use these tools for?

i) Trowel ____ (2)
ii) garden fork ____ (1)
iii) wheelbarrow ____ (1)
iv) slasher ____ (1)
v) handfork ____ (2)
vi) bushknife____ (1)

(8)

QUESTION 4

Match the statement or word **to the correct** word or statement on the right. **Then write only the letter of the correct answer** on the space provided **on the far right.**

1. Diarrhoea with blood	A. special house	________
2. Friesian	B. Oranges & Grapefruit	________
3. Bags on raised floor	C. Stick can be bent more than halfway	________
4. Orchard	D. Not resistant to ticks	________
5. Clay loam	E. Coccidiosis	________

(5)

QUESTION 5

"A school girl dies after drinking pesticide"

a). Why did the girl die here? ________________________________
____ (2)

b) Name 3 ways by which pesticides enter a human body.

i) ____
ii) ____
iii) ____ (3)

c) If you sprayed against the wind, and the chemical went straight into your eyes. What would happen to you? ________________________
____ (2)

d) What 2 things should one use to clean a chemical that came into contact with the body?

i) ____
ii) ____ (2)

(9)

QUESTION 6

Look at the maize leaf picture carefully. Then answer the questions.

a) What caused those holes? ____________________
____ (1)

b) Was it a sucking or biting animal? _____________
____ (1)

c) What chemical did you use to kill the pest?
____ (1)

(3)

QUESTION 7

On the chart provided write:

a) The number of days each crop takes from planting to harvest.

b) The month for harvesting each crop. Planting dates have been provided for you. Then answer the questions below the chart.

Name of crop	**Date on which crop was planted**	**Number of Days to harvest**	**Harvesting month**
Maize	1st September	i) ____________	v) ____________ (1)
Sweetpotato	5th October	ii) ____________	vi) ____________ (1)
Groundnuts	15th October	iii) ____________	vii) ____________ (1)
Cotton	20th October	iv) ____________	viii) ____________ (1)

c) Which one is quickest to mature? ______________________________ (1)

d) Which crop takes the longest to mature? ________________________ (1)

(10)

QUESTION 8

Give 3 ways of protecting crops in storage

i ____
ii ____
iii ____

(3)

QUESTION 9

On the space provided, write down the:

a) advantages and disadvantages of keeping **day old chicks**

a) Day old chicks

Advantages	**Disadvantages** (3)
i	
ii)	
iii	

b) Write down advantages and disadvantages of keeping **4 weeks old chicks**

b) 4 Weeks old chicks

Advantages	**Disadvantages** (3)
i)	
ii)	
iii)	

(6)

QUESTION 10

Study carefully the chart for chickens where a wrong method of feeding was used.

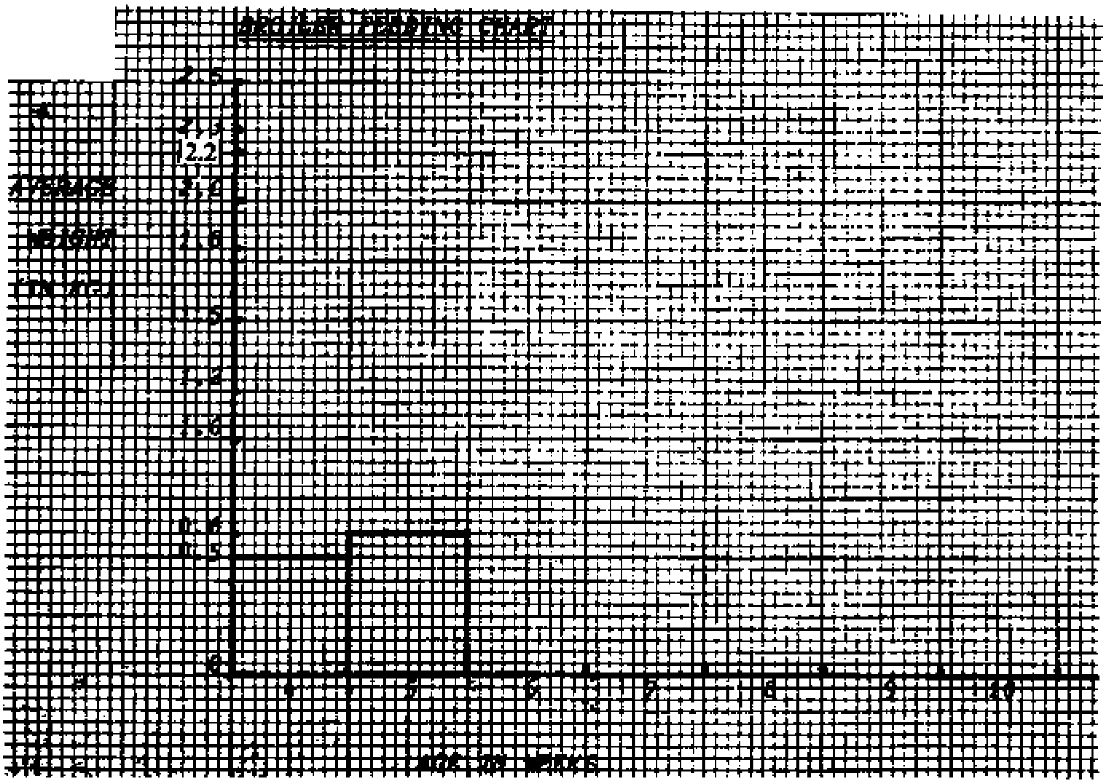
Results of feeding broilers using the wrong method of feeding:

Age in weeks: From 4 weeks of age	**Average weight of each bird in kg**
4	0.5kg
5	0.6kg
6	0.5kg
7	0.6kg
8	1.0kg
9	1.8kg
10	2.2kg

a) Plot neatly these figures on the axis provided showing the growth rate.

The first two have been done for you.

BROILER FEEDING CHART:



b) Give one essential or important element **not** properly given to the birds at the beginning of week 6 _______________________________________ (9)

QUESTION 11

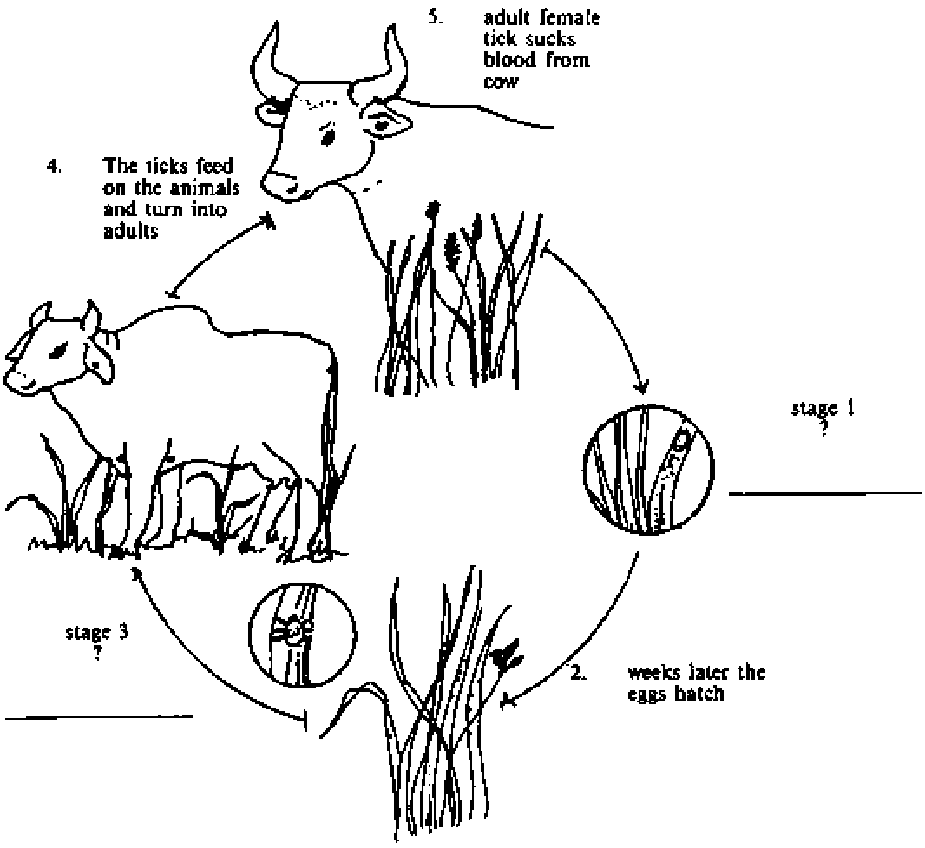
Mrs Sifundza (near Shemula Primary School) sold 320 broilers at 10 weeks, for E12,00 each.

		E	c
a) How much money did she get for them? Show how you get your answer.	Returns		
b) If she spent El 500,00 on raising the birds. Did she make a profit or loss?	Costs		
c) How much is it?	Profit / Loss		

(6)

QUESTION 12

Complete the life cycle of a tick by writing out a full sentence for stages 1 and 3 below.



Stage 1: ____

____ (2)

Stage 3: ____

____ (2)

(4)

SECTION I

ANSWER SHEET (AGRICULTURE)

INSTRUCTIONS: DETACH ANSWER SHEET BEFORE ANSWERING

CANDIDATE'S NUMBER:	

EXAMPLE BELOW:

3.8. Tanzania

3.8.1. Overview

End of Primary School Examination

1.	**Title of examination:**	Primary School Leaving Examination (PSLE)
2.	**Amount of fees charged:**	Nil
3.	**Examination after years in primary school (6, 7, 8 years):**	7 yrs
4.	**Children's entry age in primary school:**	7 yrs
5.	**Number of pupils sitting examination in 1994:**	384,762
6.	**Examination subjects offered:**	9 subjects are offered in 3 papers: • Language (Kiswahili, English) • Mathematics • General Knowledge (Civics, History, Geography, Science, Agriculture, Health and Home Science)
7.	**Language of examination:**	Kiswahili
8.	**Institution setting the examination questions:**	The National Examinations Council of Tanzania (NECTA)
9.	**Have there been any reforms in the examination questions?**	Yes
	When? (year)	1974-1980, 1981-1982, 1983-1994
	What kind?	1974-1980: PSLE consisted of a set of four question papers. These were: • English Language • Kiswahili • Mathematics • General Knowledge (Political Education, History, Science, Geography, Agriculture, Health and Home Science) 1981-1982: Number of Examination papers increased from four to five: • English Language • Kiswahili • Mathematics • Science (Natural Science, Agriculture, Health and Home Science)

		• General Knowledge (Political Education, History, Geography) During this period (1981-1982) true-false, matching, short-answer (e.g. filling in the blanks) questions were omitted. Excepting Mathematics all papers had multiple-choice type of questions. 1983-1994: PSLE papers reduced to three only: Languages, Mathematics and General Knowledge. With the introduction of a multiparty system in the country's political arena, Political Education has been discarded in favour of Civics. Again, excepting Mathematics, the other papers consist of multiple-choice questions only.
10.	**Stages of development of examination questions (please describe):**	• **Setting:** Individually done by subject specialists. • **Moderation:** Done by a panel of subject specialists. During this stage items are discussed, amended and compiled into several whole equivalent papers. • **Editing:** Done by a panel of subject specialists other than those who moderated the papers. Here the Head of the Examination Design and Development Department becomes the Chairperson of the editing panel. **Note:** All these stages are carried out within NECTA and by NECTA staff/examination officers.
11.	**Type of examination questions and distribution of different kind of questions.**	• Language: All multiple-choice type of questions. 50 items distributed as follows: Kiswahili 25 items, English 25 items. • General Knowledge: All multiple-choice type of questions. 50 items distributed as follows: Civics 10, History 10, Science 15 and Geography 15. Considering Science only: 30% recall 20% comprehension 30% application 20% higher order • Mathematics: 50 questions. Candidates were expected to work out the solutions and write the answers on separate sheets of paper. Marks are awarded only to final correct responses. No multiple-choice questions.
12.	**Is continuous assessment incorporated in the final examination?**	Yes [ ] No [x]
13.	**Are examination items pretested?**	Yes [ ] No [x]
14.	**Which professional groups are involved in setting the examination questions?**	Examination officers within NECTA

15.	**Are the same professionals who set the examination questions involved in marking papers?**	Yes [x] No [ ] Tutors and students of TTCs form the backbone of markers while the setters/ moderators/editors play the supervisory role at the marking centre.
16.	**How are examination results used for improving teaching in primary schools?**	• The Regional Education Officers (REOs) carry out evaluation after the selection. The findings are disseminated to school inspectors and teachers who use the information to improve teaching. • NECTA carries out item analysis and the results are again disseminated to the relevant educational experts including teachers. • Past examination papers are re-edited and printed in booklets by NECTA and sold to teachers, parents, pupils and other interested parties.
17.	**To what other uses are the examination results put?**	The examination results are mainly used for selection into secondary schools. It may be called Form I Entry Examination. **Note:** The Four-Year Teacher Grade B Course whose selection depended on the PSLE results has been scrapped off by the Government.
18.	**Main problem with Primary School Leaving Examinations?**	• Administrative, handling/security problems: since the examination results are mainly used for selection and the number of places available in the Government secondary schools are so few and far apart there is a cut-throat competition leading to increasing number of dishonesty cases. • Transportation problems: Tanzania is an expansive country in terms of area. Most of her roads are not in good shape thus leading to haulage problems. Lorry break-downs during dissemination of question papers and collection of answer scripts are not uncommon. In addition to transportation problem, printing and marking costs are becoming increasingly overwhelming.

3.8.2. An Overview of the 1993 Primary School Leaving Examination

by Janet P. Kitosi, National Examinations Council of Tanzania, and Ibamba P. Isengwa, Tanzania Institute of Education

The Primary School Leaving Examination in Tanzania is normally taken once a year, on a single day assigned for the purpose. The 1993 examination was taken on the 5th of October, 1993. It tested a total of 9 subjects namely English, Kiswahili, Mathematics, Political Education, History, Science, Agriculture, Home Science and Geography. However, the number of papers offered were only three because most of these subjects were combined to form one paper (Mathematics, General Knowledge, English and Kiswahili). Each of these papers contained 50 items each of which carried one Mark. Hence for the three papers a candidate could score 150 Marks.

All the 50 items of the Language and General Knowledge papers were of multiple-choice type and candidates were required to attempt all the questions in each of these papers in one and a half hours. The Mathematics paper was allocated 2 hours instead of 1 1/2 hours as with the other two papers. This is because none of the questions in this paper was a multiple-choice type. Hence candidates needed more time to do their calculations in order to get the answers to the items posed.

Except for the English section of the Language paper, all the three papers were set in Kiswahili. There is no separate paper for the science subjects. Questions testing these subjects form a section in the General Knowledge paper. This paper is divided into four sections as follows:

Section I:	Political Education	-	7 items
Section II:	History	-	8 items
Section III:	Science	-	20 items
Section IV:	Geography	-	15 items

For the 1993 examination out of the 20 science items, 15 tested Science (including Home Science) and 5 items tested Agricultural Science. For each of the three papers comprising the 1993 PSLE, two equivalent papers were set.[1] These were equivalent in the sense that they were testing the same objectives and content as can be seen in the examples given below:

[1] In 1990 the country was divided into 5 »examination zones« with 5 papers testing e.g. Science. The number of different zones was reduced over the years to two, and since 1994 to only one paper per exam subject for the whole country.

General Knowledge 1		General Knowledge 2	
Q23.	Which of the following sets of characteristics could be used to classify an animal as a reptile?	Q22.	Which of the following sets of characteristics could be used to classify an animal as a mammal?
22.	The lung is one of the excretory organs. Other such organs are:	21.	Sweating is one of the ways by which waste products are removed from the body. Other ways are:
32.	How many °C are equivalent to 158°F ?	31.	How many °F are equivalent to 40°C?

Each of these two papers was sent to half the country, i.e. 10 administrative regions because Tanzania Mainland has 20 of such regions. So the country was divided into two »Examinations Zones«.

The distribution of papers was such that adjacent regions could not get the same paper so that in case of leakage it could be localized rather than have it spread all over the country.

The National Examinations Council (NECTA) was entrusted with the role of setting, moderating, printing, distributing and marking of the 1993 PSLE papers. The Regional Education Officers (REOs) were given the tasks of selecting pupils for further education in secondary schools and also that of carrying out the quantitative and qualitative analysis of candidates' performance in the PSLE for their respective regions.

Latest Developments in Examinations in Tanzania

1. The number of equivalent papers set was reduced from three in 1992 to two in 1993, and finally in 1994 to only one exam for the whole country. This development has a direct bearing to the tremendous decrease in cases of leakages. All along NECTA has been taking deliberate efforts to educate those handling exam papers on the meaning and importance of observing a high degree of confidentiality in all issues pertaining to examinations. Furthermore NECTA is nowadays working very closely with the national security forces and the police right from the time the papers are set until when the exam is taken and marked.

2. For the first time NECTA required candidates' photographs in the 1993 examination for identification purposes. In the past there were cases where relatives or elder brothers and sisters of candidates could sit for the examination on behalf of the actual candidates. This practice was possible because the person supervising a centre normally comes from a different school and he could not tell whether the candidates appearing for the examination were actually the right ones or not.

3. Again for the first time NECTA instructed the Regional Education Officers (REOs) to establish examination centres in their regions whereby neighbouring schools could take the examination at one centre. This exercise was aimed at reducing the number of centres so that the time spent in distributing and collecting the papers could be reduced.

Problems

• Due to lack of funds and facilities, such as adequate transport, there are no pretests of the examination items.

• The number of dropouts, i.e. candidates who do not show up for the examinations, has been increasing year after year particularly in areas indulged in pastoralism and also due to girls getting pregnant and being sacked from the school before the examination time.

• Repeaters: By law Std. 5-7 pupils are not supposed to repeat classes. But through some tricky means a lot of students repeat Std. 7. However, whenever this is discovered the results in the exam are nullified.

3.8.3. Primary School Leaving Examination (PSLE) in Tanzania Mainland

by Christopher H. Mbiku, National Examinations Council of Tanzania, and Deogratias L.S. Mgema, Tanzania Institute of Education

Historical Background

Primary School Leaving Examinations (PSLE) have been in existence in Tanzania Mainland since 1967. Before 1967 there used to be the General Entrance Examination (GEE) which marked the completion of primary school education and also served as an entrance or selection examination into secondary schools. The GEE was set and administered centrally by the Examination Section in the then Directorate of Curriculum Development and Examinations at the Ministry of National Education Headquarters.

In 1971 the National Examinations Council of Tanzania (NECTA) was established. In 1974 the National Examinations Council started setting and administering the PSLE.

In 1976 the administration of the PSLE changed. It was decided that the preparation of the PSLE questions or items should remain under the central management and control of the National Examinations Council of Tanzania, and that the reproduction (or printing), distribution/administration, marking and other related activities be done by each region under the direction and control of the Regional Education Officers.

Nature and Purpose of the PSLE

From 1974 until 1980, the PSLE consisted of a set of four papers which required an average total of 5 1/2 hours. The examination was normally taken once a year on a single day assigned for the purpose. Beginning in 1981, the number of papers increased from four to five with each paper lasting one hour. These papers were Kiswahili, English, Maarifa (General Knowledge), Hisabati (Mathematics) and Sayansi (Science).

From 1971 until 1980, the type of questions (e.g. multiple-choice, true-false, essay, matching), the number of questions as well as the timing allowed for each paper varied. The fifth paper (Sayansi), introduced in the 1981 PSLE, used to be Section IV of the General Knowledge papers administered between 1971 and 1980. Beginning in 1981 the variations in the type of questions were limited. Except for the Mathematics papers, all the other papers contained mostly objective questions of multiple-choice type.

The PSLE is an achievement examination administered to serve a variety of purposes as defined for basic primary education in Tanzania Mainland.

Assumptions on the Development of PSLE

The setting of the draft papers was done by tutors in the teachers' colleges. Before the final drafts of the Primary Leaving Examination papers were submitted to the Regional Education Officers for further processing, they had to be moderated by subject specialists. The moderators took all necessary measures to ensure that the papers were well-balanced in terms of content coverage, objective and equally fair to candidates at Standard Seven (Std. VII) level for all parts of Tanzania Mainland. It is at this stage where the National Examinations Council experts ascertain the acceptability of the standard required and usability of the PSLE to test pupils with varying differences in academic competence. This aspect, however, is done without regard to geographical location of the schools. The type of PSLE items in current use consist largely of multiple-choice questions.

Test and measurement specialists recommend that trial testing (pretesting) be accorded a special phase in test construction. The merits of pretesting rest entirely upon the likelihood that it will help assemble a test with good quality questions in terms of their psychometric properties. Usually, this process of pretesting allows the **difficulty** of each question to be determined. It also helps to reveal the ability of each question to **discriminate** between strong and weak pupils. Apart from these virtues, pretesting also helps to cast light on the strengths and weaknesses of items and thereby suggests needed improvements in the development and administration of the entire examination.

Although about 70% of the PSLE questions are of the objective type, the National Examinations Council of Tanzania does not undertake pretesting activities owing to economic constraints. Suffice it to say here that NECTA is very much aware of the fact that pretesting, if well conducted, can increase the validity and reliability of an examination.

In order to determine the need for pretesting, at the PSLE level of operations, the Department of Research and Evaluation of NECTA developed a project aiming at carrying out item analysis on the 1981 PSLE papers. This project was developed on the assumption that the findings of these studies would provide a valuable picture of the kind and extent of reliance NECTA could put on the use of objective tests in national testing programmes. Specifically stated, the objectives of the project were:

- to identify items suitable for item banking;
- to carry out training programmes on test construction and other related techniques;
- to lay a firm basis for objective testing at the Primary School level.

The results of the research are contained in a book published by the Department of Research and Evaluation in March, 1983.

PSLE for the Period 1983 - 1992

In 1983, the National Examinations Council of Tanzania was once again entrusted with the roles of setting and moderating PSLE papers, reproduction (printing), distribution of the question papers up to regional headquarters and marking. The Regional Education Officers were given the following tasks in respect of PSLE:

- to distribute the question papers (already in envelopes sealed by NECTA) to examination centres/schools;

- to collect the answer-scripts from the centres and forward them to the marking centre;

- to collect the original consolidated mark sheets and the scripts after the marking exercise;

• to supervise the selection exercise;

• to carry out a quantitative and qualitative evaluation of PSLE performance of candidates.

Due to the large number of pupils (about 300,000) taking the PSLE, the examination papers have been restructured. Several major changes have been effected in the construction and administration of the PSLE.

First, the number of examination papers has been reduced from five to three: namely Lugha (Languages), Hisabati (Mathematics) and Maarifa (General Knowledge). In Lugha, Kiswahili and English are examined. This paper consists of fifty multiple-choice questions. Candidates are required to attempt all the questions in one hour and thirty minutes. In Hisabati, candidates are examined in elementary arithmetic, cartesian geometry, algebra, commercial arithmetic, statistics and coordinate geometry. This paper consists of fifty questions and candidates are required to attempt all the questions in one hour and forty-five minutes. Although the method used to arrive at answers is not required, candidates are given a working space in the question paper and answers are written on a separate sheet of paper designed for this purpose. In Maarifa, four subjects are examined.[1] These are: Political Education - 10 items, History - 10 items, Science -15 items and Geography - 15 items. All the items in this paper are multiple-choice type.

[1] Since 1993 the General Knowledge Paper consists of questions from six subjects. See also »3.8.2. An Overview of the 1993 Primary School Leaving Examination«.

For the purpose of selection of pupils to join the Government Secondary Schools, each question or item carries an equal weight so that a maximum of 150 points may be scored for all the three papers.

The second aspect of the PSLE lies in the preparation of the questions themselves. In the past, questions were set by various tutors teaching in the teacher training colleges and then moderated by the subject specialists in the National Examinations Council of Tanzania. Nowadays, the questions are set by subject specialists within NECTA and moderated by a panel of subject specialists again within NECTA. This means that the quality of the examination questions on the one hand and the security of PSLE papers on the other hand have been enhanced.

In the past, as stated above, NECTA used to set and moderate five papers for each region. These papers were different in the sense that they had different answers but were equivalent in weight and content. At present, the situation is different. NECTA has divided Tanzania Mainland into »examination zones«. These zones are not permanent. They vary in place and time. If, for example, Kilimanjaro Region belongs to zone one this year, next year it may be in zone three. In the period 1983 - 1990 there were five examination zones. Tanzania Mainland has 20 regions which means that each examination zone consisted of four scattered regions. The advantages of administering PSLE in zones lie in the security of the examination papers, in that the temptation to steal the papers or cram some of the contents therein is discouraged by the wide choice one has to make. The disadvantage of this system lies in the cost: for five zones alone one needs to set and moderate fifteen different but equivalent papers. An equivalent number of films and plates are used during printing. It is for this reason that the number of examination zones has been reduced to four and three in the years 1991 and 1992, and finally to one nationwide zone since 1994.

In order to strengthen the security of the Primary School Leaving Examination further, the National Examination Council of Tanzania has decided to work jointly with the other state organs, i.e. the National Security Force and the police. These are fully involved during the printing stage, transportation from NECTA headquarters to the regions and the marking exercise.

Finally, there comes the aspect of motivation. Apart from educating those who handle the examination papers on the meaning and importance of security, an incentive package is necessary if one is to achieve the desired goals. NECTA realized the immense value of motivation and started to implement this in 1983. It is for this reason, in conjunction with those stated above, that PSLE leakage is now history. But this does not imply that PSLE is devoid of irregularities. However, a stage has been reached where one may sigh with relief.

Marking of PSLE Scripts

One of the most important stages in the administration of examinations is the marking of candidates' scripts. The reduction of the number of PSLE question papers means that emphasis in the examination has shifted from summation to selection. To ensure fair selection, correct data must be obtained and processed accurately. The processing speed must be high enough to warrant timely delivery of the information to the decision makers (e.g. selectors). Both the data and information generated need to be stored in a form appropriate for easy retrieval.

It was in view of these demands that the National Examinations Council of Tanzania, with the aid of an IDA loan, bought a computer complex in 1985. But to acquire a computer unit is one thing and to be able to use it effectively is another. It was planned that PSLE scripts would be marked by a computer using optical mark readers and that thereafter all the data would be processed by the computer. To achieve this one requires trained personnel to handle the computer software and hardware. To date NECTA has not started marking PSLE scripts by computer for lack of sufficient manpower resources both in the schools and at NECTA headquarters. However, the Department of Research and Evaluation on its own initiative has embarked on keying the massive data for the purpose of storing and obtaining valuable statistical parameters.

At present, the marking and processing is done manually. However, precautionary measures are taken during marking to ensure that maximum reliability of the data obtained is achieved. This is accomplished mainly by using checkers at every stage of the entire marking process which includes marking, counting of marks, entering of marks in consolidated mark sheets, addition of marks and filing of consolidated mark sheets. The main consumers of PSLE data are the Regional Education Officers (REOs) and the Ministry of Education and Culture. To avoid irregularities during selection, NECTA keeps the carbon copy of all the PSLE raw marks recorded in the consolidated mark sheets (CMS). The original CMS and the scripts are returned to REOs who, after completing the selection exercise (based on the quarter system), carry out an evaluative analysis of performance of their candidates in their respective regions. These evaluative reports are used to guide or counsel the teachers in the field so that they may improve their teaching and thereby candidates' performance.

Concluding Remarks

Hundreds of thousands of pupils complete primary education annually. It is disturbing to note that only six percent (6%) are selected to join public or government secondary schools. No doubt, an examiner always faces difficult choices. Should the examiner set questions to cater for the upper group only? Should he/she consider the majority only? Or should he/she strike a balance by including items for both groups?

3.8.4 Primary School Leaving Examination 1994 - General Knowledge Paper (Section IV: Science), (English Translation)

<u>**THE UNITED REPUBLIC OF TANZANIA**</u>

<u>**NATIONAL EXAMINATIONS COUNCIL**</u>

<u>**PRIMARY SCHOOL LEAVING EXAMINATION 1994**</u>

<u>**GENERAL KNOWLEDGE**</u>

<u>Section IV: SCIENCE</u> (Choose the letter of the correct answer)

31. Blood flowing out of the heart to other parts of the body normally has

A. a lot of humidity
B. a lot of oxygen
C. no carbon dioxide
D. little oxygen
E. a lot of carbon dioxide

32. The earth's rotation around its own axis brings about

A. seasons of the year
B. eclipse of the sun
C. day and night
D. eclipse of the moon
E. high and low sea tides

33. An animal has lungs just like a fish has

A. gills
B. fins
C. scales
D. skin
E. mouth

34. Excretion is one of the characteristics of living things. Other characteristics are:

A. Hearing and seeing
B. Hearing and responding to stimuli
C. Respiring and growing
D. Eating and speaking
E. seeing and responding to stimuli

35. The type of food that is synthesized in the green parts of plants is

A. protein
B. carbohydrates
C. vitamins
D. fats
E. salts

36. One of the properties of loam soil is

A. inability to allow water to pass through
B. allowing water to pass faster than in sand
C. allowing water to flow through it as fast as it does in sand
D. allowing water, when in excess, to flow through it
E. allowing less water to pass through than in sand

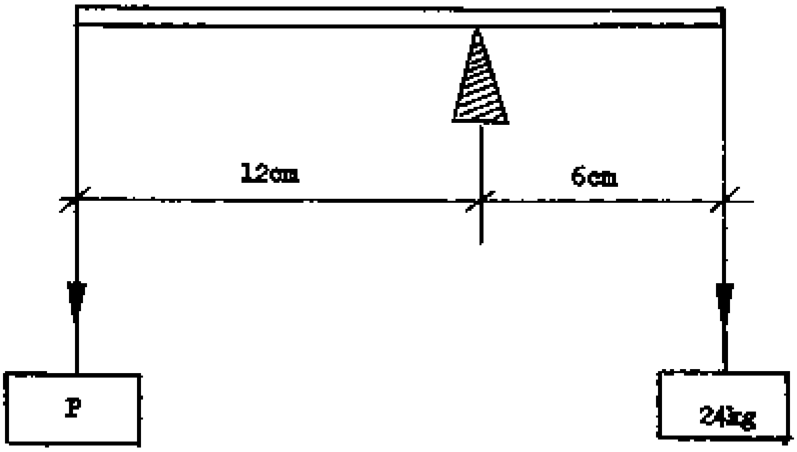
37. The source of humus that is present in the soil is

A. broken down rocks
B. insects living in the soil
C. remains of dead animals
D. remains of dead plants
E. remains of dead leaving things

38. The group of foods which provide energy to the body are

A. rice and potatoes
B. fruits and beans
C. spinach and cowpeas
D. cowpeas and fats
E. meat and fish

39. Examine the following diagram carefully and then answer the question below:



If the beam lever is in balance, the value of P in Kg is

A. 6
B. 18
C. 24
D. 30
E. 12

40. The film in a camera is like which part in the human eye?

A. Retina
B. Pupil
C. Choroid
D. Lens
E. Iris

41. For a physical object to be seen it must

A. reflect light
B. emit light
C. block light
D. transmit light
E. absorb light

42. Magnetic force is always accompanied by the following:

A. light
B. heat
C. electricity
D. wave
E. wind

43. A person standing in stagnant water without wearing shoes is most likely to be infected with

A. tape worms
B. bilharzia
C. diarrhoea
D. malaria
E. cholera

44. Which of the following is a physical change?

A. Dissolving sugar in water
B. Burning of kerosene
C. Souring of milk
D. Burning of candles
E. Rusting of iron

45. Which stage in the life cycle of a mosquito is most vulnerable by use of kerosene?

A. Egg
B. Tad-pole
C. Lava
D. Pupa
E. Adult

46. Examine the following food chain in a certain conservation area:

LIONS $\rightarrow$ ANTELOPES $\rightarrow$ GRASSES

If all lions migrate to other areas,

A. grasses will increase
B. grasses will decrease
C. grasses will remain the same
D. all antelopes will die
E. antelopes will decrease

47. Which of the following characteristics distinguishes amphibia from other animals?

A. Laying eggs, poikilothermic, does not suckle the young ones
B. Laying eggs, homoithermic, does not suckle young ones
C. Laying eggs, leads both aquatic and terrestrial life
D. Suckles young ones, homoithermic, hairy body
E. Laying eggs, breathing through spiracles, body composed of three main parts

48. Sun hemp (marijuana) is among the plants which improve the fertility of the soil. Other plants are:

A. cocoyam, potatoes
B. beans, cassava
C. potatoes, cassava
D. beans, cowpeas
E. cowpeas, potatoes

49. Which of the following sequences causes rainfall?

A. Rain $\rightarrow$ ocean $\rightarrow$ water vapour $\rightarrow$ clouds
B. Ocean $\rightarrow$ water vapour $\rightarrow$ clouds $\rightarrow$ rain
C. Water vapour $\rightarrow$ clouds $\rightarrow$ ocean $\rightarrow$ rain
D. Ocean $\rightarrow$ rainfall $\rightarrow$ water vapour $\rightarrow$ clouds
E. Water vapour $\rightarrow$ ocean $\rightarrow$ clouds $\rightarrow$ rain

50. One of the functions of blood in the human body is to

A. increase heat
B. decrease heat
C. excrete wastes
D. transport oxygen
E. digest food substances

3.8.5 Primary School Leaving Examinations 1993 - General Paper 1 (Section III: Science), (English Translation) and - General Paper 2 (Section III: Science), (English Translation)

THE UNITED REPUBLIC OF TANZANIA

NATIONAL EXAMINATIONS COUNCIL

PRIMARY SCHOOL LEAVING EXAMINATIONS 1993

GENERAL PAPER 1

SECTION III: SCIENCE

Choose the most correct answer and write down the letter corresponding to that answer in front of the question number.

16. Which one of the following refers to movement in plants?

A. Dispersal of seeds by wind
B. Growing away from light
C. Absorption of water from the soil
D. Spreading of branches in the air
E. Growing of shoots away from the stem

17. Which one of the following refers to features of insect pollinated flowers?

A. Production of abundant pollen
B. Production of odourless pollen
C. Brightly coloured
D. Faintly coloured
E. Faint odour

18. Branches are among the main parts of a plant. Other parts are:

A. Stem and fruits
B. Fruits and flowers
C. Roots and leaves
D. Roots and stem
E. Flowers and stem

19. Which type of blood cells are responsible for the transfer of oxygen in the animal body?

A. White blood cells
B. Blood platelets
C. Plasma
D. All blood cells
E. Red blood cells

20. The hawk is a vertebrate animal. Others are:

A. Snake, lizard, rat
B. Rat, snail, snake
C. Rat, bat, tortoise
D. Small fish, millipede, chameleon

21. Villi are part of the digestive system/Other structures are:

A. Heart, pancreas
B. Lungs, kidneys
C. Pancreas, kidneys
D. Tongue, large intestine
E. Small intestine, pancreas

22. The lung is one of the organs of the excretory system. Other organs are:

A. Ribs and kidneys
B. Skin and kidneys
C. Ribs and heart
D. Heart and kidneys
E. Ribs and chest

23. Which of the following sets of characteristics can be used to classify animals as reptiles?

A. They lay eggs, respire by spiracles, have three main body parts
B. They suckle their young, are warm blooded
C. They lay eggs, are cold blooded, do not suckle their young
D. They lay eggs, suckle their young, have hairy bodies
E. They lay eggs, live in water and on land

24. After Juma had analysed the soil of his farm, he found out that it was acidic. What corrective measures should be taken?

A. Leave the farm fallow
B. Add a neutralizing chemical
C. Loosen up the soil
D. Practice flat cultivation
E. Select a particular crop for planting

25. The vulture is dependent on plants in that:

A. It uses leaves to build its nest
B. It lays its eggs in tall trees
C. It eats the carcasses of herbivores
D. It hides in dense forests
E. It spends the nights in tall trees

26. Calcium is one of the nutrient elements contained in CAN Fertilizer. What are the other elements?

A. Ammonia, Nitrogen
B. Ammonia, Nickel
C. Acid, Nitrogen
D. Aluminium, Nitrogen
E. Ammonia, Neon

27. Consider the following practices:

(i) Boiling meat until it is well cooked
(ii) Covering the mouth with a handkerchief when coughing

If you observe these practices, you will be taking measures to control one of the following sets of diseases:

A. Measles, roundworms
B. Cholera, pneumonia
C. Dysentery, cholera
D. Measles, pneumonia
E. Roundworms, T.B.

28. In the human body, Vitamin B^3 and D prevent the following diseases:

A. Night blindness, pellagra
B. Night blindness, beriberi
C. Night blindness, scurvy
D. Beriberi, scurvy

29. When two substances are mixed, a chemical change takes place if there occurs a change in:

A. Composition
B. Light
C. Sound
D. Matter
E. Heat

30. If the upward force of water is less than the weight of a canoe, the canoe will:

A. Sway
B. Capsize
C. Sink
D. Be pushed up
E. Float

31. The force that enables us to walk without falling is:

A. Magnetical
B. Electrical
C. Gravitational
D. Frictional
E. Adhesional

32. How many degrees centigrade (°C) are equivalent to 158°F?

A. 58
B. 98
C. 70
D. 126
E. 190

33. In order to load sacks of maize into a lorry, which of the following machines would you use?

A. Pulley and wrench
B. Piece of timber and ladder
C. Ladder and a pole
D. Roller and ladder
E. Pulley and a pole

34. Soap is made by boiling a base with:

A. An acid
B. An alcohol
C. Spirit
D. Fat
E. Salt

35.

In the above diagrams **A** and **B** are bars of magnets. If side N of Bar **A** is brought close to side N of bar **B**, the bars will:

A. Repel
B. Attract each other
C. Join up
D. Move toward one side
E. Break

THE UNITED REPUBLIC OF TANZANIA

NATIONAL EXAMINATIONS COUNCIL

PRIMARY SCHOOL LEAVING EXAMINATION 1993

GENERAL PAPER 2

SECTION III: SCIENCE

Choose the most correct answer and write down the letter corresponding to that answer in front of the question number on the answer sheet.

16. Which one of the following is **NOT** a characteristic of living things?

A. Reproduction
B. Feeding
C. Decomposition
D. Growth
E. Response

17. Which of the following is a condition for seeds to germinate?

A. Soil
B. Organic manure
C. Fertilizer
D. Heat
E. Light

18. The seeds of "Mchunga" plant are dispersed by wind. Which of the following plants have seeds that are also dispersed in this way?

A. Kapok and cotton
B. Finger millet spinach
C. Spinach and tomatoes
D. Tomatoes and spinach
E. Tomatoes and castor

19. Which of the following are the three major parts of an insect?

A. Abdomen, head, wings
B. Head, abdomen, legs
C. Spiracles, thorax, abdomen
D. Wings, thorax, abdomen
E. Head, thorax, abdomen

20. Which of the following are developmental stages in the life cycle of a mosquito?

A. Egg, pupa, larva, adult
B. Pupa, egg, larva, adult
C. Egg, larva, pupa, adult
D. Larva, egg, pupa, adult
E. Pupa, larva, egg, adult

21. Sweating is one way through which waste products are excreted from the body. Other excretory means are:

A. Sneezing, breathing
B. Breathing, urinating
C. Spitting, urinating
D. Blowing the nose, breathing
E. Sneezing, crying

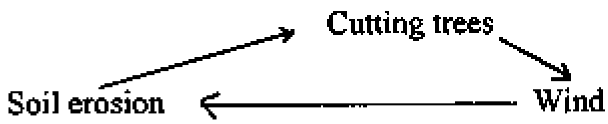
22. Which of the following sets of characteristics can be used to classify animals as MAMMALS?

A. They lay eggs, are cold blooded, do not suckle their young
B. They lay eggs, breathe through spiracles, have bodies divided into three main parts
C. They lay eggs, are warm blooded, do not suckle their young
D. They suckle their young, are warm blooded, have hairy bodies
E. They live in water and on land, they lay eggs

23. After Pazi had conducted an experiment he found out that the soil in his farm could not drain out water easily. What corrective measures should be taken?

A. Select a crop for planting
B. Loosen up the soil
C. Add a neutralizing chemical
D. Practice flat cultivation
E. Follow recommended number of times of weeding

24. Study the following diagram and then answer the question that follow.



Which of the following practices would you undertake to arrest persistent occurrance of the situation?

A. Constructing ridges
B. Planting trees
C. Filling up gullies with soil
D. Leaving the field fallow
E. Practice flat cultivation

25. Apart from cow peas, what other plants enrich the nutrient status of the soil?

A. Crotalaria, potatoes
B. Potatoes, pigeon peas
C. Crotalaria, beans
D. Beans, cassava
E. Grams, cocoyams

26. Consider the following practices:

(i) Killing of snails by chemicals
(ii) Constructing and using latrines properly

If you observe these practices, you will be taking measures to control one of the following sets of diseases:

A. Measles, roundworms
B. Pneumonia, bilharzia
C. Round worms, dysentery
D. Pneumonia, measles
E. Bilharzia, dysentery

27. In the human body vitamins C and B^1 prevent the following two diseases:

A. Beriberi, night blindness
B. Night blindness, scurvy
C. Rickets, pellagra
D. Scurvy, beriberi
E. Pellagra, scurvy

28. Which one of the following properties of light is manifested by the eclipse of the sun?

A. Light travels in a straight line
B. Light is reflected by an object
C. Light is absorbed by an object
D. Light bends when passing through an object
E. Light passes through an object

29. Which type of lenses should a short sighted person wear to correct the defect?

A. Convex
B. Semi-convex
C. Round
D. Concave
E. Semi-concave

30. The functions of mabbles ("goroli") in a machine are to:

A. Lubricate the machine
B. Reduce speed of the machine
C. Stop movement of the machine
D. Reduce friction in the machine
E. Raise temperature of the machine

31. How many degrees Fahrenheit (°F) are equivalent to 40°?

A. 72
B. 112
C. 80
D. 136
E. 104

32. How will you rescue a person affected by an electric shock?

A. Pushing him using hands
B. Pushing him using legs
C. Pushing him with a dry wooden pole
D. Pushing him with an iron rod
E. Pushing him with a wet wooden pole

33. When lighting a torch, which of the following forms of energy is changed?

A. Electrical
B. Chemical
C. Static
D. Kinetic
E. Magnetic

34. One of the ways of obtaining salt from a salt solution is by:

A. Freezing
B. Filtering
C. Decanting
D. Dissolving
E. Heating

35. Which of the following refers to a change in state?

A. Decaying of fruits
B. Formation of steam
C. Burning of paper
D. Rusting of iron
E. Souring of milk

3.9. Uganda

3.9.1. Overview

End of Primary School Examination

1.	**Title of examination:**	Uganda Primary Leaving Certificate Examination
2.	**Amount of fees charged:**	≈ US$2
3.	**Examination after years in primary school (6, 7, 8 years):**	7 yrs
4.	**Children's entry age in primary school:**	6-7 yrs
5.	**Number of pupils sitting examination in 1994:**	162,695
6.	**Examination subjects offered:**	6 subjects in 4 papers: • English • Mathematics • Social Studies/Religious Education • Basic Science & Health Education (incl. Agriculture)
7.	**Language of examination:**	English
8.	**Institution setting the examination questions:**	Uganda National Examinations Board (UNEB)
9.	**Have there been any reforms in the examination questions?**	Yes
	When? (year)	1983
	What kind?	Replacement of multiple-choice questions by structured questions.
10.	**Stages of development of examination questions (please describe):**	• Setters' workshop is organized and invited setters receive basic training through presentations.

		• Setters write items which are shredded at the workshop. • Shredded items are later moderated. • Items accepted after moderation are compiled into papers for pre-testing. • Analysis of pre-tested items is done and some items may be remoderated. • Items are banked for use when required.
11.	**Type of examination questions and distribution of different kind of questions.**	Only structured questions made up of 50% recall and comprehension and 50% higher-order questions.
12.	**Is continuous assessment incorporated in the final examination?**	Yes [ ] No [x]
13.	**Are examination items pretested?**	Yes [x] No [ ]
14.	**Which professional groups are involved in setting the examination questions?**	• Primary school teachers • School inspectors • Tutors of TTCs • Uganda National Examinations Board (UNEB) staff
15.	**Are the same professionals who set the examination questions involved in marking papers?**	Yes [x] No [ ]
16.	**How are examination results used for improving teaching in primary schools?**	A report on the work of candidates is sent out to schools, pointing out weaknesses in teaching, pupil misconceptions as seen in the scripts and areas that need more indepth approach.
17.	**To what other uses are the examination results put?**	• Selection into post primary institutions. • Certification.
18.	**Main problem with Primary School Leaving Examinations?**	• Large entry which influences cost-effectiveness. • Cost of presenting items. • Tendencies to cheat by pupils and teachers.

3.9.2. Item Writing for Primary Leaving Examinations in Uganda

by Dan Nokrach Odongo, Uganda National Examinations Board

Primary education in Uganda at present ends after 7 years of formal schooling. At the end of this period, pupils sit for the Uganda Primary Leaving Certificate Examinations administered by the Uganda National Examinations Board (UNEB).

The examinations consist of 4 written papers viz. English Language, Mathematics, Social Studies and Religious Education and Basic Science and Health Education. The results of the examination are used by the Ministry of Education and Sports for placement/selection of candidates for post-primary institutions. The results also show attainment of a level of education expected after 7 years. Schools also get a feedback through reports on the work of candidates (see chapter 4: Examples of Follow-up Communications after the Examinations).

Background History of Science Syllabus

Before 1981, the Primary Leaving Certificate Examinations were administered by the Ministry responsible for Education. Science was examined as part of a General Paper of which it comprised 25%. The Chief Examinations Secretary received whole paper drafts from setters, who were usually teachers in primary schools and tutors and lecturers in teacher training colleges. The draft questions were then moderated by the Chief Examinations Secretary, the Inspector of Schools (Primary) and the Education Officer (Primary) at Ministry Headquarters.

The items generated were all of the multiple-choice type.

The break-up of the East African Examinations Council occasioned the formation of UNEB which then took over the primary examinations from 1981. The section moved to UNEB from the Ministry of Education. In 1982 changes were made in the method of generating items. An item writers workshop was organized and participants set items. The Research Department of UNEB shredded the items. A pretest of the shredded items was organized. These measures were introduced to improve the validity, reliability and security of the items.

There was also a change in the format of the Science section of the General Paper. Subsection I was made up of 15 questions of the multiple-choice type and subsection II had 6 simple structured questions.

In 1981 the Ministry of Education decided that, in order to promote Science, the Curriculum was to be expanded. The General Paper was already too loaded and a decision was taken to split it. Two papers were born out of this; Social Studies and Religious Education, and Science. The National Curriculum Development Centre (NCDC) was asked to develop a syllabus for the Science paper. The examination paper then consisted of 40 multiple-choice questions and 15 structured questions. The new Science paper was presented for the first time in 1983, allowing for a two year period for schools to note the change.

In 1984 the use of multiple-choice questions was abolished. It was felt that multiple-choice items did not encourage originality and expression on the part of candidates. The method of testing also lent itself to easy cheating by candidates. External assistance from teachers to candidates was also easy. Another problem was the lack of trained item writers - items tended to test factual knowledge only. Instead, 40 simple structured questions formed the first part and 15 more difficult ones formed the second part. By 1988 the method of item generation whereby writers submitted complete drafts was beginning to be discarded in order to improve the security of the items. The method was finally abolished in 1990.

In 1990 the Science paper underwent another major change. The syllabus was expanded to include Health Education. It was felt that pupils leaving school after the primary cycle needed to be equipped with knowledge and ability to take care of their own health and that of the community in which they live. With the assistance of UNICEF, the Science syllabus was expanded and has become Basic Science and Health Education with Health Education weighted at about 50% of the paper. The format remained the same - 40 simple structured questions (40 marks) in Section A and 15 more difficult ones (60 marks) in Section B. This paper was presented for the first time in 1991.

The Current Situation

Since 1991, items have been generated at item writers workshops. The workshop is residential, lasts 10 working days, and is organized annually.

Participants invited are classroom teachers, lecturers and tutors in teacher-training colleges, inspectors of schools in charge of primary education, curriculum experts from NCDC and health education experts from the UNICEF Uganda country office. People who are not involved in teaching other than those above are not invited. The identified participants are then vetted and cleared by the Examinations Security Committee of UNEB. Just before the 1991 workshop, UNEB organised a major item writers course conducted by senior officers of the Board to improve on the writers' abilities and, consequently, the quality of the items.

At the workshops, participants write items rather than whole papers. The items are written according to a not too rigid table of specification (see Table of Specification). This is followed by shredding of items at the workshop and later moderation of the items in UNEB offices by a team of moderators under the guidance of the subject secretary, Test Development. The items are brought together in several parallel papers for the purpose of pretesting. Schools to be used for the pretest are randomly chosen from three categories: urban, semi-urban and rural. The result of the pretesting exercise is analysed to check the behaviour of the questions - their reliability and validity indices.

The abilities tested are knowledge, comprehension and application. The higher abilities - analysis etc. - are not expected at this level.

Accepted questions are banked using the banking form (see Item Banking Form). Banked questions are ready to be used the following year.

Proposals for Improvement of the Science Paper

The NCDC and the Ministry responsible for Education have recommended that a Practical Basic Science and Health Education paper be set. A sample paper has been submitted to UNEB. The constraints here are the volume of equipment needed at this level - about 180,000 candidates. Most schools do not have laboratories or workshops, or science equipment. The financial aspect is the other big constraint. Whereas the idea has, at the moment, been shelved, committees in both UNEB and NCDC are working towards the goal of having a practical paper included alongside the theory one. Further training of item writers and the development of tests is planned.

Question:

3.9.3. The Uganda Primary Leaving Certificate Examination in Basic Science and Health Education

by Zacky W. Eriko, Uganda National Examinations Board

1. Introduction

Several forces have greatly contributed to our current practices as regards the Uganda Primary Leaving Certificate Examination (PLE), the main features will be described later. The main forces include:

(1) Criticisms of the PLE

The commonest criticisms levelled against the PLE include:

• that it has made teaching be geared towards passing the examination only - i.e. the »examination tail« wagging the »curriculum dog« in that whatever is not examined at PLE remains either untaught or taught poorly;

• that most of the questions were of the »recall« type, testing lowest cognitive levels, hence encouraging rote learning rather than understanding or other higher cognitive abilities and skills;

• that the examination tended to favour urban school children and discriminated against rural schools;

• that too much was being demanded from the candidates such that teaching has turned into coaching; that this is done seven days a week, from January to November, hence learning becomes a torture rather than a pleasant experience for children, exerting severe physical and psychological strains on children and financial strains on parents;

• Some people even believe that a very limited area of the primary school curricula is being tested; such people tended to argue that the PLE should be expanded to cover subjects like Music, Physical Education, Art and Crafts, etc.

(2) Examination Malpractices

Over the past few years, the Board had noticed that malpractices in the examination at primary level were becoming an issue of great concern. The public on their part have not minced words in accusing the staff of the Board (in most cases erroneously) for the malpractices. They have always shouted »leakage« at every case of examination malpractices. The malpractices in the PLE fall in three broad categories: Irregularities, Misconduct and Dishonesty or Cheating. The last category, the most serious of the three, is composed of: leakage, collusion, copying, external assistance, impersonation, smuggling and substitution - of all these, the public is not aware of. They persistently think that every case is due to leakage of exams.

(3) Psychometric Considerations

As more and more of the Board's staff became acquainted with the modern techniques of measurement and evaluation, but educational assessments in particular, shortcomings were identified and changes introduced.

2. Generating Test Items and Preparation of PLE Basic Science and Health Education Paper

It is a matter of fact that setting good test items cannot be done by accident. It requires special skills that can only be acquired through training and experience. In this regard, therefore, all those experienced and dedicated teachers used by the Board as setters in the PLE have had to be carefully identified, vetted, trained and tested before being commissioned to do the job.

Due to some of the reasons given already above, the Board employs two methods of generating items that go into the PLE Basic Science and Health Education Paper:

(1) Through different people being asked to set parallel papers based on a specification grid. This has the advantage of proper balance of the various aspects of the syllabus and coherence.

(2) Through item-writers workshops in which active classroom teachers at that level, inspectors, subject specialists at the National Curriculum Development Centre and tutors in Primary Teachers' Colleges participate.

The emphasis in both cases is on having been subjected to training on test construction techniques by the Board first.

The items so generated, whether through parallel papers or workshops, or later in schools are shredded/moderated compiled into fresh papers pre-tested and analysed for level of difficulty as well as discrimination ability before being banked as items (not as papers).

At a later stage, the banked items are used to compile at least three parallel papers which are looked at by a moderation panel and later vetted and re-adjusted by a small group of the top secretariate. In this way loop-holes which could result in possible leakage of the exam are totally sealed.

3. Format of the Examination and its Administration to Candidates

(1) Format of the paper: The instructions to the candidate on the front page of the exam paper clearly state that the paper has two sections: A (made of 40 short answer questions - 40 marks); and B (15 questions - 60 marks).

The questions in section A cover a much wider area and they all carry equal marks. Those in section B cover fewer areas but in depth. The whole paper is for 2 hours 15 min. It covers Physical and Biological Sciences, Agriculture and Health Education.

(2) Administration of the PLE: Schools within a reasonable radius are grouped together at one centre and each of the examination rooms used must have representatives from each of the schools sitting there. Supervisors at each centre are appointed by the Board and these are usually qualified and experienced secondary school teachers and tutors of PTCs. The invigilators, on the other hand, are primary school teachers, appointed by the District Inspector of Schools but not from the schools sitting at a particular centre. Candidates' passport size photographs are used to identify the candidates. Through these and other measures not discussed here, the Board has been able to drastically minimize examination malpractices in the PLE.

4. Grading/Award of Certificates

The Board does not have a pre-determined boundary for a pass mark. The decision of cut-off points at grades 2, 6 and 8 are arrived at during an awards meeting in which the Chief Examiner of the paper assesses the level of difficulty of the paper (item by item) and performance by the candidates. The remaining intermediary scales on a modified 9-point scale are then worked out statistically, such that the best score is a One and the worst a Nine.

The certificate awarded is determined by the total aggregate score in the four papers and range from division 1 to 4. Those below that are ungraded.

5. Proposed Reforms

Uganda is about to embark on a massive reform of its education system at both primary school and Primary Teachers' Training levels. The National Examining body is seen to be playing a central role in this proposed World Bank financed reform. Some of the specific roles that the Board will be expected to play include:

- Introducing and incorporating continuous assessment into the examination system;
- Conducting national assessment of educational progress;
- Increasing the level of test items in the PLE to those testing higher cognitive abilities as well as relating questions to live situations; and
- Improving on feedback systems to schools and parents.

3.9.4 Uganda Primary Leaving Certificate Examination 1994 - Basic Science and Health Education

UGANDA NATIONAL EXAMINATIONS BOARD

UGANDA PRIMARY LEAVING CERTIFICATE EXAMINATION

BASIC SCIENCE AND HEALTH EDUCATION

Time Allowed: 2 hours 15 minutes

Name..

Index No								

DO NOT OPEN THIS BOOKLET UNTIL YOU ARE TOLD TO DO SO

Read the following instructions carefully:

1. The paper is made up of two Sections: A and B.

2. Section A has 40 short-answer questions (40 marks).

3. Section B has 15 questions (60 marks).

4. Attempt **ALL** questions. All answers to both Sections A and B must be written in the spaces provided.

5. All answers must be written in blue or black ball-pen or ink. Only diagrams and graph work may be **do**ne in pencil.

6. Unnecessary alteration of work will lead to loss of marks.

7. Any handwriting that cannot easily be read may lead to loss of marks.

 Turn over

SECTION A

1. How does uncontrolled burning affect our environment?

....

2. State one method by which breast milk protects newly born babies.

....

3. In the space provided below, draw a simple diagram of a molar tooth.

4. State one way in which earthworms are important to a farmer.

....

5. How does the sun-ray help in the formation of rain?

....

6. What takes place in the lungs when one breathes in and out?

....

7. John is suffering from a headache. The nurse wishes to measure John's body temperature. Why does she put the thermometer under John's arm-pit and not on his head?

....

8. How does government control the spread of a cattle disease when it breaks out in an area?

....

9. How does the skin of a person maintain his body temperature on a hot day?

....

10. Why is it not necessary for a VIP latrine to have a lid for the hole?

....

11. Why is it not good to pour paraffin into a pit latrine?

....

12. A 14 year-old child who is usually well behaved suddenly becomes rude to the parents. State one possible change in the child responsible for such a behaviour.

....

13. What is the advantage of family planning to a mother?

....

14. Why would the control of AIDS be easier than that of malaria?

....

15. Why does milk left in the open become sour after some time?

....

16. A child is found to be dehydrated. What is a possible cause of this dehydration?

....

17. What causes anaemia?

....

18. How does smoke from a fire in a room reach other areas in the same room?

....

19. A block of wood of volume 24 cm weighs 36 grams. What is its density?

....

20. A female fish lays eggs in the water. How are these eggs fertilized?

....

21. What type of change takes place when a candle melts?

....

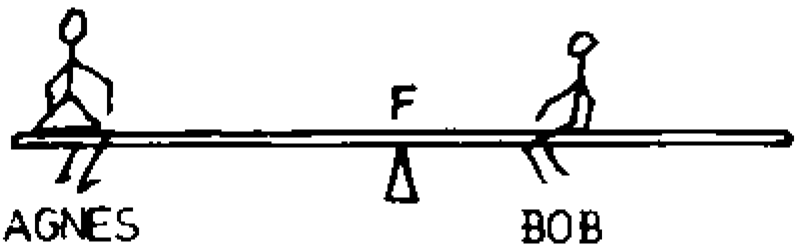
22. Pregnant women are advised to receive immunization against Tetanus. What is the importance of this immunization to the unborn child?

....

23. State any one first aid you would give to a patient who is bleeding from a deep cut on the leg.

....

24. Bob and Agnes are sitting, balanced, on a sea-saw as shown in the diagram below.



How does the diagram show that Bob is heavier ?

....

25. Why does the heart of a person who is running beat faster than normal?

....

26. State one advantage of crop-rotation.

....

27. What is the difference in movement between a ball and socket joint and a hinge joint?

....

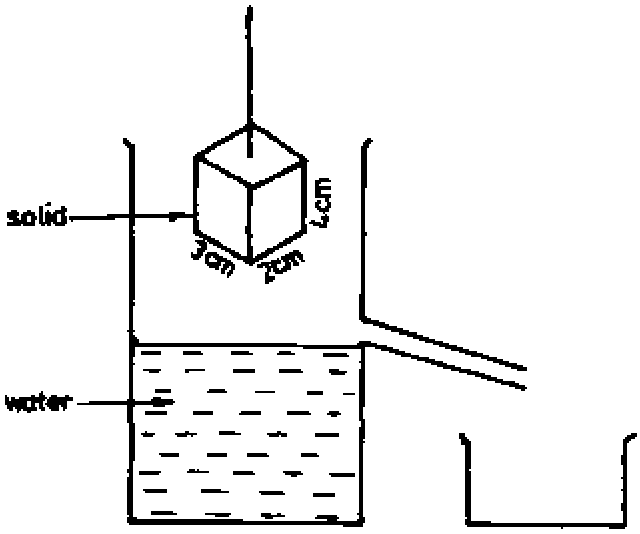
28. Why should materials made of iron be covered with paint?

....

29 Fish, reptiles and birds are vertebrates that lay eggs. State one other characteristic which is common to them.

....

The diagram below shows an experiment used to find the volume of a regular solid block. Use it to answer questions **30, 31** *and* **32**.



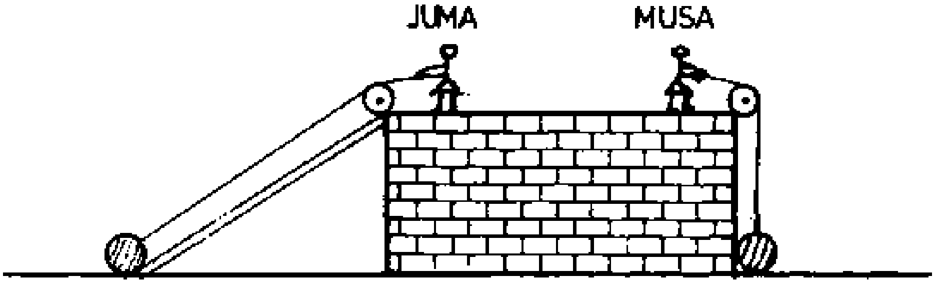
30. What is the volume of the block?

31. If the solid block is lowered into the overflow can, what volume of water will be displaced?

32. How would you confirm your answer to question 31 above?

....

The diagram below shows two boys, Musa and Juma, pulling pieces of wood of equal weights up a wall. Use it to answer questions **33** *and* **34**.



33. Which boy will use less force to pull the wood?

....

34. Explain your answer to question 33 above.

....

35. Why is resting important for the health of a person?

....

36. Muhima is sitting on a chair inside a room. Both his feet are bare. His left foot is resting on a bare cemented floor. The right foot is resting on a mat. Why would Muhima's left foot feel colder than the right foot?

....

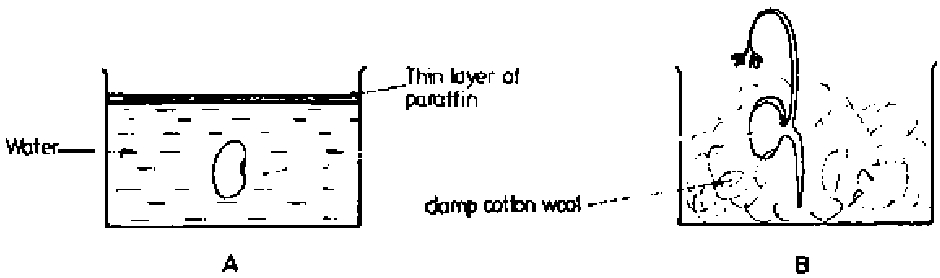
37. Why is smoking of tobacco harmful to the body?

....

38. What is the main purpose of marriage?

....

A student was finding out the conditions needed for germination of beans to lake place. She set up the experiment as shown in the diagram below. Use it to answer questions **39** *and* **40**.



39. Why did the seed in **A** not germinate?

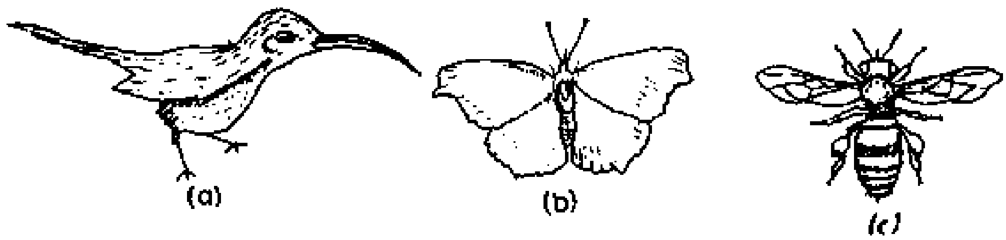
....

40. What is the purpose of the wet cotton wool in **B**?

....

SECTION B

41. Use the diagram below to answer the following questions.

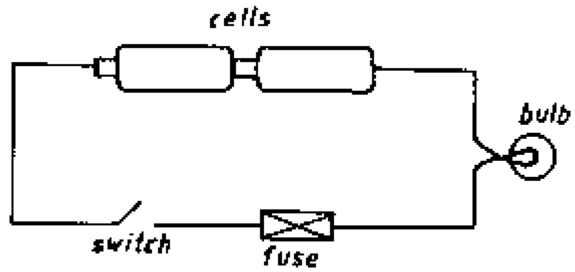


(a) In what ways do these animals have similar structures for:

(i) feeding?
....
(ii) pollination?
....
(iii) movement?
....

(b) How does one of the animals differ from the other two in its life history?
....

42. In the circuit below, when the switch was closed, the bulb lit.



(a) How would you increase the brightness of the light in the bulb?

....

(b) After a short time, when the switch was still on, the light in the bulb went off. State three possible causes for the light going off.

(i) ....
(ii) ....
(iii) ....

43. (a) A farmer who practises mixed cropping has the following crops to plant: beans, cassava, groundnuts and potatoes.

(i) Which two crops would be advisable for the farmer to plant together?
....

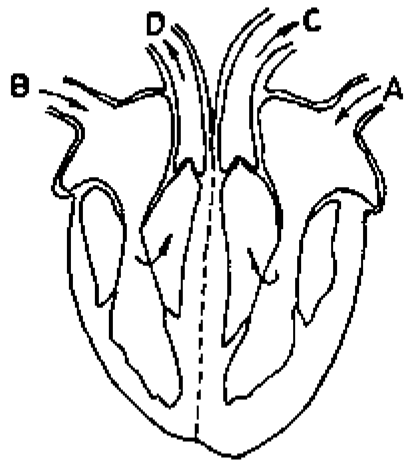
(ii) Give a reason for your answer.
....

(b) The farmer used a garden for planting maize crop only for three consecutive years (planting seasons). During the harvest in the third year, he noticed a drop in the maize yield.

(i) Suggest a reason for the drop in the maize yield.
....

(ii) How can the farmer improve his maize yield in the same garden without using fertilizers?
....

44. The diagram below is of a human heart. Use it to answer the questions which follow.



(a) What is the function of valves in the heart?

....

(b) What is the difference between the blood which enters the heart through **A** and that through **B**?

....

(c) After leaving the heart at **C** and **D** where does the blood go?

(i) **C**: ....
(ii) **D**: ....

45. In the table below, some of the diseases are given with their symptoms and prevention/control. Study it and fill in the missing information.

Name of **Disease**	**Symptoms**	**Prevention/Control**
Sleeping sickness	loss of body weight, drowsiness, swelling in the joints	
Common cold (flu)		Isolation, Avoid infected people
Measles	rash on body, high fever, cough, red eyes, sore in mouth diarrhoea and vomiting.	
	mild redness and itching of eyes, pus in eyes after sleep, scarring.	washing of eyes, avoiding to share articles with sick persons, e.g. basin towel. Medical treatment

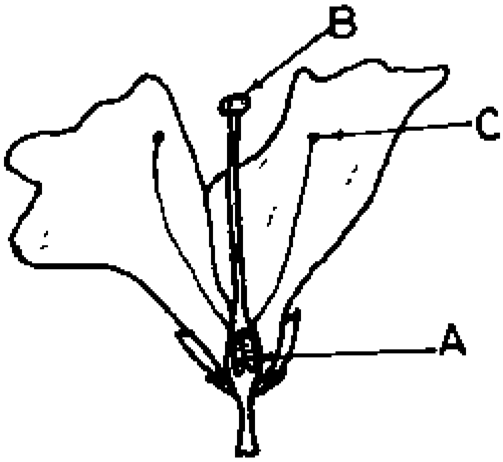
46. (a) Why should water not be used to put out fire from petrol which is burning?

(i) ....
(ii) ....

(b) Suggest two ways by which fires from petrol burning can be put out.

(i) ....
(ii) ....

47. The diagram below is of a flower. Use it to answer the questions which follow.



(a) What does the part labelled A become after fertilization?
....

(b) What is the difference in the functions of the parts labelled B and C?

(i) ....
(ii) ....

(c) Of what value are flowers to man?

48. When a drum is hit, you hear sound.

(a) How does the ear-drum help you to hear the sound?

....

(b) There is some wax in the outer ear. What is the function of the wax?

....

(c) What is the effect of too much wax in one's ear?

(i) ....
(ii) ....

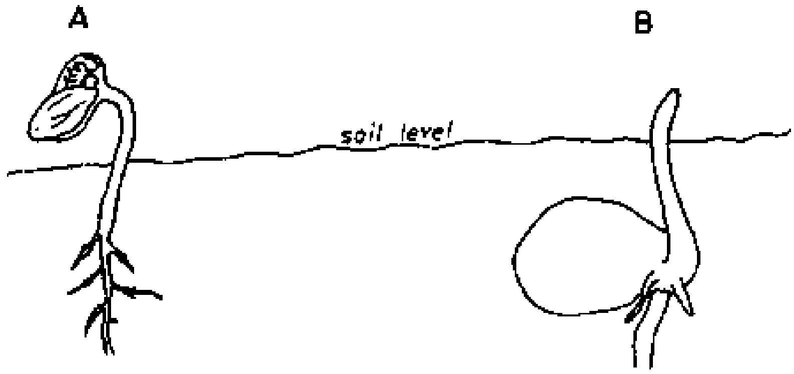
49. (a) State two factors which should be taken into account when selecting site for building a house.

(i) ....
(ii) ....

(b) How does a well-built house contribute to the health of a family?

(i) ....
(ii) ....

50. The diagram below shows how seeds change into young plants. Use it to answer the questions which follow.



(a) What is the main difference between the type of germination shown in **A** and that in **B**?

(i) ....

(ii) ....

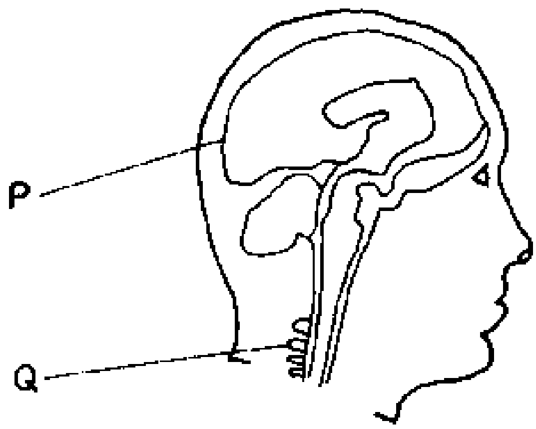
(b) Which of these two types of germination is more common in monocotyledonous plants?

....

(c) In what way does the location of the food store in **A** differ from that in **B**?

....

51. Use the diagram below to answer the questions which follow.



(a) What name is given to the part marked **P**?

....

(b) Give a function of the part marked **Q**.

....

(c) Name two sense organs shown in the diagram above, by which someone can tell that there is something burning.

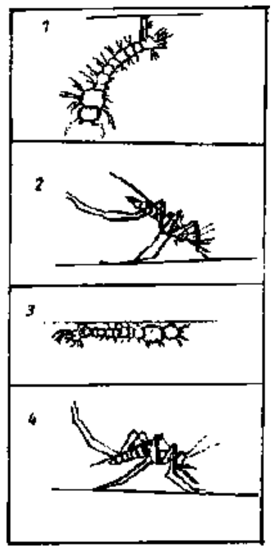
(i) ....

(ii) ....

52. List A below gives two types of mosquitoes. The drawings in B give the larvae and adult stages of mosquitoes. Write the correct number of the drawing in B against the correct mosquito in list A. Each drawing in B can be used once, more than once or not used at all.

A
Anopheles ....
Culex ....

B



53. Nakato harvested her maize crop and dried it. She put the maize in a sack and stored it on the floor, in a corner of her bedroom. Akello also harvested and dried her maize crop. Then she hung the maize on cobs above a fire place in the kitchen.

(a) Explain why Akello would have better maize grains to plant in the next season.
....

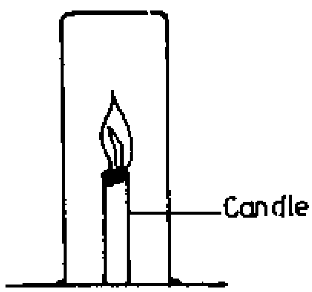
(b) Give two ways in which Nakato can improve on her storage method.

(i) ....
(ii) ....

54. (a) What shows that air is matter?

(i) ....
(ii) ....

(b) A candle is lit and placed inside a container and sealed as shown in the diagram below.



(i) Why does the candle continue burning for some time inside the sealed container?
....

(ii) Give a reason why the candle light goes off after some time.
....

55. (a) State four reasons why physical exercises are good for the body.

(i) ....
(ii) ....
(iii) ....
(iv) ....

3.9.5 Uganda Primary Leaving Certificate Examination 1993 - Basic Science and Health Education

UGANDA NATIONAL EXAMINATIONS BOARD

UGANDA PRIMARY LEAVING CERTIFICATE EXAMINATION

BASIC SCIENCE AND HEALTH EDUCATION

Time Allowed: 2 hours 15 minutes

Name...

Index No								

DO NOT OPEN THIS BOOKLET UNTIL YOU ARE TOLD TO DO SO

Read the following instructions carefully:

1. The paper is made up of Sections A and B.

2. Section A has 40 short-answer questions (40 marks).

3. Section B has 15 questions (60 marks).

4. Attempt **ALL** questions. All answers to both Sections A and B must be written in the spaces provided.

5. All answers must be written in blue or black ball-point pen or ink. Only diagrams and graph work may be done in pencil.

6. Unnecessary alteration of work will lead to loss of marks.

7. Any handwriting that cannot easily be read may lead to loss of marks.

FOR OFFICIAL USE ONLY			
SECTION	EXRS MARKS	T/L MARKS	OFFICE
A			
B			
TOTAL			

SECTION A

1. Jane put a bottle of soda in a bucket full of ice. Two hours later, she found that the soda was frozen and the bottle broken. Why did the bottle break?

....

2. What is the role of brightly coloured petals in pollination?
....

3. State one reason why loam soil is better than sandy soil for crop growing.

....

Use the drawing below to answer questions **4** *to* **8**.

4. Which of these animals lay eggs?

....

5. Which of these animals are cold-blooded?

....

6. Which one of these animals has no back-bones?

....

7. Which of these animals can fly?

....

8. Which one of these animals is a mammal?

....

9. Why would an egg from a layer not hatch into a chick after it has incubated for 21 days?

....

10. The chameleon is a slow-moving animal. State one way by which it protects itself.

....

11. Why is breast milk the best food for a baby of less than one year old?

....

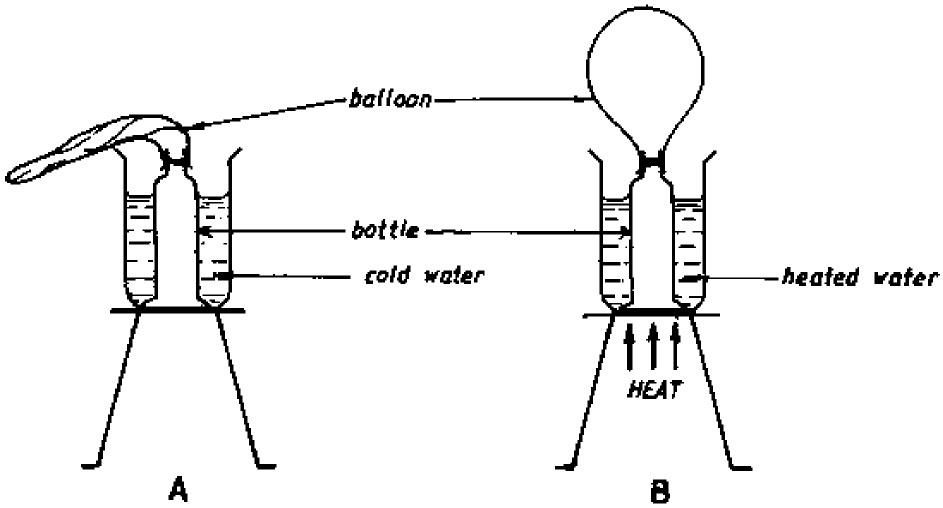
12. Why should left-over food be properly covered?

....

13. What causes malaria?

....

The diagram below shows a set-up of an experiment and its results. Use it to answer questions **14** *and* **15**.



14. Why does the balloon swell out as shown in **B**?

....

15. Suggest what you think the experiment is intended to show.

....

16. Why are people encouraged to drink boiled water?

....

17. Why must fruits and green vegetables be included in our diet?

....

18. Why does a pregnant mother need foods rich in proteins?

....

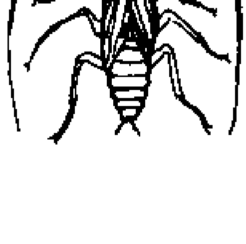
19. Why should finger-nails be kept short?

....

20. Why is the maize grain considered a fruit?

....

Use the drawing below to answer questions **21** and **22**.



21. What stage in the life cycle of a cockroach is shown in the diagram?

....

22. Give a reason for your answer to question 21.

....

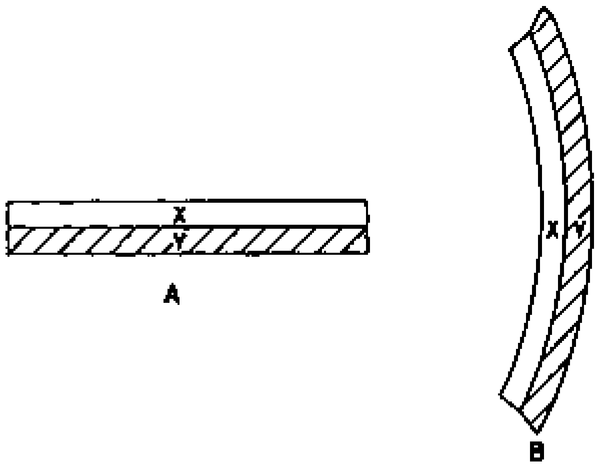
23. How does a cassava plant obtain its food when its leaves have fallen off?

....

24. Why does a piece of stone placed into water sink?

....

The diagram below shows a metalic rod made of two different metals (X and Y) bound together as shown in **A**. *When heated, the rod bends as shown in* **B**. *Use the diagram to answer questions* **25** *and* **26**.



25. Which of the metals expands faster, **X** or **Y**?

....

26. Give a reason for your answer to question 25.

....

27. What is the function of a dry cell?

....

28. Why does a wet cloth spread on a line inside a house dry?

....

29. What is a compound fracture?

....

30. What First Aid should be given to a person who gets a compound fracture on the arm?

....

31. Why must one avoid being near a person smoking?

....

32. Of what use is a ventilator of a house?

....

33. What do you understand by 'drug dependency'?

....

34. What vector(animal) carries the bubonic plague germ?

....

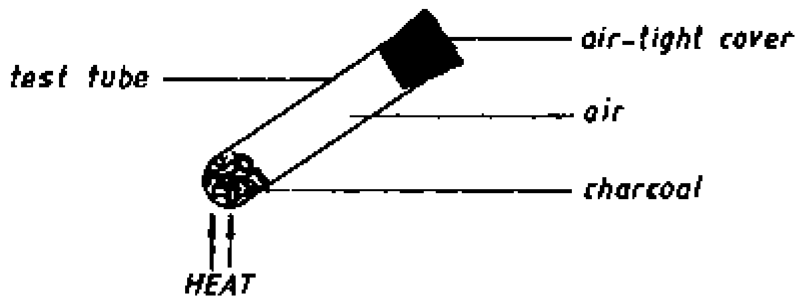
35. Why should pit-latrines be smoked from time to time?

....

36. Tonto shares his hut with goats. State one disadvantage of this practice.

....

37. Some charcoal is burnt in a container as shown in the diagram below. The container and its contents were weighed before and after burning. There was no change in the weight. Why was there no change in weight?

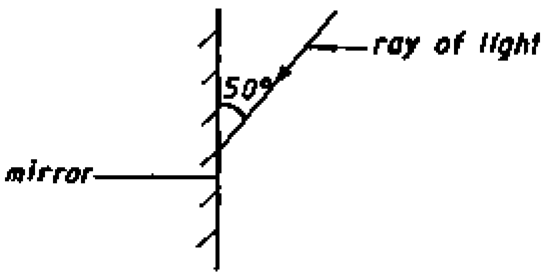


....

38. State one cause of fainting.

....

39. A ray of light meets the surface of a mirror as shown in the diagram below. Draw the reflected ray. (N.B. Use of compass not necessary).

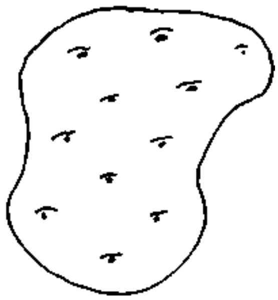


40. What is the importance of weeding in growing crops?

....

SECTION B

41. The diagram below is of an Irish potato. Use it to answer questions (a) to (d).



(a) What part of the Irish potato is shown in the diagram?

....

(b) Give a reason for your answer in (a).

....

(c) What main food value does the Irish potato have?

....

(d) How does the method of propagation of Irish potato differ from that of sweet potato?

....

42. The table below gives a list of diseases against which children should be immunized and the age in months in which the first dose of vaccine should be given.

(a) Study the table carefully and fill in the missing information.

DISEASE	AGE IN MONTHS
(i) Tuberculosis	
(ii) Tetanus	1½ months
(iii)	1½ months
(iv)	9 months

(b) What is the importance of a health card?

....

43. (a) Give two possible sources of worm infection.

(i) ....
(ii) ....

(b) State two signs of worm infection.

(i) ....
(ii) ....

44. Uganda Electricity Board generates most of its electricity at Jinja.

(a) State the source of the electrical energy.

....

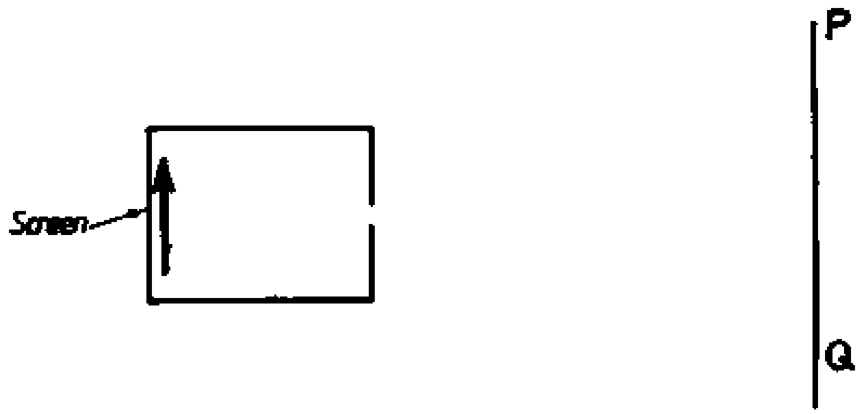
(b) How does the electricity generated at Jinja get to a consumer in Kampala?

....
....

(c) Give two uses of electricity to a family.

(i) ....
(ii) ....

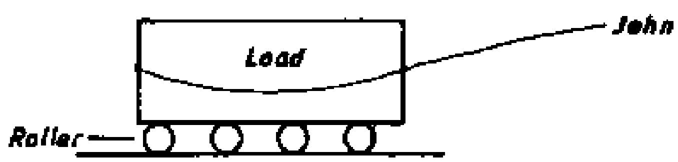
45. Below is a drawing of a pin-hole camera, with an image of an object formed on the screen. The object is located along line PQ.

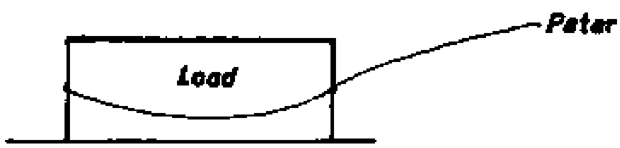


(a) Draw lines to show how the image of the object is formed.
(b) Draw the object.
(c) Compare the object and the image.

(i) ....
(ii) ....

46. John pulls a load of 50 kg over a set of metal rollers. Peter pulls another load of the same weight along the ground (see diagram below).





(a) Explain why one of the two (people) uses less force.
....

(b) What is the advantage to a driver of pouring sand on a slippery road?
....

(c) Explain your answer in (b) above.
....

47. The AIDS virus does not kill its victims.

(a) What leads a person infected with the AIDS virus to death?

....

(b) Why should one not be afraid of sitting in the same classroom with someone infected with the AIDS virus?

....

(c) What is the commonest method through which the AIDS virus is spread?

....

48. (a) How does each of the following help to maintain soil fertility:

(i) Crop rotation?...
(ii) Mulching?..

(b) Give two other ways of maintaining soil fertility.

(i) ....
(ii) ....

49. A child suddenly removed the cover of a sauce-pan full of boiling water. One arm of the child was thereby burnt by the steam.

(a) What kind of burn did the child get?

....

(b) What First Aid would you give to the child?

....

(c) Give two possible ways by which such accidents could be prevented.

(i) ....
(ii) ....

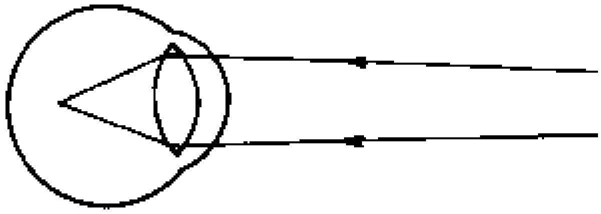
50. (a) Give two types of cattle.

(i) ....
(ii) ....

(b) Why are cattle-keepers encouraged to practise paddock system of grazing?

(i) ....
(ii) ....

51. Below is a diagram showing an eye defect.



(a) Name the eye defect shown in the diagram above.

....

(b) Give reasons for your answer in (a) above.

(i) ....
(ii) ....

(c) How can this eye defect be corrected?

52. (a) State two functions of mammalian teeth.

(i) ....
(ii) ....

(b) An elderly man has lost all his molar teeth. What feeding problem would he experience?

(i) ....
(ii) ....

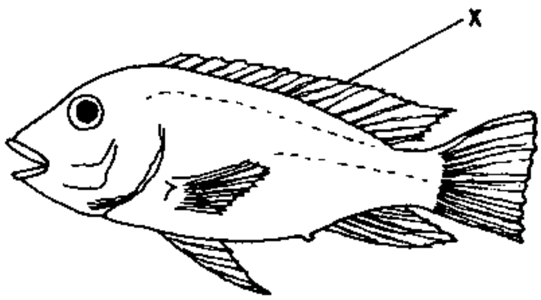
53. (a) Give two reasons why burning and rusting are considered similar reactions.

(i) ....
(ii) ....

(b) A farmer notices that whenever he leaves his hoe outside the whole day, on a clear day, it does not rust; but whenever he leaves the same hoe outside at night, it rusts. Why is this the case?

....

54. The diagram below is of a fish. Study it and use it to answer the questions that follow.



(a) Name the part labelled **X**.
(b) Mark with **Y** the position of the gills.
(c) How does a fish take in oxygen?
....

55. (a) What is an essential drug?

....

(b) Give an example of an essential drug.

....

(c) Why are prescriptions important in the treatment of sicknesses?

(i) ....
(ii) ....

3.10. Zambia

3.10.1. Overview

End of Primary School Examination

1.	**Title of examination:**	Grade VII Composite Examination
2.	**Amount of fees charged:**	≈ US$ 1
3.	**Examination after years in primary school (6, 7, 8 years):**	7 yrs
4.	**Children's entry age in primary school:**	6-7 yrs
5.	**Number of pupils sitting examination in 1994:**	179,148
6.	**Examination subjects offered:**	6 subjects (including Zambian Languages) tested in 5 papers: • English • Zambian Languages • Mathematics • Environmental Science (incl. Agriculture) • Social Studies In addition Special Papers are set in Mathematics & English to test the IQs of children (aptitude tests). The paper on Zambian Languages does not count for the selection for secondary school.
7.	**Language of examination:**	English (except for Zambian Language papers)
8.	**Institution setting the examination questions:**	Examinations Council of Zambia
9.	**Have there been any reforms in the examination questions?**	NOT YET The Council is working on an examination syllabus to improve the examinations.
10.	**Stages of development of examination questions**	• Primary school teachers and college lecturers submit items to the Council.

			• Items are scrutinized and moderated by the selecting panel. • Selected items are pre-tested in October/November. • Pretest papers are marked and item analysis produced. • Selecting panel chooses items for the final paper. • Final examinations take place. • Past examination item analysis is done.
11.	**Type of examination questions and distribution of different kind of questions.**		Multiple-choice: 30% knowledge 40% comprehension 20% application 10% problem solving
12.	**Is continuous assessment incorporated in the final examination?**		Yes [ ] No [x]
13.	**Are examination items pretested?**		Yes [ ] No [x]
14.	**Which professional groups are involved in setting the examination questions?**		• Primary school teachers • Secondary school teachers • School inspectors • Tutors of TTCs • Curriculum specialist
15.	**Are the same professionals who set the examination questions involved in marking papers?**		Yes [ ] No [x]
	If no, who marks the papers (state)?		Computer marks and processes
16.	**How are examination results used for improving teaching in primary schools?**		Not officially, but teachers use the results to judge the effectiveness of their teaching methods Completion of the syllabus
17.	**To what other uses are the examination results put?**		• Selection to grade VIII • Certification • To generate statistical reports
18.	**Main problem with Primary School Leaving Examinations?**		The quality of test items in all the subjects (most items are of the recall type)

3.10.2. State-of-the-Art of End of Primary Education Examinations in Zambia

by Simon I. Phiri, Examinations Council of Zambia

Introduction

Primary school education lasts seven years from Grade I to Grade VII. The children enroll for Grade I when they are six to seven years old and normally take the Grade VII examinations when they are 13 or 14 years old. Universal primary education has almost been attained in most regions of the country.

Every year in the first or second week of November, Grade VII Composite Examinations are held throughout the country following the laid down timetable and examination regulations.

Purpose of Examination

The main purpose of the examination is twofold:

(1) Selection for Grade VIII - limited places available - selection of the best candidates takes place.

- It is hoped that in future this examination will not be necessary once universal education up to Grade IX is achieved.

- Selection for Grade VIII is governed by the availability of places in Grade VIII.

(2) Certification - all candidates who take the examination are awarded certificates. There is no fail grade at this level.

Those not selected for Government, ZCCM Trust and Mission Secondary Schools and Basic Schools are absorbed by the following schools:

- Correspondence schools known as Open-Day Secondary Schools,
- Private schools,
- Academic Production Unit Classes Schools,
- Night schools.

Selection for Grade VIII is based on the number of points in six subjects a candidate scores (standard scores). The successful candidate will be the one who scores above a regional cut-off point. Boys and girls have different cut-off points. The cut-off points vary from region to region and depend on the number of places available in Grade VIII in a particular region.

Girls normally have a lower cut-off point than boys because:

(1) the drop out rate is higher for girls than boys, especially when the girls reach maturity age;

(2) there is less emphasis by parents for girls to be in school, they prefer boys to attend;

(3) due to a number of factors girls generally score lower marks than boys in all of the regions of the country.

Due to (1) and (2) the number of girls in school is lower than that of boys, although the female population in the country is greater than that of males by a ratio of 1.2 to 1.0. In most schools the ratio of female to male is 1:1.5. In order to address the imbalance, the government deliberately lowers the cut-off points for girls so as to increase the ratio of females selected for Grade VIII.

Type of Examination

Most Grade VII candidates sit for seven subjects namely English, Social Studies, Mathematics, Environmental Science, Special Paper One (Verbal Reasoning), Special Paper Two (Non-Verbal Reasoning) and one of the seven official Zambian languages. Candidates in trust and private schools do not sit for any Zambian language.

All the question papers consist of multiple-choice type of questions. The number of items is normally 50 or 60 depending on the subject. The candidates answer the questions on the answer cards provided by the Examinations Council of Zambia. They do this by shading what they perceive to be the correct response to an item.

The answer cards are marked and processed by computer, mainly because of the large number of candidates and because it makes it easier to:

- standardise the scores,
- produce selection listing for both sexes in order of merit for selection purposes,
- produce various statistics,
- print certificates.

Advantages and Disadvantages of Multiple-Choice Type of Examination

Advantages

- Quick processing of examination results.
- Non-human subjectivity in the marking of the cards - marking is objective.

Disadvantages

The examination does not offer the candidate the opportunity to show any originality and encourages rote learning. Quite a number of candidates cannot even spell or write their own names. The examination does not ask or test for such skills so the teachers and the candidates do not bother about them. In future a short written component will be set to reverse this anomaly.

Test Development for Examinations

Every year the Research and Test Development Unit of the Examinations Council of Zambia pretests all the items, except Zambian languages items, that will be offered in the examinations. Two papers are prepared in each subject. The pre-tests sample is taken from the candidates for that year's examination. The pre-tests are conducted in October/November when it is assumed that the candidates have completed the syllabus and are ready for examinations.

The pre-test items are analysed by the computer to find out their suitability for use in the final paper. The item analysis shows the facility value (percentage of candidates selecting an option) and the discrimination index (how the question discriminates the able from the less able candidates). For an item to be included in the final paper it should have a facility value of 40-70% and a discrimination index (or point biserial) of above 0.20. The items that are rejected may be retested after they have been reviewed. The selected good items are put in the item bank.

Both the pre-tests and the final papers are set according to the test specification of each subject.

Item Writing for Examinations

(1) Subject secretaries (employees of the Examinations Council of Zambia) send invitations for submission of items to primary school teachers and primary school teacher training lecturers countrywide. Each item writer is expected to submit at least 25 items. The teachers who submit items are paid regardless of the quality of the items. Each subject must have at least 20 item writers. The teachers are free to choose the subject area they feel they are competent in. Invitations for items are sent for all the six subjects examined at Grade VII level except the seven Zambian languages.

(2) Upon receipt of the items the subject secretaries scrutinize them with a view to reviewing and improving some of the items that may not be so perfect in construction. The selected items are then presented to a setting panel committee. The committee consists of a chairman and three to four other members including the subject secretary. The task of this committee is to come up with two full, separate papers in their subject for use in the current year's pre-test in October/November. Each paper must satisfy the test specifications for the subject.

(3) The pre-test answer cards are marked and analysed by computer, and item analysis printouts are produced.

(4) The subject secretary and the other setting panel members meet to select items for the final paper. The items are chosen according to whether they satisfy the two parameter ranges. The preferred range for facility level is 40-70% and for discrimination index the range must be above 0.20. The final paper is also set as per test specifications. This may vary from year to year but not much.

(5) After the final examination post-exam item analysis is done. The common feature for 1991 examinations e.g. is that items analysed as difficult in the pre-tests' analysis turned out to be easy - i.e. facility value was higher.

(6) The previous test specification for Science was in favour of recall-type of items. They contributed over 50% of the items in theory but in practice the paper actually in some years was over 80% recall. Beginning in 1991 an effort was made to reduce recall-type items from 50% to 30% and a new test specification was drawn up in consultation with the Curriculum Development Centre. This new test specification was implemented in the 1992 Environmental Science paper.

The Examinations Council of Zambia is working on an examination syllabus which will be different from the syllabus designed by the Curriculum Development Centre. This is because some objectives which were being tested do not contribute to the child's development after school.

(7) For the items to improve, workshops for item writers are essential.

Conclusion

The Grade VII Composite Examination is an examination which marks the end of Primary School Education. The results are awaited with much anxiety by both the candidates and their parents. This is so because of the low progression rate to Grade VIII. For most people this examination, if one is selected, is like one has won a state lottery jackpot. The Grade VII entry and selection for Grade VIII are shown below. Between 1980 and 1990 the progression rate was on average 21.76%. There was an increase in 1984 from 16.58% to 21.6% due to opening of extra Grade VIII classes in basic schools (these offer Grade I to IX). The same is true for 1989 and 1990 when a lot of basic schools were opened in the eastern and southern regions of the country. In 1993 a total of 993,705 pupils sat the exam. 54,345 pupils were selected into Grade VIII (= 28.05%).

3.10.3 Environmental Science Paper 1994

EXAMINATIONS COUNCIL OF ZAMBIA

PAPER 4 **ENVIRONMENTAL SCIENCE** **TIME: 60 MINUTES**
S/TENVSC4/G7/94

1. Read these instructions carefully.

2. **DO NOT** turn this page before you are told. Your teacher will tell you when to turn this page to begin answering the questions.

3. There are 50 questions in this **SCIENCE** paper. You will be given **EXACTLY** 60 **MINUTES** to do the questions.

4. For each question four answers are given, but only one of the four is right. Work out which is the **BEST** answer. Then, on your **ANSWER SHEET** shade the answer space of the letter of your choice in pencil.

EXAMPLE: Malaria, Leprosy and Measles are names of ...

A. plants.
B. insects.
C. minerals.
D. diseases.

The best answer is D, you would show this answer like this:-

5. You must **SHADE** your answer spaces **COMPLETELY** and **DARKLY WITH A PENCIL.** If you have to change your answer, you must rub out the shading **VERY NEATLY** before shading the new one. **USE A CLEAN RUBBER.**

6. When you have finished one page, go straight on without waiting to be told. If you have time left at the end of the question paper, use it to check your work carefully.

7. Look at your **ANSWER SHEET.** At the top it should have your name, sex, date of birth, examination number, primary school name and name of Secondary School of your choice. It should also say **PAPER 4 ENVIRONMENTAL SCIENCE** on the bottom left side.

8. You will **NOT** be able to ask questions once the examination has began.

<u>DO NOT TURN THIS PAGE UNTIL YOU ARE TOLD</u>

<u>USE ONLY A PENCIL FOR YOUR ANSWERS</u>

1. Fish can breathe under water through their ...

A. scales.
B. gills.
C. pores.
D. noses.

2. Water is put in a basin. It is heated until no more is left. The water has ...

A. filtered.
B. dissolved.
C. evaporated.
D. melted.

3. During the hot and wet season, which diseases are likely to break out due to unhygienic conditions especially in the villages and townships?

A. AIDS, T.B., cholera.
B. Cholera, typhoid, AIDS.
C. Cholera, T.B., AIDS.
D. Dysentry, cholera, typhoid.

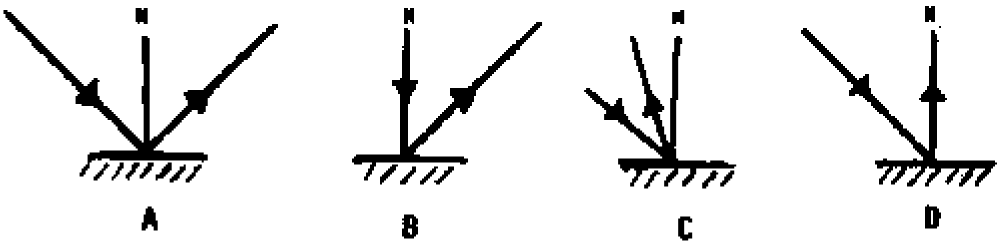
4. What is the function of white blood cells?

A. They carry oxygen around the body.
B. They carry food around the body.
C. They help to get rid of carbon dioxide.
D. They kill micro-organisms harmful to the body.

5. Which of these is not an agent of weathering?

A. Wind.
B. Rain.
C. Moon.
D. Sun.

6. Look at the diagrams on reflection. Which shows the proper reflection of a ray of light on a plane mirror?



7. Many plants which have weak stems climb on other stronger plants. They do this to get more ...

A. space.
B. fresh air.
C. sunlight.
D. warmth.

8. It is important to leave spaces between the sticks when a fire is laid ready for lighting. This is because ...

A. fewer sticks are then needed and this saves wood.
B. the smoke is made to rise easily.
C. the temperature of the flame can be controlled.
D. the air between the sticks is needed for burning.

9. Two beakers are filled with the same amount of water and put into two identical heaters. One beaker X is covered with lid while beaker Y is left exposed. Which will boil first and why?

A. Y because less heat is lost.
B. X because heat loss is reduced.
C. All because they receive equal heat.
D. None because the heat received is little.

10. Study the table carefully.

PLANT	ENERGY GIVING FOOD	BODY BUILDING FOOD	PROTECTIVE FOOD
BEAN	little	plenty	little
MANGO	little	little	plenty
GROUNDNUT	little	plenty	little
PAWPAW	little	little	plenty
IRISH POTATO	plenty	little	little

Using the Table we can say ...

A. irish potatoes and groundnuts give us plenty of protective food.
B. we get plenty of body-building food from beans and groundnuts.
C. we get plenty of protective food from beans and mangoes.
D. pawpaws and mangoes give us plenty of body-building food.

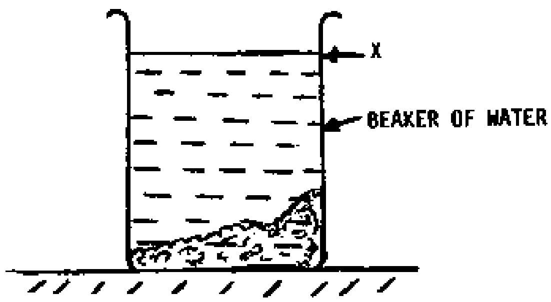
11. Which one of the following statements contains information about friction?

A. Attraction of a body to the earth.
B. Property of matter which causes it to be attracted to any piece of matter.
C. Decreases as the distance from the earth increases.
D. Offering resistance to movement between surfaces in contact.

12. When Chiko examined a lump of soil she found that it was dark in colour, was not sticky but contained some plant matter What type of soil was it?

A. Sandy soil.
B. Clay soil.
C. Swampy soil.
D. Loam soil.

13.



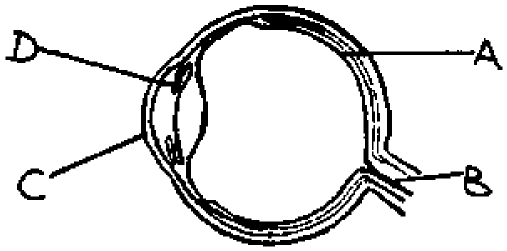
Look at the diagram. Besa dropped a lump of soil into a beaker of water. What did he probably find at X?

A. Humus.
B. Stones.
C. Sand.
D. Clay.

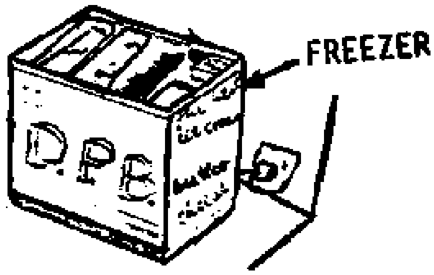
14. Dog belongs to the same group of animals as ...

A. lizard, fish and whale.
B. cow, camel and crocodile.
C. man, cat and bat.
D. chicken, pig and rat.

15. Look at the diagram of the eye. Which part controls the amount of light getting into the eye?



16. A freezer in a shop does not need a lid. The ice cream or butter inside does not melt because ...



A. cold air does not rise,
B. the fridge absorbs radiation.
C. the fridge is a good conductor.
D. the shop is freezing.

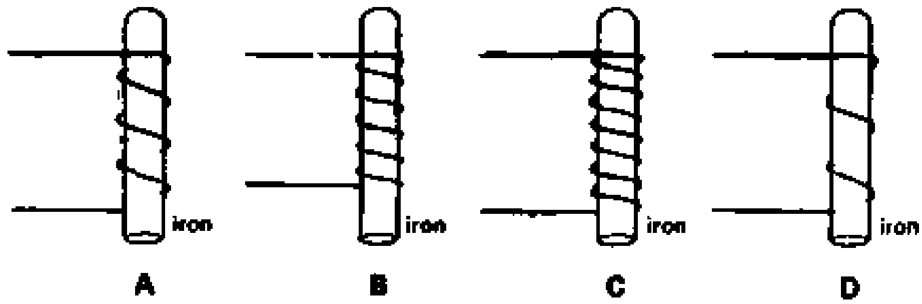
17. People can protect themselves from mosquitoes bites by ...

A. going to nearest clinic every week.
B. staying awake the whole night.
C. spraying floors with oil.
D. spraying oil on stagnant water.

18. Muleya was asked to separate sugar from a mixture of sugar and sand. Which of the following methods would be the best **way** of doing this?

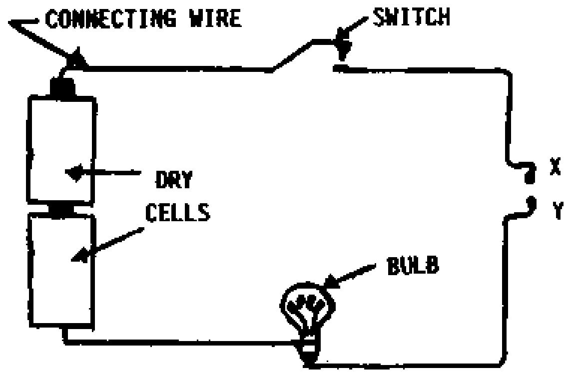
A. Filtering, evaporating, dissolving.
B. Dissolving, filtering, evaporating.
C. Evaporating, filtering, dissolving.
D. Filtering, dissolving, evaporating.

19. An electro magnet can be considered to be a temporary magnet made from a coil of wire connected to a cell and an iron piece in the centre. Which one of the electro magnets would have the weakest magnetic field?



20. Zwange made an electric tester. He tested items by connecting them to **X** and **Y**. The results are shown in the table.

Material	light
coin	on
comb	off
chalk	off
knife	on
hair	off
nail	on



The results show that electricity can pass through ...

A. the coin and nail only.
B. the comb, chalk and knife.
C. the knife, nail and coin.
D. the nail and knife only.

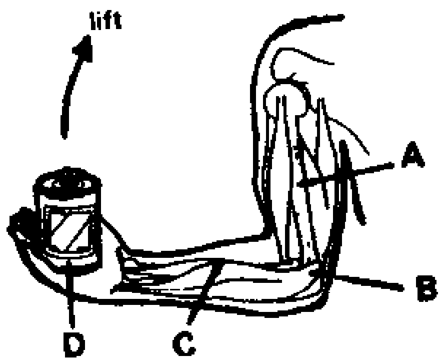
21. A potted plant in the house changed from green to yellowish. What would you do to make the plant green again?

A. Expose it to more light.
B. Put it in the dark.
C. Give it more water.
D. Give it more fertilizer.

22. Plants make fruits to ...

A. attract bees.
B. feed the leaves.
C. enable people to eat them.
D. help seed dispersal.

23. Which is a pivot in the drawing?



an arm lifting a weight

24. A female frog lays many hundreds of eggs at a time which hatch into tadpoles. What happens to all these tadpoles?

A. They all grow into frogs.
B. Many are eaten and only a few grow into frogs.
C. A few are eaten and many grow into frogs.
D. All are eaten.

25. What is the main value of compost?

A. It prevents soil erosion.
B. It puts valuable plant foods back into the soil.
C. It prevents the spread of pests and diseases.
D. It makes it possible for water to enter the soil.

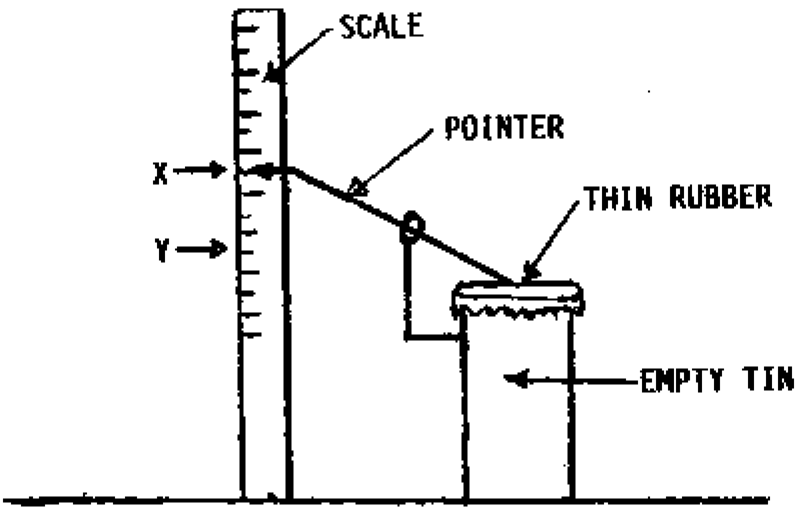
26. Which of these will expand most when heated?

A. Ice.
B. Water.
C. Air.
D. Rubber.

27. One of the factors that might increase the rate of evaporation of water is ....

A. surface area.
B. volume.
C. weight.
D. depth.

28. The diagram below shows a simple barometer prepared by the members of a Science Club. The movement of the pointer in upward and downward directions indicates the weather conditions.



It was observed that the pointer suddenly moved DOWN from X to Y. This indicates that the ...

A. air pressure has decreased.
B. air pressure has increased.
C. temperature of the air has increased.
D. amount of carbon dioxide in the air has increased.

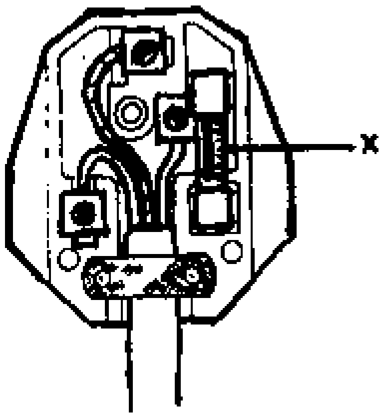
29. In the daytime leaves make use of carbon dioxide to ...

A. make food for the plant.
B. make the atmosphere cool.
C. keep the plant cool.
D. remove wastes from the plant.

30. A mother wanted to make a balanced meal with MEAT, RICE and CABBAGE. She could not get any cabbage. Which food would she use in the place of cabbage?

A. Fish.
B. Pumpkin leaves.
C. Carrots.
D. Maize.

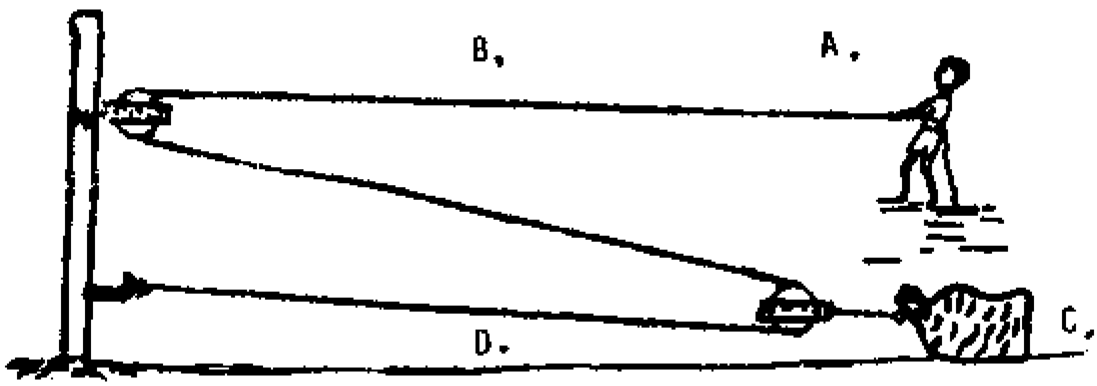
31. Look at the drawing of an electric plug below.



What is the name of the part labelled X?

A. Fuse.
B. Earth.
C. Switch.
D. Insulator.

32. The rope is pulled by Tobolo. The bag of maize will move towards



33. Before hatching, a bird embryo gets food from ...

A. seeds.
B. the yolk.
C. shell.
D. chicken's blood.

34. Lungs are like ...

A. two large empty ballons.
B. two large ballons filled with blood.
C. spaces in the body filled with bones.
D. sponges with lots of very small air pockets.

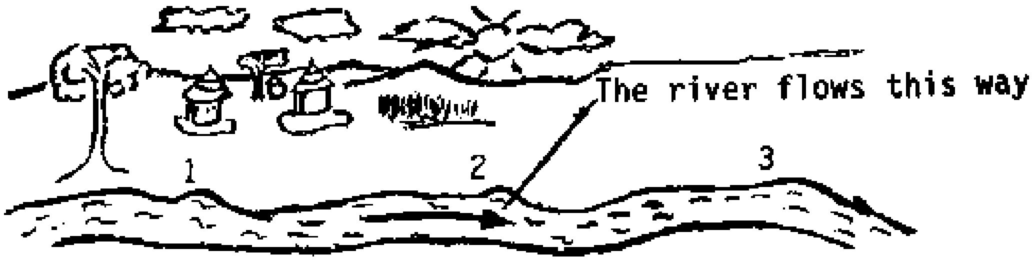
35. What energy change takes place in the pump when a boy is pumping up a bicycle tyre?

A. Heat-kinetic.
B. Heat-potential.
C. Kinetic-potential.
D. Potential-chemical.

36. A blacksmith makes an iron tyre for a wooden wheel. The iron tyre is just too small to fit over the wheel. To make it fit over the wheel, the blacksmith ...

A. heats the tyre.
B. cools the tyre.
C. heats the wheel.
D. cools the wheel.

37. This is a picture of a village along a river.



The three places marked are to be used for fetching drinking water, bathing and for animals to drink. Which is the **best** arrangement?

A. Bathing at 1, fetching drinking water at 2, animals at 3.
B. Fetching drinking water at 1, animals at 2, bathing at 3.
C. Animals at 1, bathing at 2, fetching drinking water at 3.
D. Fetching drinking water at 1, bathing at 2, animals at 3.

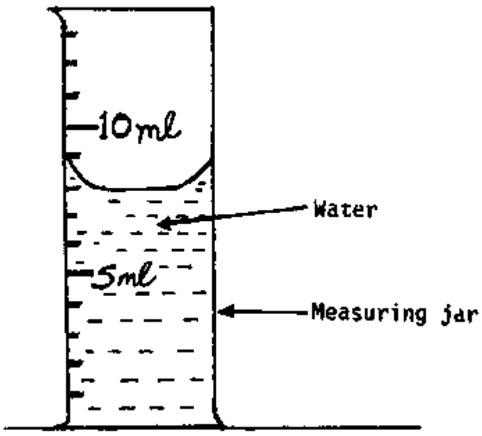
38. A food chain always starts with ...

A. Man.
B. Bread.
C. Plant.
D. Insect.

39. When Manda first walked into a dark room, he could not see anything until after sometime. This was because ...

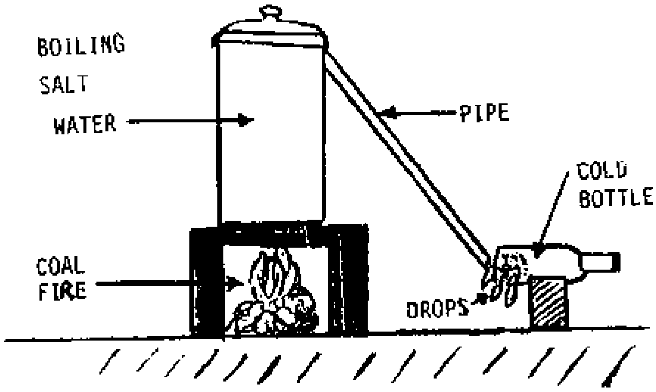
A. his pupils were too wide.
B. he was blind.
C. his pupils were too narrow.
D. his retina was damaged.

40. Look at this drawing of water in a measuring jar. How much water is in the jar?



A. 3 ml.
B. 8 ml.
C. 9 ml.
D. 13 ml.

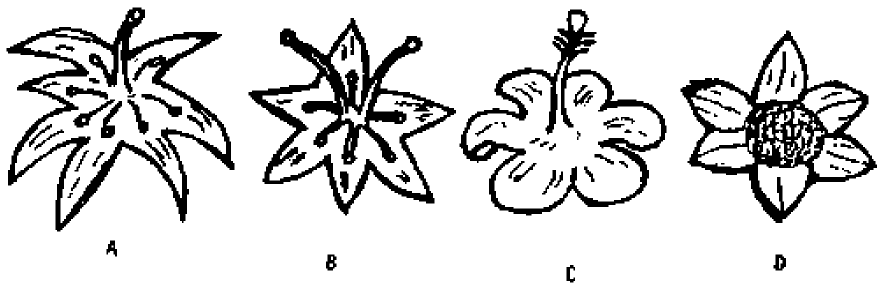
41. Study the diagram carefully.



The water drops formed are ...

A. very salty.
B. salty.
C. not salty.
D. slightly salty.

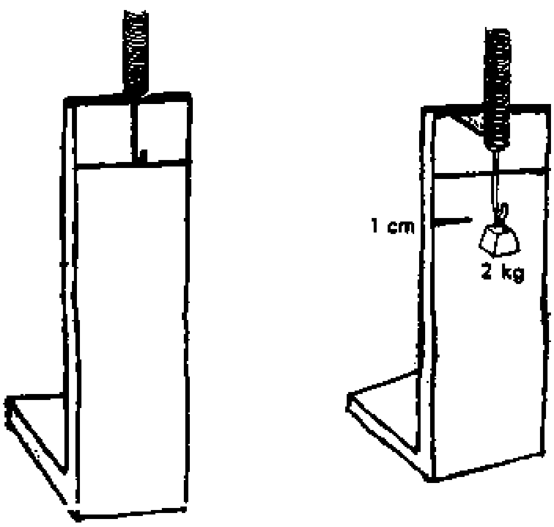
42. The teacher gave four pupils a task to do. They had to find a flower with many male parts, 2 female parts and 6 petals. Each pupil came back with a different sort of flower. Which pupil found the right flower?



43. Study the diagram carefully. A block of wood is allowed to slide down the ramp. The table shows the angle through which the ramp has to be tilted before the block will slide. Which surface gives the least friction when fixed on the bottom of the wood?

	surface	angle
A	Plastic	15°
B	Cork	22°
C	sandpaper	32°
D	polystyrene	28°

44. Look at the drawings. The length of the spring increases by 1 cm with 2 kg. How much does the length increase with 6 kg?



A. 2 cm.
B. 3 cm.
C. 6 cm.
D. 12 cm.

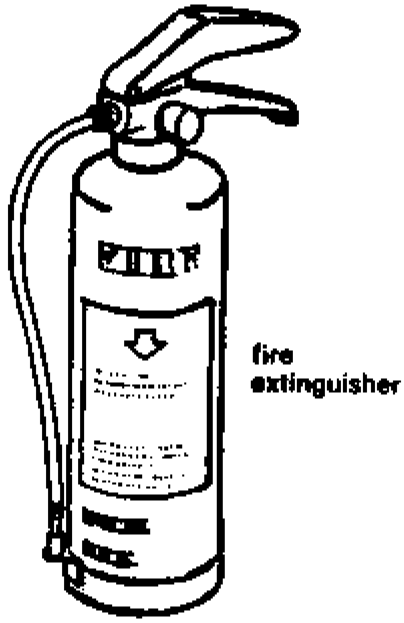
45. Nigeria has a lot of oil wells. This oil could have been formed from ...

A. coal.
B. dead plants.
C. petrol.
D. rocks.

46. The earth was formed from ...

A. dead animals which were crushed.
B. molter material which cooled down.
C. large mountains which joined together.
D. rocks which were joined together by water.

47. A picture of fire extinguisher is shown. Which set of gases can be in the fire extinguisher?



A. Oxygen and carbon dioxide.
B. Oxygen and nitrogen.
C. Carbon dioxide and nitrogen.
D. Nitrogen, oxygen and carbon dioxide.

48. Which means of communication has the shortest range?

A. Drumming.
B. Smoke signals.
C. Telephone.
D. Telex.

49. Before a smoke signal can be sent, what weather conditions must prevail?

A. Calm, sunny.
B. Windy, sunny.
C. Cloudy, windy.
D. Cloudy, dark.

50. When a gun is fired, sound and light are produced in addition to the bullet, being shot. From what energy are the sound and light produced?

A. Heat.
B. Kinetic.
C. Chemical.
D. Electrical.

STOP! GO BACK AND CHECK YOUR WORK

3.10.4 Environmental Science Paper 1993

EXAMINATIONS COUNCIL OF ZAMBIA

ENVIRONMENTAL SCIENCE

PAPER 4

TIME: 60 MINUTES

S/SENVSC4/G7/93

1. Read these instructions carefully.

2. DO NOT turn this page before you are told. Your teacher will tell you when to turn this page to begin the questions.

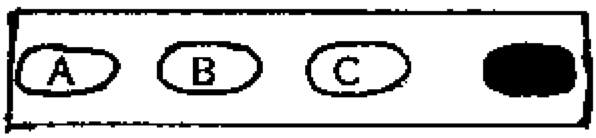
3. There are 50 questions in this SCIENCE paper. You will be given EXACTLY 60 MINUTES to do the questions.

4. For each question four answers are given, but only one of the four is right. Work out which is the BEST answer. Then, on your ANSWER SHEET shade the answer space of the letter of your choice in pencil.

EXAMPLE: Malaria, leprosy and Measles are names of ....

A. plants.
B. insects.
C. minerals.
D. diseases.

The best answer is D, you would show this answer like this:-



5. You must SHADE your answer spaces COMPLETELY and DARKLY WITH A PENCIL. If you have to change your answer, you must rub out the shading VERY NEATLY before shading the new one. USE A CLEAN RUBBER.

6. When you have finished one page, go straight on without waiting to be told. If you have time left at the end of the question paper, use it to check your work carefully

7. Look at your ANSWER SHEET. At the top it should have your name, sex, date of birth, examination number, primary school name and name of secondary school of your choice. It

should also say PAPER 4 ENVIRONMENTAL SCIENCE on the bottom left side.

8. You will NOT be able to ask questions once the examination has began.

<u>DO NOT TURN THIS PACE UNTIL YOU ARE TOLD</u>

<u>USE ONLY A PENCIL FOR YOUR ANSWERS</u>

1. The germ that causes AIDS can be mostly spread by ......

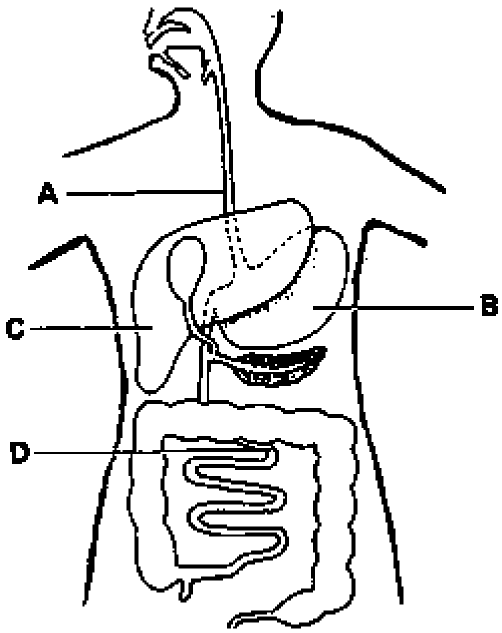
   A. sexual intercourse.
   B. sharing the toilet.
   C. shaking hands.
   D. mosquito bites.

2. A house fly can spread ....

   A. dysentry, T.B and polio.
   B. dysentry, cholera and typhoid.
   C. dysentry, cholera and TB.
   D. cholera, polio and AIDS.

3. Look at the diagram of the human food canal below.

There are parts labelled A, B, C, and D.



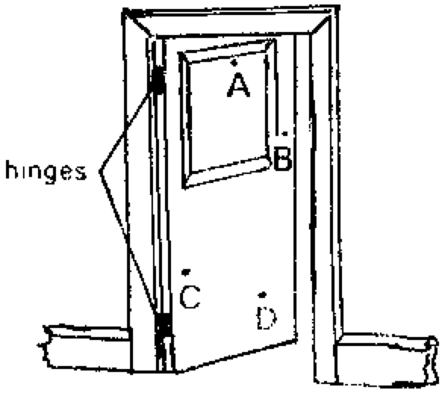
Which part is the liver?

4. At under five clinics infants and young children are immunised against the following diseases:-

   A. AIDS, Cholera, Diarrhoea and Polio.
   B. Polio, TB, Tetanus and Whooping Cough.
   C. AIDS, TB, Cholera and Whooping Cough.
   D. Polio, TB, AIDS and Cholera.

5. You have to push the door to open it.

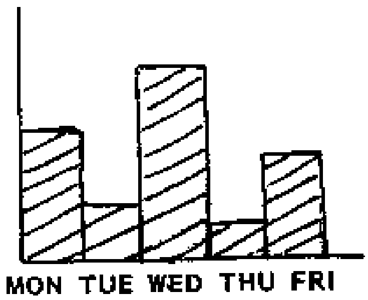
At which point would you use the smallest force?

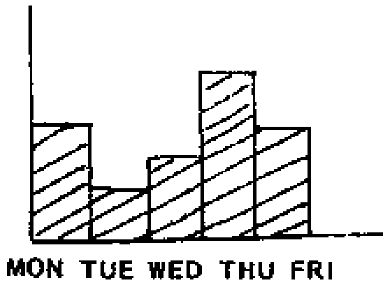


6. Blowing, over the open end of a cap of a fountain pen creates sound because ....

A. air in the cap vibrates.
B. air outside the cap vibrates.
C. lips of the person blowing vibrate.
D. air in the cap stops vibrating.

7. Here are two graphs from a school weather record, in the same week

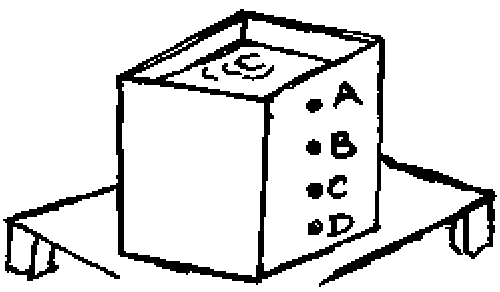




The first one shows the speed of wind. The second shows the temperature. Which statement is right?

A. The hottest day had the slowest wind.
B. The hottest day had the fastest wind.
C. The coldest day had the slowest wind.
D. The coldest day had the fastest wind.

8. Water is poured into a can that has four holes on its side. From which hole will water come out with greatest force?



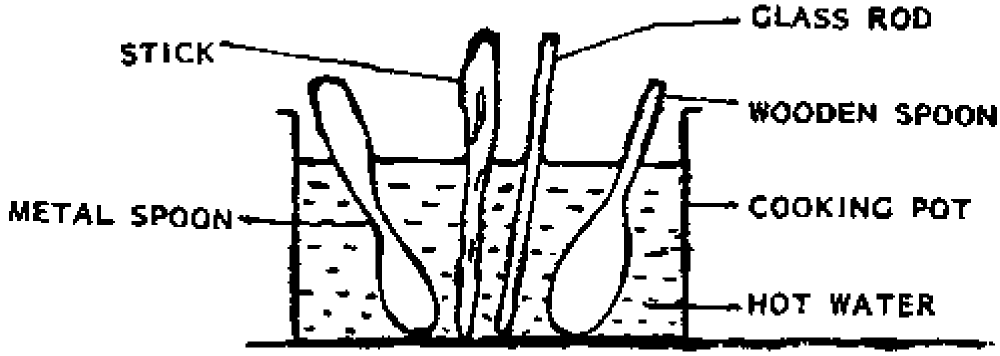
9. Seeds dispersed by wind should be ....

A. tiny and hard.
B. light and featherly.
C. heavy and featherly.
D. flat and hard.

10. Some valleys are not suitable for rearing cattle because.......

A. they are hot.
B. there is too much water.
C. they are tsetse fly infested.
D. there are a lot of wild animals.

11. The diagram shows a cooking pot containing very hot water. There are four things dipping into it.



After ten minutes, which of the following will feel the hottest?

A. Glass rod.
B. Stick.
C. Wooden spoon.
D. Metal spoon.

12. Weather forecasting is important because ....

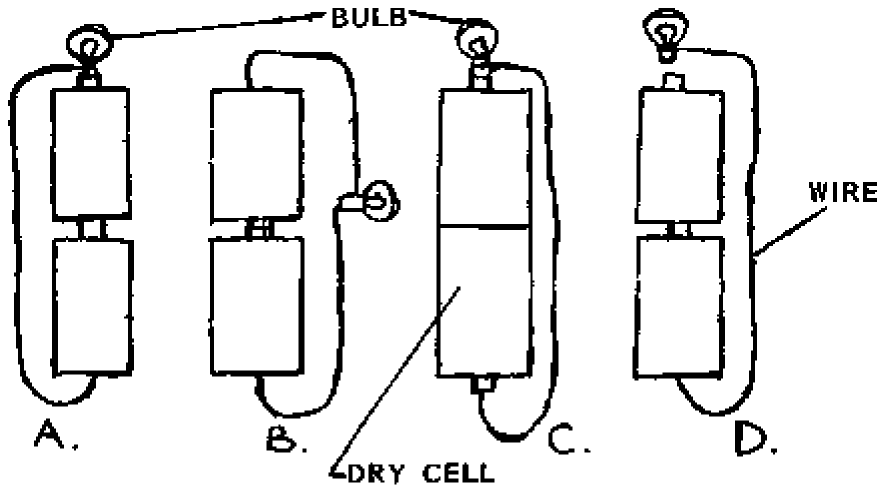
A. farmers can plan their work.
B. wind direction can be changed.
C. rainfall can be changed.
D. drought will not occur in the country.

13. Below is a diagram of a telephone system.

What is X?

A. Mouth Piece.
B. Ear Piece.
C. Radio.
D. Switch Board.

14. Study the four diagrams of electric circuits below. Which one will light?



15. Why should we switch off lights when they are not needed?

A. To make room cooler,
B. To help save energy.
C. To use more charcoal.
D. To recharge the bulbs.

16. Samples of water were collected from Kafue, Luangwa, Kabompo and Chambeshi rivers. Which sample will show the greatest amount of pollution and why?

A. Luangwa because it is a fast flowing river.
B. Kabompo because it flows through a rain forest.
C. Kafue because it flows through Industrialised areas.
D. Chambeshi because it flows into Bangweulu Swamps.

17. As the earth goes around the sun it rotates from ....

A. east to west.
B. north to south.
C. west to east.
D. south to north.

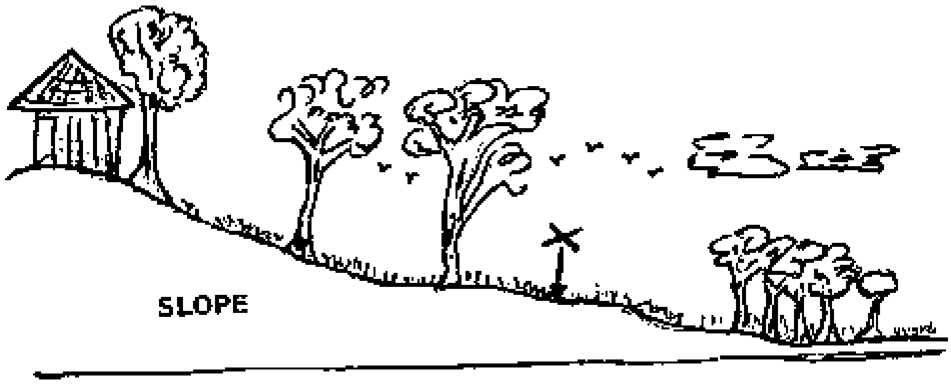
18. Animal manure is better than artificial fertilizer because ....

A. it is cheap and is easy to apply.
B. it fertilizes the soil as well as improves the soil structure.
C. it is black and contains plant food in large quantities.
D. it provides more nitrogen than artificial fertilizers.

19. The property of copper that makes it useful to the world is its ...

A. bright colour.
B. softness.
C. good conductivity.
D. good insulation.

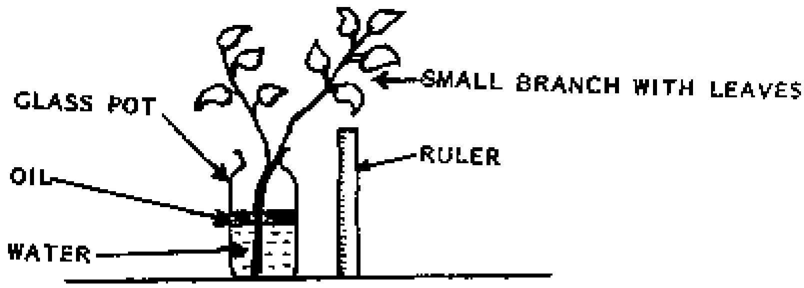
20. Study the diagram below and answer the question that follows.



We can stop soil erosion at X by......

A. ploughing across the slope.
B. ploughing along the slope.
C. cutting down trees.
D. burning the area around.

21. A boy sets up an experiment shown in the diagram below. Every twelve hours the boy measures the height of the water in the glass pot.



What is the most likely thing the boy is trying to find out?

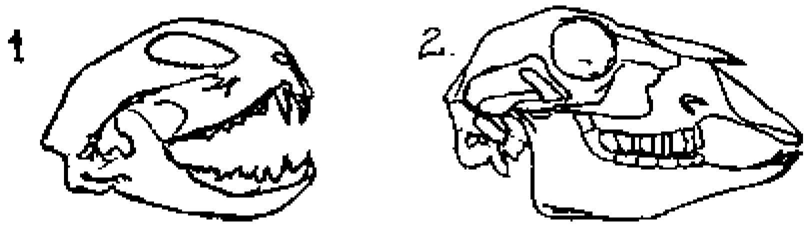
A. Whether oil will kill the plant.
B. Whether the plant needs carbon dioxide and oxygen,
C. Whether the plant needs carbon dioxide alone.
D. Whether the plant uses up water.

22.

The drawings show the feet of three different birds. Below are four pairs of statements. Pick out the answer where BOTH statements are correct.

A. Foot 1 is of a bird of prey and foot 3 is of a swimming bird.
B. Foot 2 is of a perching bird and foot 3 is of Bird of prey.
C. Foot 3 is of a swimming bird and foot 2 is of a bird of prey.
D. Foot 1 is of a bird of prey and foot 2 is of a swimming bird.

23. Look at these drawings. They are the jaws of two different animals. Which of the following is true?



A. Both animals feed on plants only.
B. Animal 1 feeds on plants and animal 2 feeds on meat.
C. Animal 1 feeds on meat and animal 2 feeds on plants.
D. Both animals feed on meat only.

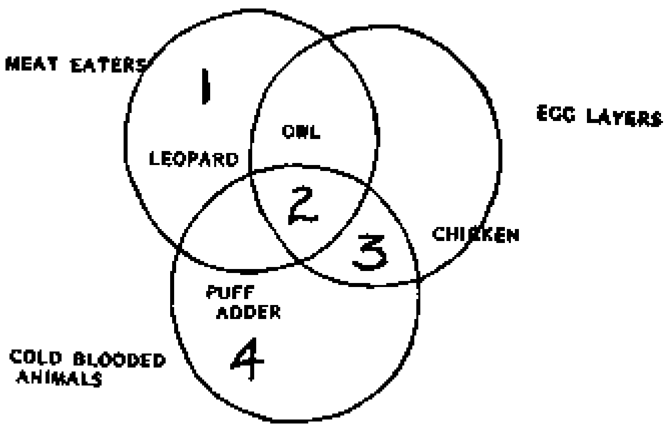
24. A vacuum flask keeps a hot drink warm for a long time because it..

A. radiates heat out.
B. reduces the heat escaping.
C. reduces the light getting out.
D. keeps warming the drink.

25. Water can exist as ....

A. liquid, air and gas.
B. solid, liquid and gas.
C. nitrogen, oxygen and water vapour.
D. oxygen, nitrogen and carbon dioxide.

26.

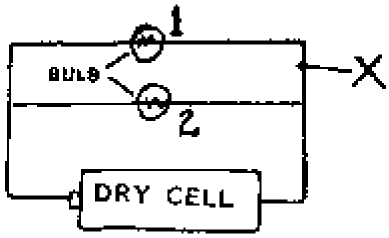


The tortoise is a cold-blooded animal that eats plants and lays eggs. Which number shows its correct position on the diagrams?

A. 1.
B. 2.
C. 3.
D. 4.

27. Look at the diagram. The wire is broken at X. What happens?

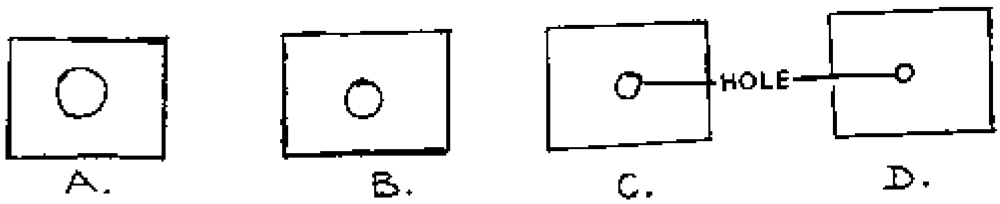
A. Both bulbs will stay a light,
B. Only bulb 1 will go out.
C. Only bulb 2 will go out.
D. Both bulbs will go out.



28. What energy changes take place when the battery lights up the bulb?

A. Electrical → Might → chemical.
B. Light → electrical → potential.
C. Chemical → electrical → heat and light.
D. Heat → kinetic → heat and light,

29. The diagrams show different size holes of a camera. Which hole will give the best image if the inside of the pinhole camera is painted black?



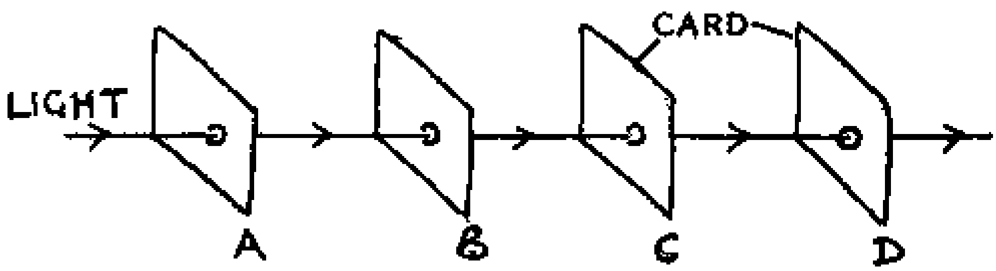
30. The best way to make a piece of steel into a magnet is by:

A. Stroking a magnet with the piece of steel.
B. Stroking the piece of steel with a magnet in the same direction.
C. Stroking the piece of steel with a magnet in different directions
D. Hitting the piece of steel with a magnet.

31. A boy pulls a box across a table. The friction is most if the table ....

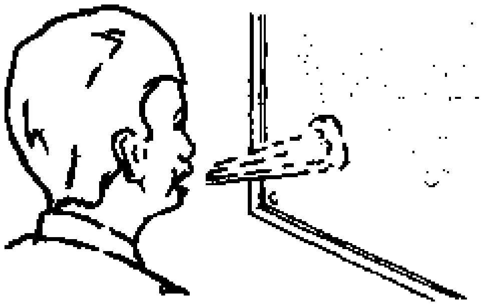
A. is rough.
B. is smooth.
C. has beads on it.
D. has rollers on it.

32. Look at the diagram. If the hole in CARD C is covered, there will be no light between:



A. A and B.
B. B and C.
C. C and D.
D. A and D.

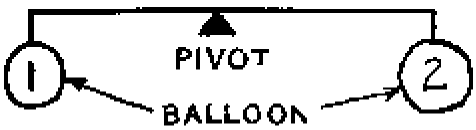
33. In the picture below a boy is shown breathing out in front of a mirror.



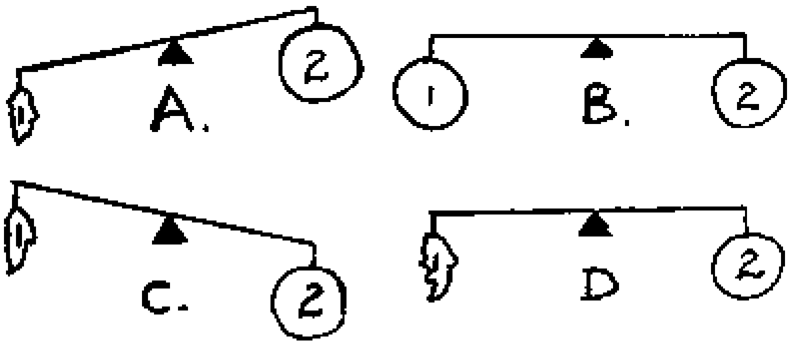
Which change is taking place on the mirror?

A. melting.
B. freezing.
C. evaporation.
D. condensation.

34. Study the diagram below:



Two balloons 1 and 2 balance horizontally. Balloon 1 is slowly losing air until all the air is lost. Which diagram correctly shows what happened?



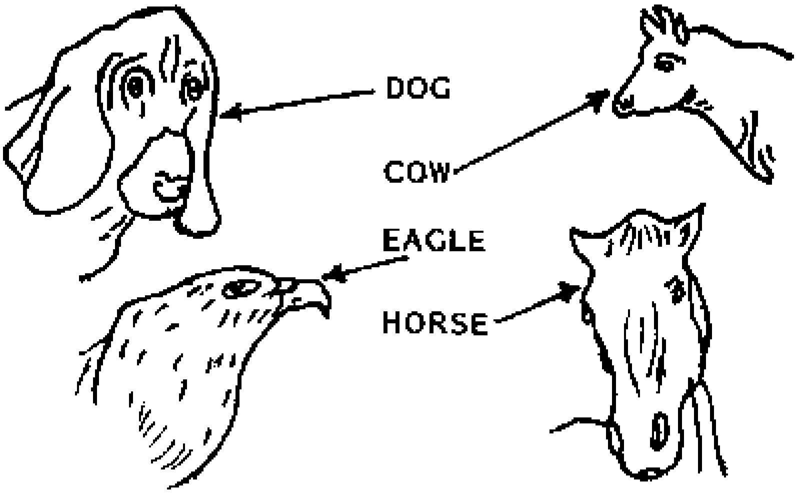
35. Gravity can act only on ....

A. large masses on the earth.
B. all things on the ground.
C. things around and on the earth.
D. things at the south and north poles.

36. When a person breathes out during respiration the air contains

A. more oxygen, less carbon dioxide and more nitrogen than ordinary air.
B. more nitrogen, less oxygen and more carbon dioxide than ordinary air.
C. more carbon dioxide, less oxygen and more water vapour than ordinary air.
D. less nitrogen and oxygen than ordinary air.

37.



Given above is a set of four common animals. Study them carefully.

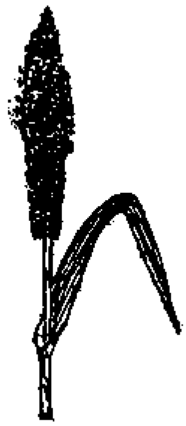
The DOG is different from the other animals shown because it is the only animal in the set that ......

A. eats meat.
B. suckles its young.
G. eats meat and suckles its young.
D. is a domestic animal.

38. An example of an animal which is cold-blooded <u>and</u> has a backbone is a ....

A. snail.
B. snake.
C. giraffe.
D. hippo.

39. Look at the drawing of a plant below.



Pollination in this plant is most likely to be carried out by ....

A. bees.
B. wind.
C. moths.
D. water.

40. Heat is lost more rapidly by a surface which is ....

A. red.
B. black.
C. white.
D. silver.

41. The correct list of gases in ordinary air starting with the most abundant is ....

A. oxygen, nitrogen, carbon dioxide.
B. nitrogen, oxygen, carbon dioxide.
C. oxygen, carbon dioxide, nitrogen.
D. carbon dioxide oxygen nitrogen.

42. The string of a guitar can be made to give higher pitch and louder sound by ....

A. lengthening the string and plucking it harder.
B. Shortening the string and plucking it harder.
C. lengthening the string and plucking it gently.
D. shortening the string and plucking it gently.

43.

Plants EATEN BY Animals DIE AND BROKEN UP BY Microbes.

In the diagram above, microbes play the part of ....

A. producers.
B. consumers.
C. decomposers.
D. parasites.

44. Which of these crops would do better in a drought stricken area?

A. Maize.
B. Millet.
C. Rice.
D. Potatoes.

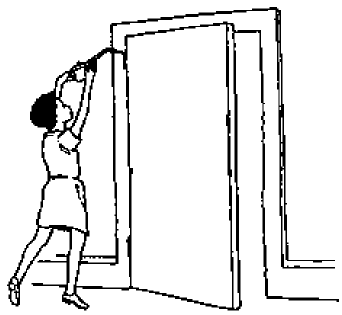
45. 30 ml of sand is poured into 30 ml of peas. After mixing, the volume is less than 60 ml.

This is because the grains of sand ....

A. melt into the peas,
B. fit between the peas,
C. are all the same size,
D. are harder than the peas.

46. The hinges on a door are oiled. When the door is moved, the friction in the hinges is ....

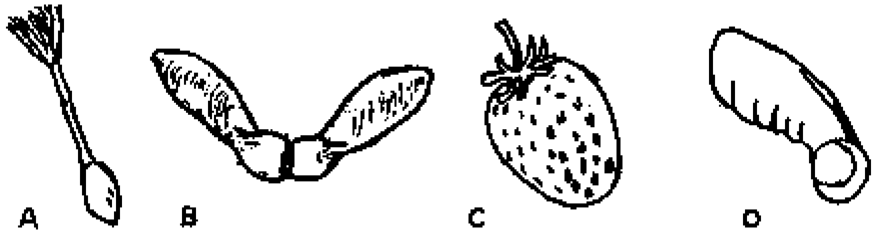
A. the same,
B. bigger than before,
C. smaller than before,
D. Slightly more than before.



47. Fertilization takes place in plants when ....

A. seeds join with fruits,
B. pollen grains join with ovules,
C. pollen grains are carried to the stigma,
D. pollen grains are released from a flower.

48. Look at the drawings below.



Which one is not scattered by wind?

49. Seeds are dispersed so that when young seedlings grow they

A. can be fertilized.
B. will be pollinated.
C. are not overcrowded.
D. Cannot be eaten by ants.

50. Salt is dissolved in water while stirring continously until more dissolves. More salt could be dissolved by ...

A. cooling.
B. heating.
C. shaking.
D. vapourizing.

3.11. Zanzibar

3.11.1. Overview

End of Primary School Examination

1.	**Title of examination:**	Form 1 Entrance Examination
2.	**Amount of fees charged:**	Nil
3.	**Examination after years in primary school (6, 7, 8 years):**	7 yrs
4.	**Children's entry age in primary school:**	7 yrs
5.	**Number of pupils sitting examination in 1994:**	7,189
6.	**Examination subjects offered:**	9 subjects • Science • Mathematics • Geography • History

		• Kiswahili • English • Political Education • Arabic • Religious Studies
7.	**Language of examination:**	Kiswahili
8.	**Institution setting the examination questions:**	Ministry of Education, Dept. of Higher, Science and Technical Education
9.	**Have there been any reforms in the examination questions?**	Yes
	When? (year)	1993
	What kind?	Children are in future tested after class 7 of primary school to select some for special secondary schools (Technical Schools, Islamic Schools, Science Schools, French Language School)
10.	**Stages of development of examination questions (please describe):**	• Primary school teachers write items in all subjects individually • Items reviewed by one moderator (Primary school teachers and school inspectors and exam officers) per subject at national level • Moderators set final exam paper
11.	**Type of examination questions and distribution of different kind**	Straight-forward recall questions only
12.	**Is continuous assessment incorporated in the final examination?**	Yes [ ] No [x]
13.	**Are examination items pretested?**	Yes [ ] No [x]
14.	**Which professional groups are involved in setting the examination questions?**	• Primary school teachers • School inspectors • Curriculum designers • Exam officers of the Ministry of Education
15.	**Are the same professionals who set the examination questions involved in marking papers?**	Yes [x] No [ ]
16.	**How are examination results used for improving teaching in primary schools?**	./.
17.	**To what other uses are the examination results put?**	Selection for Secondary School (Form 1) and assessing the general performance of primary schools
18.	**Main problem with Primary School Leaving Examinations?**	• Lack of skills and experience in designing test items • No facilities for proper data analysis and item banking • Lack of skills and experience in item analysis

3.11.2. An Overview of the 1993 Primary School Leaving Examination

by Ministry of Education

Background

Zanzibar consists of two islands - Unguja and Pemba. It provides 10 years of compulsory basic education. At the end of seven years of primary school there is a common examination, called Form 1 Entrance Examination.

Setting of the Examination

All primary schools are individually asked by their respective District Education Officers (DEOs) to set papers according to the level of the National Form 1 Entrance Examination. These papers are brought to the examination office by the DEOs. Each year, 3 to 4 papers from different Districts are given to one experienced primary school teacher for moderation. The paper that has been approved by the moderator is the one that becomes the National Paper (one man moderation).

Administration of the Examination

The examination is normally administered in the month of November each year. A total of 9 subjects are examined at this level and it takes 5 days to administer them.

Supervision of the Exam

The examination is supervised at national level. Most of the supervisors are head teachers or assistant head teachers. Schools in Unguja are supervised by people from Pemba and vice versa.

Invigilation

Invigilation is done at regional level by teachers of different schools. Teachers from one region are sent to another region for invigilation. Teachers from the hosting schools are not permitted to be present in school, unless assigned a special duty.

Despatching of Answer Scripts

Answer scripts are collected at the examination offices everyday. The papers are stored at the office waiting for marking. Since Zanzibar is a small country it is possible to collect all the papers on the same day.

Attendance

In 1993, out of 9,710 registered candidates from 128 primary schools 9,200 (94.75%) sat for the examination. The rest were reported to either have dropped out of the school between the time of registration and the time of examination or to be sick during the examination period.

These pupils are normally allowed to repeat the last year of primary school and re-sit for the National Examination.

Objectives of Zanzibar Primary School Leaving Examination

1. To select few students who will be admitted to Secondary Schools with special biases. From the 1993 examination, 290 (3.2%) candidates were selected to enter 8 secondary institutions with the following specializations:

- 2 Technical Secondary Schools which each take 40 students every year.

• 1 Muslim Academy which takes 40 students every year.

This institution, in addition to the normal secondary school subjects, also teaches Arabic and Islamic Studies.

• 1 French Secondary School which takes 40 students every year.

• 1 Secondary School with the emphasis on Science accommodating 40 students every year.

• 10 students are sent to Tabora Military School in Mainland Tanzania.

Students who are admitted in these Secondary Schools study O-level subjects and sit for the National (Tanzania) O-level Exam. Vacancies in the secondary schools are distributed quarterly to all districts, whereby female students will be considered preferentially to increase their enrollment.

2. To identify repeaters, e.g. candidates who performed poorly.

3. To assess the general performance of the schools, for both teachers and students.

4. To assess the performance of individual students at the end of their primary education.

Results

Out of 9,200 candidates who sat for the Examination, 8,463 (91.9%) were taken to secondary schools. This is because, in Zanzibar we have ten years of compulsory education (8 primary + 2 secondary). However, this system will be changed to 7 plus 3 years, where the 8th year is used as a preparatory year to secondary school. Emphasis at this stage is put on English and Mathematics. Official statistics of the examinations only show the averages of different subjects for different schools. No further statistical analysis is employed, due to lack of skills and resources.

Comments on the Performance

Generally the performance on the 1993 primary education examination was not satisfactory. Pass mark had to be lowered to an average of 20% in order to admit about 90% of the students in Form 1. All schools performed very poorly in all subjects, except in History.

Examination Problems

During the December 1993 »Science Camp« an analysis of the 1993 Science and Mathematics Examination question papers was carried out (»Science Camp« is a research activity project which has been conducted annually during the month of December since 1988).

This research project tries to define efficient methods for the teaching of Science. From the analysis we found out that our examinations consist mainly of straight forward recall questions and ask pupils to reproduce from memory. It was realized that encouraging enquiry, reasoning and problem solving in teaching Science has also to be reflected in the examinations.

It is hoped that in the next years, questions will be included that require problem solving and enquiry based skills.

3.11.3 Form 1 Entrance Examinations 1994 - Science Paper (English Translation)

Candidate's Number ....

ZANZIBAR REVOLUTIONARY GOVERNMENT

MINISTRY OF EDUCATION

SCIENCE

TIME: 1.30 HOURS.

<u>INSTRUCTIONS TO CANDIDATE</u>

ANSWER ALL QUESTIONS IN THIS PAPER

THIS PAPER CONTAINS 8 WRITTEN PAGES

Candidate's Number ....

CHOOSE THE MOST CORRECT ANSWER AND WRITE THE LETTER IN THE BRACKET PROVIDED.

Example:

The gas that animals use most is

A. Carbondioxide
B. Oxygen
C. Hydrogen
D. Nitrogen (B)

1. Choose one set of living organisms without a vertebral column among the following set given:

A. Butterfly, tortoise, bat, mouse.
B. Snake, millipede, lizard, chameleon
C. Millipede, snail, cockroach, chameleon
D. Grasshopper, millipede, butterfly, snail.( )

2. What are the necessary needs for the life of animals.

A. Food, water and medicine
B. Food, air and medicine
C. Food, water and air
D. Protein, starch and oil ( )

3. Most insects have 4 stages in their life cycle. The correct sequence is.

A. Egg, larva, pupa, adult insect.
B. Larva, egg, pupa, adult insect.
C. Egg, pupa, Larva, adult insect.
D. Larva, pupa, egg, adult insect. ( )

4. Which is the most important difference between animals and plants ?.

A. Animals moves while plants don't.
B. Animals feed on food while plants don't.
C. Plants manufacture their own food while animals don't.
D. Plants have a short life cycle than animals. ( )

5. One among the following is not an excretory organ. Which organ is this ?.

A. Tongue
B. Skin
C. Lungs.
D. Kidney ( )

6. Roots are the most important part of the plant because:

A. They hold the branches of the tree.
B. They add the thickness of the stem
C. They make food.
D. They absorb mineral salts from the soil. ( )

7. After being measured by the doctor, Khatib, has been found to have a temperature of about 37°C. In Fahrenheit, this is equivalent to

A. 37°F
B. 69°F
C. 66.6°F
D. 98.6°F ( )

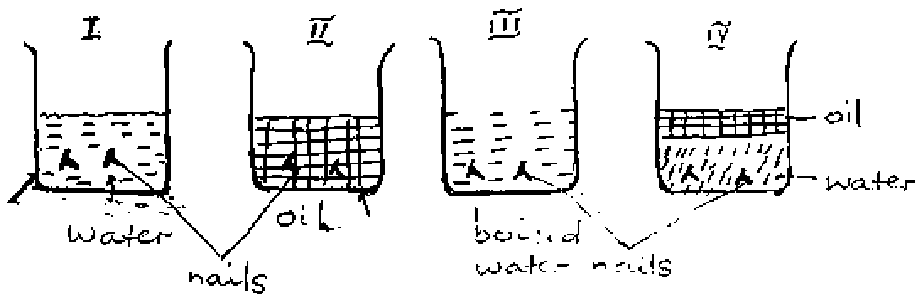
8. Sugar which has dropped in a sauce pan containing water can be separated by using which method ?

A. Boiling and evaporation.
B. Filtering the mixture.
C. Decantation.
D. Solidifying the mixture. ( )

9. Which among the following set of items are appropriate to use in measuring and recording the height of a growing plant in a shamba?

A. Ruler, pencil, book.
B. Ruler, pencil, ink.
C. Notebook, pencil, measuring, scale.
D. Notebook, ruler, and a piece of thread ( )

10. Std 8 pupils of Uroa School, did an experiment to find the factors that cause rusting. They did their experiment as shown in diagram I, II, III, IV, below. They left the experiment for one week.



Rusting will occur in

A. Diagram I only.
B. Diagram II and III.
C. Diagram II and IV.
D. Diagram IV only. ( )

11. The density (gm/cm^3) of an object having a mass 2.06 gm and a volume 2.0 cm^3 is

A. 0.97
B. 1.03
C. 4.06
D. 4.12 ( )

12. Which among the following object is a 2^{nd} class lever?.

A. Human arm
B. Crowbar
C. Scissors
D. Wheel barrow ( )

13. One pupil in her experiment has sown some bean seeds in 3 different type of soils - loamy soil, clay and sandy soil. All had equal weight. She waters the plant with equal amount of water at the same time in the morning. In this expt, the student could be able to find.

A. That water is necessary for seed germination.
B. That the amount of water affect growth.
C. The type of soil which is good for planting beans.
D. The best time for watering bean seedlings. ( )

14. Which among the following statements is <u>false</u>?

A. Electric current is a flow of electron.
B. When the guitar strings are tightened, vibrations increase.
C. During eclipse of the sun, the earth is found between the sun and the moon.
D. Magnetism can pass through the paper. ( )

15. Choose among the following example below, that show the correct sequence of a food chain in living organisms.

A. Plant .... hen ...... grasshopper ...... cat.
B. Plant .... grasshopper .... hen ..... cat.
C. Cat .... grasshopper .... plant ...... hen.
D. Hen .... grasshopper .... plant .... cat. ( )

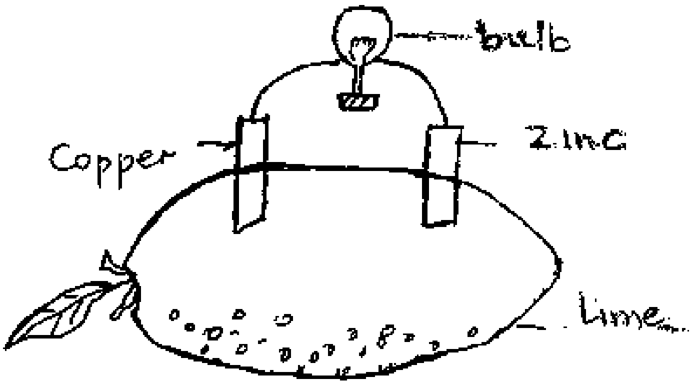
16. NPK fertilisers provide plant with the following nutrients except one. Which is this?

A. Calcium
B. Phosphorus
C. Potassium
D. Nitrogen. ( )

17. The load in a rod with one wheel has a weight of 90 Newton, and effort to be used will be 30 Newton. Therefore the mechanical advantage (MA) is

A. 90
B. 30
C. 60
D. 3 ( ).

18.



The diagram above shows how lime can be used to produce electricity. Which among the following is the correct sequence that show how energy conversion occur until the bulb gives out light?.

A. Electric energy ...... chemical energy ...... heat energy ...... light energy.
B. Chemical energy .... electric energy .... heat energy .... light energy.
C. Chemical energy .... heat energy .... electric energy .... light energy.
D. Light energy .... heat energy .... Chemical energy .... light energy. ( )

19. Haji can see very well distant objects but has a problem to see near objects, therefore the doctor advices him to wear glasses with:

A. convex lens
B. Concave lens.
C. Thin lens
D. Flat lens. ( )

20. Which among the beaks of the following birds have been correctly matched with the type of food it eats.

A.  .... for eating meat.
B.  .... for sucking nectar from flowers.
C.  .... for eating fish.
D.  .... for cracking seeds. ( )

SECTION B

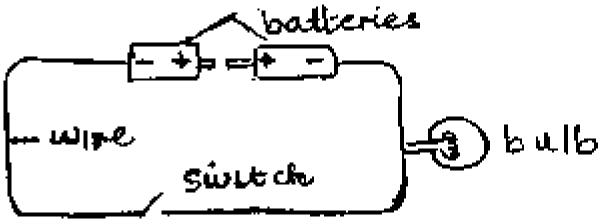
Fill in the correct answer in the blank spaces.

21. Optic Nerve transmit .... messages to the brain while .... nerve transmit hearing messages to the brain.

22. Complete the table below.

Vertebrate	Body Covered with	Blood Type	Reproduction by.
Mammal	....	....	....
....	....	warm	lay eggs
....	moist skin	....	lay eggs
Reptile	scales	....	....

23. The diagram of the circuit below does not work. You are required to correct it. Draw the correct diagram.



24. Look at the picture below, then answer the questions that follows.

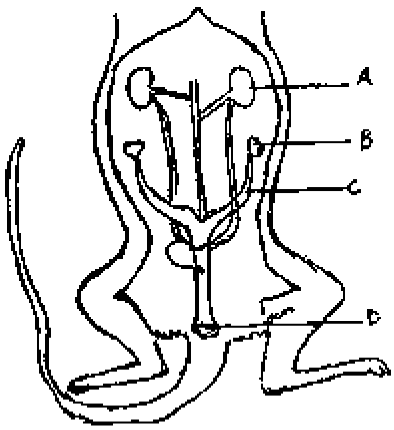
Name two characteristics from the picture that show that the organism is living.

i) ....
ii) ....

25. Fill in the correct answer in the blank spaces.

i. Bulb uses .... energy. This is converted to ...... energy.
ii. Electric iron uses .... energy. This is converted to .... energy.
iii. Telephone uses .... energy. This is converted to .... energy.
iv. Television uses .... energy. This is converted to ...... energy.

26.



The diagram above shows the reproductive system of a female mouse. Write the name of parts labelled with letter.

A. ....
B. ....
C. ....
D. ....

3.11.4 Form 1 Entrance Examinations 1993 - Science Paper (English Translation)

S.M.Z

MINISTRY OF EDUCATION, ZANZIBAR.

FORM ONE ENTRANCE EXAMINATIONS, 1993.

SCIENCE

TIME: 1 HOUR 30 MINUTES.

INSTRUCTIONS.

ANSWER ALL THE QUESTIONS IN THIS PAPER.

THIS PAPER CONSISTS OF 3 PRINTED PAGES.

SECTION A.

CHOOSE THE CORRECT ANSWER AND WRITE ITS LETTER ON THE BLANK SPACES.

1. Blood is made up of ....

   A. White blood corpuscles and protein.
   B. Plasma, red blood corpuscles and white blood corpuscles.
   C. Water and salts.

2. Objects that allow electricity to flow are called ....

   A. Insulator
   B. Galvanometer
   C. Conductor

3. Bat is an animal that belong to the group ....

   A. Mammals
   B. Birds
   C. Reptiles

4. Matter is made up of ....

   A. Electrons
   B. Protons
   C. Atoms

5. Amoeba and paramecium are organisms which belong to a group .....

   A. Protozoa
   B. Reptiles
   C. Amphibian

SECTION B.

FILL IN THE BLANK SPACES.

1. The two types of skeletons are .... skeleton and .... skeleton.

2. Rusting can be prevented by ....

3. Generator produce direct current ....

4. Skin is made up of ..... parts, which are .... and ....

5. Food in an animal pass through the ....

SECTION C.

ANSWER THE FOLLOWING QUESTIONS.

1. Mention the five sense organs in living organism.

....

2. Briefly explain the meaning of balanced diet.

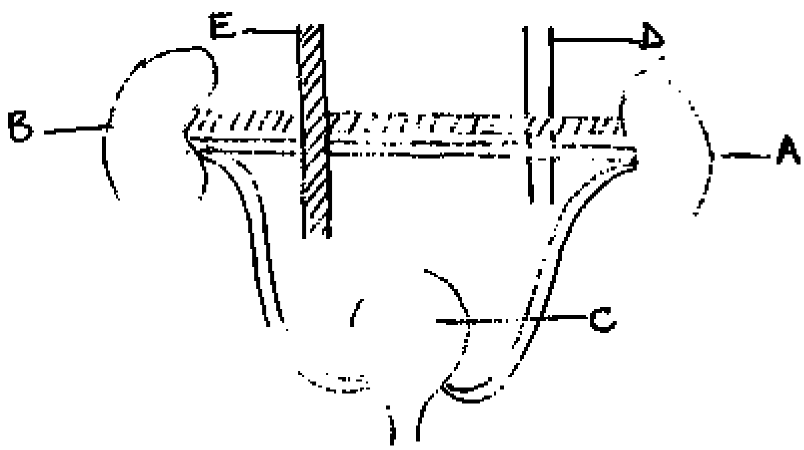
....

3. Draw

(a) a short sighted eye.
(b) a diagram of a lens to show how short sighted is corrected.

4. With an aid of a diagram, briefly explain how to make a transformer.

5. Label the parts indicated with letters.



3.12. Zimbabwe

3.12.1. Overview

End of Primary School Examination

1.	**Title of examination:**	Grade 7 Examination
2.	**Amount of fees charged:**	Nil
3.	**Examination after years in primary school (6, 7, 8 years):**	7 yrs
4.	**Children's entry age in primary school:**	5 1/2-6 yrs
5.	**Number of pupils sitting examination in 1994:**	306,706
6.	**Examination subjects offered:**	6 subjects in 4 papers: • Shona or Ndebele • Mathematics • English • General Paper (Religious & Moral Education/Social Studies, Science & Agriculture)
7.	**Language of examination:**	English (except for African languages)
8.	**Institution setting the examination questions:**	Examinations Branch, Ministry of Education and Culture
9.	**Have there been any reforms in the examination questions?**	Yes
	When? (year)	1990
	What kind?	General Paper (consisting of items from Social Studies, Science and Agriculture, Religious and Moral Education) and African languages (Shona or Ndebele) were introduced in the Grade 7 Examinations.
10.	**Stages of development of examination questions (please describe):**	• Items are generated by regional panels and Curriculum Development Unit. Items are moderated at regional panel meetings and selected for presentation at National Panel (teachers are involved). • National Panel consisting of representatives from regional panels moderate items submitted by regional panels and select them for constructing papers to be presented. • National Panel selects items that have been pre-tested for final examinations.

11.	**Type of examination questions and distribution of different kind of questions.**	Multiple-choice items only: 30% knowledge 40% comprehension 20% application 10% problem solving
12.	**Is continuous assessment incorporated in the final examination?**	Yes [ ] No [x]
13.	**Are examination items pretested?**	Yes [x] No [ ]
14.	**Which professional groups are involved in setting the examination questions?**	• Primary school teachers • School inspectors • Curriculum developers in Curriculum Development Unit (CDU) • Examination specialists
15.	**Are the same professionals who set the examination questions involved in marking papers?**	Yes [ ] No [x]
	If no, who marks the papers (state)?	Marked by optical mark reader/computer.
16.	**How are examination results used for improving teaching in primary schools?**	• Examination papers that have been written by candidates remain in the school for future use of teachers or pupils. • Reports on performance of candidates in an examination are circulated to schools.
17.	**To what other uses are the examination results put?**	Evaluation of primary school system for national government and relevant section of Ministry of Education, e.g. district education offices.
18.	**Main problem with Primary**	• Items have tended to test recall at the expense of other mental skills. • Pupils may not take them seriously where the examinations are not used for selection. • Because of large candidature multiple-choice tests only are administered. Skills that are not well measured by such questions are therefore not measured in the primary examination.

3.12.2. Analysis of End of Primary Education Examination in Zimbabwe

by Nelson Muzambi, Examinations Branch, Ministry of Education

1. The duration of primary education in Zimbabwe is 7 years. Assessment of pupils from Grade 1 (year 1) to Grade 6 (year 6) is entirely school-based, with each school being responsible for producing end-of-term and end-of-year reports for each pupil.

2. The Grade 7 Examinations, the end of primary education examinations, are set by the Examinations Branch. Authority for setting, moderating, administering, marking and awarding is vested in the Secretary for Education and Culture, with the Examinations Branch as the executing body.

3. The purpose of the examination is to certify that pupils have completed seven years of primary education and to record levels of individual pupil competency in four subject areas. The examination is not used as a selection tool because promotion is automatic to the next grade. The outcome of automatic promotion is that many pupils who proceed to their first year of secondary education (form 1) do not have the skills to function at that education level.

4. Pupils in Grade 7 take four tests: English, Mathematics, an African language (Shona or Ndebele) and a General Paper. The General Paper comprises items from Environmental Science, Social Studies and Religious and Moral Education syllabi. All the tests are written in English with the exception of the African languages. Each subject test (examination) is composed of one paper of 50 multiple-choice questions. Pupils are allowed two hours per paper.

5. The multiple-choice questions are written by nine regional panels, consisting of experienced teachers and education officers (supervisors). Each region is responsible for selecting a certain number of items but with little guidance from the Examinations Branch.

6. Each regional panel is represented at national subject panel meetings arranged by the Examinations Branch. At these meetings, questions for the final examination papers and pre-test papers are selected, based on a set of skill assessment objectives.

7. All final examination questions have to be pretested before they are administered to the candidates. Computerised item analysis is done on an old system which determines each item's discrimination index, facility index and P-value. Items that perform well in pretests are the only ones that are selected for the final papers to ensure that the final product suits the broad spectrum of candidates in the schools. Multiple-choice tests were introduced in the Grade 7 Examination in 1984. The reaction from parents and other concerned parties was mixed, with a significant number criticizing the tests because they thought they lacked validity and could be done by »idiots«.

8. The Government printer in Harare prints each year's examinations in one colour on newsprint. The Examinations Branch distributes the examination papers via the postal service to each of the 5,800 schools nationwide. Teachers administer each subject as stipulated on the examinations timetable. The teachers are not given training in test administration or security. Used examination papers are left at the schools for use by both teachers and pupils.

9. Scanner sheets completed by the candidates are marked by optical mark readers. The Branch currently produces score reports from the data tape on an old processing system. The score reports consist of the certificates given to each pupil who completes the test. The certificate lists a grade of 1-9 for each subject convertible into a 'percentage equivalent' according to a scale printed on the back of the certificate. A grade 1-6 represents a pass. Scores are not compared between groups such as schools or regions.

10. A comprehensive report on the Grade 7 Examination is written at the end of each year. The information in the report is meant to help Grade 5-7 teachers improve teaching of the various subjects. The report includes statistics on pass rate and comments on the performance of candidates in the separate subjects.

3.12.3. Examination Problems Encountered

by Margareter Chirongoma, Examinations Branch, Ministry of Education

1. There is general lack of expertise in the multiple-choice item construction.

2. There is need to produce more comprehensive reports on the Grade 7 Examination for every subject pointing out the strengths and weaknesses of the items. This would go a long way to assist the teachers to improve their ability to develop items for school based assessment.

3. As for the General Paper 50 items are not enough to effectively test four subjects, namely,

- Social Studies
- Environmental Science (incl. Agriculture)
- Religious and Moral Education
- Home Economics.

In the »General Paper« Science and Agriculture are examined from question 31-50, which is only 20 items. So it is almost impossible to give a good coverage of the syllabus. Therefore there is need to test each subject separately as has been suggested by teachers who completed the questionnaire sent out to schools to evaluate the 1993 Grade 7 Examinations.

4. Scores from continuous assessment do not contribute to the final grade such that the grade one acquires in the national examination may not be a true reflection of one's performance.

5. Language development is hindered since the objective tests do not promote free expression.

Printed by the Government Printer, Harare

3.12.4 Grade 7 Examination 1994 - General Paper (Science and Agriculture)

MINISTRY OR EDUCATION AND CULTURE
ZIMBABWE

GRADE SEVEN EXAMINATION, 1994
GENERAL PAPER

Date: Wednesday, 19 October 1994   Time: 2 hours

INSTRUCTIONS TO CANDIDATES

1. Read ALL the instructions carefully.

2. DO NOT open this booklet until you are told to do so by the invigilator.

3. Use ONLY a 2HB pencil for all entries on the answer sheet.

4. If you wish to change your answer, ERASE it COMPLETELY with a pencil rubber and then shade the new choice.

5. If MORE than ONE circle is shaded for any one answer, that answer will be regarded as WRONG.

6. When you are told to start, choose ONE correct answer from the suggested answers and shade it VERY DARK.

7. If you DO NOT understand the instructions ask the invigilator to explain them to you BEFORE you start.

8. Answer ALL the questions on the separate answer sheet provided.

This question paper comprises 18 printed pages.

Questions 1-30 refer to Religious and Moral Education and Social Studies.

Use figure 1 to answer question 31.

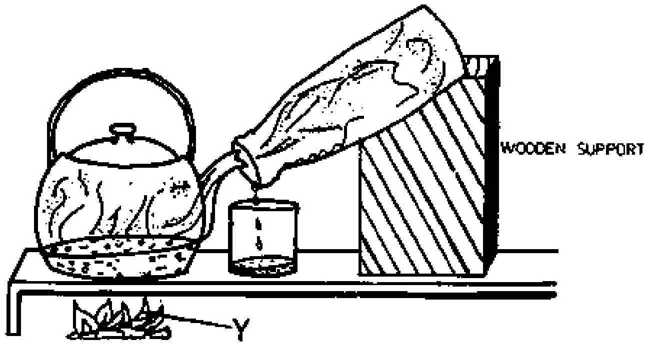


Figure 1

31. What is produced at Y that causes the water to boil?

A. Heat.
B. Light.
C. Smoke.
D. Steam.
E. vapour.

32. Which of the following is a water-borne disease?

A. Cold.
B. Dysentery.
C. Malaria.
D. Measles.
E. Tetanus.

Use figure 2 to answer question 33.

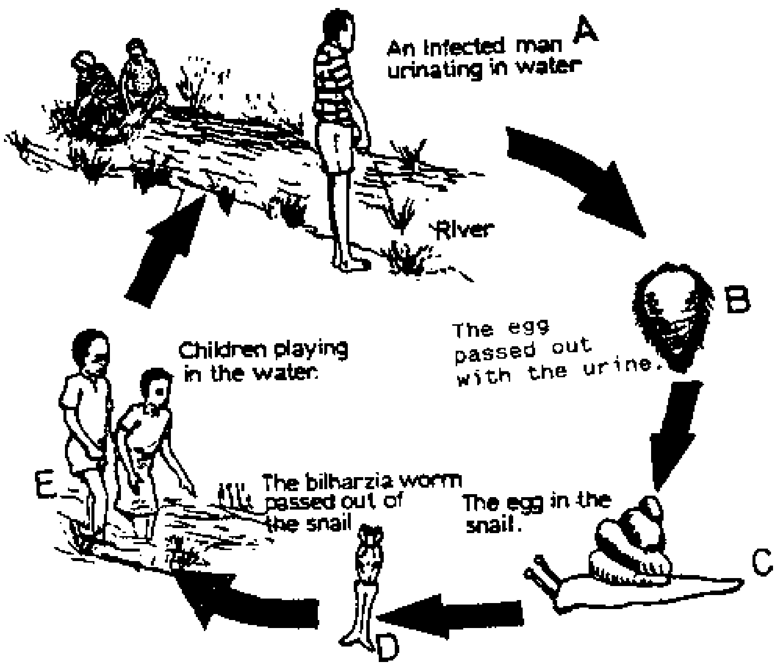

Figure 2

33. At which point of the bilharzia cycle A, B, C, D or E does the bilharzia parasite enter the body?

Use figure 3 to answer question 34.

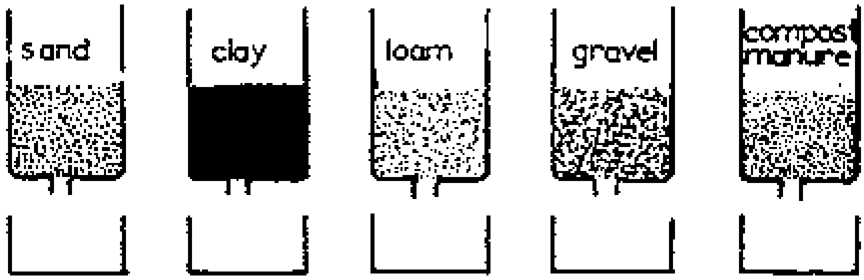

Figure 3

34. Equal volumes of water are poured into equal volumes of different kinds of substances. After a set time, which substance will have allowed the least amount of water to go through?

A. Clay.
B. Gravel.
C Loam.
D. Manure.
E. Sand.

Use figure 4 to answer question 35.

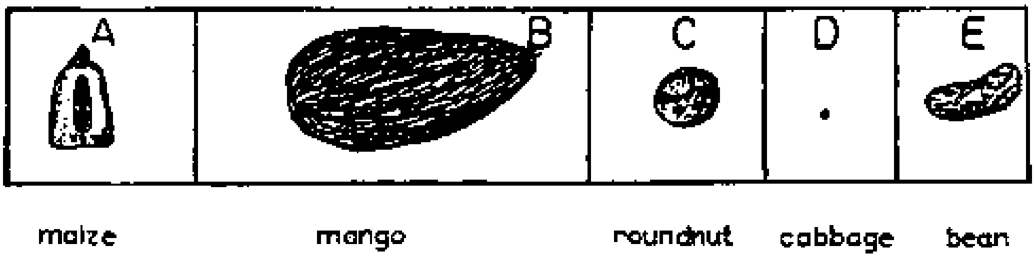

Figure 4

35. Which seed is likely to germinate last under the same conditions?

Use figure 5 to answer question 36.

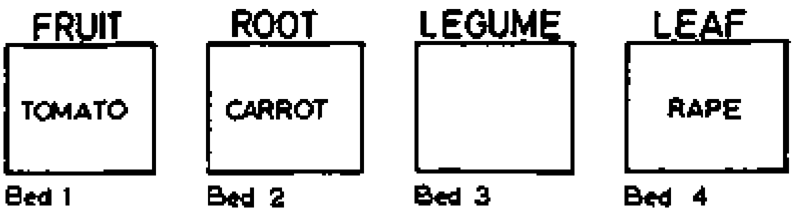

Figure 5

36. This diagram shows a four year crop rotation for a garden. In this rotation which crop would be in bed 3?

A. Beans.
B. Cabbage.
C. Lettuce.
D. Onion.
E. Spinach.

37. Which weather condition is best for transplanting seedlings.

A. Cool and dry.
B. Hot and humid.
C. Cloudy and damp.
D. Dry and calm.
E. Windy and dry.

38. To which plant family do maize, rice and wheat belong?

A. Grass.
B. Fruit.
C. Legume.
D. Tuber.
E. Vegetables.

39. Green plants need the following to make food and grow

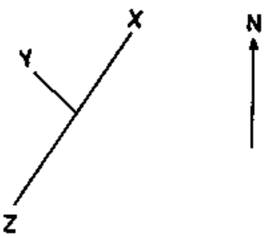
A. Bees, sunlight and air.
B. Soil, worms and water.
C. Sunlight, air and water.
D. Manure, air and sunlight.
E. Clay, water and air.

40. Mulching helps the soil to

A. lose a lot of water.
B. shelter the roots.
C. keep moisture for a longer period.
D. lose water at a faster rate.
E. become water-logged.

Use figure 6 to answer question 41.

Figure 6



41. The direction of X from Y is

A. North.
B. North East.
C. North West.
D. South.
E. South West.

42. If a transparent plastic bag is tied over some leaves of a living plant what will be seen in the plastic bag after several hours?

A. Air.
B. Dry leaves.
C. Insects.
D. No change.
E. Water drops.

Use figure 7 to answer question 43.

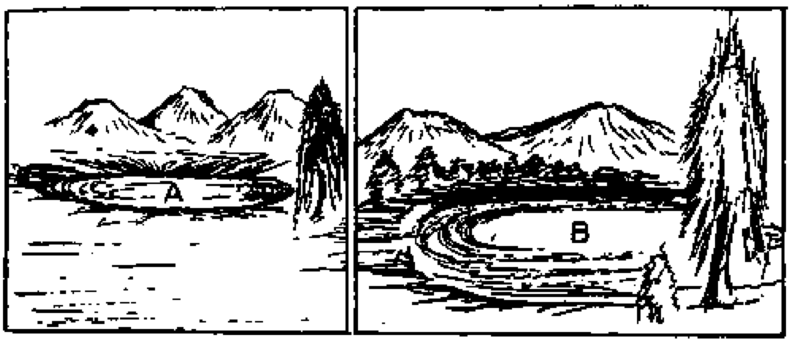


Figure 7

43. Pools A and B are in the same area. They have equal amounts of water. Why does pool B lose more water by evaporation than pool A?

Because pool B

A. has strong winds over it.
B. is in a very dry place.
C. stores much more water.
D. is not sheltered by the hills.
E. has a bigger surface area.

44. What type of fuel do steam engines use?

A. Coal.
B. Diesel.
C. Electricity.
D. Paraffin.
E. Petrol.

The diagrams in figure 8 show simple electric circuits.

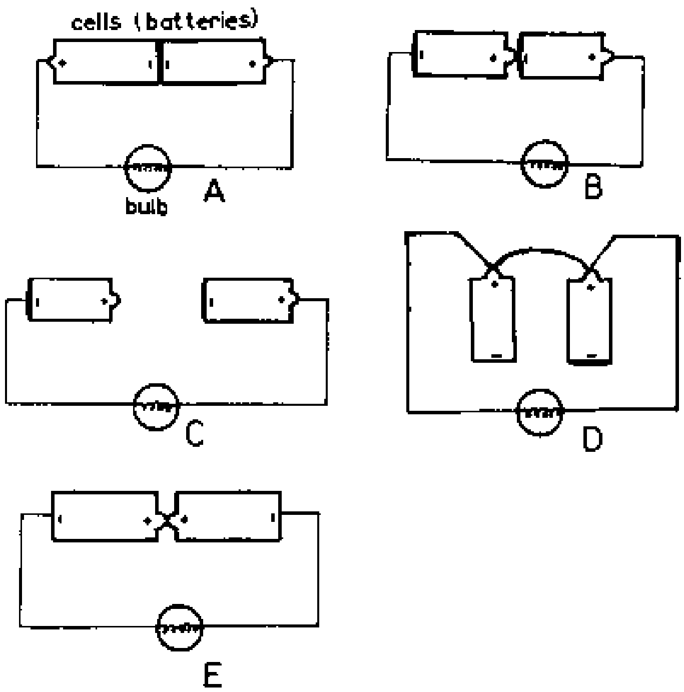

Figure 8

45. Which bulb will light up?

Use figure 9 to answer question 46.

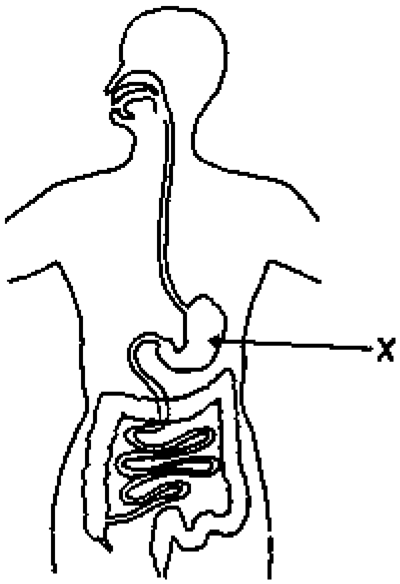

Figure 9

46. Name the part labelled X.

A. Heart.
B. Intestines.
C. Liver.
D. Lungs.
E. Stomach.

Use the map of Zimbabwe in figure 10 to answer the question that follows.

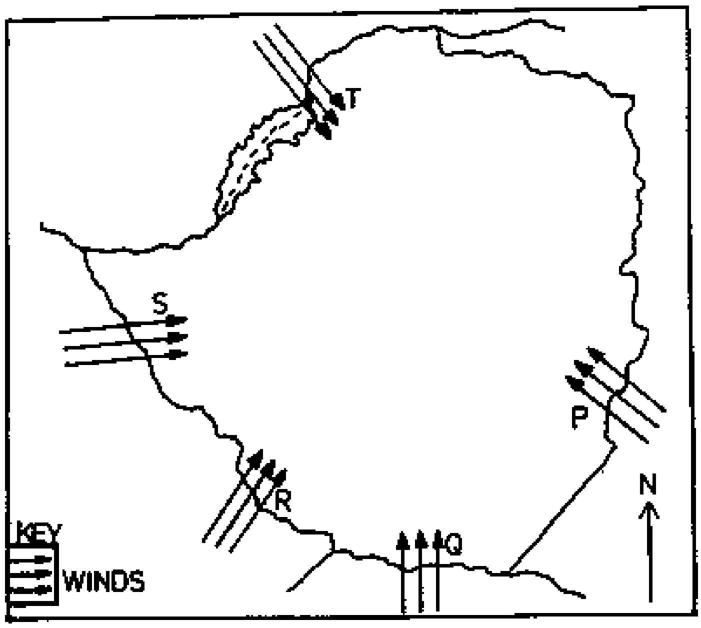

Figure 10

47. Which of the winds P, Q, R, S or T bring most rains to Zimbabwe when they meet:

A. T and S.
B. R and S.
C. R and Q.
D. R and T.
E. P and T.

48. Use figure 11 to answer question 48.

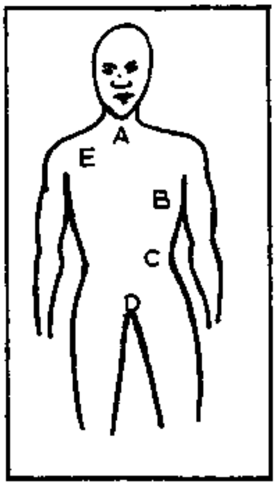

Figure 11

48. Which letter shows the position of the heart.

49. What should people do to make unprotected water safe for drinking?

A. Boil it.
B. Add salt.
C Keep it cool.
D. Let it settle.
E. Sieve it.

Use figure 12 to answer question 50.

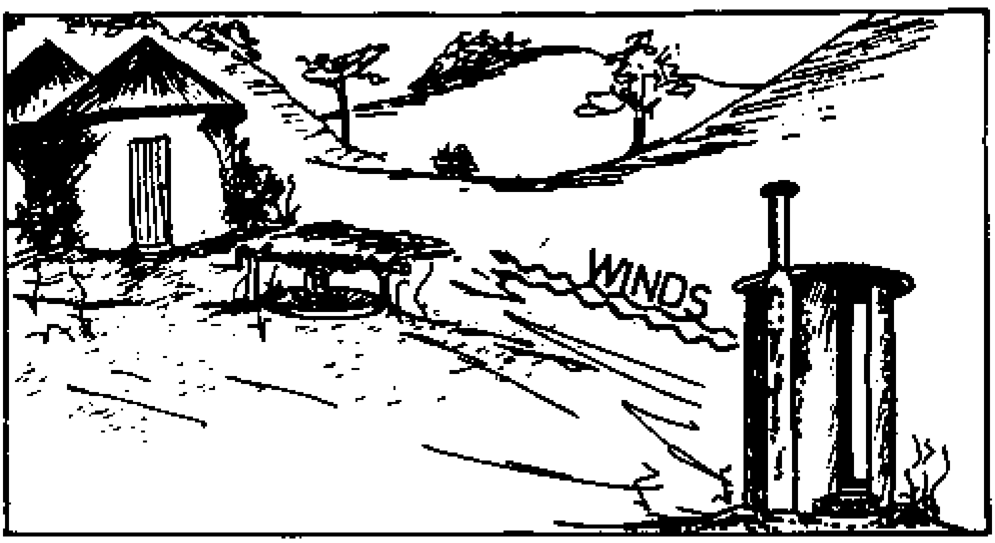

Figure 12

50. The winds of the area shown are mostly coming from the east. The set up of the home is wrong because the

A. living huts are far from the toilet.
B. protected well is not supposed to be between the huts and toilet.
C. smell from the toilet is continuously blown to the huts.
D. toilet water will flow to the well.
E. toilet should be nearer to the well.

3.12.5 Grade 7 Examination 1993 - General Paper (Science and Agriculture)

MINISTRY OR EDUCATION AND CULTURE
ZIMBABWE

GRADE SEVEN EXAMINATION, 1993
GENERAL PAPER

Date: Wednesday, 20 October 1993   Time: 2 hours

INSTRUCTIONS TO CANDIDATES

*1. Read **ALL** the instructions carefully.*

*2. **DO NOT** open this booklet until you are told to do so by the invigilator.*

*3. Use **ONLY** a pencil for all entries on the answer sheet.*

*4. If you wish to change your answer, **ERASE** it **COMPLETELY** with a pencil rubber and then shade the new choice.*

*5. If **MORE** than **ONE** circle is shaded for any one answer, that answer will be regarded as **WRONG.***

*6. When you are told to start, choose **ONE** correct answer from the suggested answers and shade it **VERY DARK.***

*7. If you **DO NOT** understand the instructions ask the invigilator to explain them to you **BEFORE** you start.*

*8. Answer **ALL** the questions on the separate answer sheet provided.*

This paper comprises 13 printed pages.

Printed by the Government Printer, Harare.

Questions 1-30 refer to Religious and Moral Education and Social Studies.

Use figure 1 to answer question 31.

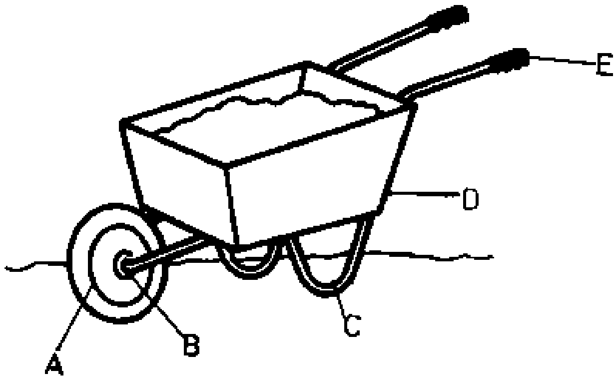

Figure 1

31. Which part of the wheelbarrow has to be greased in order to reduce friction?

32. Bilharzia parasites live in one of the following creatures,

A. water spiders.
B. water worms.
C. water slugs.
D. water snails.
E. water scorpions.

33. The shape of the earth is

A. a circle.
B. an oblong.
C. a sphere.
D. a trapezium.
E. flat.

34. The sun's energy is called

A. chemical.
B. electrical.
C. hydro-electric.
D. thermal.
E. solar.

35. People are scared of AIDS because

A. the disease has no cure.
B. the disease cannot be easily cured.
C. the disease is foreign to Zimbabwe.
D. doctors fear to touch patients with it.
E. it kills only young people.

36. Which crop gives most proteins?

A. Maize.
B. Soya beans.
C. Sorghum.
D. Wheat.
E. Millet.

37. The low land between mountains or hills is called a

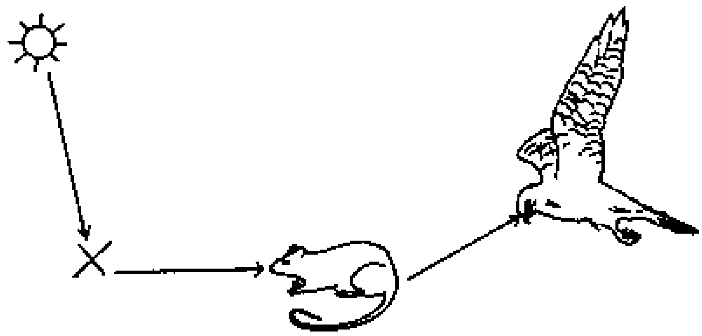
A. field.
B. forest.
C. plateau.
D. slope.
E. valley.

38. Animals that eat other animals are called

A. browsers.
B. carnivores.
C. grazers.
D. herbivores.
E. insect eaters.

Use Figure 2 to answer question 39.

Figure 2



39. What part of food chain represented by X is missing?

A. Air.
B. Carnivore's.
C. Plants.
D. Soil.
E. Water.

40. If you are outside and there is lightning what must you do to protect yourself?

A. Stand very still.
B. Shelter under a tree.
C. Run away fast.
D. Crouch down.
E. Don't have enemies.

41. A class recorded the number of boxes of tomatoes it sold for three days per week for three weeks. The following is their recording.

DAY	WEEK 1	WEEK 2	WEEK 3
MONDAY	𝍸 𝍸 I	𝍸 𝍸 III	𝍸 𝍸
WEDNESDAY	𝍸 I	𝍸 II	𝍸 III
FRIDAY	𝍸 𝍸 III	𝍸 𝍸 𝍸	𝍸 𝍸 II

If the class wanted to sell the most tomatoes which two days should they choose?

A. Wednesday and Friday.
B. Tuesday and Thursday.
C. Monday and Thursday.
D. Monday and Friday.
E. Wednesday and Monday.

42. Which of these is man-made?

A. Cotton.
B. Linen.
C. Nylon.
D. Silk.
E. Wool.

43. What do green plants use to make plant food?

A. Air, food, sunlight.
B. Food, roots, water.
C. Roots, sunlight, air.
D. Soil, air, sunlight.
E. Water, sunlight, air.

44. What must be done with empty pesticide containers?

A. Clean them.
B. Destroy them.
C. Store food in them.
D. Store water in them.
E. Sell them to others.

45. It is good to grow plants in fish ponds because

A. fish like small water plants in a pond.
B. of some fish in the pond.
C. oxygen given off by plants is used by the fish.
D. the green colour of the plants attracts fish in the pond.
E. the plants help the fish to swim.

Use figure 3 to answer question 46.

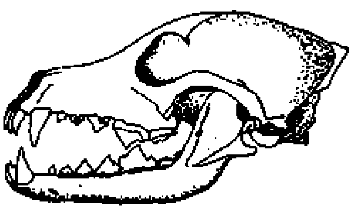


Figure 3

46. The skull is likely to be that of an animal that fed on

A. other animals.
B. tree leaves.
C. house flies.
D. earth worms.
E. tall grass.

Use figure 4 to answer question 47.

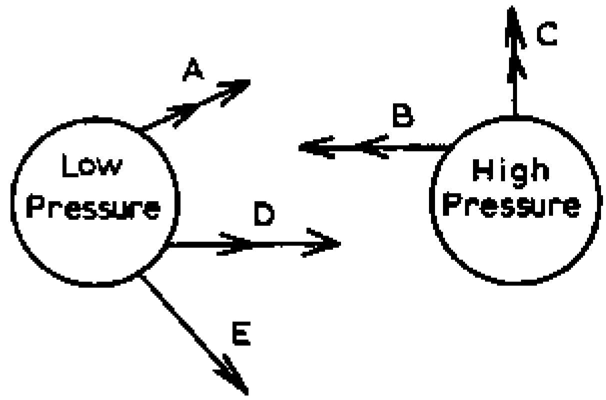

Figure 4

47. Which arrow shows the direction the wind will blow to?

Use figure 5 to answer question 48.

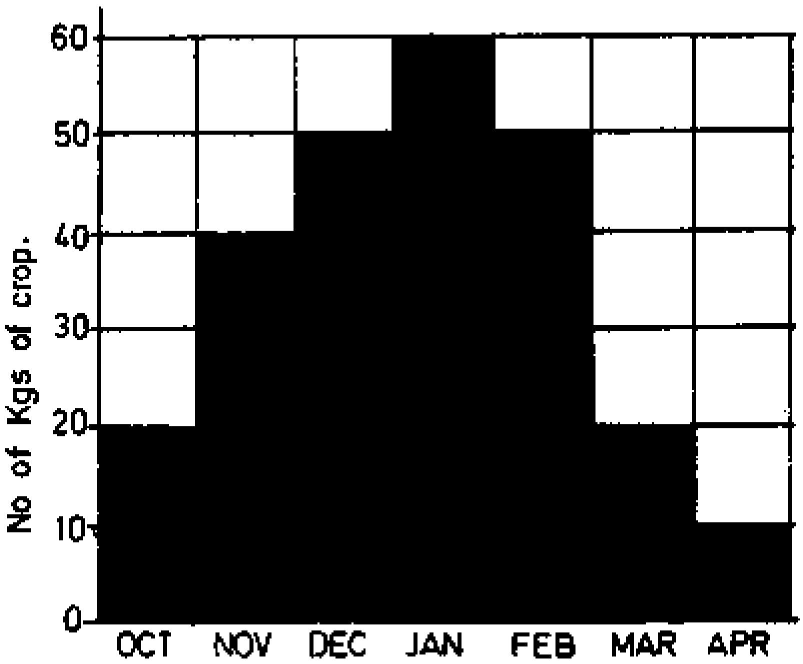

Figure 5

48. The graph shows the number of kilograms of a crop harvested. Choose a statement true of the graph.

A. The largest harvest was in February.
B. 20Kg of crop was harvested in April.
C. The second largest harvest was in January.
D. The largest harvest was in January.
E. November had the largest harvest.

Use figure 6 to answer question 49.

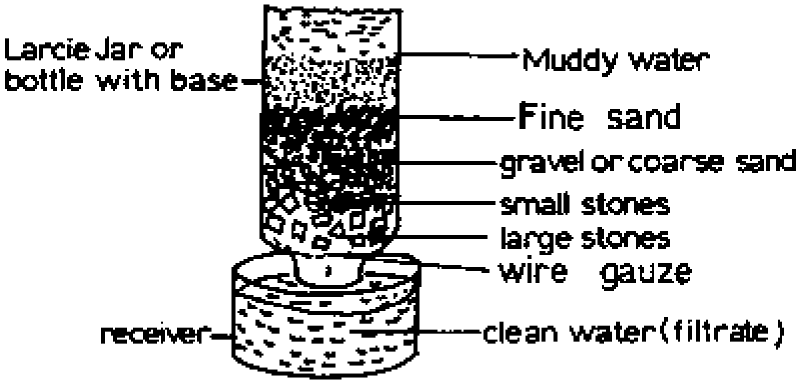

Figure 6

49. During filtration of water, fine sand is put in the filter because it

A. does not allow the dirt particles to pass through.
B. holds the larger pebbles and stones.
C. helps water run easily.
D. is not washed away by the water.
E. takes away salt from the water.

Use Figure 7 to answer question 50.

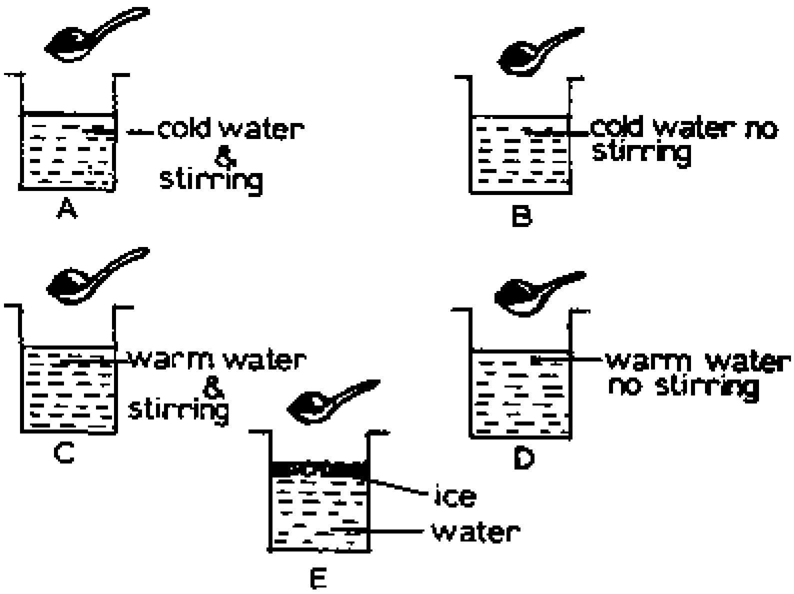

Figure 7

50. The jars in the diagram contain equal amounts of water. In which of the jars will table salt dissolve fastest?

A.
B.
C.
D.
E.

4. Examples of Follow-up Communications after the Examinations

4.1. Kenya Certificate of Primary Education (KCPE) 8-4-4 K.C.P.E. Newsletter 1992 (abstracts)

by Research Section, Kenya National Examinations Council

THE KENYA NATIONAL EXAMINATIONS COUNCIL
8-4-4
K.C.P.E
NEWSLETTER
1992

Introduction

The Kenya National Examinations Council has been producing KCPE Newsletters for the last six years. During this time, classroom teachers have had access to information about pupils' weaknesses in examinations. Teachers should have realised that pupils generally make the same type of mistakes and tend to be weak in certain areas of the syllabus. In the past, possible causes of these mistakes and possible approaches to teaching that would improve learning and hence performance have been suggested.

Teachers have, no doubt, obtained a lot of useful information from both formal and informal assessment of their pupils. The Newsletter is not meant to be a one way form of communication. It is meant to initiate dialogue between the Kenya National Examinations Council and classroom teachers.

We would like to encourage teachers to send to us their suggestions as to why pupils continue to perform poorly in certain areas of the syllabus in spite of our highlighting their weaknesses in these areas and even recommending corrective measures. We would like teachers to make use of the newsletter by making constructive suggestions and recommendations so that their experiences can benefit many teachers. They could, for example, suggest those methods of teaching that they have used and proved effective in enhancing the learning of those topics that pupils often have problems with. They could also give pupils' weaknesses that have not been highlighted in these newsletters. The information we are requesting teachers to provide could be sent to the Council, as a separate report, together with the tear-off post-examination questionnaire provided at the back of the newsletter which we encourage teachers to continue responding to.

Science

INTRODUCTION

The Science section of the Science and Agriculture paper was set in accordance with the general aims stated in the syllabus that have to be achieved over the 8-year primary education cycle. It tested the various skills that the candidates were expected to have acquired during their 8 years of primary education. The skills were tested using different content areas from the syllabus.

Table 1 shows these skills and the performance of the candidates in each skill. Similar information is also included for the 1990 KCPE for purpose of comparison.

Table 1

MAIN SKILLS TESTED	MEAN % OF CANDIDATES SCORING CORRECTLY	
	1990	**1991**
Recall	49.20	47.94
Comprehension	53.40	53.47
Application	29.12	39.40
Higher abilities (analysis, synthesis & evaluation)	63.04	60.30

From the table above, it can be observed that the performance of the candidates was poorer in those questions that tested application of knowledge in the two years. Teachers should therefore pay more attention to the application of the knowledge and skills that the pupils learn to their everyday life experiences.

OVERALL PERFORMANCE

An indication of performance in each of the 30 Science items is shown in Figure 6. In this figure, the relative difficulty of each item can be seen at a glance. In addition, the performance of the candidates in the 1991 KCPE Science section is given in Table 2 below. This is based on a random sample of 24,136 candidates. The 1990 performance is also provided in the table for comparison.

Table 2

	1990	**1991**
MEAN RAW MARK/30	15.02	14.78
STANDARD DEVIATION	4.13	4.48

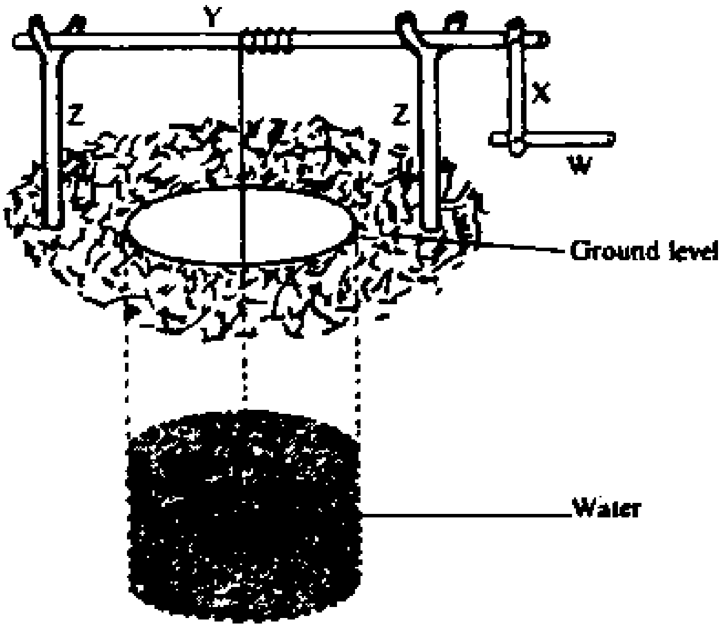
From table 2, the following conclusions could be made:

(i) The overall performance in 1991 is comparatively lower although the spread of the candidates is slightly better.

(ii) there is no significant difference in performance in the two years.

Question 18

18. Fatuma raised some water from a well using a winch like the one shown in the diagram below.



Which one of the following would help her to reduce the effort needed to raise the water? Increasing the length of the part labelled

A. W
B. X
C. Y
D. Z

RESPONSE PATTERN

Option	A	B*	C	D
% choosing the option	47.13	18.61	19.93	13.54
Mean mark in other questions	14.05	17.29	13.84	15.48

The question was testing the application of knowledge on machines. To choose the correct answer, the candidates were expected to understand the relationship between the effort used and the effort distance. The effort is inversely proportional to the distance through which it moves. Thus, the longer the part labelled X is, the less the effort used.

About 50% of the candidates in the sample chose option A implying that the effort distance is the part labelled W which is incorrect. Others thought the part labelled Y is the effort distance. Such a confusion could only result from pupils' lack of knowledge on simple machines. Pupils cannot understand this topic fully if they are taught by chalk and talk method. They should be given a chance to do things and find out for themselves.

Question 26

26. The slowest way of recycling carbon in sawdust is by

A. putting the sawdust in the cowshed
B. putting the sawdust in the shamba
C. using the sawdust in a jiko for cooking
D. using the sawdust for making hardboards.

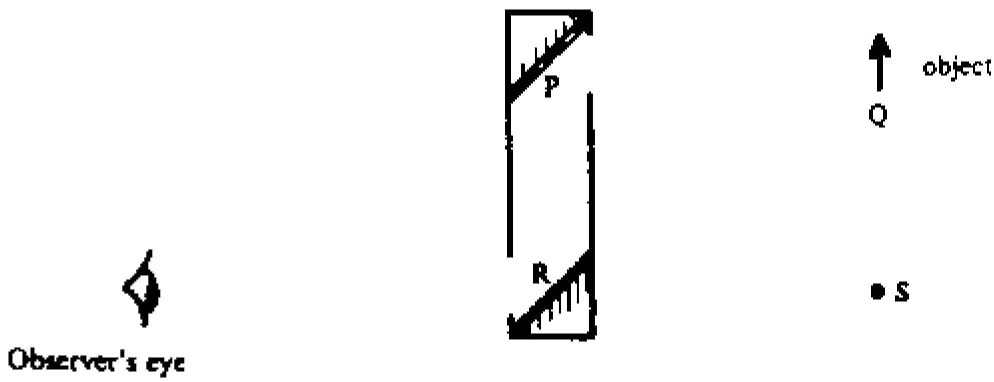
RESPONSE PATTERN

Option	A	B	C	D*
% choosing the option	20.30	26.09	23.47	29.21
Mean mark in other questions	14.87	14.99	13.30	15.82

This question was testing the candidates' knowledge on what happens to sawdust under different conditions. It was scored correctly by the bright candidates. The response pattern also shows that the mean mark in the rest of the question was a mark or two about the sample mean. This indicates that there was an element of guessing by most candidates. This would result from lack of understanding of what recycling of carbon in sawdust means. The correct option, D, was missed by many candidates probably due to their ignorance of what hardboard is. The poor performance on this item could also have resulted from the candidates' choosing an answer in haste before they could clearly understand what was being asked for. The word »slowest« in the stem was key to choosing the correct answer. Thus there is need for teachers to urge their pupils to try to understand what is being asked for before choosing an answer.

Question 27

27. The diagram below represents a periscope, an object and an observer's eye.



The image of the object as seen by the observer will appear at

A P
B Q
C R
D S

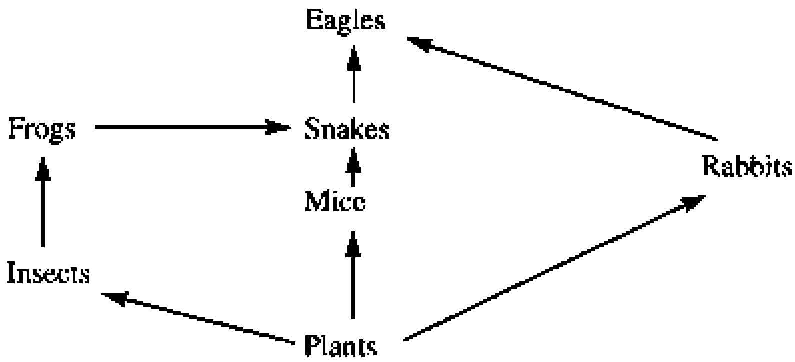
RESPONSE PATTERN

Option	A	B	C	D*
% choosing the option	16.84	15.10	51.26	15.99
Mean mark in other questions	13.72	12.82	15.86	14.50

A periscope uses plain mirrors and therefore the candidates were expected to use their knowledge of the properties of a plain mirror to answer this question. The small percentage of candidates who scored this item correctly shows that most candidates did not have this knowledge. More than half of the candidates in the sample chose option C which shows that the image is formed on the mirror. Anyone who has ever used a plain mirror to view himself/herself knows that this is not true. One's image always appears to be formed behind the mirror. Simple experiments done by the pupils using plain mirrors would help them to know that the image of an object placed in front of a plain mirror is formed behind the mirror. Thus teachers should seize every possible moment to have their pupils perform simple experiments to make their acquisition of scientific concepts easier and faster.

<u>Question 28</u>

28. Study the diagram of the food web below and answer the question that follows.



Which of the following animals should be most abundant in the food web?

A. Insects
B. Snakes
C. Frogs
D. Rabbits

RESPONSE PATTERN

Option	A*	B	C	D
% choosing the option	10.70	65.89	7.70	14.84
Mean mark in other questions	14.84	15.15	13.87	13.75

The candidates were expected to know that a food web is a complex feeding relationship of organisms consisting of several food chains. In each food chain, the most abundant organisms are those at the lowest trophic level and the numbers of organisms decrease as one goes up the food chain. In this question, insects, mice and rabbits occupy the same trophic level, that is, they all feed on plants. Ideally, their numbers are expected to be similar but in this food web, snakes and eagles have an alternative source of food. Snakes feed on frogs and mice while eagles feed on snakes and rabbits. On the other hand, frogs have no alternative source of food for they feed only on insects. Thus insects should be more abundant compared to mice and rabbits because they are the only source of food to the frogs.

The fact that about 65% of the candidates chose option B shows that they did not understand how numbers of organisms in a food web vary depending on the trophic level a particular organism occupies. To help the pupils understand clearly feeding relationships and their influence on the numbers of organisms, teachers should approach this topic from a practical point of view. A small scale ecological study would help pupils to understand better than if food webs and food chains are explained merely by use of drawings on the chalk board.

GENERAL COMMENTS AND ADVICE TO TEACHERS

1. Questions that were based on topics that ought to have been taught practically were poorly done in most cases. This indicates that some of the teachers could be teaching Science largely theoretically. It is advisable that teachers should try to have their pupils perform most of the simple experiments. This would enhance their acquisition of Scientific knowledge and formation of sound Scientific concepts. Science should be taught through an investigatory approach whenever possible.

2. Candidates' poor performance in some questions resulted from their lack of knowledge on the relevant syllabus topics. This could have been due to poor syllabus coverage or ineffective instruction. Teachers should plan their teaching to ensure that each syllabus topic is given the attention it deserves. Poor planning causes backlog of work which forces teachers to teach in haste, and hence disregarding the pupils' learning pace, only serves to confuse them.

3. Most of the questions that the candidates found difficult also required the candidates to reason out and extrapolate learned information. Teachers are advised, therefore, to train their pupils in the art of reasoning and applying learned information to new situations.

Agriculture

INTRODUCTION

The analysis of performance in Agriculture is based on a sample of 24,136 candidates drawn from both rural and urban schools. Table 1 below shows a summary of the overall performance in the Agriculture section of the Science and Agriculture paper.

Table 1

Year	1990	1991
RAW MEAN OUT OF 30	17.60	16.97
STANDARD DEVIATION	3.71	4.26

Table 1 shows that there was a slight drop in performance compared to the previous year. However, there was a better spread of marks as indicated by the bigger Standard Deviation. The performance of candidates in all questions is shown in Figure 7.

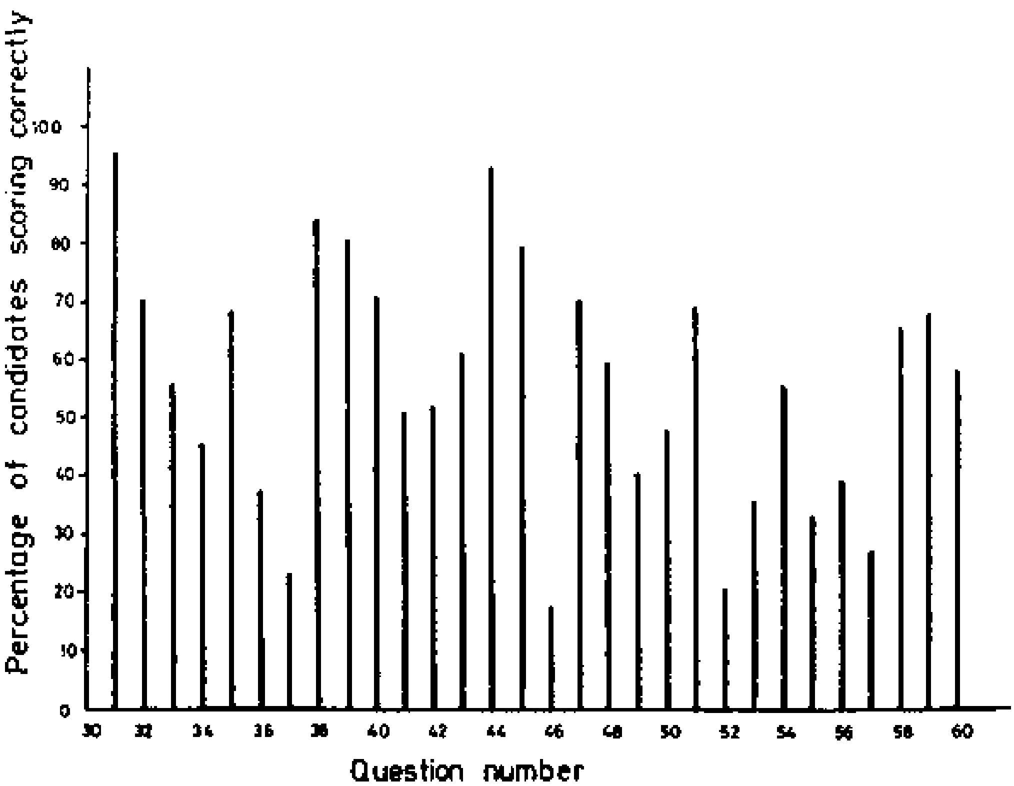


FIGURE 7 - AGRICULTURE

From Figure 7, it is evident that candidates found some questions more difficult than others. Questions which were scored correctly by less than 30% of the candidates are considered to be difficult. The performance of candidates in these questions is shown in Table 2.

Table 2

Question Number	37	46	52	55	57
% of candidates choosing correct response	23.90	17.28	21.82	31.16	27.85

ANALYSIS OF THE DIFFICULT QUESTIONS

In each question discussed, a response pattern showing the percentage of candidates choosing each of the four responses and their mean marks in other questions is given. The correct response in each question is indicated with an asterisk (*).

Question 37

37. Which set of symptoms given below indicates fowl pox disease in chicken?

A. Dullness and swellings on the head.
B. Diarrhoea and lack of appetite.
C. Crowding and stretching of the neck.
D. Diarrhoea and crowding.

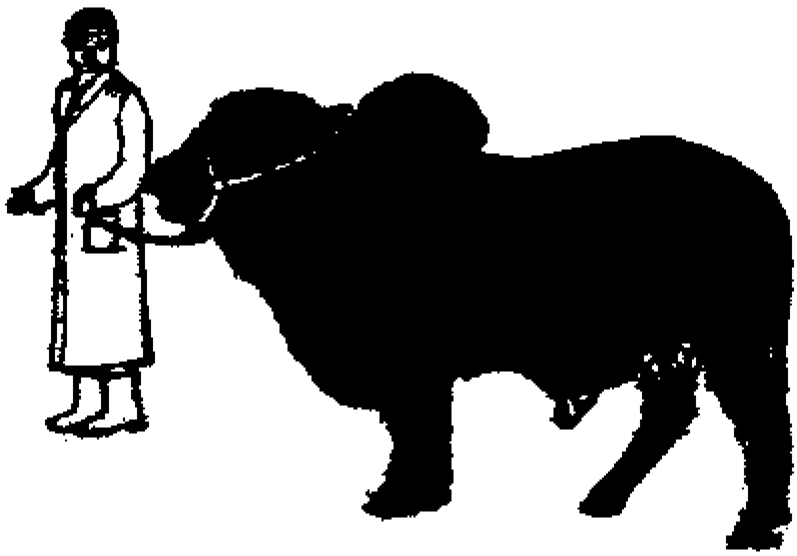
RESPONSE PATTERN

Option	A*	B	C	D
% choosing the option	23.90	42.24	20.30	12.95
Mean mark in other questions	17.91	17.09	15.94	16.79

In this question, many candidates chose Diarrhoea and lack of appetite as symptoms for fowl pox disease in chicken. It is true that loss of appetite is a symptom for so many diseases and diarrhoea is also a symptom of a few intestinal diseases. However, these should not be confused with fowl pox disease which is manifested by characteristic swellings on the head. Pupils should be familiar with the general causes of livestock diseases, their symptoms and control measures since death of livestock is a major cause of loss in livestock production. The schools which may not have livestock are encouraged to take their pupils to institutions or farms where the required animals are kept.

Question 46

46. The illustration below shows a herdsman leading a bull for exercise using a halter.



Leading a bull this way is NOT safe because the halter

A. will hurt the bull
B. will interfere with the feeding of the bull
C. will interfere with the breathing of the bull
D. is not sufficient to restrain the bull.

RESPONSE PATTERN

Option	A	B	C	D*
% choosing the option	7.76	35.74	38.54	17.28
Mean mark in other questions	16.06	17.06	16.81	17.78

A small percentage of candidates got the correct response in this question. They were the more able candidates as seen from their mean mark in other items. Responses B and C attracted high percentages of candidates. Since these responses referred to the halter interfering with either the feeding or the breathing of the bull, many candidates thought the halter is tied so tightly that it will interfere with the animal. Many candidates were merely guessing the answer. It can be deduced that many candidates had neither seen a halter, which is a specially designed rope for restraining cattle, nor handled bulls or seen bulls being walked around for exercise. The safest way to handle bulls is to fix a leadstick onto the bull-ring at the nose. Since the skin at the bull's nose onto which the ring is fixed is delicate, a bull will keep calm as any violent movement will hurt it. It should be borne in mind that bulls can be vicious and should always be handled with care. However docile they may appear to be, bulls should not be taken for granted.

Question 52

52. Which one of the following factors will influence the efficiency of farm labour?

A. Size of the farm.
B. Market for the produce.
C. The number of farming activities in the farm.
D. Training on relevant skills.

RESPONSE PATTERN

Option	A	B	C	D*
% choosing the option	27.28	13.08	37.17	21.82
Mean mark in other questions	16.95	15.27	16.68	18.69

The question was testing how to manage farm labour for efficient performance of farm work. Labour efficiency refers to the ability of workers to carry out a given task well and fast. To be able to do this, training on the relevant skills is necessary.

The response pattern indicated a lot of guess work. Response C attracted the highest percentage of candidates followed by A. The number of farming activities in the farm like growing maize, bananas, wheat, and rearing poultry and pigs cannot influence the efficiency of farm labour because in a well managed farm, labour is usually attached to a given enterprise. Alternatively, workers would be assigned a few tasks within one or more enterprises which the workers can manage.

Question 55

55. The reason for washing the udder with warm water before milking a cow is to

A. kill germs on the udder
B. enable the cow to produce more milk
C. remove dirt from the udder
D. soften the teats.

RESPONSE PATTERN

Option	A	B	C*	D
% choosing the option	36.35	7.08	31.16	22.92
Mean mark in other questions	16.58	16.14	17.65	17.03

This question was not so poorly done. It was scored correctly by slightly more than 30% of the candidates. Since it was a borderline case, it is also worth discussing.

The majority of the candidates chose the wrong option A. Warm water does not kill germs. The temperature of water capable of killing germs can scald the skin of the milkman and the cow's udder. It was the more able candidates who scored the right response. Apart from removing dirt from the udder, warm water also helps to stimulate milk let down in the udder.

Question 57

57. A farmer noticed his crop growing slowly and the leaves showing purple colouration. What plant nutrient was lacking in the soil?

A. Nitrogen.
B. Phosphorus.
C. Potassium.
D. Sulphur.

RESPONSE PATTERN

Option	A	B*	C	D
% choosing the option	48.35	27.85	17.51	5.63
Mean mark in other questions	17.20	17.74	16.25	15.76

The response pattern reveals that only 27.85% of candidates in the sample, who happen to be the most able ones got the correct response. A high percentage of candidates chose Nitrogen. Whereas deficiency of Nitrogen results in slow or stunted growth, purple colouration is never observed. A characteristic deficiency symptom for Nitrogen is yellow colouration. Some deficiency symptoms of major plant elements overlap. However, there are certain unique symptoms for each element. It is important to remember that all the macro-nutrient elements are very important for plant nutrition and pupils should learn about their roles, and deficiency symptoms exhibited in growing plants.

GENERAL GUIDANCE TO TEACHERS

It has already been pointed out that teachers should arrange for their pupils to visit farms or agricultural institutions. They should also cover all the parts of the syllabus.

We would add that teachers should give exercises based on various cognitive levels to their pupils. This will ensure that the pupils do not only memorise what they have been taught, but are also encouraged to think on their own and argue out answers to questions.

4.2. Lesotho Primary School Leaving Examination P.S.L.E. Report (May 1990) (abstracts)[1]

[1] This report has been compiled by the Evaluation, Research and Testing Division of the N.C.D.C. It has been prepared by the various subjects divisions at the centre using the item analyses prepared by the Education Statistics Unit at the centre.

by National Curriculum Development Centre (N.C.D.C.), Ministry of Education

(N C D C)
MINISTRY OF EDUCATION
1989 P.S.L.E. REPORT
MAY 1990

EVALUATION, RESEARCH AND TESTING DIVISION
P.O. BOX 1126
MASERU

Introduction

This is the first report of the Primary School Leaving Examinations (P.S.L.E.) since the establishment of the item bank. Since we would like to keep the reliability of the PSLE tests good we shall not quote the items that were in the tests but try to refer to whatever was in the item and needs attention, as closely as possible. After all we teach concepts and not items although items are used to find out if the concepts have been learnt or not. Examples, which are not necessarily the items which were in the tests, may be shown in the report.

Comments which can be addressed to: Education Testing Officer, N.C.D.C., P.O. Box 1126, Maseru 100 will be welcomed and useful to improve on this report.

This report is supposed to assist the teachers in improving on their instruction where necessary, or even to commend them where the instruction has been good. The report should serve as a mirror to the teachers, this is because the achievement of pupils does, in a way, reflect how effective the teaching has been. The teachers are thus encouraged to use this report maximally and give feedback, as much as they can.

In this report no comments have been made on Papers One and Two of English and Sesotho but hope to include them in future.

Science (General)

PURE SCIENCE

When referring to respiration in plants »stomata« and »breathing holes« should not be considered as different things altogether because in actual fact stomata are holes through which a plant breathes and it could be correct to say »stomata« are »breathing holes«.

The functions of the different parts of a seed, like the radicle, the inside, outer covering should be distinguished. The pupils seemed to confuse the functions of these parts.

Pupils still seem not to be sure of the different parts of a flower, they are not able to identify the different parts from a drawing. When teaching such topics it is necessary to have a sample of a flower for example or observe fertilisation by agents such as bees. The topic should be treated as practical as possible.

The distinction between an amphibian and a reptile need to be made since the pupils seem to confuse the two. There are some reptiles that are amphibians and those that are not.

Pupils seem not to be clear about when contraction takes place and when expansion takes place due to the effect of heat. For these two concepts to be learnt well, they should be taught practically, the pupils should observe expansion taking place and also contraction and be aware which effect of heat causes either of them and be sure which word is used for which process.

The changes from one state of matter to another do not seem to be very clear to the pupils like from solid to liquid, liquid to gas and the reverse. These should also be taught practically so that pupils can see as to what changes take place under which circumstances and the words used for the different changes.

The direction in a food chain should have meaning like »from - to«, which would imply that from one thing the next is produced or found. Various examples should be given to explain the chain. If the direction is in the opposite direction that seems to confuse the pupils.

HOME ECONOMICS

Pupils do not seem to be aware of all the different methods of cooking. All methods of cooking should be clearly explained to the pupils, even if they are not all demonstrated. These explanations should, of course, be accompanied by examples in which the different methods are used.

It seems that the functions of different foodstuffs have been well-taught. The term »complete food« does not seem to be familiar to some pupils. There is need to clearly explain what is meant by »complete food« giving the example of young ones that live only on one kind of food but survive. This implies that the one food that the young ones live on is sufficient for their livelihood hence it is a »complete food«. That is why breastfeeding is recommended more than anything else for babies.

The grouping of various food-stuffs should be clearly explained to pupils and they should be given regular exercises in classifying different foodstuffs. In other words, when given a certain kind of food pupils should be able to state what nutrient or nutrients the particular food has and thus be able to differentiate foods according to their nutrients.

HEALTH AND PHYSICAL EDUCATION

Pupils do not seem to know about diseases that are caused by pests that are not found locally. There is need when teaching about diseases caused by pests, to include even those diseases that are not found locally, like the tropical diseases.

What is taught about personal hygiene and can be done practically should then be taught practically and whenever possible let the pupils practise it at school, for example, washing one's hands when one comes from the toilet. Pupils do not seem to be aware of some of common personal hygiene practices which they could learn easily through practice.

There is need to explain to pupils the dangers of some of the unhygienic practices, for example it should be made clear why eating food from a rubbish pit or bin may be dangerous, that is, how it can cause diseases.

When teaching about care of the different parts of the body emphasis should be laid on improper common practices and these should be discouraged explaining what dangers those might have to the particular part of the body, for example, the rubbing of the eye when there seems to be a foreign particle that has entered the eye.

It seems not to be clear to pupils as to what exactly happens to people who die because there is a coal fire burning inside a closed house with no fireplace with a chimney. It should be explained that they die because of inhaling the poisonous gas, carbon monoxide and not necessarily because there was no oxygen to be inhaled, it should be made clear that it is the presence of the carbon monoxide in the blood system that causes the death.

Causes of the common diseases, especially those that may be epidemic should be known to the pupils, this will be of help to the students to advise on how epidemic diseases can be avoided where possible or to stop one if it is already taking place.

AGRICULTURE

When teaching pupils about the improvement of soil that is poor more emphasis should be laid on the use of manure rather that on the use of artificial fertilizers which only provide nutrients to the plants and not necessarily improving the quality of the soil.

The use of the term »seed bed« should be discouraged instead the term »nursery bed« should be used because it is more correct. More emphasis should be laid on the techniques of planting vegetables. It should be known which vegetables should be planted directly and which can be transplanted and it should be explained why.

In the teaching of the subject the use of common words should be encouraged. For example, the term »organic matter« could be used instead of »humus«. This is because some pupils seemed not to know the meaning of the word »humus«.

Candidates did not seem to be clear as to how one type of soil differs from another. The pupils should be taught in detail the characteristics of the different types of soil. They should know the structure, the capacity to hold water, their nutritive value and so on.

It seemed not to be clear to pupils the need to prune trees. It should be clearly explained why trees should be pruned, how they should be pruned and when they should be pruned. Advantages gained should be given as against disadvantages of unpruned trees.

TRIAL SCIENCE

The topic on magnetism seems to be well-treated, the pupils are aware of the basic concepts in magnetism, but they seem to lack the practical experience. Thus more practical work, even in the form of demonstrations should be done.

The meanings of the words »float« and »sink« do not seem to be distinguishable to the pupils. The distinction should be clearly made between these two words and this could be done with the assistance of a demonstration with a few substances that sink in certain liquids, especially water, and those that float in those liquids. Here should be included liquids that float on other liquids. It should be explained that floatation depends on density, for example, if the volume of a substance can be increased while its mass remains the same then its density decreases (it becomes lighter) and it can float, like an inflated balloon.

Pupils do not seem to be aware of the interdependence between the various species of nature. In the teaching of ecology emphasis should be laid on how one thing depends on the existence of another and how that second one depends on yet another thing. For example, animals depend on plants for food while the plants depend on the sun for energy.

Pupils only hear about certain instruments used for measuring various quantities in science but have no idea as to how the instruments look like, and thus how they work. As much as possible instruments used to make measurements should be shown to students and they should use them, if possible, but if it is not possible demonstrations should be made on their use.

Some pupils cannot make the difference between solution, solvent and solute. First, it is necessary to clearly explain the process of dissolving and then make the distinction between the solvent and the solute and hence the mixture, which is the solution.

Practical work should be done with balances to explain the state of equilibrium and of no equilibrium. It should be clear as to how the balance swings when there is a heavier load on one side.

Since breathing organs differ from animal to animal or between certain families of animals it should be clearly explained how these differ including the names used for different breathing organs.

Some pupils could not differentiate between certain animals according to their structure. More detail should be given when teaching about structure of different animals, for example, which are covered with scales, which with no bones, which with legs and so on.

The use of machines, that is, levers and pulleys should be done practically because the pupils seem not to be aware how some of the machines work.

The water retaining capacity of soil should be taught practically and the kind of soil suitable for making bricks should be explained to pupils. The fact that soil has air inside it should be shown practically.

Some pupils seemed not to be clear of the life stages of an insect, this could be taught as suggested in the syllabus.

The difference between perimeter and area should be clarified, as it seemed not clear to some pupils.

Conduction of electricity should be taught practically.

More emphasis should be laid in the teaching of friction, especially the effects of friction.

Pupils should be taught different kinds of clouds and also stars, it should not be taken for granted that they know them. For clouds, the examples given should be familiar to the pupils.

SUMMARY

The test with the highest reliability was Mathematics with a (Kuder-Richardson Formula 20) KR20 reliability coefficient of 0.861, this was followed by Trial Science with 0.816 then English Paper 3 with 0.768 next Social Studies with 0.751 and then Sesotho with 0.719 and lastly Science (General) with 0.711.

The following table shows the total score, the mean score and the standard deviation (S.D.) for each paper (here the Papers I and II for Sesotho and English have been included but Trial Science is not).

Paper	**Science**	**Social Studies**	**Maths**	**Sesotho Paper I**	**Sesotho Paper II**	**Sesotho Paper III**	**English Paper I**	**English Paper II**	**English Paper III**
Total Score	50	50	50	25	15	40	24	18	50
Mean	22,21	26,41	27,6	16,63	10,23	30,08	9,02	7,25	25,46
S.D.	7,09	7,56	8,53	2,77	2,05	4,24	4,23	2,42	7,55

The total number of candidates was 26,181 and the overall pass percentage was 82.3, that is 21,539 candidates passed. There were 2,774 first, 4,867 second and 13,898 third class passes and 4,642 failed.

2.0 BASIC SCIENCE & HEALTH EDUCATION

In Basic Science and Health Education, the common errors encountered during the marking were:

- confused facts on parasites and vectors e.g. Question 44.

- The language and expression were poor, use of mother tongue in some scripts.

- Spellings were poor.

- Lack of understanding of instructions. Could not explain or describe as expected.

- Poor illegible handwriting.

- Use of guess work especially on questions concerning sex.

SECTION A

1. How do we prevent babies from getting measles?

We prevent babies from getting measles by immunisation

2. How is rusting similar to breathing?

3. What First-Aid would you give to a person who has been bitten by a snake?

The first-Aid would you give a person who has been bitten by a snake by fracture

4. Why should children be stopped from eating a lot of sweets?

5. What is the main method through which AIDS can be spread from one person to another?

The main method through which AIDS can be spread from one person to another by sexual intercouse

6. Why should drinking water be boiled?

We should drinking water be boiled because the water was contaminated

7. Name the common substances used to make an oral rehydration solution.

The common substance used to make an oral rehydration solution hydration

8. What is the best food for a baby of less than one year?

The best food of for a baby of less than one year is milk

9. To which group of food crops does rice belong?

The group of food crops does rice belong is called serious

10. Give one reason why vitamin C is important in our diet.

because vitamin C is important when you built

2.1 Sample of a poor script

The sample scripts show that the candidate has little knowledge of the subject matter. In the 1st sample, he cannot express himself correctly in English although he tries to answer in full sentences. Spellings are very important especially of Science words as a candidate can fail because of that, for instance answers given to question 9. 'serious' - may be the candidate wanted to write 'cereals', question 12. 'longershitedness' was 'long sightedness'.

SECITON A

1. How do we prevent babies from getting measles?

We prevent babies from getting measles by immunisation at nine months.

2. How is rusting similar to breathing?

Rusting is similar to breathing because they both need oxygen in order to take place.

3. What First-Aid would you give to a person who has been bitten by a snake?

The first Aid I would give to a person bitten by a snake is tying a piece of cloth above the bitten part to prevent poison from going to the heart & take to a health worker

4. Why should children be stopped from eating a lot of sweets?

Children should be stopped from eating alot of sweets because eating alot of sweets causes dental car..

5. What is the main method through which AIDS can be spread from one person to another?

Aids can be spread from one person to another mainly by have sexual intercourse with an infected person.

6. Why should drinking water be boiled?

Drinking water should be boiled to kill germs.

7. Name the common substances used to make an oral rehydration solution.

Salt, sugar and water are the common substances used to make an oral rehydration solution

8. What is the best food for a baby of less than one year?

Breast milk is the best food for a baby of less than one year.

9. To which group of food crops does rice belong?

Rice belongs to a group of food crops called ~~carbohydrates~~ cereals.

10. Give one reason why vitamin C is important in our diet.

Vitamin C is important in our diet because it protects us from scurvy.

11. Name one way through which foot and mounth disease is spread among cattle.

Foot and mouth disease is spread among cattle when the infected ones feed together with the uninfected ones.

2.2 Sample of good script

A good candidate answers in full sentences, and puts in detail to show that he/she understands the subject.

DSE in Brief

The German Foundation for International Development (DSE) is an institution which provides a forum for development policy dialogue and the initial and advanced training of specialists and executive personnel from developing and transitional countries. In addition, it supports German experts preparing themselves for their assignments in developing countries and maintains the Federal Republic of Germany's largest centre for documentation and information on development cooperation issues.

Conferences, meetings, seminars and training courses support projects which serve economic and social development, thus contributing to an effective, sustainable and wide-ranging development process.

The DSE cooperates with partners at home and abroad. A considerable number of the programmes take place in the developing countries, and the rest in Germany. Since 1960 the DSE has given advanced professional training to more than 120,000 decision-makers, specialists and executive personnel from over 150 countries. Through its dialogue and training events the DSE currently reaches more than 10,000 participants annually.

Founded in 1959, the DSE contributes to development cooperation on the basis of the guidelines of the German Federal Government's development policy. The institutional donor is the Federal Ministry for Economic Cooperation and Development (BMZ). Some of the DSE programmes are, however, financed by other donors (e.g. other Federal ministries, the Federal Länder, the European Union).

Also, the Federal Länder of Baden-Württemberg, Bavaria, Berlin, North Rhine-Westphalia and Saxony have made conference and training centres available. Since its establishment, the DSE has been jointly financed by the Federation and the Länder. This finds expression in the decentralized structure of the German Foundation with its specialized departments (Centres) and conference centres in a number of Federal Länder.

Definition

learning	=	change of behavior due to experiences
learning theory	=	behavior theory to explain and to predict behavior

Through learning we acquire new…

...knowledge

we know more than before

...skills

we do things better than before

...attitudes

we hold a different opinion than before

...patterns of behavior

we behave differently than before

Learning can be categorized according to the…

...cognitive area

head

development of ideas and concepts

...psychomotor area

hand

development of movement

...affective area

heart

development of values and attitudes

Different ways of learning…

… of human beings

trial and error

observation and imitation

repetition

instilling something in the mind

insight

repeated perception

adaptation

….

Different ways of learning…

… of animals

conditioning

reinforcement

trial and error

Learning theories: 2 major schools of thinking

Behaviorism	focus on human behavior and its conditions; learning is based on forming associations between stimuli and responses; emphasis on measurable and observable components of human behavior
Cognitivism	focus on brain activities such as cognition and insight; learning is a process of discovering and understanding relationships, of organizing and re-organizing information into meaningful patterns; emphasis on perception, decision making, processing of information, understanding, problem solving

The three steps of human learning

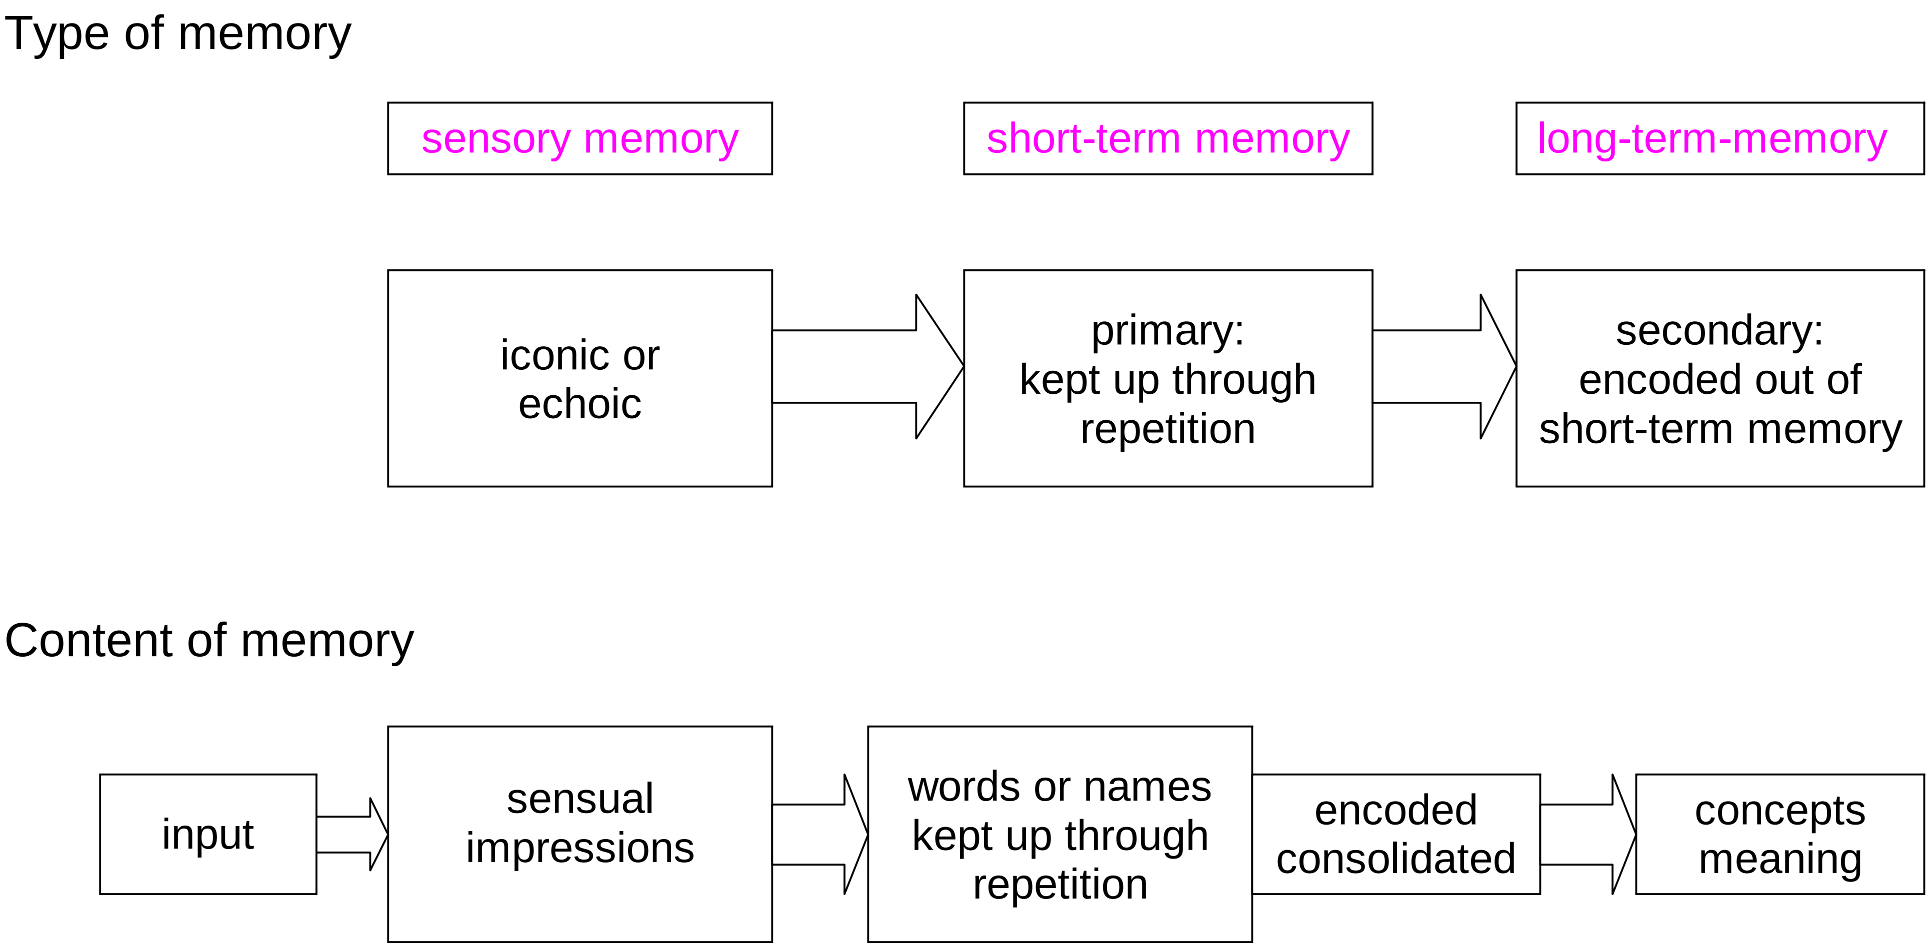
We have not learnend something until we have…

instilled it in our mind

appreciated it

experienced it

The three components of the memory – a model



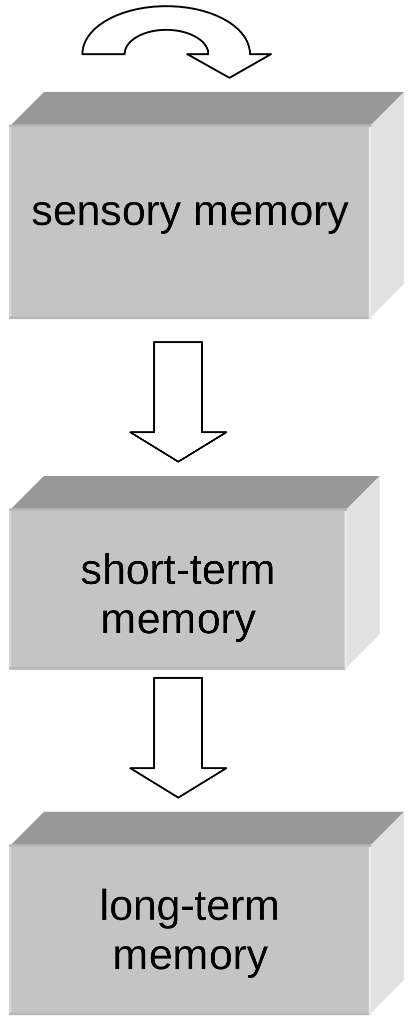
The sequence of learning

Preparation phase concentrating, perceiving

Acquisition phase naming, understanding

Storage phase repeating, encoding

Memory phase abstracting, linking



How to prepare information for storage

- Be conscious of meaning
- Learn sensible material
- Structure learning material
- Make abstracts from meaning
- Link unknown to known information
- Make use of mediators, particularly visuals

How to remember information

- Organise material
- Portion material
- Repeat material
- Learn in intervals (short breaks at the beginning, longer breaks later)
- Make use of memotechniques
- Review material
- Application is the best revision

Acquiring and remembering information

10%	by reading
20%	by hearing
30%	by seeing
40%	by seeing and hearing
60%	by talking about it
80%	by exploring and phrasing on your own
90%	by exploring and overcoming difficulties on your own

How learning is made enjoyable

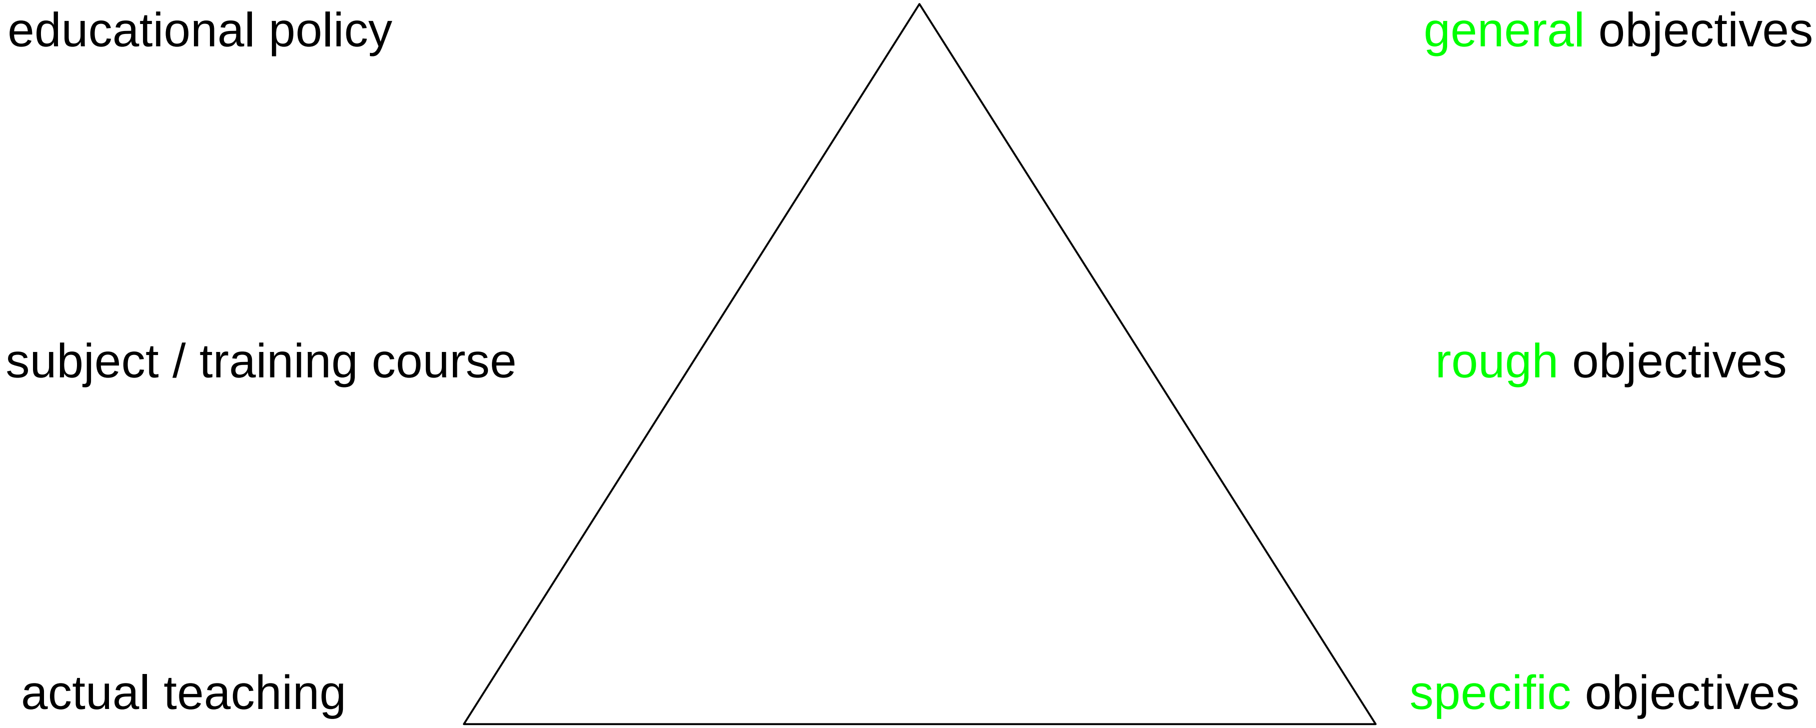
- Motivate students
- Create interest in the subject
- Enhance curiosity of students
- Show links to personal life of students
- Create opportunities for achievement
- Give praise and recognition

- Show your own enthusiasm
- Enjoy teaching

Learning objectives should be...

S pecific	stated in action verbs
M easurable	indicating minimum level of concept response
A ttainable	according to trainee potential and field of expertise
R ealistic	resource- and reality-based
T ime bound	be in coherence with the training timetable

Taxonomy of learning objectives



psychomotor (hand)	cognitive (head)	affective (heart)
perception	knowledge	receiving
set-up	comprehension	responding
guided response	application	valuing
internalized response	analysis	transferring
complex response	synthesis	creating
	evaluation	

Method

= a way or manner of doing something;

= the use of an orderly system as opposed to luck

Teaching method

= the way a teacher uses to impart knowledge to students

= the way of developing skills and capabilities

= the way of facilitating exchange of experiences

The right choice of method

1. Does this method lead us to our learning goal?
2. Does this method fit to our subject?
3. Does this method address the target group?
4. Are all participants – teacher as well as students – able to handle the method?
5. Is it possible to realize this method?

Didactical arrangements

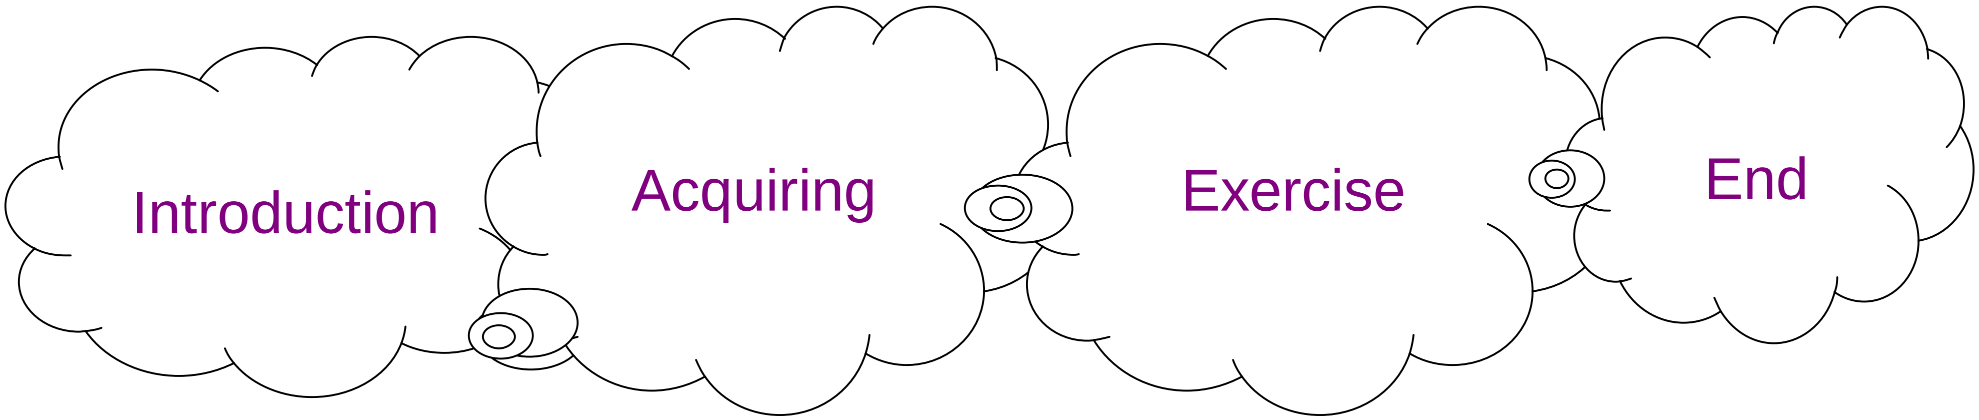
20 – minutes – rule

Teacher-centered	each part not longer than 20 min	e.g. lecture, presentation
Students-centered	each part not shorter than 20 min	e.g. group work, partner work

Alternation – rule

Receiving activities	-	giving activities
Breathe in	-	breathe out

Basic structure of lessons



5 min	25 min	25 min	5 min

Introduction	Acquiring	Exercise	End
should	should	should	should
- orient and motivate	- impart topic	- apply new knowledge using variety of methods	- summarize, repeat, generalize
- connect topic to known subjects	- illustrate topic (e.g. with experiment)		- give prospect for coming lesson
- attract attention	- guide to new insight		- give test or homework
			- check, assess, evaluate

The four step method

1. Step:

Preparation of student

2. Step:

Demonstration and explanation

3. Step:

Student activity

4. Step:

Exercising and strengthening

1. Step:

Preparation of student

- take away the shyness
- motivate
- show the objectives and tasks
- evaluate the knowledge
- familiarize with the work place
- give advice concerning safety

2. Step:

Demonstration and explanation

- position the student so that s/he is standing in the same direction to the work piece
- demonstrate the whole procedure in original time
- in case of complicated procedures divide them into modules and teach them step by step
- repeat the demonstration and make single steps visible
- say what you are doing, how and why you are doing it in that way
- give the opportunity to ask questions

3. Step:

Student activity

- encourage the student
  to try it on his/her own

- don't interrupt the student
  in his/her first attempts

- make comments on serious mistakes

- precision is more important than speed

- let the student say
  what s/he is doing, how and why

4. Step:

Exercising and strengthening

- give enough time to exercise
- acknowledge progress
- control that no mistakes are done during exercising
- change conditions of exercising
- slow adaptation to real working condition

Questions as instruments for...

- Guiding the attention of students
- Arousing the curiosity of students
- Arousing the appreciation of problems
- Initiating thinking
- Saving of results
- Evaluating students
- Disciplining students

Different kinds of questions…

concerning…

- Knowledge
- Process
- Relationship
- Content
- Comprehension
- Thinking

Open questions

Closed questions

Questions to avoid

- Chain questions
- Leading questions
- Echo questions
- Trick questions
- Rhetorical questions

Demanding too much in…

- Factual way
- Linguistic way
- Intellectual way

Demanding too little

Question formulation	Effect
Starting with an interrogative Why What Who When Where HoW	Make a problem evident
Only one question per sentence	Focus on one problem; not demanding too much nor too little
Short, precise questions	Get the problem fast
Give the question to the whole group	All students are included, start to think
Give enough time	Thinking without time pressure; chance to give reasons for the answer
Formulate open questions	Initiate thinking; opinion forming

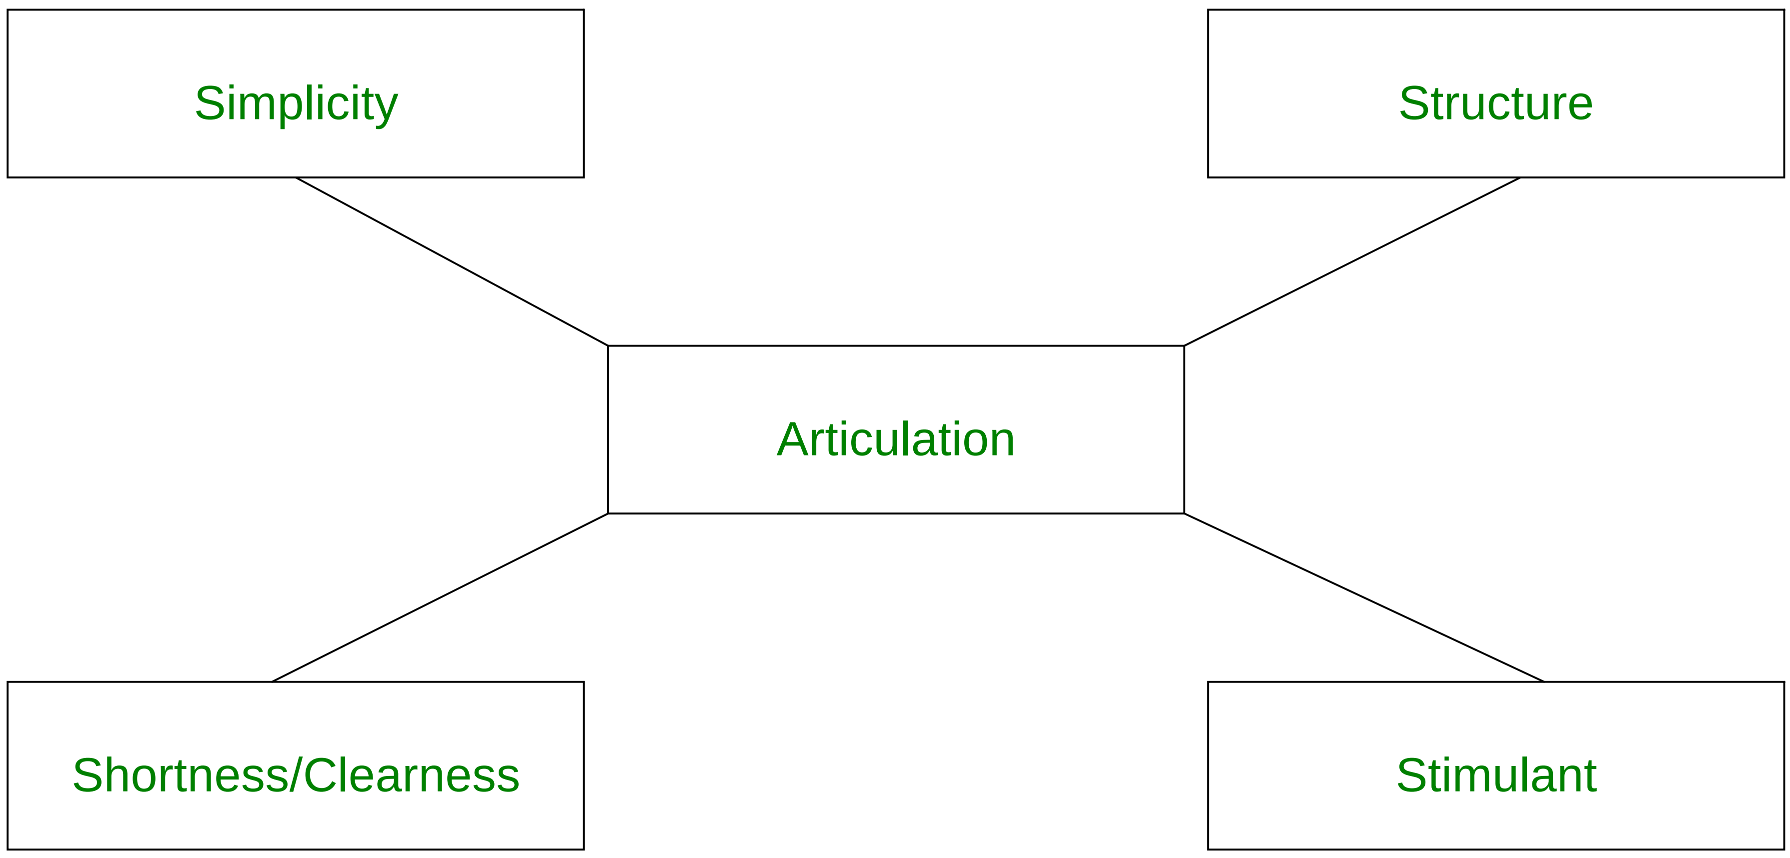
Good questions…

- make the class curious
- are answered lightly and fast
- show what is happening in the group
  (what the others think)
- touch common interest
- include the students' personality
- do not close an issue, they lead further
- show the targets
- make wishes visible
- may lead to a new question

Bad Questions…

- are leading questions
- demand yes or no
- try to show up the lack of knowledge of others
- serve the self-portrayal of the teacher

Comprehensibility of lectures



Simplicity

- Speak in simple terms
- Avoid complicated formulation or foreign words
- Give explanations of specific terms
- Use simple constructed sentences

Shortness/Clearness

- Use short sentences
- Be exact in what you say
- Be concentrated to the objective
- Be precise in your statement
- Give only important and necessary explanations
- Maximize your time

Structure

The visible structure

- State the topic
- Give reasons for topic
- Follow outlined structure
- Summarize

The inner structure

- Logical flow of information
- Link different items
- No jumping from one idea to another
- Emphasize important, not unimportant items
- Red thread must be visible

Stimulant

- Support statements by stories
- Use pictorial language, give examples
- Visualize statements
- Present data and facts by comparison
- Give own opinion
- Be creative in formulation
- Show own interest
- Create an atmosphere
- Include other opinions
- React to audience

Articulation

Voice

speak loud and clear

make pauses, especially when you move

speak slowly

apply verbal emphasis

express enthusiasm

Face

face the audience

look to the eyes of the audience

don’t look from the corner of your eye

show facial expressions related to what you say

Articulation

Posture & bearing

vertical, frontal, open, not hidden

stay with both feet on the ground

raised head, but not snooty

Arms and hands

resting position

pictorial gestures according to the speech

slow, quiet movement

avoid movement below waist

Movement

move goal-oriented, not at random

calmly handle your tools

control movements

change the front sometimes, go beside the audience

Main preparation steps

- Lay down theme
- Choose material
- Order it
- Structure it
- Limit it to essential part
- Make list of main points and facts
- Show red thread
- Estimate time frame
- Shorten

Structure of lectures

Introduction-Mainpart-End

Introduction	Greetings, Theme, Objectives Organizational affaires Motivation
Transition to mainpart	
Mainpart Central idea 1 Central idea 2 Central idea 3	4 Structural elements: • Signposts – important information • Bridges – make links • Fences – limit topic • Markings – give meaning 4 Relaxation elements: • Questions • Examples • Comparisons • Persons
Transition to the end	
End	Result/Conclusion Summarize Generalization/Prospects

Functions of visualization

- Animation
- Information
- Documentation
- Illustration
- Securing of results

Enhancing

- Learning process
- Remembering information
- Retrieving information

Some basic rules….

… for writing:

- Form columns
- Avoid whole sentences
- Use key words
- Avoid wide spacing between letters
- Avoid bold letters
- Use capital and small letters
- Same letter size for same importance
- Think of reading habits (top left to down right)
- Use only known abbreviations
- Check writing from the distance
- Show links by same colour and form

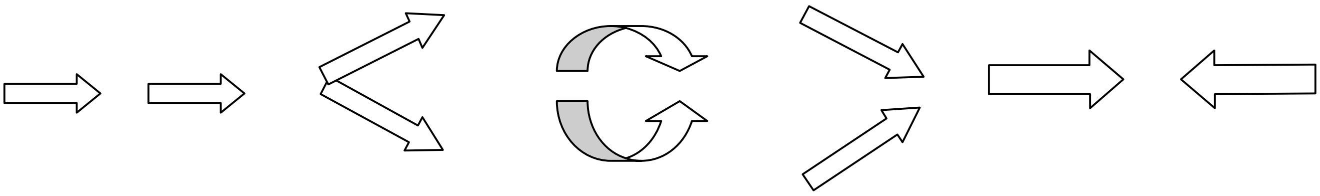
Some basic rules….

…for colour coding

- Use neutral colour (black) for main parts
- Use red for calling the attention
- Use other colours (green, orange, blue) for emphasis
- Group according to colour (e.g. positive – negative)

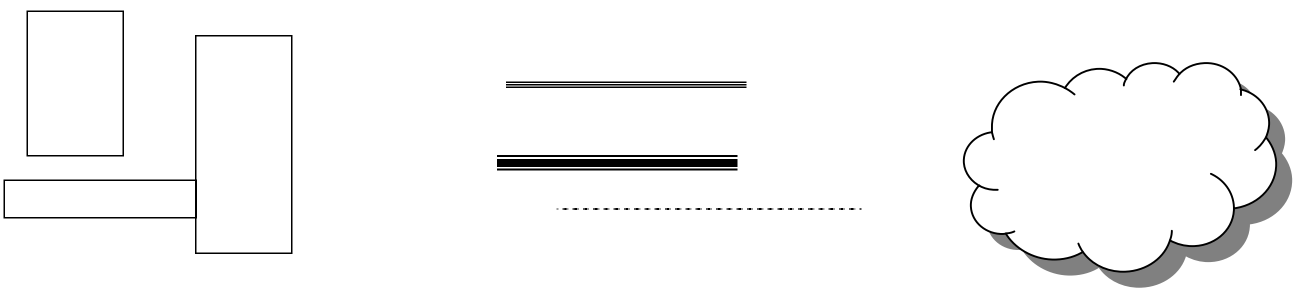
Examples of design elements

arrows

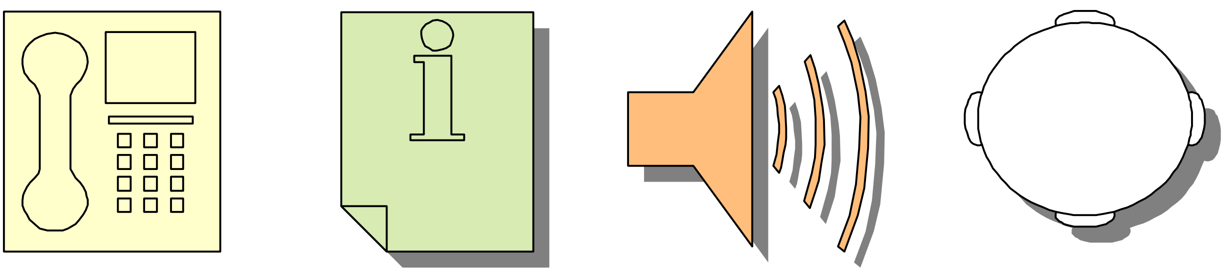


linear diverging cyclic converging contrary

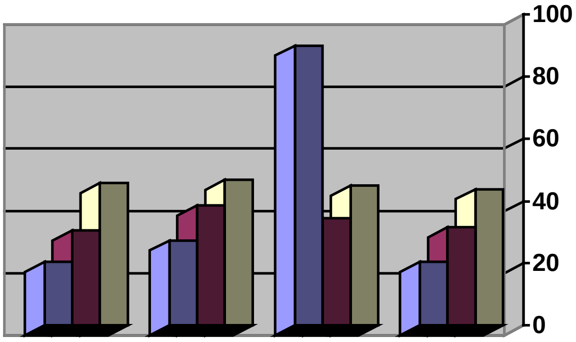
rectangulars, lines, stripes, clouds



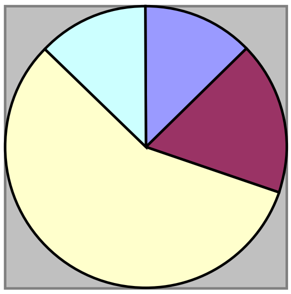
pictograms



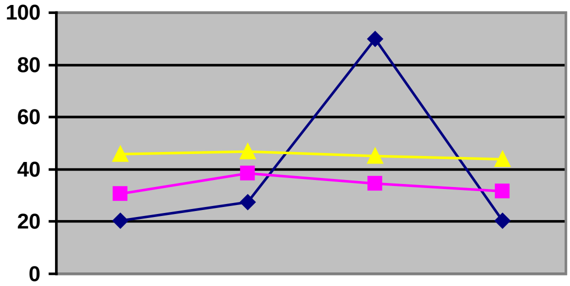
charts



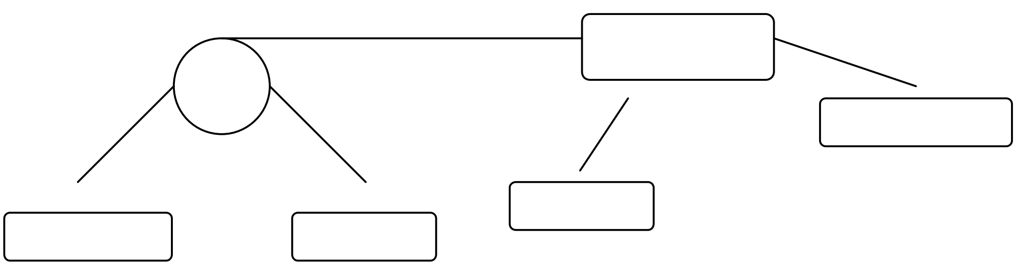
Column chart: comparison of sizes



Pie chart: the whole and its parts



Curve chart: visualizing developments



Organigram/flow chart: visualizing structures and procedures

Requirements for teaching

Address all senses

- Multi channel information
- Allow for cognitive and affective perception
- Facilitate active visualization

Link teaching to reality

- Use originals
- Combine originals with media
- Combine theory and practice
- Incorporate professional experience

Requirements for teaching

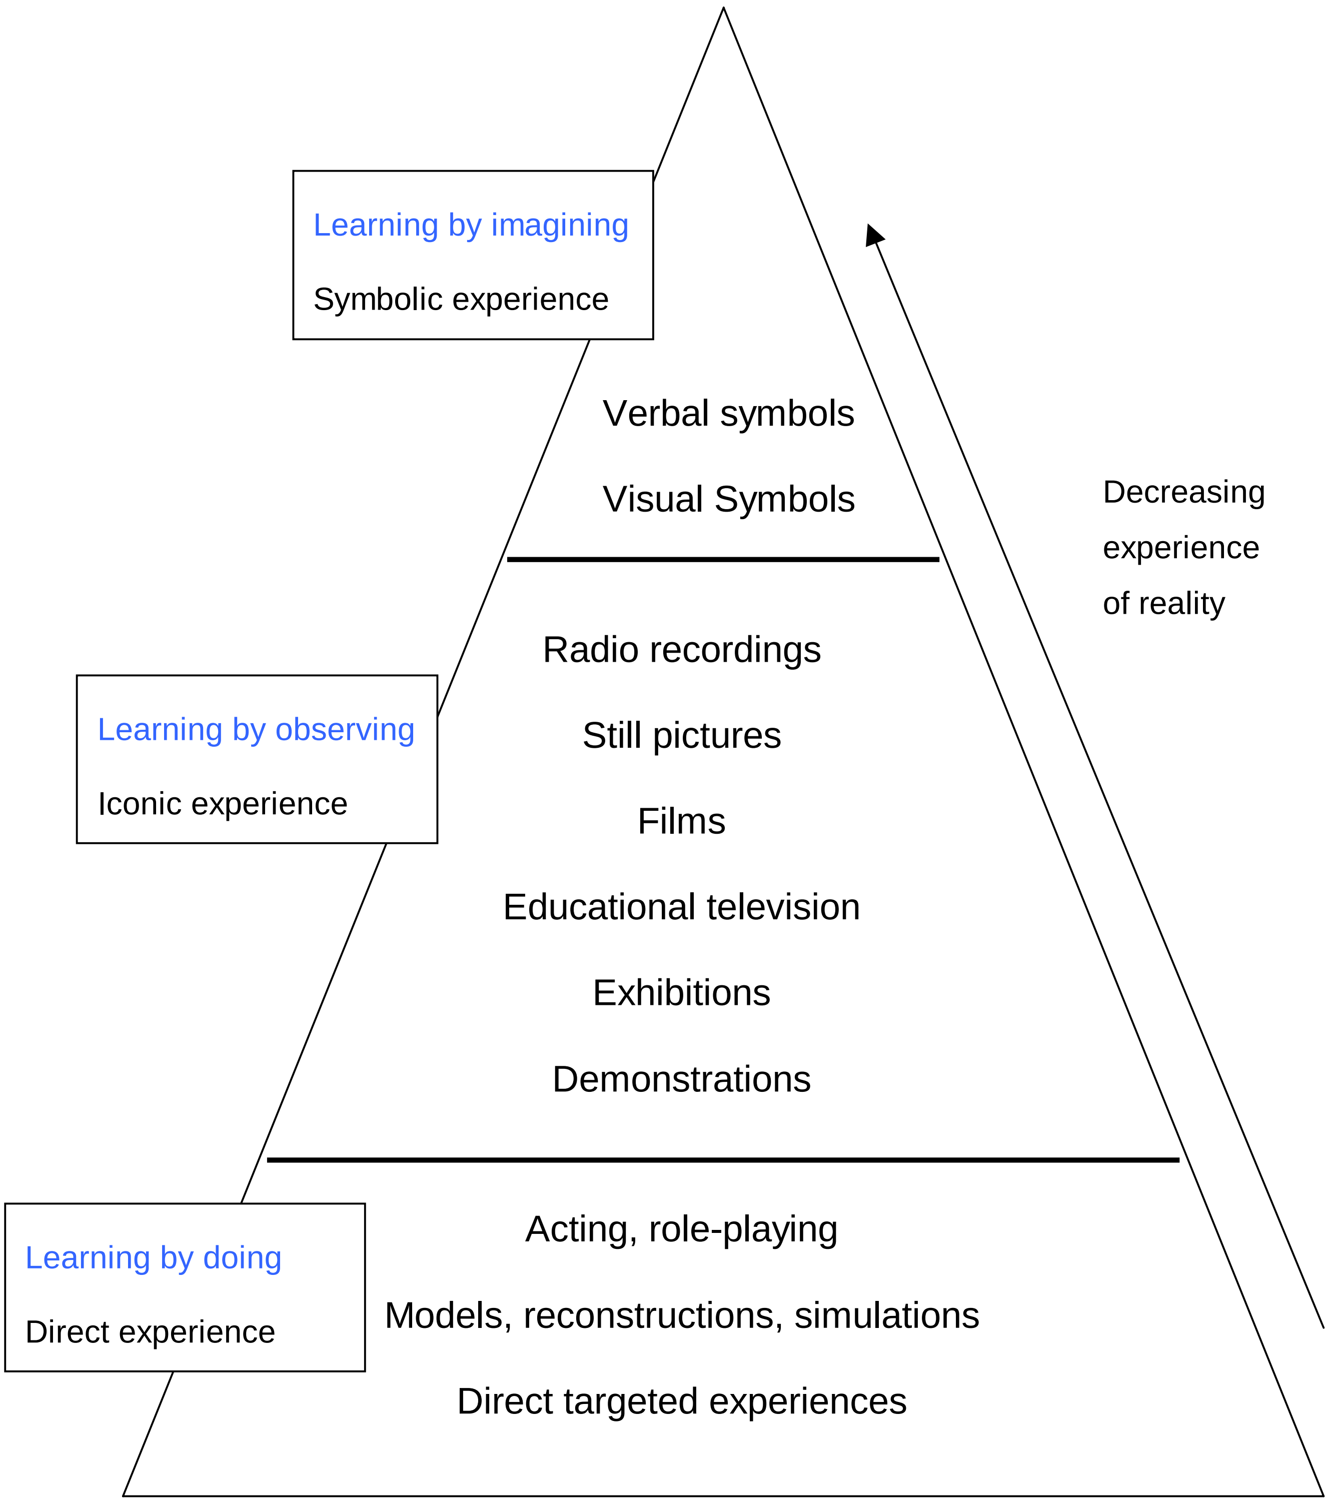
Observe teaching principles

- Show only the essentials
- Simplify complex and complicated processes
- Proceed from the simple to the complicated
- Proceed from the known to the unknown
- Proceed from the concrete to the abstract

Involve students

- Avoid ready made solutions
- Allow students' to work independently with media
- Encourage teamwork

The hierarchy of media in teaching



Control

... shows teacher results of his/her work

… gives teacher clues for further lesson design

... student can assess performance and own status of development

… student receives praise and/or incentive to change behavior

Main goal:

stimulation of high learning results

Control should be…

objective

comparable

evaluable

Control should…

…correspond to learning objectives:

cognitive

affective

psychomotor

time

quality

quantity

Kinds of Control

- Regular control
- Control questions
- Exercises

- Performance controls
- Tests

- Pieces of work
- Examinations

THE USE OF SCAFFOLDS

Definition:
A scaffold is a framework of metal or wooden poles and planks used as a temporary platform from which building repair or construction is carried out. Dependent scaffolds are usually fixed on a house or a wall and cannot stand freely while there are poles only on one side of the scaffold while the other side is connected with the building, which gives it a proper stability. Independent scaffolds do not require the support of any wall or building because of having poles on both sides, which allow erecting them independently. Scaffolds can carry workers and material but one must be careful not to put too many loads like blocks and motor so that the planks cannot carry the load and will break down.

The Use of Scaffolds

Definition:
A scaffold is a framework of metal or wooden poles and planks used as a temporary platform from which building repair or construction is carried out.

Dependent scaffolds are usually fixed on a house or a wall and cannot stand freely while there are poles only on one side of the scaffold while the other side is connected with the building, which gives it a proper stability.

Independent scaffolds do not require the support of any wall or building because of having poles on both sides, which allow erecting them independently.

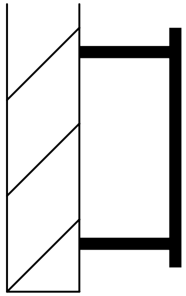
Scaffolds can carry workers and material but one must be careful not to put too many loads like blocks and motor so that the planks cannot carry the load and will break down.

The Use of Scaffolds

Scaffolds are put up when work has to be done above men's height.
They carry persons and construction material.

Types of scaffolds

<u>Dependent Scaffold</u>



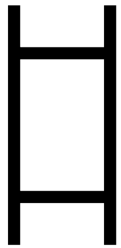
Are fixed onto the
Building and cannot
Stand alone.

Are more stable but
Cannot be erected
Freely.

<u>Independent Scaffold</u>

can be erected
without connecting
It to a building.

can be erected
everywhere but
Are not as stable.



Do not overload scaffolds! Be careful when working on them!

The two sides of the brain

Left	**L**ogic brain	c**R**eativ brain	**R**ight
	Speech	Creativity (new combinations)	
	Calculations	Artistic activity	
	Intellectual Analysis	Musical ability/Rhythm	
	Reading	Emotions	
	Writing	Comprehension	
	Naming	Perception of abstract patterns	
	Ordering	Spatial abilities	
	Sequencing	Facial expressions	
	Complex motor sequences	Holistic ability	
	Critique	Intuition	
	Evaluation	Images	
	Logic	Colours
