# Wikipedia:WikiProject Medicine/Open Textbook of Medicine

From Wikipedia, the free encyclopedia

## Variants

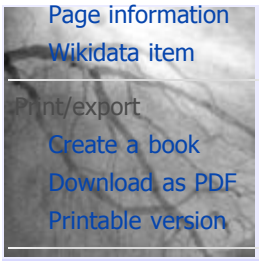
Wikipedia:WikiProject Medicine

Welcome to the **Offline Medical Encyclopedia** by Wikipedia. This is a complete collection of all health care, sanitation, anatomy, and medication related topics from Wikipedia in an offline format. Like Wikipedia all content is open access, meaning that it is free to download, reuse, share, and build upon.

We are working to develop these apps in a number of languages, including English, Persian, Chinese, and Hindi. There are ongoing efforts to increase access to medical information in all languages in collaboration with Translators Without Borders among others. If you like this app and are interested in helping us make it better please join Wikipedia:WikiProject Medicine or contact us directly.

Please keep in mind that this is volunteer generated content. While we try our best to make it as accurate as possible it is not perfect. Thus we request that you use common sense.

James Heilman, MD, CCFP(EM)
The Teams at WikiProject Medicine &
Translators Without Borders



### Cardiology
Abdominal aortic aneurysm • Aortic stenosis • Atrial fibrillation • Cardiac arrhythmia • Cardiovascular disease • Coronary artery disease • Heart failure • Myocardial infarction • Peripheral artery disease • Pulmonary embolism • Rheumatic fever • Syncope

### Children's health
Circumcision • Cleft lip and palate • Congenital heart defect • Down syndrome • Epilepsy • Female genital mutilation • Fetal alcohol spectrum disorder • Klinefelter syndrome • Sickle-cell disease • Spina bifida • Sudden infant death syndrome • Turner syndrome

### Dermatology
Abscess • Acne vulgaris • Allergy • Angular cheilitis • Atopic dermatitis • Candidiasis • Cellulitis • Chickenpox • Dermatitis • Hair loss • Head lice infestation • Herpes simplex • Herpes zoster • Measles • Psoriasis • Scabies

### Ears nose throat

Benign paroxysmal positional vertigo • Hearing loss • Mandibular fracture • Nasal polyp • Nose bleed • Otitis externa • Otitis media • Pharyngitis • Strep throat • Tinnitus • Vertigo

### Endocrinology

Addison's disease • Cushing's syndrome • Delirium tremens • Diabetes • DM type 1 • DM type 2 • Gestational diabetes • Graves' disease • Hypernatremia • Hyperthyroidism • Hypoglycemia • Hyponatremia • Hypothyroidism • Obesity • Primary hyperaldosteronism • Vitamin B12 deficiency

### General surgery

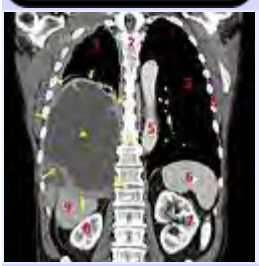
Appendicitis • Bowel obstruction • Celiac disease • Crohn's disease • Diarrhea • Gallstone • Gastritis • Gastrointestinal bleeding • Gastrointestinal perforation • Hemorrhoid • Hernia • Irritable bowel syndrome • Pancreatitis • Peptic ulcer disease • Pernicious anemia • Ulcerative colitis • Volvulus

### Infectious disease

African trypanosomiasis • Ascariasis • Buruli ulcer • Cellulitis • Chagas disease • Common cold • Cysticercosis • Drancunculiasis • Ebola virus disease • Hepatitis A • Hepatitis B • Hepatitis C • HIV/AIDS • Leprosy • Lyme disease • Malaria • Meningitis • Rabies • Syphilis • Tuberculosis • Yellow fever • Zika fever

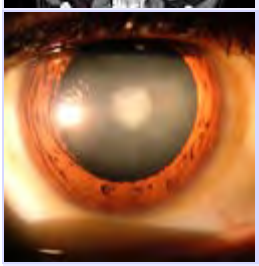
### Medications

Birth control • Carbamazapine • Cephalexin • Cholera vaccine • Cocaine • Dapsone • Diazepam • HCTZ • Ibuprofen • Influenza vaccine • Ipratropium bromide • Ketamine • Levofloxacin • Measles vaccine • Metoprolol • Mifepristone • Morphine • Nystatin • Paracetamol (acetaminophen) • Propofol • Salbutamol



### Oncology

Brain tumor • Breast cancer • Cancer • Cervical cancer • Colon cancer • Endometrial cancer • Esophageal cancer • Glioblastoma multiforme • Leukemia • Lung cancer • Lymphoma • Melanoma • Mesothelioma • Ovarian cancer • Pancreatic cancer • Prostate cancer • Skin cancer • Stomach cancer



### Ophthalmology

Amblyopia • Cataracts • Color blind • Conjunctivitis • Detached retina • Sjögren's syndrome • Glaucoma • Macular degeneration • Refractive error • Trachoma

### Psychiatry

ADHD • Alcoholism • Anorexia nervosa • Anxiety • Asperger syndrome • Autism • Bipolar disorder • Borderline personality disorder • Bulimia nervosa • Eating disorder • Depression • Obsessive-compulsive disorder • Phobia • Post traumatic stress disorder •

Schizophrenia • Suicide

**Rheumatology**
Carpal tunnel syndrome • Fibromyalgia • Gout • Low back pain • Osteoarthritis • Osteoporosis • Plantar fasciitis • Psoriasis • Rheumatoid arthritis • Sarcoidosis • Sciatica

**Women's health**
Abortion • Breastfeeding • Childbirth • Dysmenorrhea • Eclampsia • Ectopic pregnancy • Endometriosis • Hyperemesis gravidarum • Menopause • Menstruation • Morning sickness • Obstructed labor • Ovarian cyst • Polycystic ovarian syndrome • Pre eclampsia • Pregnancy • Premenstrual syndrome • Preterm birth • Trichomoniasis • Uterine fibroid

User:Jmh649. In real life I go by James Heilman. I am a Canadian ER doc. I have been editing here since July 6th, 2008.

James Heilman, MD, CCFP-EM, Clinical Faculty member of the Department of Emergency Medicine, Faculty of Medicine, University of British Columbia (Clinical Assistant Professor)[2][3]

P.S. My spelling and grammar are poor, so thank you for correcting them. If something I write is completely unintelligible, please send me a request for clarification.

## COI

I am entirely a volunteer here. I do not accept money or honorariums for any efforts related to wikis, Wikipedia or the Internet. I do not and have not accepted any money from the Wikimedia Foundation or associated chapters in the last four years. This includes not accepting them paying for either travel or accommodation expenses. Prior to that I received about $1500 of funding for travel from the Canadian chapter. In 2012/2013 I donated to the WMF funds more than required to reimburse this amount.[4]

I do accept travel costs for speaking events from organizations that can afford it other than the WMF. I do not and have never accepted pharmaceutical company funding. I do not have any financial COI with respect to the subjects I edit. User:Docjames is a different editor.

## Current projects

- List of simplified articles ready for translation
- Wiki Project Med Foundation
- The Wikipedia Journal live **here**
- Cochrane collaboration
- Collaborating with journals
- Collaboration with WHO
- Collaboration with UCSF
- Collaboration with the NIH
- Tech requests
- Collaboration with Syracuse
- Medical Stats

- Med cost

**Authority control** ORCID: 0000-0002-1347-7700 ·

## Staff

I have personally hired a part time staff member (User:Lucas559) as of Jun 2015 to assist with a number of medicine related projects including: the translation task force, copyright detection bot, assisting students who are enrolled in classes we are collaborating with, and fundraising for Wiki Project Med Foundation. He will not vote in any discussion that I have already done so and vise versa. Discussion around the creation of his position is partly **here**.

### Students

Students who work with me at the East Kootenay Regional receive instruction on editing Wikipedia. Therefore you may see multiple accounts working on similar medical content coming from my hospitals IP address.

## Words I find inspiring

*Main page: My inspirations*

> It is not the critic who counts; not the man who points out how the strong man stumbles, or where the doer of deeds could have done them better. The credit belongs to the man who is actually in the arena, whose face is marred by dust and sweat and blood; who strives valiantly; who errs, who comes short again and again, because there is no effort without error and shortcoming; but who does actually strive to do the deeds; who knows great enthusiasms, the great devotions; who spends himself in a worthy cause; who at the best knows in the end the triumph of high achievement, and who at the worst, if he fails, at least fails while daring greatly, so that his place shall never be with those cold and timid souls who neither know victory nor defeat.Theodore Roosevelt[1] I am a proud fighter for open knowledge.[2]

"Truth is mighty and will prevail. There is nothing the matter with this, except that it ain't so." Mark Twain

## Thoughts

We face a struggle between those who see our future as a technology organization supported by people versus those who see our future as a organization of people supported by technology. I am squarely in the latter camp. Wikipedia at its best is written one sentence at a time following the consideration of the available sources. The singularity is not near.

## My test area

## Resources

Edit links

[ view module • edit ]

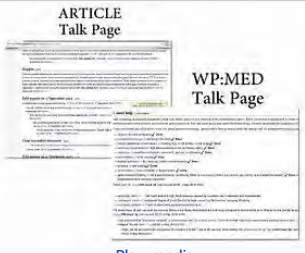
## Guidelines and Policies

- Wikipedia is an encyclopedia and has a distinct style that may take some time getting used to.
- It is important that we only use the best sources and that we give them due weight. Setting us apart from scientific papers we prefer secondary sources over primary sources. We'd rather cite a review article than an original trial.
- To get you started and to explain why this is important we have a number of guides and guidelines:

| | |
|---|---|
| **WP:MEDRS** | **WP:MEDMOS** |
| **Reliable Sources** | **Manual of Style** |
| **WP:MEDCOI** | **WP:MEDHOW** |
| **Conflicts of Interest** | **How to edit** |

*Our guides complement Wikipedia:Policies and guidelines and take great care to explain why they are relevant.*

**More resources**



Play media

An introductory video about how to edit Wikipedia and medicine.

## The Wikipedia Medical Library

The **Wikipedia Library** is a resource for anyone who want to use Wikipedia or to do research to help expand and improve Wikipedia.
*Specialised resources for Medical editors coming soon*

- **Need help finding sources?**: **Help:Find sources**
- **Need help finding your local library?**: **Wikipedia:Find your library**
- **Found a source that you can't access?** *Check out the*: **Resource Exchange**
  *Or try an Interlibrary loan*

We have an offline version of our healthcare content. **Download the Android app** and access all this content when there's no Internet. (other languages)

## Research

[ view module • edit ]

Wikipedia can be a great resource for getting to know a field — and it can give you an encyclopaedic overview of a subject, acting as a spring-board letting you dive deeper. It should however not be used as your only source when performing research, and you should never blindly trust Wikipedia. Over the years quite a literature has been amassed surround the reliability and biases of Wikipedia. To see some of the studies that have been produced on the quality and scope of medical information on Wikipedia take a look at some of the research:

**On Wikipedia and Medicine**

**2016**

*This list is incomplete. We try to keep the list free of bias, but encourage you not to take our word for it — so here are some suggested searches*:

- *PubMed: wikipedia, wikipedia AND medicine*

## About

[ view module • edit ]

**WikiProject Medicine** was started in 2004 by Dr. Jacob de Wolff as WikiProject Clinical Medicine with the later branch WikiProject Preclinical Medicine. These merged and WikiProject Medicine has since been one of Wikipedia's most active WikiProjects. **WP:MED** as it is known aims to manage and help in curation of Wikipedia's medical articles. We write articles and discuss all manner of issues on our talk page: *WT:MED*.

Through the years we've built up a catalogue of sub-projects and task-forces which vary in their activity, you can find some of them at the task force page

WikiProject Medicine is the English arm of an international community of Wikimedia medical projects — more of which can be found through the international WikiProject Med Foundation — on the Meta-wiki.

*Other early arms were the the German WikiProjekt Medizin which started in 2006 and the French Projet Médecine and Spanish Wikiproyecto Medicina and a number of others!*

Wiki Project Med Foundation: *a nonprofit corporation promoting development of medical content on Wikimedia projects*

WikiProject Medicine: *the sister project on Wiktionary*

WikiProject Medicine: *the partner project on Wikidata*

Wikiversity School of Medicine: *medical education resources*

From Wikipedia, the free encyclopedia

*This article is about the Internet encyclopedia. For Wikipedia's home page, see Main Page. For Wikipedia's visitor introduction, see Wikipedia:About. For other uses, see Wikipedia (disambiguation).*

**Wikipedia** (/ˌwɪkɪˈpiːdiə/ or /ˌwɪkiˈpiːdiə/ *WIK-i-PEE-dee-ə*) is a free online encyclopedia that aims to allow anyone to edit articles.[3] Wikipedia is the largest and most popular general reference work on the Internet[4][5][6] and is ranked among the ten most popular websites.[7] Wikipedia is owned by the nonprofit Wikimedia Foundation.[8][9][10]

Wikipedia was launched on January 15, 2001, by Jimmy Wales and Larry Sanger.[11] Sanger coined its name,[12][13] a portmanteau of *wiki*[notes 4] and encyclo*pedia*. There was only the English language version initially, but it quickly developed similar versions in other languages, which differ in content and in editing practices. With 5,323,768 articles, the English Wikipedia is the largest of the more than 290 Wikipedia encyclopedias. Overall, Wikipedia consists of more than 40 million articles in more than 250 different languages[15] and as of February 2014, it had 18 billion page views and nearly 500 million unique visitors each month.[16]

In 2005, *Nature* published a peer review comparing 42 science articles from *Encyclopædia Britannica* and Wikipedia, and found that Wikipedia's level of accuracy approached *Encyclopædia Britannica*'s.[17] Criticism of Wikipedia includes claims that it exhibits systemic bias, presents a mixture of "truths, half truths, and some falsehoods",[18] and that in controversial topics, it is subject to manipulation and spin.[19]

# History

*Main article: History of Wikipedia*

## Nupedia

Other collaborative online encyclopedias were attempted before Wikipedia, but none were so successful.[20]

Wikipedia began as a complementary project for Nupedia, a free online English-language encyclopedia project whose articles were written by experts and reviewed under a formal process.[11] Nupedia was founded on March 9, 2000, under the ownership of Bomis, a web portal company. Its main figures were Jimmy Wales, the CEO of Bomis, and Larry Sanger, editor-in-chief for Nupedia and later Wikipedia. Nupedia was licensed initially under its own Nupedia Open Content License, switching to the GNU Free Documentation License before Wikipedia's founding at the urging of Richard Stallman.[21] Sanger and Wales founded Wikipedia.[22][23] While Wales is credited with defining the goal of making a publicly editable encyclopedia,[24][25] Sanger is credited with the strategy of using a wiki to reach that goal.[26] On January 10, 2001, Sanger proposed on the Nupedia mailing list to create a wiki as a "feeder" project for Nupedia.[27]

Jimmy Wales and Larry Sanger

Wikipedia originally developed from another encyclopedia project called Nupedia

## Launch and early growth

Wikipedia was launched on January 15, 2001, as a single English-language edition at www.wikipedia.com,[28] and announced by Sanger on the Nupedia mailing list.[24] Wikipedia's policy of "neutral point-of-view"[29] was codified in its first months. Otherwise, there were relatively few rules initially and Wikipedia operated independently of Nupedia.[24] Originally, Bomis intended to make Wikipedia a business for profit.[30]

Wikipedia gained early contributors from Nupedia, Slashdot postings, and web search engine indexing. By August 8, 2001, Wikipedia had over 8,000 articles.[31] On September 25, 2001, Wikipedia had over 13,000 articles.[32] By the end of 2001, it had grown to approximately 20,000 articles and 18 language editions. It had reached 26 language editions by late 2002, 46 by the end of 2003, and 161 by the final days of 2004.[33] Nupedia and Wikipedia coexisted until the former's servers were taken down permanently in 2003, and its text was incorporated into Wikipedia. The English Wikipedia passed the mark of two million articles on September 9, 2007, making it the largest encyclopedia ever assembled, surpassing even the 1408 *Yongle Encyclopedia*, which had held the record for almost 600 years.[34]

The Great Book of Knowledge, Part 1, Ideas with Paul Kennedy, CBC, January 15, 2014

Citing fears of commercial advertising and lack of control in Wikipedia, users of the Spanish Wikipedia forked from Wikipedia to create the *Enciclopedia Libre* in February 2002.[35] These moves encouraged Wales to announce that Wikipedia would not display advertisements, and to change Wikipedia's domain from *wikipedia.com* to *wikipedia.org*.[36]

Though the English Wikipedia reached three million articles in August 2009, the growth of the edition, in terms of the numbers of articles and of contributors, appears to have peaked around early 2007.[37] Around 1,800 [38]

articles were added daily to the encyclopedia in 2006; by 2013 that average was roughly 800. A team at the Palo Alto Research Center attributed this slowing of growth to the project's increasing exclusivity and resistance to change.[39] Others suggest that the growth is flattening naturally because articles that could be called "low-hanging fruit"—topics that clearly merit an article—have already been created and built up extensively.[40][41][42]

In November 2009, a researcher at the Rey Juan Carlos University in Madrid (Spain) found that the English Wikipedia had lost 49,000 editors during the first three months of 2009; in comparison, the project lost only 4,900 editors during the same period in 2008.[43][44] *The Wall Street Journal* cited the array of rules applied to editing and disputes related to such content among the reasons for this trend.[45] Wales disputed these claims in 2009, denying the decline and questioning the methodology of the study.[46] Two years later, in 2011, Wales acknowledged the presence of a slight decline, noting a decrease from "a little more than 36,000 writers" in June 2010 to 35,800 in June 2011. In the same interview, Wales also claimed the number of editors was "stable and sustainable".[47] A 2013 article titled "The Decline of Wikipedia" in MIT's *Technology Review* questioned this claim. The article revealed that since 2007, Wikipedia had lost a third of the volunteer editors who update and correct the online encyclopedia and those still there have focused increasingly on minutiae.[48] In July 2012, *the Atlantic* reported that the number of administrators is also in decline.[49] In the November 25, 2013, issue of *New York* magazine, Katherine Ward stated "Wikipedia, the sixth-most-used website, is facing an internal crisis".[50]

## Recent milestones

Wikipedia blackout protest against SOPA on January 18, 2012

Play media
A promotional video of the Wikimedia Foundation that encourages viewers to edit Wikipedia, mostly reviewing 2014 via Wikipedia content

In January 2007, Wikipedia entered for the first time the top-ten list of the most popular websites in the United States, according to comScore Networks. With 42.9 million unique visitors, Wikipedia was ranked number 9, surpassing the *New York Times* (#10) and Apple (#11). This marked a significant increase over January 2006, when the rank was number 33, with Wikipedia receiving around 18.3 million unique visitors.[51] As of March 2015, Wikipedia has rank 5[7][52] among websites in terms of popularity according to Alexa Internet. In 2014, it received 8 billion pageviews every month.[53] On February 9, 2014, *The New York Times* reported that Wikipedia has 18 billion page views and nearly 500 million unique visitors a month, "according to the ratings firm comScore."[16]

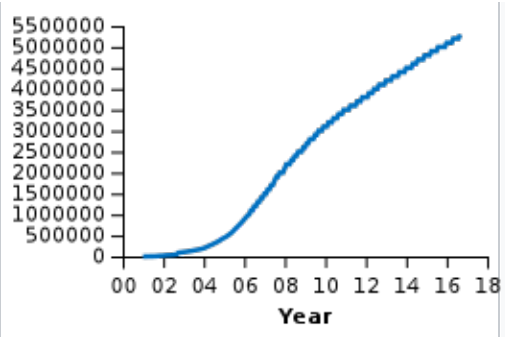
On January 18, 2012, the English Wikipedia participated in a series of coordinated protests against two proposed laws in the United States Congress—the Stop Online Piracy Act (SOPA) and the PROTECT IP Act (PIPA)—by blacking out its pages for 24 hours.[54] More than 162 million people viewed the blackout explanation page that temporarily replaced Wikipedia content.[55][56]

Loveland and Reagle argue that, in process, Wikipedia follows a long tradition of historical encyclopedias that accumulated improvements piecemeal through "stigmergic accumulation".[57][58]

On January 20, 2014, Subodh Varma reporting for *The Economic Times* indicated that not only had Wikipedia's growth flattened but that it has "lost nearly 10 per cent of its page-views last year. That's a decline of about 2 billion between December 2012 and December 2013. Its most popular versions are leading the slide: page-views of the English Wikipedia declined by 12 per cent, those of German version slid by 17 per cent and the Japanese version lost 9 per cent."[59] Varma added that, "While Wikipedia's managers think that this could be due to errors in counting, other experts feel that Google's Knowledge Graphs project launched last year may be gobbling up Wikipedia users."[59] When contacted on this matter, Clay Shirky, associate professor at New York University and fellow at Harvard's Berkman Center for Internet and Security indicated that he suspected much of the page view decline was due to Knowledge Graphs, stating, "If you can get your question answered from the search page, you don't need to click [any further]."[59]

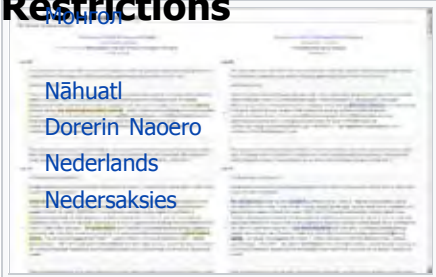
## Openness

Unlike traditional encyclopedias, Wikipedia follows the procrastination principle[notes 5][61] regarding the security of its content.[61] It started almost entirely open—anyone could create articles, and any Wikipedia article could be edited by any reader, even those who did not have a Wikipedia account. Modifications to all articles would be published immediately. As a result, any article could contain inaccuracies such as errors, ideological biases, and nonsensical or irrelevant text.



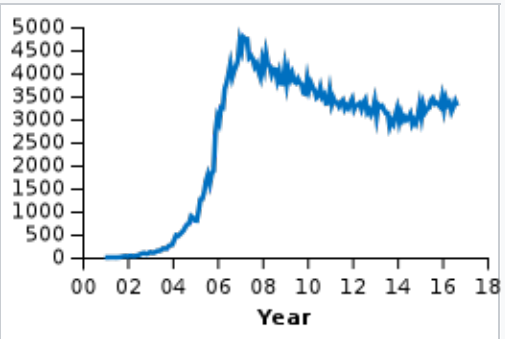
Number of Wikipedia articles[60]

## Restrictions



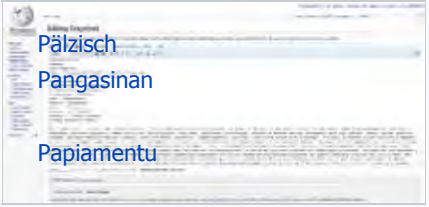
Differences between versions of an article are highlighted as shown

Due to the increasing popularity of Wikipedia, popular editions, including the English version, have introduced editing restrictions in some cases. For instance, on the English Wikipedia and some other language editions, only registered users may create a new article.[62] On the English Wikipedia, among others, some particularly controversial, sensitive and/or vandalism-prone pages have been protected to some degree.[63][64] A frequently vandalized article can be *semi-protected* or *extended confirmed protected*, meaning that only autoconfirmed or extended confirmed editors are able to modify it.[65] A particularly contentious article may be locked so that only administrators are able to make changes.[66]



Wikipedia editors with >100 edits per month[60]

In certain cases, all editors are allowed to submit modifications, but review is required for some editors, depending on certain conditions. For example, the German Wikipedia maintains "stable versions" of articles,[67] which have passed certain reviews. Following protracted trials and community discussion, the English Wikipedia introduced the "pending changes" system in December 2012.[68] Under this system, new and unregistered users' edits to certain controversial or vandalism-prone articles are reviewed by established users before they are published.[69]



The editing interface of Wikipedia

## Review of changes

Although changes are not systematically reviewed, the software that powers Wikipedia provides certain tools allowing anyone to review changes made by others. The "History" page of each article links to each revision.[notes 6][70] On most articles, anyone can undo others' changes by clicking a link on the article's history page. Anyone can view the latest changes to articles, and anyone may maintain a "watchlist" of articles that interest them so they can be notified of any changes. "New pages patrol" is a process whereby newly created articles are checked for obvious problems.[71]

In 2003, economics PhD student Andrea Ciffolilli argued that the low transaction costs of participating in a wiki create a catalyst for collaborative development, and that features such as allowing easy access to past versions of a page favor "creative construction" over "creative destruction".[72]

## Vandalism

*Main article: Vandalism on Wikipedia*

Any edit that changes content in a way that deliberately compromises the integrity of Wikipedia is considered vandalism. The most common and obvious types of vandalism include insertion of obscenities and crude humor. Vandalism can also include advertising language and other types of spam.[73] Sometimes editors commit vandalism by removing information or entirely blanking a given page. Less common types of vandalism, such as the deliberate addition of plausible but false information to an article, can be more difficult to detect. Vandals can introduce irrelevant formatting, modify page semantics such as the page's title or categorization, manipulate the underlying code of an article, or use images disruptively.[74]

Obvious vandalism is generally easy to remove from Wikipedia articles; the median time to detect and fix vandalism is a few minutes.[75][76] However, some vandalism takes much longer to repair.[77]

American journalist John Seigenthaler (1927–2014), subject of the Seigenthaler incident

In the Seigenthaler biography incident, an anonymous editor introduced false information into the biography of American political figure John Seigenthaler in May 2005. Seigenthaler was falsely presented as a suspect in the assassination of John F. Kennedy.[77] The article remained uncorrected for four months.[77] Seigenthaler, the founding editorial director of *USA Today* and founder of the Freedom Forum First Amendment Center at Vanderbilt University, called Wikipedia co-founder Jimmy Wales and asked whether he had any way of knowing who contributed the misinformation. Wales replied that he did not, although the perpetrator was eventually traced.[78][79] After the incident, Seigenthaler described Wikipedia as "a flawed and irresponsible research tool".[77] This incident led to policy changes at Wikipedia, specifically targeted at tightening up the verifiability of biographical articles of living people.[80]

# Policies and laws

*See also: Wikipedia:Five Pillars*

**External video**

Wikimania, *60 Minutes*, CBS, 20 minutes, April 5, 2015, co-founder Jimmy Wales at Fosdem

Content in Wikipedia is subject to the laws (in particular, copyright laws) of the United States and of the U.S. state of Virginia, where the majority of Wikipedia's servers are located. Beyond legal matters, the editorial principles of Wikipedia are embodied in the "five pillars" and in numerous policies and guidelines intended to appropriately shape content. Even these rules are stored in wiki form, and Wikipedia editors write and revise the website's policies and guidelines.[81] Editors can enforce these rules by deleting or modifying non-compliant material. Originally, rules on the non-English editions of Wikipedia were based on a translation of the rules for the English Wikipedia. They have since diverged to some extent.[67]

## Content policies and guidelines

According to the rules on the English Wikipedia, each entry in Wikipedia must be about a topic that is encyclopedic and is not a dictionary entry or dictionary-like.[82] A topic should also meet Wikipedia's standards of "notability",[83] which generally means that the topic must have been covered in mainstream media or major academic journal sources that are independent of the article's subject. Further, Wikipedia intends to convey only knowledge that is already established and recognized.[84] It must not present original research. A claim that is likely to be challenged requires a reference to a reliable source. Among Wikipedia editors, this is often phrased as "verifiability, not truth" to express the idea that the readers, not the encyclopedia, are ultimately responsible for checking the truthfulness of the articles and making their own interpretations.[85] This can at times lead to the removal of information that is valid.[86] Finally, Wikipedia must not take sides.[87] All opinions and viewpoints, if attributable to external sources, must enjoy an appropriate share of coverage

within an article.[88] This is known as neutral point of view (NPOV).

# Governance

*Further information: Wikipedia:Administration*

Wikipedia's initial anarchy integrated democratic and hierarchical elements over time.[89][90] An article is not considered to be owned by its creator or any other editor and is not vetted by any recognized authority.[91] Wikipedia's contributors avoid a tragedy of the commons by internalizing benefits. They do this by experiencing flow and identifying with and gaining status in the Wikipedia community.[92]

## Administrators

Editors in good standing in the community can run for one of many levels of volunteer stewardship: this begins with "administrator",[93][94] privileged users who can delete pages, prevent articles from being changed in case of vandalism or editorial disputes, and try to prevent certain persons from editing. Despite the name, administrators are not supposed to enjoy any special privilege in decision-making; instead, their powers are mostly limited to making edits that have project-wide effects and thus are disallowed to ordinary editors, and to implement restrictions intended to prevent certain persons from making disruptive edits (such as vandalism).[95][96]

Fewer editors become administrators than in years past, in part because the process of vetting potential Wikipedia administrators has become more rigorous.[97]

*Bureaucrats* name new administrators, solely upon the recommendations from the community.

## Dispute resolution

Wikipedians often have disputes regarding content, which may result in repeatedly making opposite changes to an article, known as edit warring.[98][99] Over time, Wikipedia has developed a semi-formal dispute resolution process to assist in such circumstances. In order to determine community consensus, editors can raise issues at appropriate community forums,[notes 7] or seek outside input through third opinion requests or by initiating a more general community discussion known as a request for comment.

## Arbitration Committee

*Main article: Arbitration Committee*

The Arbitration Committee presides over the ultimate dispute resolution process. Although disputes usually arise from a disagreement between two opposing views on how an article should read, the Arbitration Committee explicitly refuses to directly rule on the specific view that should be adopted. Statistical analyses suggest that the committee ignores the content of disputes and rather focuses on the way disputes are conducted,[100] functioning not so much to resolve disputes and make peace between conflicting editors, but to weed out problematic editors while allowing potentially productive editors back in to participate. Therefore, the committee does not dictate the content of articles, although it sometimes condemns content changes when it deems the new content violates Wikipedia policies (for example, if the new content is considered biased). Its remedies include cautions and probations (used in 63% of cases) and banning editors from articles (43%), subject matters (23%) or Wikipedia (16%). Complete bans from Wikipedia are generally limited to instances of impersonation and anti-social behavior. When conduct is not impersonation or anti-social, but rather anti-consensus or in violation of editing policies, remedies tend to be limited to warnings.[101]

# Community

*Main article: Wikipedia community*

Each article and each user of Wikipedia has an associated "Talk" page. These form the primary communication channel for editors to discuss,

coordinate and debate.[102]

Wikipedia's community has been described as cult-like,[103] although not always with entirely negative connotations.[104] The project's preference for cohesiveness, even if it requires compromise that includes disregard of credentials, has been referred to as "anti-elitism".[105]

Wikipedians sometimes award one another virtual barnstars for good work. These personalized tokens of appreciation reveal a wide range of valued work extending far beyond simple editing to include social support, administrative actions, and types of articulation work.[106]

Wikipedia does not require that its editors and contributors provide identification.[107] As Wikipedia grew, "Who writes Wikipedia?" became one of the questions frequently asked on the project.[108] Jimmy Wales once argued that only "a community ... a dedicated group of a few hundred volunteers" makes the bulk of contributions to Wikipedia and that the project is therefore "much like any traditional organization".[109] In 2008, a *Slate* magazine article reported that: "According to researchers in Palo Alto, 1 percent of Wikipedia users are responsible for about half of the site's edits."[110] This method of evaluating contributions was later disputed by Aaron Swartz, who noted that several articles he sampled had large portions of their content (measured by number of characters) contributed by users with low edit counts.[111]

The English Wikipedia has 5,323,768 articles, 29,893,763 registered editors, and 119,453 active editors. An editor is considered active if they have made one or more edits in the past thirty days.

Editors who fail to comply with Wikipedia cultural rituals, such as signing talk page comments, may implicitly signal that they are Wikipedia outsiders, increasing the odds that Wikipedia insiders may target or discount their contributions. Becoming a Wikipedia insider involves non-trivial costs: the contributor is expected to learn Wikipedia-specific technological codes, submit to a sometimes convoluted dispute resolution process, and learn a "baffling culture rich with in-jokes and insider references".[112] Editors who do not log in are in some sense second-class citizens on Wikipedia,[112] as "participants are accredited by members of the wiki community, who have a vested interest in preserving the quality of the work product, on the basis of their ongoing participation",[113] but the contribution histories of anonymous unregistered editors recognized only by their IP addresses cannot be attributed to a particular editor with certainty.

Wikipedians and British Museum curators collaborate on the article Hoxne Hoard in June 2010

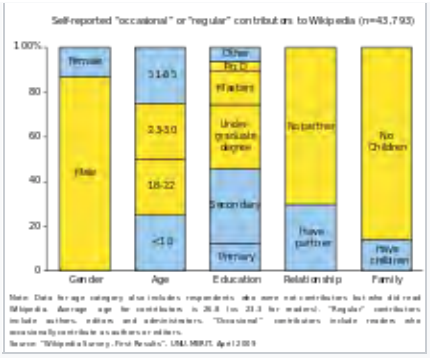
A 2007 study by researchers from Dartmouth College found that "anonymous and infrequent contributors to Wikipedia [...] are as reliable a source of knowledge as those contributors who register with the site".[114] Jimmy Wales stated in 2009 that "(I)t turns out over 50% of all the edits are done by just .7% of the users... 524 people... And in fact the most active 2%, which is 1400 people, have done 73.4% of all the edits."[109] However, *Business Insider* editor and journalist Henry Blodget showed in 2009 that in a random sample of articles, most content in Wikipedia (measured by the amount of contributed text that survives to the latest sampled edit) is created by "outsiders", while most editing and formatting is done by "insiders".[109]

A 2008 study found that Wikipedians were less agreeable, open, and conscientious than others,[115][116] although a later commentary pointed out serious flaws, including that the data showed higher openness, that the differences with the control group were small as were the samples.[117] According to a 2009 study, there is "evidence of growing resistance from the Wikipedia community to new content".[118]

## Diversity

One study found that the contributor base to Wikipedia "was barely 13%" [119]

women; the average age of a contributor was in the mid-20s". A 2011 study by researchers from the University of Minnesota found that females comprised 16.1% of the 38,497 editors who started editing Wikipedia during 2009.[120] In a January 2011 *New York Times* article, Noam Cohen observed that just 13% of Wikipedia's contributors are female according to a 2008 Wikimedia Foundation survey.[121] Sue Gardner, a former executive director of the Wikimedia Foundation, hoped to see female contributions increase to 25% by 2015.[122] Linda Basch, president of the National Council for Research on Women, noted the contrast in these Wikipedia editor statistics with the percentage of women currently completing bachelor's degrees, master's degrees and PhD programs in the United States (all at rates of 50 percent or greater).[123]



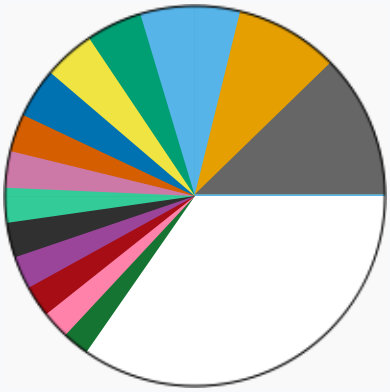
Wikipedia editor demographics (2008)

In response, various universities have hosted edit-a-thons to encourage more women to participate in the Wikipedia community. In fall 2013, 15 colleges and universities — including Yale, Brown, and Pennsylvania State — offered college credit for students to "write feminist thinking" about technology into Wikipedia.[124] Estimates of the diversity of contributors by educational level have indicated that sixty-two percent of Wikipedia's editors are at the high school and undergraduate college level of education.[125]

In August 2014, Wikipedia co-founder Jimmy Wales said in a BBC interview that the Wikimedia Foundation was "... really doubling down our efforts ..." to reach 25% of female editors (originally targeted by 2015), since the Foundation had "totally failed" so far. Wales said "a lot of things need to happen ... a lot of outreach, a lot of software changes".[126] Andrew Lih writing in the New York Times was quoted by Bloomberg News in December 2016 as supporting Wales comments concerning shortfalls in Wikipedia's outreach to female editors. Lih states his concern with the question indicating that: "How can you get people to participate in an (editing) environment that feels unsafe, where identifying yourself as a woman, as a feminist, could open you up to ugly, intimidating behavior".[127]

## Language editions

There are currently 295 language editions of Wikipedia (also called *language versions*, or simply *Wikipedias*). Thirteen of these have over one million articles each (English, Swedish, Cebuano, German, Dutch, French, Russian, Italian, Spanish, Waray-Waray, Polish, Vietnamese and Japanese), five more have over 500,000 articles (Portuguese, Chinese, Ukrainian, Catalan and Persian), 40 more have over 100,000 articles, and 76 more have over 10,000 articles.[128][129] The largest, the English Wikipedia, has over 5.3 million articles. As of December 2016, according to Alexa, the English subdomain (en.wikipedia.org; English Wikipedia) receives approximately 55% of Wikipedia's cumulative traffic, with the remaining split among the other languages (Russian: 8%; Spanish: 7%; Japanese: 6%; French: 4%).[7] As of January 2017, the six largest language editions are (in order of article count) the English, Swedish, Cebuano, German, Dutch, and French Wikipedias.[130]

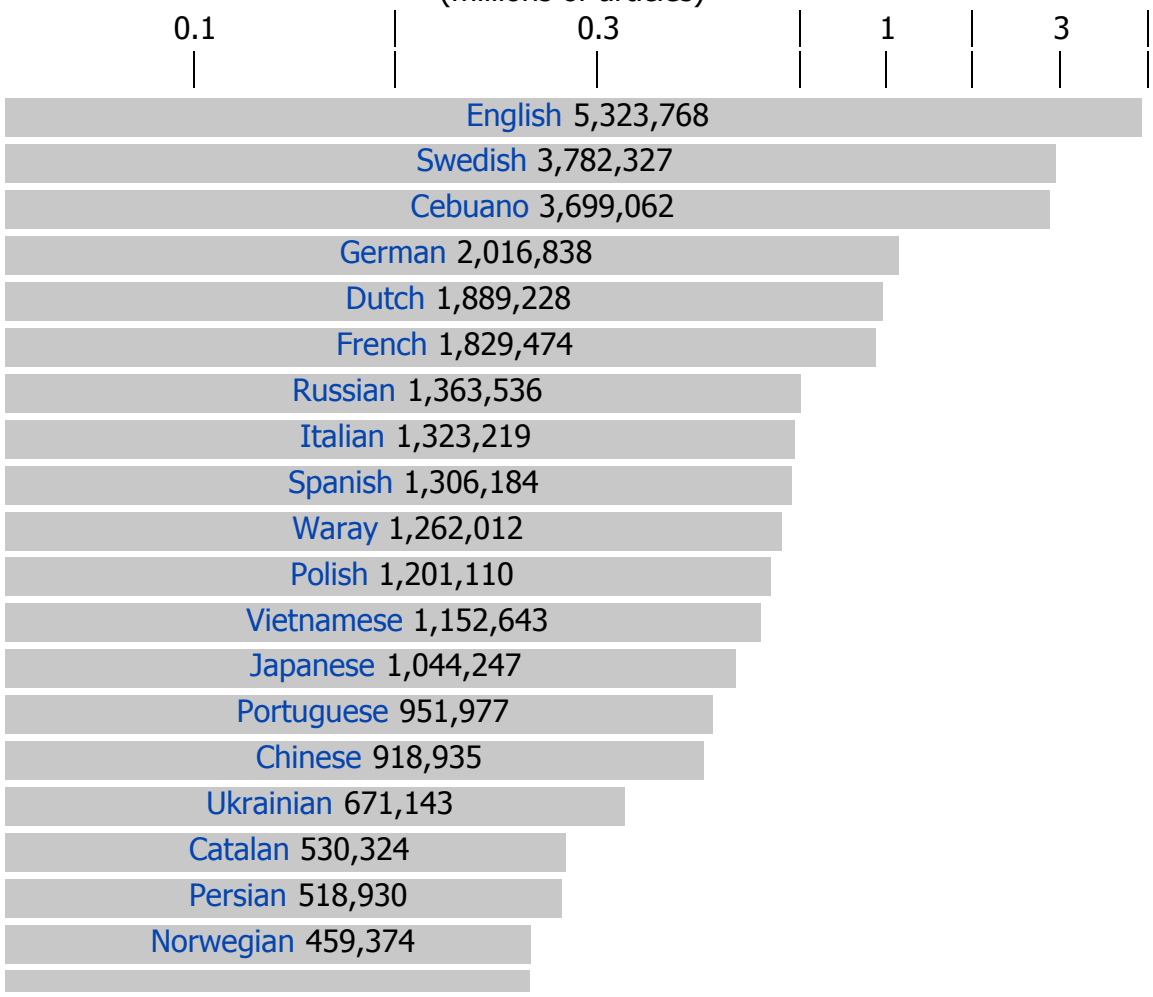


**Distribution of the 43,186,661 articles in**

**different language editions (as of 4 January 2017)**[131]

- English (12.3%)
- Swedish (8.8%)
- Cebuano (8.6%)
- German (4.7%)
- Dutch (4.4%)
- French (4.2%)
- Russian (3.2%)
- Italian (3.1%)
- Spanish (3%)
- Waray (2.9%)
- Polish (2.8%)
- Vietnamese (2.7%)
- Japanese (2.4%)
- Portuguese (2.2%)
- Other (34.7%)

**Logarithmic graph of the 20 largest language editions of Wikipedia**
(as of 4 January 2017)[132]
(millions of articles)

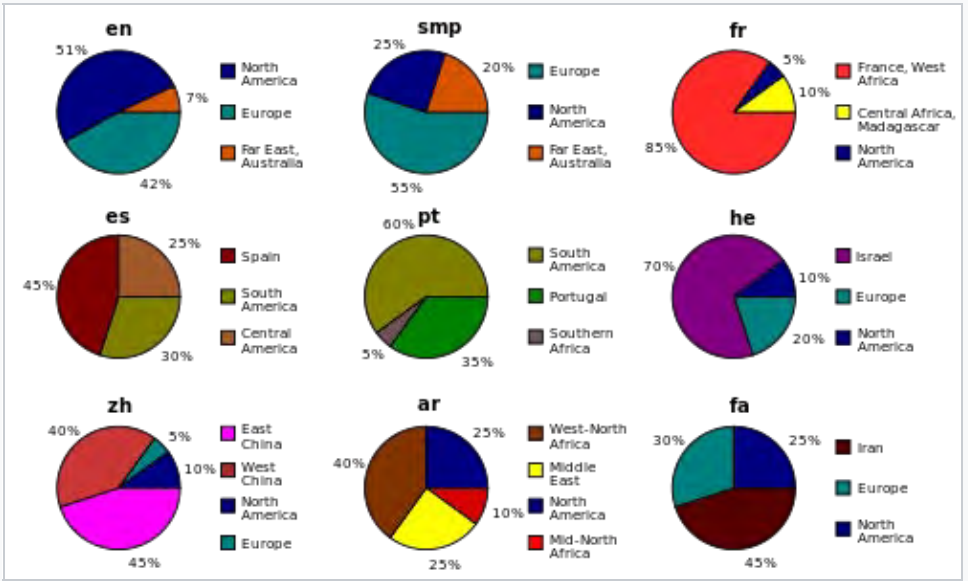


Arabic 455,997

**The unit for the numbers in bars is articles.** Since Wikipedia is based on the Web and therefore worldwide, contributors to the same language edition may use different dialects or may come from different countries (as is the case for the English edition). These differences may lead to some conflicts over spelling differences (e.g. *colour* versus *color*)[133] or points of view.[134]

Though the various language editions are held to global policies such as "neutral point of view", they diverge on some points of policy and practice, most notably on whether images that are not licensed freely may be used under a claim of fair use.[135][136][137]

Jimmy Wales has described Wikipedia as "an effort to create and distribute a free encyclopedia of the highest possible quality to every single person on the planet in their own language".[138] Though each language edition functions more or less independently, some efforts are made to supervise them all. They are coordinated in part by Meta-Wiki, the Wikimedia Foundation's wiki devoted to maintaining all of its projects (Wikipedia and others).[139] For instance, Meta-Wiki provides important statistics on all language editions of Wikipedia,[140] and it maintains a list of articles every Wikipedia should have.[141] The list concerns basic content by subject: biography, history, geography, society, culture, science, technology, and mathematics. As for the rest, it is not rare for articles strongly related to a particular language not to have counterparts in another edition. For example, articles about small towns in the United States might only be available in English, even when they meet notability criteria of other language Wikipedia projects.



Estimation of contributions shares from different regions in the world to different Wikipedia editions

Translated articles represent only a small portion of articles in most editions, in part because fully automated translation of articles is disallowed.[142] Articles available in more than one language may offer "interwiki links", which link to the counterpart articles in other editions.

A study published by *PLOS ONE* in 2012 also estimated the share of contributions to different editions of Wikipedia from different regions of the world. It reported that the proportion of the edits made from North America was 51% for the English Wikipedia, and 25% for the simple English Wikipedia.[143] The Wikimedia Foundation hopes to increase the number of editors in the Global South to thirty-seven percent by 2015.[144]

On March 1, 2014, *The Economist* in an article titled "The Future of Wikipedia" cited a trend analysis concerning data published by Wikimedia stating that: "The number of editors for the English-language version has fallen by a third in seven years."[145] The attrition rate for active editors in English Wikipedia was cited by *The Economist* as substantially in contrast to statistics for Wikipedia in other languages (non-English Wikipedia). *The Economist* reported that the number of contributors with an average of five of more edits per month was relatively constant since 2008 for Wikipedia in other languages at approximately 42,000 editors within narrow seasonal variances of about 2,000 editors up or down. The attrition rates for editors in English Wikipedia, by sharp comparison, were cited as peaking in 2007 at approximately 50,000 editors which has dropped to 30,000 editors as of the start of 2014. At the quoted trend rate, the number of active editors in English Wikipedia has lost approximately 20,000 editors to attrition since 2007, and the documented trend rate indicates the loss of another 20,000 editors by 2021, down to 10,000 active editors on English Wikipedia by 2021 if left unabated.[145] Given that the trend analysis published in *The Economist* presents the number of active editors for Wikipedia in other languages (non-English Wikipedia) as remaining relatively constant and successful in sustaining its numbers at approximately 42,000 active editors, the contrast has pointed to the

effectiveness of Wikipedia in other languages to retain its active editors on a renewable and sustained basis.[145] No comment was made concerning which of the differentiated edit policy standards from Wikipedia in other languages (non-English Wikipedia) would provide a possible alternative to English Wikipedia for effectively ameliorating substantial editor attrition rates on the English language Wikipedia.[146]

# Critical reception

*See also: Academic studies about Wikipedia and Criticism of Wikipedia*

Several Wikipedians have criticized Wikipedia's large and growing regulation, which includes over 50 policies and nearly 150,000 words as of 2014.[147][148]

Critics have stated that Wikipedia exhibits systemic bias. Columnist and journalist Edwin Black criticizes Wikipedia for being a mixture of "truth, half truth, and some falsehoods".[18] Articles in *The Chronicle of Higher Education* and *The Journal of Academic Librarianship* have criticized Wikipedia's Undue Weight policy, concluding that the fact that Wikipedia explicitly is not designed to provide correct information about a subject, but rather focus on all the major viewpoints on the subject and give less attention to minor ones, creates omissions that can lead to false beliefs based on incomplete information.[149][150][151]

Journalists Oliver Kamm and Edwin Black noted how articles are dominated by the loudest and most persistent voices, usually by a group with an "ax to grind" on the topic.[18][152] An article in *Education Next* Journal concluded that as a resource about controversial topics, Wikipedia is notoriously subject to manipulation and spin.[19]

In 2006, the *Wikipedia Watch* criticism website listed dozens of examples of plagiarism in the English Wikipedia.[153]

## Accuracy of content

*Main article: Reliability of Wikipedia*

Articles for traditional encyclopedias such as *Encyclopædia Britannica* are carefully and deliberately written by experts, lending such encyclopedias a reputation for accuracy.[154] Conversely, Wikipedia is often cited for factual inaccuracies and misrepresentations. However, a peer review in 2005 of forty-two scientific entries on both Wikipedia and *Encyclopædia Britannica* by the science journal *Nature* found few differences in accuracy, and concluded that "the average science entry in Wikipedia contained around four inaccuracies; *Britannica*, about three."[17] Reagle suggested that while the study reflects "a topical strength of Wikipedia contributors" in science articles, "Wikipedia may not have fared so well using a random sampling of articles or on humanities subjects."[155] The findings by *Nature* were disputed by *Encyclopædia Britannica*,[156][157] and in response, *Nature* gave a rebuttal of the points raised by *Britannica*.[158] In addition to the point-for-point disagreement between these two parties, others have examined the sample size and selection method used in the *Nature* effort, and suggested a "flawed study design" (in *Nature*'s manual selection of articles, in part or in whole, for comparison), absence of statistical analysis (e.g., of reported confidence intervals), and a lack of study "statistical power" (i.e., owing to small sample size, 42 or 4 x $10^1$ articles compared, vs >$10^5$ and >$10^6$ set sizes for *Britannica* and the English Wikipedia, respectively).[159]

As a consequence of the open structure, Wikipedia "makes no guarantee of validity" of its content, since no one is ultimately responsible for any claims appearing in it.[160] Concerns have been raised by *PC World* in 2009 regarding the lack of accountability that results from users' anonymity,[161] the insertion of false information,[162] vandalism, and similar problems.

Economist Tyler Cowen wrote: "If I had to guess whether Wikipedia or the median refereed journal article on economics was more likely to be true, after a not so long think I would opt for Wikipedia." He comments that some traditional sources of non-fiction suffer from systemic biases and novel results, in his opinion, are over-reported in journal articles and relevant information is omitted from news reports. However, he also cautions that errors are frequently found on Internet sites, and that academics and experts must be vigilant in correcting them.[163]

Critics argue that Wikipedia's open nature and a lack of proper sources for most of the information makes it [164]

unreliable. Some commentators suggest that Wikipedia may be reliable, but that the reliability of any given article is not clear.[165] Editors of traditional reference works such as the *Encyclopædia Britannica* have questioned the project's utility and status as an encyclopedia.[166]

**External video**

Inside Wikipedia – Attack of the PR Industry, Deutsche Welle, 7:13 mins[167]

Wikipedia's open structure inherently makes it an easy target for Internet trolls, spammers, and various forms of paid advocacy seen as counterproductive to the maintenance of a neutral and verifiable online encyclopedia.[70][168] In response to paid advocacy editing and undisclosed editing issues, Wikipedia was reported in an article by Jeff Elder in *The Wall Street Journal* on June 16, 2014, to have strengthened its rules and laws against undisclosed editing.[169] The article stated that: "Beginning Monday [from date of article], changes in Wikipedia's terms of use will require anyone paid to edit articles to disclose that arrangement. Katherine Maher, the nonprofit Wikimedia Foundation's chief communications officer, said the changes address a sentiment among volunteer editors that, 'we're not an advertising service; we're an encyclopedia.'"[169][170][171][172][173] These issues, among others, had been parodied since the first decade of Wikipedia, notably by Stephen Colbert on *The Colbert Report*.[174]

Most university lecturers discourage students from citing any encyclopedia in academic work, preferring primary sources;[175] some specifically prohibit Wikipedia citations.[176][177] Wales stresses that encyclopedias of any type are not usually appropriate to use as citeable sources, and should not be relied upon as authoritative.[178] Wales once (2006 or earlier) said he receives about ten emails weekly from students saying they got failing grades on papers because they cited Wikipedia; he told the students they got what they deserved. "For God's sake, you're in college; don't cite the encyclopedia", he said.[179]

In February 2007, an article in *The Harvard Crimson* newspaper reported that a few of the professors at Harvard University were including Wikipedia articles in their syllabi, although without realizing the articles might change.[180] In June 2007, former president of the American Library Association Michael Gorman condemned Wikipedia, along with Google,[181] stating that academics who endorse the use of Wikipedia are "the intellectual equivalent of a dietitian who recommends a steady diet of Big Macs with everything".

A Harvard law textbook, *Legal Research in a Nutshell* (2011), cites Wikipedia as a "general source" that "can be a real boon" in "coming up to speed in the law governing a situation" and, "while not authoritative, can provide basic facts as well as leads to more in-depth resources".[182]

## Medical information

*See also: Health information on Wikipedia*

On March 5, 2014, Julie Beck writing for *The Atlantic* magazine in an article titled "Doctors' #1 Source for Healthcare Information: Wikipedia", stated that "Fifty percent of physicians look up conditions on the (Wikipedia) site, and some are editing articles themselves to improve the quality of available information."[183] Beck continued to detail in this article new programs of Dr. Amin Azzam at the University of San Francisco to offer medical school courses to medical students for learning to edit and improve Wikipedia articles on health-related issues, as well as internal quality control programs within Wikipedia organized by Dr. James Heilman to improve a group of 200 health-related articles of central medical importance up to Wikipedia's highest standard of articles using its Featured Article and Good Article peer review evaluation process.[183] In a May 7, 2014, follow-up article in *The Atlantic* titled "Can Wikipedia Ever Be a Definitive Medical Text?", Julie Beck quotes Wikiproject Medicine's Dr. James Heilman as stating: "Just because a reference is peer-reviewed doesn't mean it's a high-quality reference."[184] Beck added that: "Wikipedia has its own peer review process before articles can be classified as 'good' or 'featured.' Heilman, who has participated in that process before, says 'less than 1 percent' of Wikipedia's medical articles have passed.[184]

## Quality of writing

In 2008, researchers at Carnegie Mellon University found that the quality of a Wikipedia article would suffer rather than gain from adding more writers when the article lacked appropriate explicit or implicit coordination.[185] For instance, when contributors rewrite small portions of an entry rather than making full-length revisions, high- and low-quality content may be intermingled within an entry. Roy Rosenzweig, a

history professor, stated that *American National Biography Online* outperformed Wikipedia in terms of its "clear and engaging prose", which, he said, was an important aspect of good historical writing.[186] Contrasting Wikipedia's treatment of Abraham Lincoln to that of Civil War historian James McPherson in *American National Biography Online*, he said that both were essentially accurate and covered the major episodes in Lincoln's life, but praised "McPherson's richer contextualization [...] his artful use of quotations to capture Lincoln's voice [...] and [...] his ability to convey a profound message in a handful of words." By contrast, he gives an example of Wikipedia's prose that he finds "both verbose and dull". Rosenzweig also criticized the "waffling—encouraged by the npov policy—[which] means that it is hard to discern any overall interpretive stance in Wikipedia history". By example, he quoted the conclusion of Wikipedia's article on William Clarke Quantrill. While generally praising the article, he pointed out its "waffling" conclusion: "Some historians [...] remember him as an opportunistic, bloodthirsty outlaw, while others continue to view him as a daring soldier and local folk hero."[186]

Other critics have made similar charges that, even if Wikipedia articles are factually accurate, they are often written in a poor, almost unreadable style. Frequent Wikipedia critic Andrew Orlowski commented: "Even when a Wikipedia entry is 100 per cent factually correct, and those facts have been carefully chosen, it all too often reads as if it has been translated from one language to another then into to a third, passing an illiterate translator at each stage."[187] A study of articles on cancer was undertaken in 2010 by Yaacov Lawrence of the Kimmel Cancer Center at Thomas Jefferson University limited to those Wikipedia articles which could be found in the *Physician Data Query* and excluding Wikipedia articles written at the "start" class or the "stub" class level. Lawrence found the articles accurate but not very readable, and thought that "Wikipedia's lack of readability (to non-college readers) may reflect its varied origins and haphazard editing".[188] *The Economist* argued that better-written articles tend to be more reliable: "inelegant or ranting prose usually reflects muddled thoughts and incomplete information".[189]

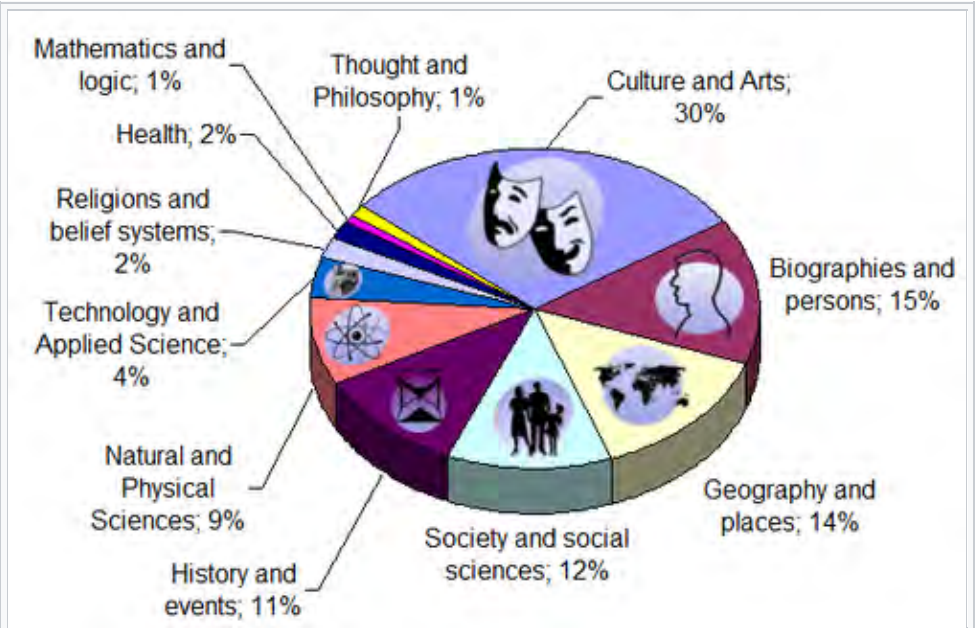
## Coverage of topics and systemic bias

*See also: Notability in the English Wikipedia and Criticism of Wikipedia § Systemic bias in coverage*

Wikipedia seeks to create a summary of all human knowledge in the form of an online encyclopedia, with each topic covered encyclopedically in one article. Since it has terabytes of disk space, it can have far more topics than can be covered by any printed encyclopedia.[190] The exact degree and manner of coverage on Wikipedia is under constant review by its editors, and disagreements are not uncommon (see deletionism and inclusionism).[191][192] Wikipedia contains materials that some people may find objectionable, offensive, or pornographic because Wikipedia is not censored. The policy has sometimes proved controversial: in 2008, Wikipedia rejected an online petition against the inclusion of images of Muhammad in the English edition of its Muhammad article, citing this policy. The presence of politically, religiously, and pornographically sensitive materials in Wikipedia has led to the censorship of Wikipedia by national authorities in China,[193] Pakistan,[194] and the United Kingdom,[195] among other countries.

A 2008 study conducted by researchers at Carnegie Mellon University and Palo Alto Research Center gave a distribution of topics as well as growth (from July 2006 to January 2008) in each field:[196]

- Culture and the arts: 30% (210%)
- Biographies and persons: 15% (97%)
- Geography and places: 14% (52%)
- Society and social sciences: 12% (83%)
- History and events: 11% (143%)
- Natural and physical sciences: 9% (213%)
- Technology and the applied sciences: 4% (−6%)
- Religions and belief systems: 2% (38%)
- Health: 2% (42%)



- Mathematics and logic: 1% (146%)
- Thought and philosophy: 1% (160%)

Pie chart of Wikipedia content by subject as of January 2008[196]

These numbers refer only to the quantity of articles: it is possible for one topic to contain a large number of short articles and another to contain a small number of large ones. Through its "Wikipedia Loves Libraries" program, Wikipedia has partnered with major public libraries such as the New York Public Library for the Performing Arts to expand its coverage of underrepresented subjects and articles.[197]

A 2011 study conducted by researchers at the University of Minnesota indicated that male and female editors focus on different coverage topics. There was a greater concentration of females in the People and Arts category, while males focus more on Geography and Science.[198]

## Coverage of topics and selection bias

Research conducted by Mark Graham of the Oxford Internet Institute in 2009 indicated that the geographic distribution of article topics is highly uneven. Africa is most underrepresented.[199]

An editorial in *The Guardian* in 2014 noted that women porn stars are better covered than women writers as a further example.[200]

## Systemic bias

When multiple editors contribute to one topic or set of topics, systemic bias may arise, due to the demographic backgrounds of the editors. In 2011, Wales noted that the unevenness of coverage is a reflection of the demography of the editors, which predominantly consists of young males with high education levels in the developed world (cf. previously).[47] The October 22, 2013 essay by Tom Simonite in MIT's *Technology Review* titled "The Decline of Wikipedia" discussed the effect of systemic bias and policy creep on the downward trend in the number of editors.[48]

Systemic bias on Wikipedia may follow that of culture generally, for example favoring certain nationalities, ethnicities or majority religions.[201] It may more specifically follow the biases of Internet culture, inclining to being young, male, English-speaking, educated, technologically aware, and wealthy enough to spare time for editing. Biases of its own may include over-emphasis on topics such as pop culture, technology, and current events.[201]

Taha Yasseri of the University of Oxford, in 2013, studied the statistical trends of systemic bias at Wikipedia introduced by editing conflicts and their resolution.[202][203] His research examined the counterproductive work behavior of edit warring. Yasseri contended that simple reverts or "undo" operations were not the most significant measure of counterproductive behavior at Wikipedia and relied instead on the statistical measurement of detecting "reverting/reverted pairs" or "mutually reverting edit pairs". Such a "mutually reverting edit pair" is defined where one editor reverts the edit of another editor who then, in sequence, returns to revert the first editor in the "mutually reverting edit pairs". The results were tabulated for several language versions of Wikipedia. The English Wikipedia's three largest conflict rates belonged to the articles *George W. Bush*, *Anarchism* and *Muhammad*.[203] By comparison, for the German Wikipedia, the three largest conflict rates at the time of the Oxford study were for the articles covering (i) *Croatia*, (ii) *Scientology* and (iii) *9/11 conspiracy theories*.[203]

## Identifying the filter-bubble problem

Dimitra Kessenides, writing for Bloomberg News Weekly, identified the 'filter-bubble' problem as a recurrent and long-standing issue at Wikipedia.[204] As Kessenides states: "If the only way to get an article about the developing world published on Wikipedia was to know a former board member, it was hard to imagine how a random editor in Johannesburg or Bangalore would have any hope... This so-called filter-bubble problem, coined by Eli Pariser, co-founder of the viral video site Upworthy, is the idea that the internet can contribute to the insularity of certain communities. Filter bubbles have been blamed for the spread of misinformation during the 2016 presidential election and for the failure of pundits in the U.K. to anticipate Brexit... Wikipedia's filter-bubble problem is a particularly acute threat for an organization whose stated mission is 'to empower and engage people around the world.'"[204]

## Explicit content

*See also: Internet Watch Foundation and Wikipedia and Reporting of child pornography images on Wikimedia Commons*

Wikipedia has been criticized for allowing information of graphic content. Articles depicting arguably objectionable content (such as *Feces*, *Cadaver*, *Human penis*, *Vulva*, and *Nudity*) contain graphic pictures and detailed information easily available to anyone with access to the internet, including children.

> Problem? What problem? So, you didn't know that Wikipedia has a porn problem?
>
> — Larry Sanger, [205]

The site also includes sexual content such as images and videos of masturbation and ejaculation, photographs of nude children, illustrations of zoophilia, and photos from hardcore pornographic films in its articles.

The Wikipedia article about *Virgin Killer*—a 1976 album from German heavy metal band Scorpions—features a picture of the album's original cover, which depicts a naked prepubescent girl. The original release cover caused controversy and was replaced in some countries. In December 2008, access to the Wikipedia article *Virgin Killer* was blocked for four days by most Internet service providers in the United Kingdom after it was reported by a member of the public as child pornography,[206] to the Internet Watch Foundation (IWF), which issues a stop list to Internet service providers. IWF, a non-profit, non-government-affiliated organization, later criticized the inclusion of the picture as "distasteful".[207]

In April 2010, Sanger wrote a letter to the Federal Bureau of Investigation, outlining his concerns that two categories of images on Wikimedia Commons contained child pornography, and were in violation of US federal obscenity law.[208] Sanger later clarified that the images, which were related to pedophilia and one about lolicon, were not of real children, but said that they constituted "obscene visual representations of the sexual abuse of children", under the PROTECT Act of 2003.[209] That law bans photographic child pornography and cartoon images and drawings of children that are obscene under American law.[209] Sanger also expressed concerns about access to the images on Wikipedia in schools.[210] Wikimedia Foundation spokesman Jay Walsh strongly rejected Sanger's accusation,[211] saying that Wikipedia did not have "material we would deem to be illegal. If we did, we would remove it."[211] Following the complaint by Sanger, Wales deleted sexual images without consulting the community. After some editors who volunteer to maintain the site argued that the decision to delete had been made hastily, Wales voluntarily gave up some of the powers he had held up to that time as part of his co-founder status. He wrote in a message to the Wikimedia Foundation mailing-list that this action was "in the interest of encouraging this discussion to be about real philosophical/content issues, rather than be about me and how quickly I acted".[212] Critics, including Wikipediocracy, noticed that many of the pornographic images deleted from Wikipedia since 2010 have reappeared.[213]

## Privacy

One privacy concern in the case of Wikipedia is the right of a private citizen to remain a "private citizen" rather than a "public figure" in the eyes of the law.[214][notes 8] It is a battle between the right to be anonymous in cyberspace and the right to be anonymous in real life ("meatspace"). A particular problem occurs in the case of an individual who is relatively unimportant and for whom there exists a Wikipedia page against her or his wishes.

In January 2006, a German court ordered the German Wikipedia shut down within Germany because it stated the full name of Boris Floricic, aka "Tron", a deceased hacker. On February 9, 2006, the injunction against Wikimedia Deutschland was overturned, with the court rejecting the notion that Tron's right to privacy or that of his parents was being violated.[215]

Wikipedia has a "Volunteer Response Team" that uses the OTRS system to handle queries without having to reveal the identities of the involved parties. This is used, for example, in confirming the permission for using individual images and other media in the project.[216]

## Sexism

Wikipedia has been described as harboring a battleground culture of sexism and harassment.[217][218] The perceived toxic attitudes and tolerance of violent and abusive language are also reasons put forth for the

gender gap in Wikipedia editors.[219] In 2014, a female editor who requested a separate space on Wikipedia to discuss improving civility had her proposal referred to by a male editor using the words "the easiest way to avoid being called a cunt is not to act like one."[220]

# Operation

A group of Wikipedia editors may form a WikiProject to focus their work on a specific topic area, using its associated discussion page to coordinate changes across multiple articles.[221]

## Wikimedia Foundation and Wikimedia movement affiliates

*Main article: Wikimedia Foundation*

Wikimedia Foundation logo

Wikipedia is hosted and funded by the Wikimedia Foundation, a non-profit organization which also operates Wikipedia-related projects such as Wiktionary and Wikibooks. The foundation relies on public contributions and grants to fund its mission.[222] The foundation's 2013 IRS Form 990 shows revenue of $39.7 million and expenses of almost $29 million, with assets of $37.2 million and liabilities of about $2.3 million.[223]

In May 2014, Wikimedia Foundation named Lila Tretikov as its new executive director, taking over for Sue Gardner.[224] The *Wall Street Journal* reported on May 1, 2014, that Tretikov's information technology background from her years at University of California offers Wikipedia an opportunity to develop in more concentrated directions guided by her often repeated position statement that, "Information, like air, wants to be free."[225][226] The same *Wall Street Journal* article reported these directions of development according to an interview with spokesman Jay Walsh of Wikimedia, who "said Tretikov would address that issue (paid advocacy) as a priority. 'We are really pushing toward more transparency... We are reinforcing that paid advocacy is not welcome.' Initiatives to involve greater diversity of contributors, better mobile support of Wikipedia, new geo-location tools to find local content more easily, and more tools for users in the second and third world are also priorities, Walsh said."[225]

Following the departure of Tretikov from Wikipedia due to issues concerning the use of the "superprotection" feature which some language versions of Wikipedia have adopted, Katherine Maher became the third executive director the Wikimedia Foundation in June 2016.[227] Maher has stated that one of her priorities would be the issue of editor harassment endemic to Wikipedia as identified by the Wikipedia board in December. Maher stated regarding the harassment issue that: "It establishes a sense within the community that this is a priority... (and that correction requires that) it has to be more than words."[228]

Wikipedia is also supported by many organizations and groups that are affiliated with the Wikimedia Foundation but independently-run, called Wikimedia movement affiliates. These include Wikimedia chapters (which are national or sub-national organizations, such as Wikimedia Deutschland and Wikimédia France), thematic organizations (such as Amical Wikimedia for the Catalan language community), and user groups. These affiliates participate in the promotion, development, and funding of Wikipedia.

## Software operations and support

*See also: MediaWiki*

The operation of Wikipedia depends on MediaWiki, a custom-made, free and open source wiki software platform written in PHP and built upon the MySQL database system.[229] The software incorporates programming features such as a macro language, variables, a transclusion system for templates, and URL redirection. MediaWiki is licensed under the GNU General Public License and it is used by all Wikimedia projects, as well as many other wiki projects. Originally, Wikipedia ran on UseModWiki written in Perl by Clifford Adams (Phase I), which initially required CamelCase for article hyperlinks; the present double bracket style was incorporated later. Starting in January 2002 (Phase II), Wikipedia began running on a PHP wiki engine with a MySQL database; this software was custom-made for Wikipedia by Magnus Manske. The Phase

II software was repeatedly modified to accommodate the exponentially increasing demand. In July 2002 (Phase III), Wikipedia shifted to the third-generation software, MediaWiki, originally written by Lee Daniel Crocker.

Several MediaWiki extensions are installed[230] to extend the functionality of the MediaWiki software.

In April 2005, a Lucene extension[231][232] was added to MediaWiki's built-in search and Wikipedia switched from MySQL to Lucene for searching. The site currently uses Lucene Search 2.1,[233][*needs update*] which is written in Java and based on Lucene library 2.3.[234]

In July 2013, after extensive beta testing, a WYSIWYG (What You See Is What You Get) extension, VisualEditor, was opened to public use.[235][236][237][238] It was met with much rejection and criticism, and was described as "slow and buggy".[239] The feature was turned off afterward.

## Automated editing

Computer programs called bots have been used widely to perform simple and repetitive tasks, such as correcting common misspellings and stylistic issues, or to start articles such as geography entries in a standard format from statistical data.[240][241][242] One controversial contributor massively creating articles with his bot was reported to create up to ten thousand articles on the Swedish Wikipedia on certain days.[243] There are also some bots designed to automatically warn editors making common editing errors (such as unmatched quotes or unmatched parenthesis).[244] Edits misidentified by a bot as the work of a banned editor can be restored by other editors. An anti-vandal bot tries to detect and revert vandalism quickly and automatically.[241] Bots can also report edits from particular accounts or IP address ranges, as was done at the time of the MH17 jet downing incident in July 2014.[245] Bots on Wikipedia must be approved prior to activation.[246]

According to Andrew Lih, the current expansion of Wikipedia to millions of articles would be difficult to envision without the use of such bots.[247]

## Wikiprojects, and assessments of articles' importance and quality

*Main article: WikiProject*

A "WikiProject" is a group of contributors who want to work together as a team to improve Wikipedia. These groups often focus on a specific topic area (for example, women's history), a specific location or a specific kind of task (for example, checking newly created pages). The English Wikipedia currently has over 2,000 WikiProjects and activity varies.[248]

In 2007, in preparation for producing a print version, the English Wikipedia introduced an assessment scale of the quality of articles.[249] Articles are rated by Wikiprojects. The range of quality classes begins with "Stub" (very short pages), followed by "Start", "C" and "B" (in increasing order of quality). Community peer review is needed for the article to enter one of the highest quality classes: either "A", "good article" or the highest, "featured article". Of the about 4.4 million articles and lists assessed as of March 2015, a little more than 5000 (0.12%) are featured articles, and a little less than 2000 (0.04%) are featured lists. One featured article per day, as selected by editors, appears on the main page of Wikipedia.[250][251]

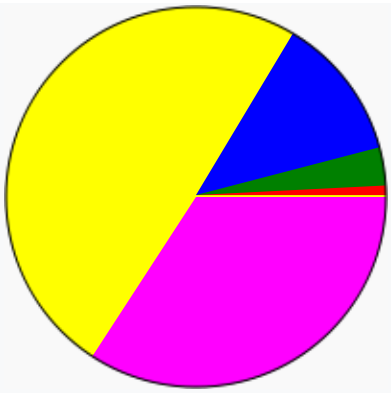
The articles can also be rated as per "importance" as judged by a Wikiproject. Currently, there are 5 importance categories: "low", "mid", "high", "top", and "???" for unclassified/unsure level. For a particular article, different Wikiprojects may assign different importance levels.

The Wikipedia Version 1.0 Editorial Team has developed a table (shown below) that displays data of all rated articles by quality and importance, on the English Wikipedia. **If an article or list receives different ratings by two or more Wikiprojects, then the highest rating is used in the table, pie-charts, and bar-chart.** The software regularly auto-updates the data.

Researcher Giacomo Poderi found that articles tend to reach featured status via the intensive work of a few editors.[252] A 2010 study found unevenness in quality among featured articles and concluded that the community process is ineffective in assessing the quality of articles.[253]

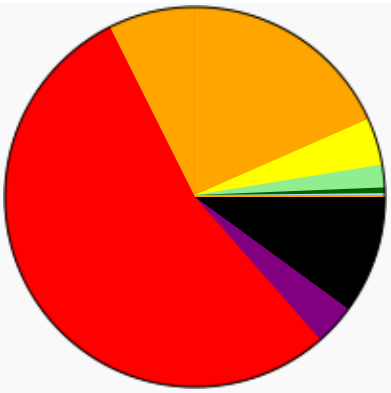
| **All rated articles by quality** |  |
|---|---|

| Quality | Top | High | Mid | Imp | Tota |
|---|---|---|---|---|---|
| FA | 1,171 | 1,800 | 1,700 | | 5, |
| FL | 141 | 561 | 655 | | 2, |
| A | 220 | 424 | 578 | | 1, |
| GA | 2,077 | 4,743 | 9,249 | | 27, |
| B | 12,001 | 22,770 | 34,814 | | 10, |
| C | 10,208 | 29,424 | 65,651 | | 38, |
| Start | 17,179 | 75,511 | 304,019 | | 53, |
| Stub | 4,229 | 30,906 | 225,394 | | 42, |
| List | 2,996 | 11,171 | 34,005 | | 01, |
| Assessed | 50,222 | 177,310 | 676,065 | | 95, |
| Unassessed | 140 | 408 | 1,794 | | 56, |
| **Total** | **50,362** | **177,718** | **677,859** | **2,** | **51,** |



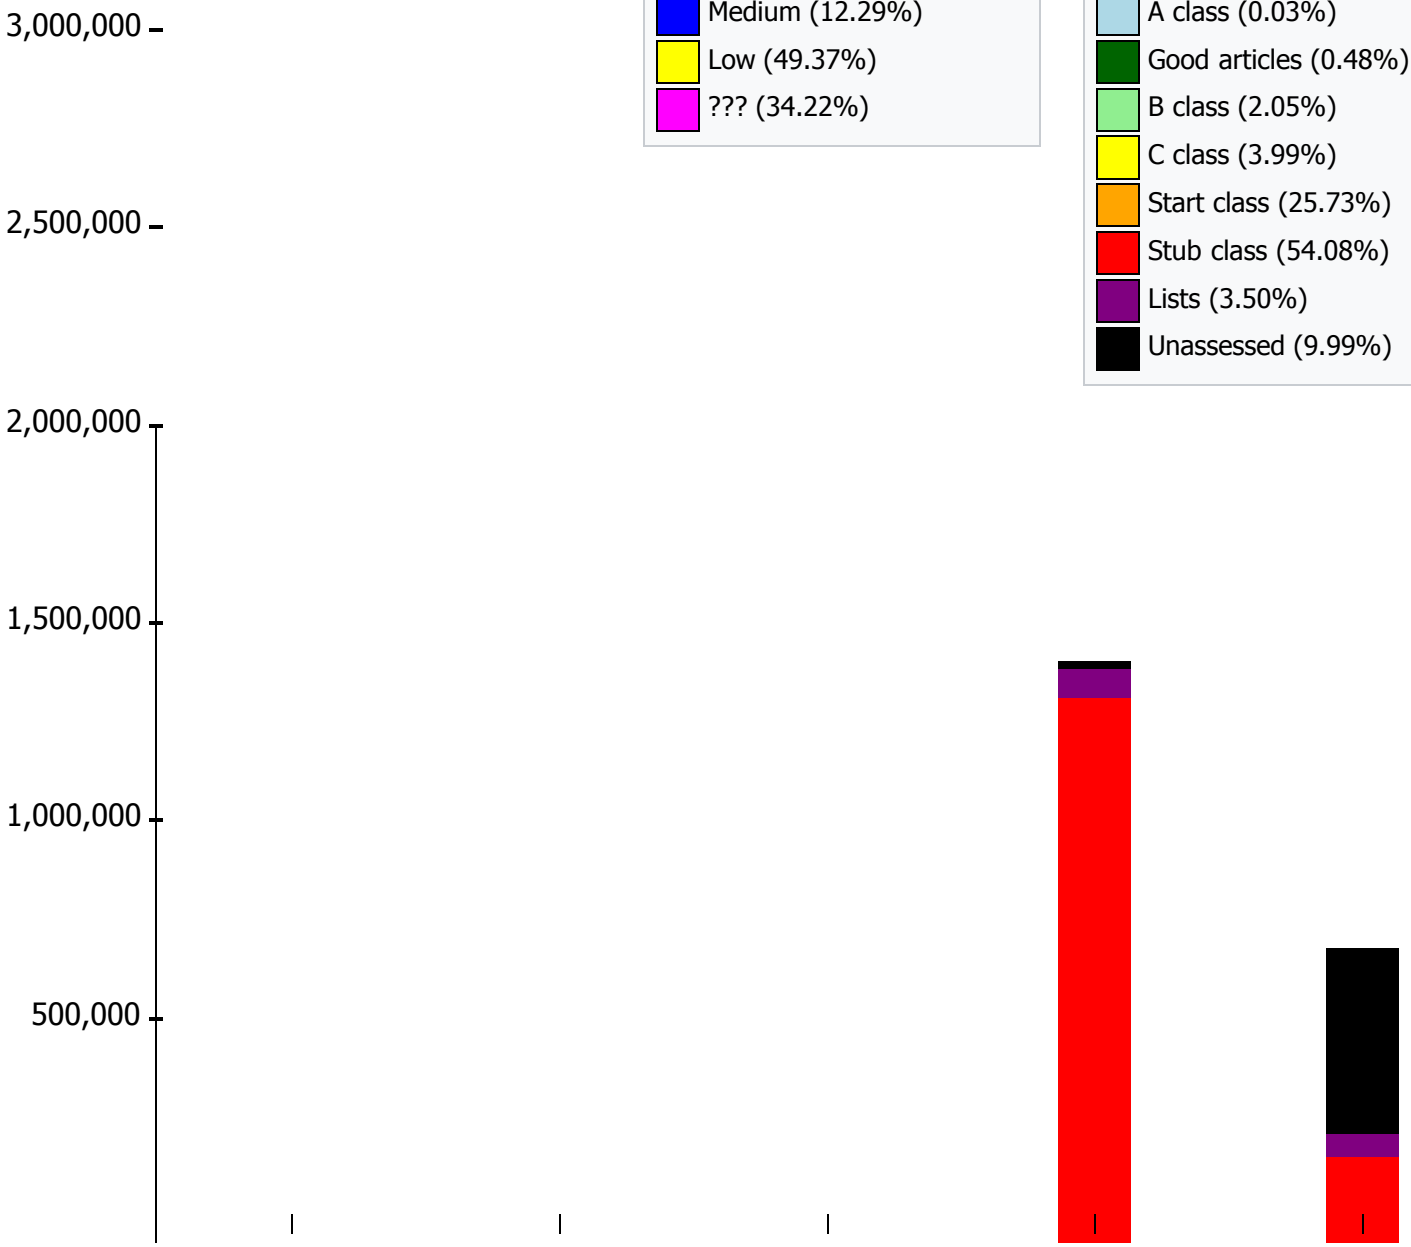
**Importance-wise distribution of over 4.8 million articles and lists on the English Wikipedia, as of 5 April 2015**[254]

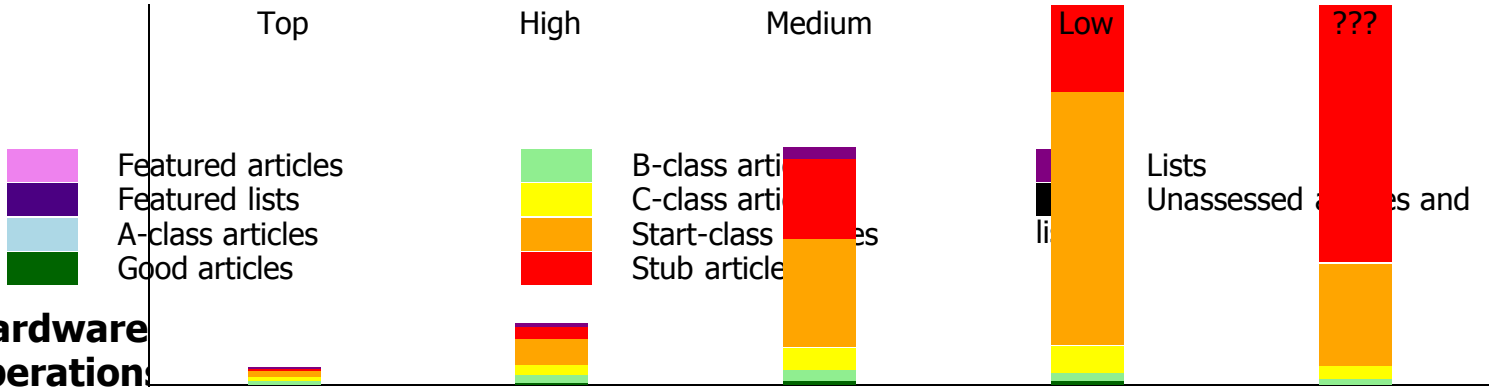
- Top (0.91%)
- High (3.21%)
- Medium (12.29%)
- Low (49.37%)
- ??? (34.22%)



**Quality-wise distribution of over 4.8 million articles and lists on the English Wikipedia, as of 3 April 2015**[254]

- Featured articles (0.11%)
- Featured lists (0.04%)
- A class (0.03%)
- Good articles (0.48%)
- B class (2.05%)
- C class (3.99%)
- Start class (25.73%)
- Stub class (54.08%)
- Lists (3.50%)
- Unassessed (9.99%)

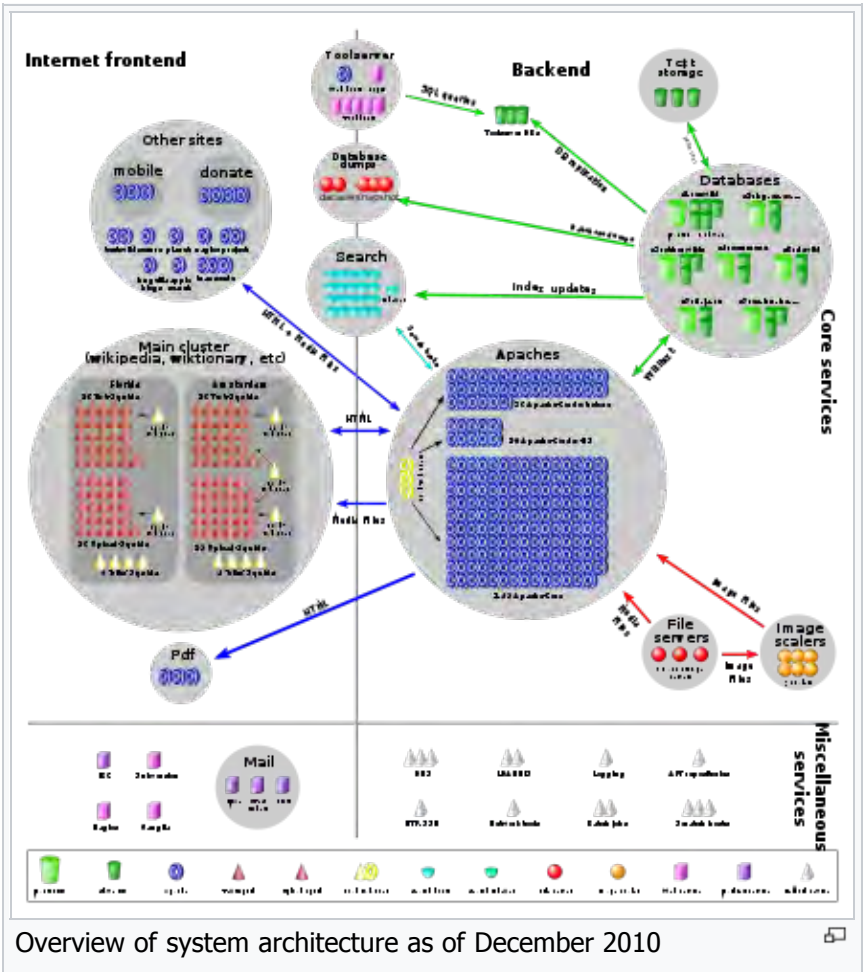




## Hardware operations and support

*See also: Wikimedia Foundation § Hardware*

Wikipedia receives between 25,000 and 60,000 page requests per second, depending on time of day.[255] As of 2008 page requests are first passed to a front-end layer of Squid caching servers.[256][*needs update*] Further statistics, based on a publicly available 3-month Wikipedia access trace, are available.[257] Requests that cannot be served from the Squid cache are sent to load-balancing servers running the Linux Virtual Server software, which in turn pass them to one of the Apache web servers for page rendering from the database. The web servers deliver pages as requested, performing page rendering for all the language editions of Wikipedia. To increase speed further, rendered pages are cached in a distributed memory cache until invalidated, allowing page rendering to be skipped entirely for most common page accesses.



Overview of system architecture as of December 2010

Wikipedia currently runs on dedicated clusters of Linux servers (mainly Ubuntu).[258][259] As of December 2009, there were 300 in Florida and 44 in Amsterdam.[260] By January 22, 2013, Wikipedia had migrated its primary data center to an Equinix facility in Ashburn, Virginia.[261][262]

## Internal research and operational development

In accordance with growing amounts of incoming donations exceeding seven digits in 2013 as recently reported,[48] the Foundation has reached a threshold of assets which qualify its consideration under the principles of industrial organization economics to indicate the need for the re-investment of donations into the internal research and development of the Foundation.[263] Two of the recent projects of such internal research and development have been the creation of a Visual Editor and a largely under-utilized "Thank" tab which were developed for the purpose of ameliorating issues of editor attrition, which have met with limited success.[48][239] The estimates for reinvestment by industrial organizations into internal research and development was studied by Adam Jaffe, who recorded that the range of 4% to 25% annually was to be recommended, with high end technology requiring the higher level of support for internal reinvestment.[264] At the 2013 level of contributions for Wikimedia presently documented as 45 million dollars, the computed budget level recommended by Jaffe and Caballero for reinvestment into internal research and development is between 1.8 million and 11.3 million dollars annually.[264] In 2016, the level of contributions were reported by Blomberg News as being at $77 million annually, updating the Jaffe estimates for the higher level of support to between 3.08 million and 19.2 million dollars annually.[264]

## Internal news publications

Community-produced news publications include the English Wikipedia's *The Signpost*, founded in 2005 by Michael Snow, an attorney, Wikipedia administrator and former chair of the Wikimedia Foundation board of trustees.[265] It covers news and events from the site, as well as major events from other Wikimedia projects, such as Wikimedia Commons. Similar publications are the German-language *Kurier*, and the Portuguese-language *Correio da Wikipédia*. Other past and present community news publications on English Wikipedia include the "Wikiworld" web comic, the *Wikipedia Weekly* podcast, and newsletters of specific WikiProjects like *The Bugle* from WikiProject Military History and the monthly newsletter from The Guild of Copy Editors. There are also a number of publications from the Wikimedia Foundation and multilingual publications such as the Wikimedia Blog and *This Month in Education*.

# Access to content

## Content licensing

When the project was started in 2001, all text in Wikipedia was covered by the GNU Free Documentation License (GFDL), a copyleft license permitting the redistribution, creation of derivative works, and commercial use of content while authors retain copyright of their work.[266] The GFDL was created for software manuals that come with free software programs licensed under the GPL. This made it a poor choice for a general reference work: for example, the GFDL requires the reprints of materials from Wikipedia to come with a full copy of the GFDL text. In December 2002, the Creative Commons license was released: it was specifically designed for creative works in general, not just for software manuals. The license gained popularity among bloggers and others distributing creative works on the Web. The Wikipedia project sought the switch to the Creative Commons.[267] Because the two licenses, GFDL and Creative Commons, were incompatible, in November 2008, following the request of the project, the Free Software Foundation (FSF) released a new version of the GFDL designed specifically to allow Wikipedia to relicense its content to CC BY-SA by August 1, 2009. (A new version of the GFDL automatically covers Wikipedia contents.) In April 2009, Wikipedia and its sister projects held a community-wide referendum which decided the switch in June 2009.[268][269][270][271]

The handling of media files (e.g. image files) varies across language editions. Some language editions, such as the English Wikipedia, include non-free image files under fair use doctrine, while the others have opted not to, in part because of the lack of fair use doctrines in their home countries (e.g. in Japanese copyright law). Media files covered by free content licenses (e.g. Creative Commons' CC BY-SA) are shared across language editions via Wikimedia Commons repository, a project operated by the Wikimedia Foundation. Wikipedia's accommodation of varying international copyright laws regarding images has led some to observe that its photographic coverage of topics lags behind the quality of the encyclopedic text.[272]

The Wikimedia Foundation is not a licensor of content, but merely a hosting service for the contributors (and [273][274]

licensors) of the Wikipedia. This position has been successfully defended in court.

## Methods of access

Because Wikipedia content is distributed under an open license, anyone can reuse or re-distribute it at no charge. The content of Wikipedia has been published in many forms, both online and offline, outside of the Wikipedia website.

- **Websites** – Thousands of "mirror sites" exist that republish content from Wikipedia: two prominent ones, that also include content from other reference sources, are Reference.com and Answers.com. Another example is Wapedia, which began to display Wikipedia content in a mobile-device-friendly format before Wikipedia itself did.
- **Mobile apps** – A variety of mobile apps provide access to Wikipedia on hand-held devices, including both Android and iOS devices (see Wikipedia apps). (See also Mobile access.)
- **Search engines** – Some web search engines make special use of Wikipedia content when displaying search results: examples include Bing (via technology gained from Powerset)[275] and DuckDuckGo.
- **Compact discs, DVDs** – Collections of Wikipedia articles have been published on optical discs. An English version, 2006 Wikipedia CD Selection, contained about 2,000 articles.[276][277] The Polish-language version contains nearly 240,000 articles.[278] There are German- and Spanish-language versions as well.[279][280] Also, "Wikipedia for Schools", the Wikipedia series of CDs / DVDs produced by Wikipedians and SOS Children, is a free, hand-checked, non-commercial selection from Wikipedia targeted around the UK National Curriculum and intended to be useful for much of the English-speaking world.[281] The project is available online; an equivalent print encyclopedia would require roughly 20 volumes.
- **Printed books** – There are efforts to put a select subset of Wikipedia's articles into printed book form.[282][283] Since 2009, tens of thousands of print-on-demand books that reproduced English, German, Russian and French Wikipedia articles have been produced by the American company Books LLC and by three Mauritian subsidiaries of the German publisher VDM.[284]
- **Semantic Web** – The website DBpedia, begun in 2007, extracts data from the infoboxes and category declarations of the English-language Wikipedia. Wikimedia has created the Wikidata project with a similar objective of storing the basic facts from each page of Wikipedia and the other WMF wikis and make it available in a queriable semantic format, RDF. This is still under development. As of Feb 2014 it has 15,000,000 items and 1,000 properties for describing them.

Obtaining the full contents of Wikipedia for reuse presents challenges, since direct cloning via a web crawler is discouraged.[285] Wikipedia publishes "dumps" of its contents, but these are text-only; as of 2007 there was no dump available of Wikipedia's images.[286]

Several languages of Wikipedia also maintain a reference desk, where volunteers answer questions from the general public. According to a study by Pnina Shachaf in the Journal of Documentation, the quality of the Wikipedia reference desk is comparable to a standard library reference desk, with an accuracy of 55%.[287]

## Mobile access

*See also: Help:Mobile access*

Wikipedia's original medium was for users to read and edit content using any standard web browser through a fixed Internet connection. Although Wikipedia content has been accessible through the mobile web since July 2013, *The New York Times* on February 9, 2014, quoted Erik Möller, deputy director of the Wikimedia Foundation, stating that the transition of internet traffic from desktops to mobile devices was significant and a cause for concern and worry.[16] The article in *The New York Times* reported the comparison statistics for mobile edits stating that, "Only 20 percent of the readership of the English-language Wikipedia comes via mobile devices, a figure substantially lower than the percentage of mobile traffic for other media sites, many of which approach 50 percent. And the shift to mobile editing has lagged even more."[16] *The New York Times* reports that Möller has assigned "a team of 10 software developers focused on mobile", out of a total of approximately 200 employees working at the Wikimedia Foundation. One principal concern cited by *The New York Times* for the

The mobile version of the English Wikipedia's main page

"worry" is for Wikipedia to effectively address attrition issues with the number of editors which the online encyclopedia attracts to edit and maintain its content in a mobile access environment.[16]

*Bloomberg BusinessWeek* reported in July 2014 that Google's Android mobile apps have dominated the largest share of global smartphone shipments for 2013 with 78.6% of market share over their next closest competitor in iOS with 15.2% of the market.[288] At the time of the Tretikov appointment and her posted web interview with Sue Gardner in May 2014, Wikimedia representatives made a technical announcement concerning the number of mobile access systems in the market seeking access to Wikipedia. Directly after the posted web interview, the representatives stated that Wikimedia would be applying an all-inclusive approach to accommodate as many mobile access systems as possible in its efforts for expanding general mobile access, including BlackBerry and the Windows Phone system, making market share a secondary issue.[226] The latest version of the Android app for Wikipedia was released on July 23, 2014, to generally positive reviews, scoring over four of a possible five in a poll of approximately 200,000 users downloading from Google.[289] The latest version for iOS was released on April 3, 2013, to similar reviews.[290]

Access to Wikipedia from mobile phones was possible as early as 2004, through the Wireless Application Protocol (WAP), via the Wapedia service. In June 2007 Wikipedia launched en.mobile.wikipedia.org, an official website for wireless devices. In 2009 a newer mobile service was officially released,[291] located at en.m.wikipedia.org, which caters to more advanced mobile devices such as the iPhone, Android-based devices or WebOS-based devices. Several other methods of mobile access to Wikipedia have emerged. Many devices and applications optimize or enhance the display of Wikipedia content for mobile devices, while some also incorporate additional features such as use of Wikipedia metadata (See Wikipedia:Metadata), such as geoinformation.[292][293]

Wikipedia Zero is an initiative of the Wikimedia Foundation to expand the reach of the encyclopedia to the developing countries.[294]

Andrew Lih and Andrew Brown both maintain editing Wikipedia with smart phones is difficult and this discourages new potential contributors. Several years running the number of Wikipedia editors has been falling and Tom Simonite of *MIT Technology Review* claims the bureaucratic structure and rules are a factor in this. Simonite alleges some Wikipedians use the labyrinthine rules and guidelines to dominate others and those editors have a vested interest in keeping the status quo.[48] Lih alleges there is serious disagreement among existing contributors how to resolve this. Lih fears for Wikipedia's long term future while Brown fears problems with Wikipedia will remain and rival encyclopedias will not replace it.[295][296]

# Cultural impact

## Readership

Wikipedia is extremely popular. In February 2014, *The New York Times* reported that Wikipedia is ranked fifth

globally among all websites, stating "With 18 billion page views and nearly 500 million unique visitors a month [...] Wikipedia trails just Yahoo, Facebook, Microsoft and Google, the largest with 1.2 billion unique visitors."[16]

In addition to logistic growth in the number of its articles,[297] Wikipedia has steadily gained status as a general reference website since its inception in 2001.[298] About 50% of search engine traffic to Wikipedia comes from Google,[299] a good portion of which is related to academic research.[300] The number of readers of Wikipedia worldwide reached 365 million at the end of 2009.[301] The Pew Internet and American Life project found that one third of US Internet users consulted Wikipedia.[302] In 2011 *Business Insider* gave Wikipedia a valuation of $4 billion if it ran advertisements.[303]

According to "Wikipedia Readership Survey 2011", the average age of Wikipedia readers is 36, with a rough parity between genders. Almost half of Wikipedia readers visit the site more than five times a month, and a similar number of readers specifically look for Wikipedia in search engine results. About 47% of Wikipedia readers do not realize that Wikipedia is a non-profit organization.[304]

## Cultural significance

*Main article: Wikipedia in culture*

Wikipedia's content has also been used in academic studies, books, conferences, and court cases.[305][306][307] The Parliament of Canada's website refers to Wikipedia's article on same-sex marriage in the "related links" section of its "further reading" list for the Civil Marriage Act.[308] The encyclopedia's assertions are increasingly used as a source by organizations such as the US federal courts and the World Intellectual Property Organization[309] – though mainly for *supporting information* rather than information decisive to a case.[310] Content appearing on Wikipedia has also been cited as a source and referenced in some US intelligence agency reports.[311] In December 2008, the scientific journal *RNA Biology* launched a new section for descriptions of families of RNA molecules and requires authors who contribute to the section to also submit a draft article on the RNA family for publication in Wikipedia.[312]

Wikipedia Monument in Słubice, Poland

Wikipedia has also been used as a source in journalism,[313][314] often without attribution, and several reporters have been dismissed for plagiarizing from Wikipedia.[315][316][317]

In 2006, *Time* magazine recognized Wikipedia's participation (along with YouTube, Reddit, MySpace, and Facebook[318]) in the rapid growth of online collaboration and interaction by millions of people worldwide.

In July 2007 Wikipedia was the focus of a 30-minute documentary on BBC Radio 4[319] which argued that, with increased usage and awareness, the number of references to Wikipedia in popular culture is such that the word is one of a select band of 21st-century nouns that are so familiar (Google, Facebook, YouTube) that they no longer need explanation.

On September 28, 2007, Italian politician Franco Grillini raised a parliamentary question with the minister of cultural resources and activities about the necessity of freedom of panorama. He said that the lack of such freedom forced Wikipedia, "the seventh most consulted website", to forbid all images of modern Italian buildings and art, and claimed this was hugely damaging to tourist revenues.[320]

On September 16, 2007, *The Washington Post* reported that Wikipedia had become a focal point in the 2008 US election campaign, saying: "Type a candidate's name into Google, and among the first results is a Wikipedia page, making those entries arguably as important as any ad in defining a candidate. Already, the presidential entries are being edited, dissected and debated countless times each day."[321] An October 2007 Reuters article, titled "Wikipedia page the latest status symbol", reported the recent phenomenon of how having a Wikipedia article vindicates one's notability.[322]

Play media

Wikipedia, an introduction –

Active participation also has an impact. Law students have been assigned to write Wikipedia articles as an exercise in clear and succinct writing for an uninitiated audience.[323]

A working group led by Peter Stone (formed as a part of the Stanford-based project *One Hundred Year Study on Artificial Intelligence*) in its report called Wikipedia "the best-known example of crowdsourcing... that far exceeds traditionally-compiled information sources, such as encyclopedias and dictionaries, in scale and depth."[324]

## Awards

Wikipedia won two major awards in May 2004.[325] The first was a Golden Nica for Digital Communities of the annual Prix Ars Electronica contest; this came with a €10,000 (£6,588; $12,700) grant and an invitation to present at the PAE Cyberarts Festival in Austria later that year. The second was a Judges' Webby Award for the "community" category.[326] Wikipedia was also nominated for a "Best Practices" Webby award.

In 2007, readers of brandchannel.com voted Wikipedia as the fourth-highest brand ranking, receiving 15% of the votes in answer to the question "Which brand had the most impact on our lives in 2006?"[327]

In September 2008, Wikipedia received Quadriga *A Mission of Enlightenment* award of Werkstatt Deutschland along with Boris Tadić, Eckart Höfling, and Peter Gabriel. The award was presented to Wales by David Weinberger.[328]

In 2015, Wikipedia was awarded both the annual Erasmus Prize, which recognizes exceptional contributions to culture, society or social sciences,[329] and the Spanish Princess of Asturias Award on International Cooperation.[330] Speaking at the Asturian Parliament in Oviedo, the city that hosts the awards ceremony, Jimmy Wales praised the work of the Asturian language Wikipedia users.[331] The night of the ceremony, members of the Wikimedia Foundation held a meeting with Wikipedians from all parts of Spain, including the local Asturian community.

## Satire

*See also: Category:Parodies of Wikipedia.*

Many parodies target Wikipedia's openness and susceptibility to inserted inaccuracies, with characters vandalizing or modifying the online encyclopedia project's articles.

Comedian Stephen Colbert has parodied or referenced Wikipedia on numerous episodes of his show *The Colbert Report* and coined the related term *wikiality*, meaning "together we can create a reality that we all agree on—the reality we just agreed on".[174] Another example can be found in "Wikipedia Celebrates 750 Years of American Independence", a July 2006 front-page article in *The Onion*,[332] as well as the 2010 *The Onion* article "'L.A. Law' Wikipedia Page Viewed 874 Times Today".[333]

In an episode of the television comedy *The Office* U.S., which aired in April 2007, an incompetent office manager (Michael Scott) is shown relying on a hypothetical Wikipedia article for information on negotiation tactics in order to assist him in negotiating lesser pay for an employee.[334] The tactics he used failed, as a joke about the unreliability of Wikipedia and what anyone can do to change its contents. Viewers of the show tried to add the episode's mention of the page as a section of the actual Wikipedia article on negotiation, but this effort was prevented by other users on the article's talk page.[335]

"My Number One Doctor", a 2007 episode of the television show *Scrubs*, played on the perception that Wikipedia is an unreliable reference tool with a scene in which Dr. Perry Cox reacts to a patient who says that

a Wikipedia article indicates that the raw food diet reverses the effects of bone cancer by retorting that the same editor who wrote that article also wrote the *Battlestar Galactica* episode guide.[336]

In 2008, the comedic website *CollegeHumor* produced a video sketch named "Professor Wikipedia", in which the fictitious Professor Wikipedia instructs a class with a medley of unverifiable and occasionally absurd statements.[337]

The *Dilbert* comic strip from May 8, 2009, features a character supporting an improbable claim by saying "Give me ten minutes and then check Wikipedia."[338]

In July 2009, BBC Radio 4 broadcast a comedy series called *Bigipedia*, which was set on a website which was a parody of Wikipedia. Some of the sketches were directly inspired by Wikipedia and its articles.[339]

In 2010, comedian Daniel Tosh encouraged viewers of his show, *Tosh.0*, to visit the show's Wikipedia article and edit it at will. On a later episode, he commented on the edits to the article, most of them offensive, which had been made by the audience and had prompted the article to be locked from editing.[340][341]

On August 23, 2013, the *New Yorker* website published a cartoon with this caption: "Dammit, Manning, have you considered the pronoun war that this is going to start on your Wikipedia page?"[342]

In December 2015, John Julius Norwich stated, in a letter published in *The Times* newspaper, that as an historian he resorted to Wikipedia "at least a dozen times a day", and had never yet caught it out. He described it as "a work of reference as useful as any in existence", with so wide a range that it is almost impossible to find a person, place or thing that it has left uncovered, and that he could never have written his last two books without it.[343][344]

## Sister projects – Wikimedia

*Main article: Wikimedia project*

Wikipedia has also spawned several sister projects, which are also wikis run by the Wikimedia Foundation. These other Wikimedia projects include Wiktionary, a dictionary project launched in December 2002,[345] Wikiquote, a collection of quotations created a week after Wikimedia launched, Wikibooks, a collection of collaboratively written free textbooks and annotated texts, Wikimedia Commons, a site devoted to free-knowledge multimedia, Wikinews, for citizen journalism, and Wikiversity, a project for the creation of free learning materials and the provision of online learning activities.[346] Of these, only Commons has had success comparable to that of Wikipedia. Another sister project of Wikipedia, Wikispecies, is a catalogue of species. In 2012 Wikivoyage, an editable travel guide, and Wikidata, an editable knowledge base, launched.

## Publishing

The most obvious economic effect of Wikipedia has been the death of commercial encyclopedias, especially the printed versions, e.g. *Encyclopaedia Britannica*, which were unable to compete with a product that is essentially free.[347][348][349] Nicholas Carr wrote a 2005 essay, "The amorality of Web 2.0", that criticized websites with user-generated content, like Wikipedia, for possibly leading to professional (and, in his view, superior) content producers' going out of business, because "free trumps quality all the time". Carr wrote: "Implicit in the ecstatic visions of Web 2.0 is the hegemony of the amateur. I for one can't imagine anything more frightening."[350] Others dispute the notion that Wikipedia, or similar efforts, will entirely displace traditional publications. For instance, Chris Anderson, the editor-in-chief of *Wired Magazine*, wrote in *Nature* that the "wisdom of crowds" approach of Wikipedia will not displace top scientific journals, with their rigorous peer review process.[351]

A group of Wikimedians of the Wikimedia DC chapter at the 2013 DC Wikimedia annual meeting standing in front of the *Encyclopædia Britannica (back left)* at the US National Archives

There is also an ongoing debate about the influence of Wikipedia on the biography publishing business. "The worry is that, if you can get all that information from Wikipedia, what's left for biography?" said Kathryn Hughes, professor of life writing at UEA and author of *The Short Life and Long Times of Mrs Beeton* and *George Eliot: the Last Victorian*.[352]

### Scientific use

Wikipedia has seen been widely used as a corpus for linguistic research in computational linguistics, information retrieval and natural language processing. In particular, it commonly serves as a target knowledge base for the entity linking problem, which is then called "wikification",[353] and to the related problem of word sense disambiguation.[354] Methods similar to wikification can in turn be used to find "missing" links in Wikipedia.[355]

In 2015, French researchers Dr José Lages of the University of Franche-Comté in Besançon and Dima Shepelyansky of Paul Sabatier University in Toulouse published a global university ranking based on Wikipedia scholarly citations.[356][357][358] They used PageRank "followed by the number of appearances in the 24 different language editions of Wikipedia (descending order) and the century in which they were founded (ascending order)."[358]

## Related projects

A number of interactive multimedia encyclopedias incorporating entries written by the public existed long before Wikipedia was founded. The first of these was the 1986 BBC Domesday Project, which included text (entered on BBC Micro computers) and photographs from over 1 million contributors in the UK, and covered the geography, art, and culture of the UK. This was the first interactive multimedia encyclopedia (and was also the first major multimedia document connected through internal links), with the majority of articles being accessible through an interactive map of the UK. The user interface and part of the content of the Domesday Project were emulated on a website until 2008.[359]

Several free-content, collaborative encyclopedias were created around the same period as Wikipedia (e.g. Everything2),[360] with many later being merged into the project (e.g. GNE).[361] One of the most successful early online encyclopedias incorporating entries by the public was h2g2, which was created by Douglas Adams in 1999. The h2g2 encyclopedia is relatively light-hearted, focusing on articles which are both witty and informative.

Subsequent collaborative knowledge websites have drawn inspiration from Wikipedia. Some, such as Susning.nu, Enciclopedia Libre, Hudong, and Baidu Baike likewise employ no formal review process, although some like Conservapedia are not as open. Others use more traditional peer review, such as Encyclopedia of Life and the online wiki encyclopedias Scholarpedia and Citizendium. The latter was started by Sanger in an attempt to create a reliable alternative to Wikipedia.[362]

105. ^ Larry Sanger (December 31, 2004). "Why Wikipedia Must Jettison Its Anti-Elitism". *Kuro5hin, Op–Ed*. "There is a certain mindset associated with unmoderated Usenet groups [...] that infects the collectively-managed Wikipedia project: if you react strongly to trolling, that reflects poorly on you, not (necessarily) on the troll. If you [...] demand that something be done about constant disruption by trollish behavior, the other listmembers will cry "censorship", attack you, and even come to the defense of the troll. [...] The root problem: anti-elitism, or lack of respect for expertise. There is a deeper problem [...] which explains both of the above-elaborated problems. Namely, as a community, Wikipedia lacks the habit or tradition of respect for expertise. As a community, far from being elitist, it is

anti-elitist (which, in this context, means that expertise is not accorded any special respect, and snubs and disrespect of expertise is tolerated). This is one of my failures: a policy that I attempted to institute in Wikipedia's first year, but for which I did not muster adequate support, was the policy of respecting and deferring politely to experts. (Those who were there will, I hope, remember that I tried very hard.)"

## Notes

1. ^ Many (but not all) of the glyphs featured are equivalent to the English letter W or sounds "wi", "wo" or "wa". See Wikipedia logo.

2. ^ Registration is required for certain tasks such as editing protected pages, creating pages in the English Wikipedia, and uploading files.
3. ^ For an user to be considered active in a given month, one or more actions have had to be made in said month.
4. ^ Wikis are a type of website. The word "wiki" itself is from the Hawaiian word for "quick".[14]
5. ^ The procrastination principle dictates that you should wait for problems to arise before solving them.
6. ^ Revisions with libelous content, criminal threats, or copyright infringements may be removed completely.
7. ^ See for example the Biographies of Living Persons Noticeboard or Neutral Point of View Noticeboard, created to address content falling under their respective areas.
8. ^ See "Libel" by David McHam for the legal distinction

# Translation Task Force

**Shortcuts:**
**WP:MTP**
**WP:MEDT**
**WP:MEDTRANS**
**WP:TWB**
**WP:TTF**

The **Healthcare Translation Task Force**[1] – brings high quality, easy to understand health information into as many languages as possible.

It was created as a joint venture between WikiProject Medicine, Wiki Project Med Foundation, and Translators Without Borders. We have **together** translated over **1,900** articles in more than **90** languages! This translated content is getting about **40 million** views a year.[2]

Texts are translated where they are needed the most — currently: diseases, medications and drugs, anatomy, nutrition, sanitation, and women's health. To see our list of articles for translation check out: **our summaries**.

WIKIPROJECT MEDICINE | Wiki Project Med Foundation | TRANSLATORS WITHOUT BORDERS | RUBRIC

# LANGUAGE SHOULDN'T BE A BARRIER FOR HEALTH INFORMATION!

# What's happening

We have an offline version of our healthcare content. **Download the Android app** and access all this content when there's no Internet. (other languages)

**News**

*Last updated: April 2016*

## 2016

- 500 short articles ready for translation
- Launch of offline medical apps in 10 languages.[3]

**April**

- **58** Vaccine articles live during April (165 total)
- **Rubric donated 9 articles in African and Indian languages on sanitation and preventable infectious disease!**

**March**

- **29** articles translated !+ 30?

| WikiProject Medicine 100x1000 | Full | Su |

| **Language goal** | 50 | 100 |
| **Translations done** | 637 | 1,3 |
| **FA/GA translations** | 65 | 12 |
| **Needing integration** | Done | 4 |
| | | Last 2016 |

# Get invovled

**Community organization**
We need Wikipedians to engage the community on the different Wikipedias.

**Assessing content**
We need local-language speakers to determine which articles need to be translated into the target language.

**Translating**
We are always on the look-out for dedicated translators to work directly with our content, especially in smaller languages!

**Integration**
Translated articles need to be integrated into local Wikipedias. This process is done manually and needs to be in harmony with existing local articles.

**Posting jobs on Translators Without Borders website**

# Why help?

Wikipedia zero

We're working together with **Wikipedia Zero** to spread knowledge where it is needed the most!

We need people to manage languages. This involves posting new translation jobs on the TWB website.

**Template installation**

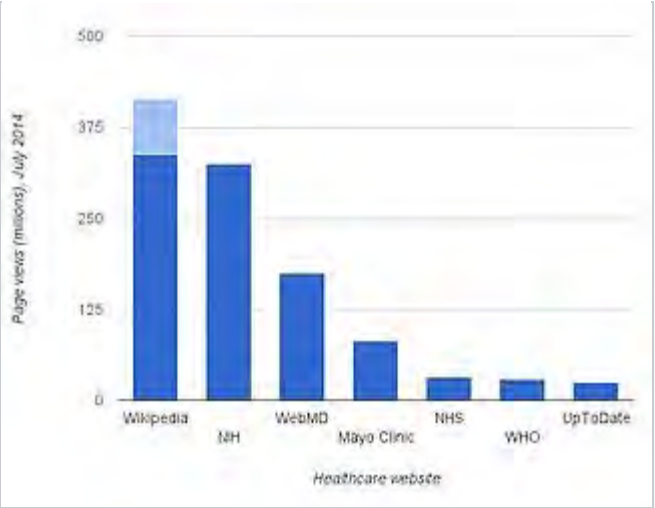
For translations to be more useful templates and modules should be installed. We need people with the technical know-how to help out.

**Programming**

Several of our processes are in need of simplification and many could be improved with bots.

**Writing content for the translation project**

Writing for translations may be slightly different from writing other articles on Wikipedia. If you are interested in improving articles contact James Heilman (*jmh649@gmail.com*) or simply create a Wikipedia account and start editing.



Health care site traffic comparison in July 2014. Light blue portions represent official Wikimedia Foundation data for all medical articles. Other data is estimated from SimilarWeb.[1]

Wikipedia is the most used health care resource on the Internet–both by unique visitors and by pageviews. For all those interested in global health this is an opportunity to help bring high quality healthcare information to the world.

In the beginning effort primarily concentrated on 80 medical articles of global significance. In the month of February 2012 these pages *in English* received a total of 10.6 million page views.[4]

In 2014 we switched our efforts to a larger number of shorter articles as we believe translating more short articles rather than fewer long articles will have a greater impact. A more in depth breakdown can be found at popular pages of the translation taskforce

As of July 2014, the more than 500 full articles translated via this project received over 1.2 million pages views per month (see **here**) in their local languages.

**Translators without Borders** is a non-profit organization[1] set up to provide translation services for humanitarian non-profits. It was established in 2010 as a sister organization of Traducteurs Sans Frontières, founded in 1993 by Lori Thicke and Ros Smith-Thomas of Lexcelera. As of 2012 it had about 1600 vetted volunteer translators.[2] Translators without Borders aims to close the language gaps that hinder critical humanitarian efforts by connecting nonprofit humanitarian organizations with a volunteer community of professional translators, building language translation capacity at the local level and raising awareness globally about language barriers.[3]

The organization works for humanitarian non-profit organizations that need information translated. Some of those groups are Doctors Without Borders, Medecins du Monde, UNICEF, Oxfam, Handicap International. Some examples of information translated by Translators without Borders includes reports, vital health information, and crisis response material for organizations responding to emergencies around the world, such as Burundi, Liberia and Greece. The organization translates millions of words per year.[4] According to their website, Translators without Borders has donated over 30 million translated words to non-profits, which is equivalent to over $6 million released for NGOs.

Translators without Borders is a 501(c)3 non-profit corporation in the U.S.

# Working with translators [edit]

## Translators without Borders Workspace [edit]

ProZ.com created an online automated translation platform for Translators without Borders in May 2011. This translation center is called the Translators without Borders Workspace. Approved non-profits post translation projects and TWB volunteer translators pick up the jobs they wish to work with.

The use of the Workspace greatly increased the productivity of Translators without Borders. When projects were handled manually, TWB translated 29 projects, with 37,000 words of text, in seven language pairs, for nine different organizations. In January 2012, seven months after the Translators without Borders Workspace was completed, they translated 183 projects, with 280,000 words, in 25 language pairs, for 24 organizations.[5] In 2015 Translators without Borders reported to have delivered 7 million translated words through 780 projects to 214 aid organizations.[6]

## Volunteers [edit]

People who volunteer to be translators on the Translators without Borders website must be a professional translator with a minimum qualification of 4 years professional translation experience or 2 years of professional translation experience and a university degree in translation or a related subject.[7] Applications are fast-tracked for translators American Translators Association (ATA) certified, at Lionbridge, ProZ.com Certified PRO or with a MITI qualification from the UK Institute of Translating and Interpreting. These fast-track applicants are given credentials to join the Translators without Borders Workspace.

# Projects [edit]

## Words of Relief project [edit]

Words of Relief (WoR) is a translation crisis relief network intended to improve Communications with Communities (CwC) when the crisis response humanitarian workers and affected populations do not speak the same language. Words of Relief works to eliminate linguistic barriers[8] that can impede vital response and relief efforts during and after a crisis by doing the following:[9]

- Translating key crisis and disaster messages into the relevant languages and disseminating openly before crises occur.
- Building a spider network of diaspora translators who can translate from world languages into regional languages and who are trained to assist right away.
- Creating a crowd sourced, online (and mobile) application that connects the translation team with aid workers and data aggregators

The Spider Network volunteers for the Words of Relief project

who need immediate help (entitled the Words of Relief Digital Exchange - WoRDE).[10]

Words of Relief was piloted from January, 2014 to May, 2015 in Nairobi, Kenya and concentrated on Swahili and Somali. Approximately 475,000 words of crisis relief content from various sources including the Infoasaid Message Library were translated.

The Words of Relief model has been deployed to respond to several crises worldwide, including the Ebola emergency[11] in West Africa and the Nepal earthquake.[12] Rapid Response Teams in Arabic, Persian, Greek, Kurdish and Urdu are currently providing rapid translations for aid organizations along the refugee route in Europe. Teams of professional volunteers work with partners to translate information on reception centres and ferry strikes, signage for the centres, and health information.

Words of Relief relies on a crowd-sourced, online (and mobile) application, called the Words of Relief Digital Exchange (WoRDE). The platform was launched in 2014 and it connects teams of rapid response translators with aid workers to do translations during a sudden onset crisis.

Words of Relief is supported by the Humanitarian Innovation Fund (HIF), a program managed by ELRHA. The Words of Relief Digital Exchange is funded by Microsoft's Technology for Good.[13]

Infograph showing the impact of translation

## Information in the Right Language [edit]

An Impact Study was conducted to measure the comprehensibility of English information posters compared with translated Swahili posters and it showed that there is a very clear difference in the levels of comprehension, in favour of the translated Swahili poster. Initially, only eight per cent of respondents answered simple questions about the disease correctly. When respondents were given simple information about the disease in English, correct answers rose to 16%. But when given this information in Swahili, respondents got 92% of the questions correct.

## The HealthPhone project [edit]

One of the Translators without Borders projects is in partnership with the Mother and Child Health and Education Trust in India. HealthPhone, which was founded and created by Nand Wadhwani, creates health videos that are preloaded to phones throughout India and beyond.[14] The videos cover a variety of health issues, such as breastfeeding, malnutrition, post-natal and newborn care, and more.[15]

Through translators, videos are subtitled so that people throughout India (and in Africa) who do not speak or read the source language can learn from the videos. So far videos have been subtitled into about 10 Indic languages, Swahili and Spanish.

## Simple Words for Health [edit]

Simple Words for Health (SWFH), a simplified medical terminology resource, was set up in 2014. SWFH is a database of 12,000 essential medical terms that have been simplified and translated into more than 40 world languages by qualified doctors and trained medical translators.

## Wikipedia [edit]

In 2011, Translators without Borders began a collaborative effort to translate key medical articles on English Wikipedia into other languages.[16] The WikiProject Medicine Translation Task Force first improves the 8 medical articles deemed most essential to WP:GA or WP:FA status.[17] When the articles are improved, they are translated into simplified English by Content Rules (the simplified English is provided on the Wikipedia simplified English site) and a goal of more than 100 languages. Eventually, the hope is articles will be translated into all of the 285 languages that Wikipedia exists in. This process is expected to take several years.

All content is available through mobile networks and some content without data charges through the Wikipedia mobile partners Telnor, Orange and STC in Africa, South East Asia and the Middle East. Many of the articles are available in spoken Wikipedia. Some of these articles are also pending publication in open access general medical journals.

### Training Center in Kenya [edit]

In April 2012, Translators without Borders opened its first Healthcare Translation Center in Nairobi. In the Center, located in Nairobi Kenya, new translators are trained to work in Kiswahili, as well as a number of the other 42 languages spoken in Kenya. Since the Center was first launched in 2012, basic translation training has been provided to over 250 people. This project focuses on healthcare information translated into Swahili.[18]

The purpose of the Healthcare Translation Center is to intensively train local Kenyans to become professional translators. These translators assist in the process of getting healthcare information out in Swahili. These translators are recruited to the training center due to backgrounds in language or in health.

## Management [edit]

Translators without Borders is managed by a board of directors. Day-to-day operations are managed by a staff who report to an Executive Director, a Director of External Affairs and a Programs Director.

# Abdominal aortic aneurysm

From Wikipedia, the free encyclopedia

**Abdominal aortic aneurysm** (**AAA** or **triple A**)[1] is a localized enlargement of the abdominal aorta such that the diameter is greater than 3 cm or more than 50% larger than normal diameter.[2] They usually cause no symptoms except when ruptured.[2] Occasionally, abdominal, back, or leg pain may occur.[3] Large aneurysms can sometimes be felt by pushing on the abdomen.[3] Rupture may result in pain in the abdomen or back, low blood pressure, or loss of consciousness, and often results in death.[2][4]

AAAs occur most commonly in those over 50 years old, in men, and among those with a family history.[2] Additional risk factors include smoking, high blood pressure, and other heart or blood vessel diseases.[5] Genetic conditions with an increased risk include Marfan syndrome and Ehlers-Danlos syndrome. AAAs are the most common form of aortic aneurysm.[6] About 85% occur below the kidneys with the rest either at the level of or above the kidneys.[2] In the United States, screening with ultrasound is recommended for males between 65 and 75 years of age with a history of smoking.[7] In the United Kingdom, screening all men over 65 is recommended.[2] Once an aneurysm is found, further ultrasounds are typically done on a regular basis.[3]

Not smoking is the single best way to prevent the disease. Other methods of prevention include treating high blood pressure, treating high blood cholesterol and not being overweight. Surgery is usually recommended when an AAA's diameter grows to >5.5 cm in males and >5.0 cm in females.[2] Other reasons for repair include the presence of symptoms and a rapid increase in size (more than one centimeter per year).[3] Repair may be either by open surgery or endovascular aneurysm repair (EVAR).[2] As compared to open surgery, EVAR has a lower risk of death in the short term and a shorter hospital stay, but may not always be an option.[2][8][9] There does not appear to be a difference in longer term outcomes between the two.[10] With EVAR there is a higher need for repeat procedures.[11]

AAAs affect between 2 and 8% of males over the age of 65. Rates among women are one-fourth as high. In those with an aneurysm less than 5.5 cm the risk of rupture in the next year is less than 1%. Among those with an aneurysm between 5.5 and 7 cm, the risk is about 10%, while for

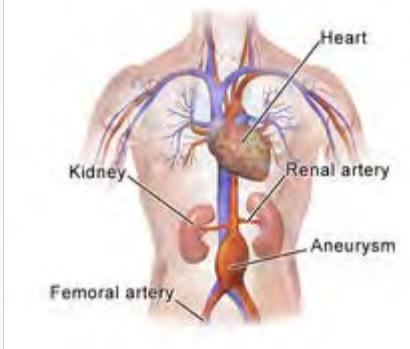
those with an aneurysm greater than 7 cm the risk is about 33%. Mortality if ruptured is 85% to 90%.[2] During 2013, aortic aneurysms resulted in 152,000 deaths, up from 100,000 in 1990.[12] In the United States AAAs resulted in between 10,000 and 18,000 deaths in 2009.[6]

Contents

## Signs and symptoms [edit]

The vast majority of aneurysms are asymptomatic. However, as abdominal aortic aneurysms expand, they may become painful and lead to pulsating sensations in the abdomen or pain in the chest, lower back, or scrotum.[13] The risk of rupture is high in a symptomatic aneurysm, which is therefore considered an indication for surgery. The complications include rupture, peripheral embolization, acute aortic occlusion, and aortocaval (between the aorta and inferior vena cava) or aortoduodenal (between the aorta and the duodenum) fistulae. On physical examination, a palpable and pulsatile abdominal mass can be noted. Bruits can be present in case of renal or visceral arterial stenosis.[14]



Abdominal aortic aneurysm location

### Aortic rupture [edit]

*Main article: Aortic rupture*

The signs and symptoms of a ruptured AAA may include severe pain in the lower back, flank, abdomen or groin. A mass that pulses with the heart beat may also be felt.[4] The bleeding can lead to a hypovolemic shock with low blood pressure and a fast heart rate. This may lead to brief passing out.[4]

The mortality of AAA rupture is as high as 90 percent. 65 to 75 percent of patients die before they arrive at the hospital and up to 90 percent die before they reach the operating room.[15] The bleeding can be

retroperitoneal or into the abdominal cavity. Rupture can also create a connection between the aorta and intestine or inferior vena cava.[16] Flank ecchymosis (appearance of a bruise) is a sign of retroperitoneal bleeding, and is also called Grey Turner's sign.[14][17]

Aortic aneurysm rupture may be mistaken for the pain of kidney stones, or muscle related back pain.[4]

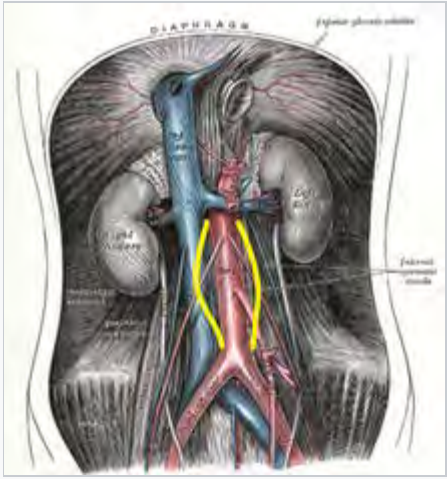
## Causes [edit]

The exact causes of the degenerative process remain unclear. There are, however, some hypotheses and well-defined risk factors.[18]

- Tobacco smoking: More than 90% of people who develop an AAA have smoked at some point in their lives.[19]
- Alcohol and hypertension: The inflammation caused by prolonged use of alcohol and hypertensive effects from abdominal edema which leads to hemorrhoids, esophageal varices, and other conditions, is also considered a long-term cause of AAA.
- Genetic influences: The influence of genetic factors is high. AAA is four to six times more common in male siblings of known patients, with a risk of 20-30%.[20] The high familial prevalence rate is most notable in male individuals.[21] There are many hypotheses about the exact genetic disorder that could cause higher incidence of AAA among male members of the affected families. Some presumed that the influence of alpha 1-antitrypsin deficiency could be crucial, while other experimental works favored the hypothesis of X-linked mutation, which would explain the lower incidence in heterozygous females. Other hypotheses of genetic etiology have also been formulated.[14] Connective tissue disorders, such as Marfan syndrome and Ehlers-Danlos syndrome, have also been strongly associated with AAA.[16] Both relapsing polychondritis and pseudoxanthoma elasticum may cause abdominal aortic aneurysm.[22]
- Atherosclerosis: The AAA was long considered to be caused by atherosclerosis, because the walls of the AAA frequently carry an atherosclerotic burden. However, this hypothesis cannot be used to explain the initial defect and the development of occlusion, which is observed in the process.[14]
- Other causes of the development of AAA include: infection, trauma, arteritis, and cystic medial necrosis.[16]

## Pathophysiology [edit]

The most striking histopathological changes of the aneurysmatic aorta are seen in the tunica media and intima layers. These changes include the accumulation of lipids in foam cells, extracellular free cholesterol crystals, calcifications, thrombosis, and ulcerations and ruptures of the layers. Adventitial inflammatory infiltrate is present.[16] However, the degradation of the tunica media by means of a proteolytic process seems to be the basic pathophysiologic mechanism of AAA development. Some researchers report increased expression and activity of matrix metalloproteinases in individuals with AAA. This leads to elimination of elastin from the media, rendering the aortic wall more susceptible to the influence of blood pressure.[14] Other reports have suggested the serine protease granzyme B may contribute to aortic aneurysm rupture through the cleavage of decorin, leading to disrupted collagen organization and reduced tensile strength of the adventitia.[23][24] There is also a reduced amount of vasa vasorum in the abdominal aorta (compared to the thoracic aorta); consequently, the tunica media must rely mostly on diffusion for nutrition, which makes it more susceptible to damage.[25]



A plate from *Gray's Anatomy* with yellow lines depicting the most common infrarenal location of the AAA

Hemodynamics affect the development of AAA, which has a predilection for the infrarenal aorta. The histological structure and mechanical characteristics of the infrarenal aorta differ from those of the thoracic

aorta. The diameter decreases from the root to the aortic bifurcation, and the wall of the infrarenal aorta also contains a lesser proportion of elastin. The mechanical tension in the abdominal aortic wall is therefore higher than in the thoracic aortic wall. The elasticity and distensibility also decline with age, which can result in gradual dilatation of the segment. Higher intraluminal pressure in patients with arterial hypertension markedly contributes to the progression of the pathological process.[16] Suitable hemodynamic conditions may be linked to specific intraluminal thrombus (ILT) patterns along the aortic lumen, which in turn may affect AAA's development.[26]

## Diagnosis [edit]

An abdominal aortic aneurysm is usually diagnosed by physical exam, ultrasound, or CT. Plain abdominal radiographs may show the outline of an aneurysm when its walls are calcified. However, this is the case in less than half of all aneurysms. Ultrasonography is used to screen for aneurysms and to determine the size of any present. Additionally, free peritoneal fluid can be detected. It is noninvasive and sensitive, but the presence of bowel gas or obesity may limit its usefulness. CT scan has a nearly 100% sensitivity for an aneurysm and is also useful in preoperative planning, detailing the anatomy and possibility for endovascular repair. In the case of suspected rupture, it can also reliably detect retroperitoneal fluid. Alternative less often used methods for visualization of an aneurysm include MRI and angiography.

An aneurysm ruptures if the mechanical stress (tension per area) exceeds the local wall strength; consequently, peak wall stress (PWS)[27] and peak wall rupture risk (PWRR)[28] have been found to be more reliable parameters than diameter to assess AAA rupture risk. Medical software allows computing these rupture risk indices from standard clinical CT data and provides a patient-specific AAA rupture risk diagnosis.[29] This type of biomechanical approach has been shown to accurately predict the location of AAA rupture.[30]

### Classification [edit]

Abdominal aortic aneurysms are commonly divided according to their size and symptomatology. An aneurysm is usually defined as an outer aortic diameter over 3 cm (normal diameter of the aorta is around 2 cm).[31] If the outer diameter exceeds 5.5 cm, the aneurysm is considered to be large.[32] A ruptured AAA is a clinical diagnosis involving the presence of the triad of abdominal pain, shock, and a pulsatile abdominal mass. If these conditions are present, indicating AAA rupture, no further clinical investigations are needed before surgery.[33]

## Prevention [edit]

- Smoking cessation
- Treatment of hypertension

## Screening [edit]

The U.S. Preventive Services Task Force recommends a single screening ultrasound for abdominal aortic aneurysm in males age 65 to 75 years who have a history of smoking.[7] There is an estimated number needed to screen of approximately 850 people.[34] It is unclear if screening is useful in women aged 65 to 75 who have smoked and they recommend against screening in women who have never smoked.[7]

Repeat ultrasounds should be carried out in those who have an aortic size greater than 3.0 cm.[35] In those whose aorta is between 3.0 and 3.9 cm this should be every three years, if between 4.0 and 4.4 cm every two year, and if between 4.5 and 5.4 cm every year.[35]

In the United Kingdom one time screening is recommended in all males over 65 years of age.[2] Australia has no guideline on screening.[36]

## Management [edit]

The treatment options for asymptomatic AAA are conservative management, surveillance with a view to eventual repair, and immediate repair. Two modes of repair are available for an AAA: open aneurysm repair (OR), and endovascular aneurysm repair (EVAR). An intervention is often recommended if the aneurysm grows more than 1 cm per year or it is bigger than 5.5 cm.[37] Repair is also indicated for symptomatic aneurysms.

### Conservative [edit]

Conservative management is indicated in people where repair carries a high risk of mortality and in patients where repair is unlikely to improve life expectancy. The mainstay of the conservative treatment is smoking cessation.

Surveillance is indicated in small asymptomatic aneurysms (less than 5.5 cm) where the risk of repair exceeds the risk of rupture.[37] As an AAA grows in diameter, the risk of rupture increases. Surveillance until an aneurysm has reached a diameter of 5.5 cm has not been shown to have a higher risk as compared to early intervention.[38][39]

### Medication [edit]

No medical therapy has been found to be effective at decreasing the growth rate or rupture rate of asymptomatic AAAs.[2] Blood pressure and lipids should, however, be treated per usual.[31]

## Surgery [edit]

Surgery for an abdominal aortic aneurysm is known as AAA surgery or AAA repair.

The threshold for repair varies slightly from individual to individual, depending on the balance of risks and benefits when considering repair versus ongoing surveillance. The size of an individual's native aorta may influence this, along with the presence of comorbidities that increase operative risk or decrease life expectancy. Evidence; however, does not support repair if the size is between 4 cm and 5.5 cm.[37]

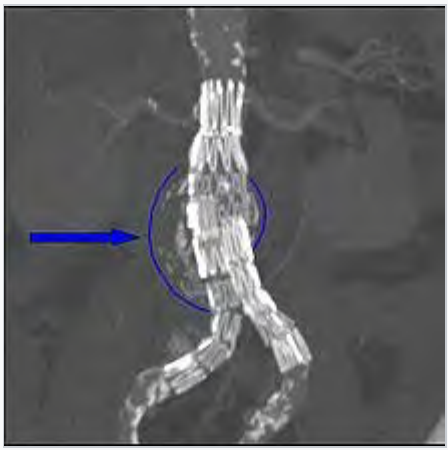
## Open repair [edit]

*Main article: Open aortic surgery*

Open repair is indicated in young patients as an elective procedure, or in growing or large, symptomatic or ruptured aneurysms. The aorta must be clamped off during the repair, denying blood to the abdominal organs and sections of the spinal cord; this can cause a range of complications. It is essential to make the critical part of the operation fast, so the incision is typically made large enough to facilitate the fastest repair. Recovery after open AAA surgery takes significant time. The minimums are a few days in intensive care, a week total in the hospital and a few months before full recovery.

## Endovascular repair [edit]

*Main article: Endovascular aneurysm repair*



Abdominal aortic endoprosthesis, CT scan, original aneurysm marked in blue

Endovascular repair first became practical in the 1990s and although it is now an established alternative to open repair, its role is yet to be clearly defined. It is generally indicated in older, high-risk patients or patients unfit for open repair. However, endovascular repair is feasible for only a proportion of AAAs, depending on the morphology of the aneurysm. The main advantages over open repair are that there is less peri-operative mortality, less time in intensive care, less time in hospital overall and earlier return to normal activity. Disadvantages of endovascular repair include a requirement for more frequent ongoing hospital reviews, and a higher chance of further procedures being required. According to the latest studies, the EVAR procedure does not offer any benefit for overall survival or health-related quality of life compared to open surgery, although aneurysm-related mortality is lower.[40][41][42][43] In patients unfit for open repair, EVAR plus conservative management was associated with no benefit, more complications, subsequent procedures and higher costs compared to conservative management alone.[44] Endovascular treatment for paraanastomotic aneurysms after aortobiiliac reconstruction is also a possibility.[45] A 2014 Cochrane review found tentative evidence of no difference in outcomes between endovascular and open repair of ruptured AAA in the first month.[46]

## Rupture [edit]

In those with aortic rupture of the AAA, treatment is immediate surgical repair. There appears to be benefits to allowing permissive hypotension and limiting the use of intravenous fluids during transport to the operating room.[47]

# Prognosis [edit]

Although the current standard of determining rupture risk is based on maximum diameter, it is

| AAA Size (cm) | Growth rate (cm/yr)[48] | Annual rupture risk (%)[49] |
|---|---|---|
| 3.0-3.9 | 0.39 | 0 |

| | | |
|---|---|---|
| 4.0-4.9 | 0.36 | 0.5-5 |
| 5.0-5.9 | 0.43 | 3-15 |
| 6.0-6.9 | 0.64 | 10-20 |
| >=7.0 | - | 20-50 |

known that smaller AAAs that fall below this threshold (diameter<5.5 cm) may also rupture, and larger AAAs (diameter>5.5 cm) may remain stable.[50][51] In one report, it was shown that 10–24% of ruptured AAAs were less than 5 cm in diameter.[51] It has also been reported that of 473 non-repaired AAAs examined from autopsy reports, there were 118 cases of rupture, 13% of which were less than 5 cm in diameter. This study also showed that 60% of the AAAs greater than 5 cm (including 54% of those AAAs between 7.1 and 10 cm) never experienced rupture.[52] Vorp *et al.* later deduced from the findings of Darling *et al.* that if the maximum diameter criterion were followed for the 473 subjects, only 7% (34/473) of cases would have succumbed to rupture prior to surgical intervention as the diameter was less than 5 cm, with 25% (116/473) of cases possibly undergoing unnecessary surgery since these AAAs may never have ruptured.[52]

Alternative methods of rupture assessment have been recently reported. The majority of these approaches involve the numerical analysis of AAAs using the common engineering technique of the finite element method (FEM) to determine the wall stress distributions. Recent reports have shown that these stress distributions have been shown to correlate to the overall geometry of the AAA rather than solely to the maximum diameter.[53][54][55] It is also known that wall stress alone does not completely govern failure as an AAA will usually rupture when the wall stress exceeds the wall strength. In light of this, rupture assessment may be more accurate if both the patient-specific wall stress is coupled together with patient-specific wall strength. A non-invasive method of determining patient-dependent wall strength was recently reported,[56] with more traditional approaches to strength determination via tensile testing performed by other researchers in the field.[57][58][59] Some of the more recently proposed AAA rupture-risk assessment methods include: AAA wall stress;[27][60][61] AAA expansion rate;[62] degree of asymmetry;[55] presence of intraluminal thrombus (ILT);[63] a rupture potential index (RPI);[64][65] a finite element analysis rupture index (FEARI);[66] biomechanical factors coupled with computer analysis;[67] growth of ILT;[68] geometrical parameters of the AAA;[69] and also a method of determining AAA growth and rupture based on mathematical models.[70][71]

The post-operative mortality for an already ruptured AAA has slowly decreased over several decades but remains higher than 40%.[33] However, if the AAA is surgically repaired before rupture, the post-operative mortality rate is substantially lower: approximately 1-6%.[72]

## Epidemiology [edit]

The occurrence of AAA varies by ethnicity. In the United Kingdom the rate of AAA in Caucasian men older than 65 years is about 4.7%, while in Asian men it is 0.45%.[73] It is also less common in individuals of African, and Hispanic heritage.[2] They occur four times more often in men than women.[2]

There are at least 13,000 deaths yearly in the U.S. secondary to AAA rupture.[2] The peak number of new cases per year among males is around 70 years of age, the percentage of males affected over 60 years is 2–6%. The frequency is much higher in smokers than in non-smokers (8:1), and the risk decreases slowly after smoking cessation.[74] In the U.S., the incidence of AAA is 2–4% in the adult population.[14]

Rupture of the AAA occurs in 1–3% of men aged 65 or more, the mortality is 70–95%.[32]

## History [edit]

The first historical records about AAA are from Ancient Rome in the 2nd century AD, when Greek surgeon Antyllus tried to treat the AAA with proximal and distal ligature, central incision and removal of thrombotic material from the aneurysm. However, attempts to treat the AAA surgically were unsuccessful until 1923. In

that year, Rudolph Matas (who also proposed the concept of endoaneurysmorrhaphy), performed the first successful aortic ligation on a human.[75] Other methods that were successful in treating the AAA included wrapping the aorta with polyethene cellophane, which induced fibrosis and restricted the growth of the aneurysm. Albert Einstein was operated on by Rudolph Nissen with use of this technique in 1949, and survived five years after the operation, though he eventually died when the aneurysm ruptured.[76] Endovascular aneurysm repair was first performed in the late 1980s and has been widely adopted in the subsequent decades. Endovascular repair was first used for treating a ruptured aneurysm in Nottingham in 1994[77]

Former presidential candidate Bob Dole had an abdominal aortic aneurysm in 2001 and was treated surgically by vascular surgeon Kenneth Ouriel. The operation was successful. In 1993, country music singer Conway Twitty died from AAA, and actor George C. Scott also died of an Abdominal Aneurysm.[78]

## Society and culture [edit]

In 2001 former presidential candidate Bob Dole underwent surgery for an abdominal aortic aneurysm in which a team of surgeons led by Doctor Kenneth Ouriel inserted a stent graft:

> “Ouriel said that the team inserted a Y-shaped tube through an incision in Dole's leg and placed it inside the weakened portion of the aorta. The aneurysm will eventually contract around the stent, which will remain in place for the rest of Dole's life.[78]”

— *Associated Press*

Actor Robert Jacks, who played Leatherface in *Texas Chainsaw Massacre: The Next Generation*, died from an abdominal aneurysm on August 8, 2001, just one day shy of his 42nd birthday. His father also died from the same cause when Robert was a child.

Musician Conway Twitty died in June 1993 from an abdominal aortic aneurysm, aged 59, two months before the release of what would be his final studio album, *Final Touches*.

## Research [edit]

### Risk assessment [edit]

There have been many calls for alternative approaches to rupture risk assessment over the past number of years, with many believing that a biomechanics-based approach may be more suitable than the current diameter approach. Numerical modeling is a valuable tool to researchers allowing approximate wall stresses to be calculated, thus revealing the rupture potential of a particular aneurysm. Experimental models are required to validate these numerical results and provide a further insight into the biomechanical behavior of the AAA. *In vivo*, AAAs exhibit a varying range of material strengths[79] from localised weak hypoxic regions[80] to much stronger regions and areas of calcifications.[81]

### Experimental models [edit]

Experimental models can now be manufactured using a novel technique involving the injection-moulding lost-wax manufacturing process to create patient-specific anatomically correct AAA replicas.[82] Work has also focused on developing more realistic material analogues to those *in vivo*, and recently a novel range of silicone-rubbers was created allowing the varying material properties of the AAA to be more accurately represented.[83] These rubber models can also be used in a variety of experimental testing from stress analysis using the photoelastic method[84] to deterimining whether the locations of rupture experimentally correlate with those predicted numerically.[85] New endovascular devices are being developed that are able to treat more complex and tortuous anatomies.[86]

## Prevention and treatment [edit]

An animal study showed that removing a single protein prevents early damage in blood vessels from triggering a later-stage, complications. By eliminating the gene for a signaling protein called cyclophilin A (CypA) from a strain of mice, researchers were able to provide complete protection against abdominal aortic aneurysm.[87]

Other recent research identified Granzyme B (GZMB) (a protein-degrading enzyme) to be a potential target in the treatment of abdominal aortic aneurysms. Elimination of this enzyme in mice models both slowed the progression of aneurysms and improved survival.[88][89]

# Aortic stenosis

From Wikipedia, the free encyclopedia

*Not to be confused with coarctation of the aorta.*

**Aortic stenosis** (**AS** or **AoS**) is the narrowing of the exit of the left ventricle of the heart (where the aorta begins), such that problems result. It may occur at the aortic valve as well as above and below this level. It typically gets worse over time. Symptoms often come on gradually with a decreased ability to exercise often occurring first. If heart failure, loss of consciousness, or heart related chest pain occurs due to AS the outcomes are worse. Loss of consciousness typically occurs with standing or exercise. Signs of heart failure include shortness of breath especially when lying down, at night, or with exercise, and swelling of the legs. Thickening of the valve without narrowing is known as aortic sclerosis.[1]

Causes include being born with a bicuspid aortic valve and rheumatic fever. A bicuspid aortic valve affects about one to two percent of the population while rheumatic heart disease mostly occurring in the developing world. A normal valve, however, may also harden over the decades. Risk factors are similar to those of coronary artery disease and include smoking, high blood pressure, high cholesterol, diabetes, and being male. The aortic valve usually has three leaflets and is located between the left ventricle of the heart and the aorta. AS typically results in a heart murmur. Its severity can be divided into mild, moderate, severe, and very severe based on ultrasound of the heart findings.[1]

Aortic stenosis is typically followed using repeated ultrasounds. Once it has become severe treatment primarily involves valve replacement surgery with transcatheter aortic valve replacement (TAVR) being an option in some who are at high risk from surgery. Valves may either be mechanical or bioprosthetic with each having risks and benefits. Another less invasive procedure, balloon aortic valvuloplasty (BAV) may result in benefit but this is for only for a few months. Complications like heart failure may be treated as per normal in those with mild to moderate AS. In those with severe disease a number of medications should be avoided including ACE inhibitors, nitroglycerin, and some beta blockers.[1] Nitroprusside or phenylephrine may be used in those with decompensated heart failure depending on the blood pressure.[1][2]

Aortic stenosis is the most common valvular heart disease in the developed world.[3] It affects about 2% of people who are over 65 years of age.[1] Estimated rates are not known in most of the developing world as of 2014.[4] In those who have symptoms, without repair, the chance of death at five years is about 50%

**Aortic stenosis**

In the center an aortic valve with severe stenosis due to rheumatic heart disease. The valve is surrounded by the aorta. The pulmonary trunk is at the lower right. The right coronary artery, cut lengthwise, is at the lower left. The left main coronary artery, also cut lengthwise, is on the right.

Video explanation of aortic valve disease

## Signs and symptoms [edit]

Symptoms related to aortic stenosis depend on the degree of stenosis. Most people with mild to moderate aortic stenosis do not have symptoms. Symptoms usually present in individuals with severe aortic stenosis, though they may occur in those with mild to moderate aortic stenosis as well. The three main symptoms of aortic stenosis are loss of consciousness, anginal chest pain and shortness of breath with activity or other symptoms of heart failure such as shortness of breath while lying flat, episodes of shortness of breath at night, or swollen legs and feet.[3][6] It may also be accompanied by the characteristic "Dresden china" appearance of pallor with a light flush.[7]

### Angina [edit]

Angina in setting of heart failure also increases the risk of death. In people with angina, the 5-year mortality rate is 50% if the aortic valve is not replaced.

Angina in the setting of AS occurs due to left ventricular hypertrophy (LVH) that is caused by the constant production of increased pressure required to overcome the pressure gradient caused by the AS. While the muscular layer of the left ventricle thickens, the arteries that supply the muscle do not get significantly longer or bigger, so the muscle may not receive enough blood supply to meet its oxygen requirement. This ischemia may first be evident during exercise when the heart muscle requires increased blood supply to compensate for the increased workload. The individual may complain of anginal chest pain with exertion. At this stage, a cardiac stress test with imaging may be suggestive of ischemia.

Eventually, however, the heart muscle will require more blood supply at rest than can be supplied by the coronary artery branches. At this point there may be signs of *ventricular strain pattern* (ST segment

depression and T wave inversion) on the EKG, suggesting subendocardial ischemia. The subendocardium is the region that is most susceptible to ischemia because it is the most distant from the epicardial coronary arteries.

## Syncope [edit]

Syncope (fainting spells) from aortic valve stenosis is usually exertional.[3][8] In the setting of heart failure it increases the risk of death. In people with syncope, the 3 year mortality rate is 50%, if the aortic valve is not replaced.[9]

It is unclear why aortic stenosis causes syncope. One popular theory is that severe AS produces a nearly fixed cardiac output.[10] When a person with aortic stenosis exercises, their peripheral vascular resistance will decrease as the blood vessels of the skeletal muscles dilate to allow the muscles to receive more blood to allow them to do more work. This decrease in peripheral vascular resistance is normally compensated for by an increase in the cardiac output. Since people with severe AS cannot increase their cardiac output, the blood pressure falls and the person will faint due to decreased blood perfusion to the brain.

A second theory as to why syncope may occur in AS is that during exercise, the high pressures generated in the hypertrophied left ventricle cause a vasodepressor response, which causes a secondary peripheral vasodilation that, in turn, causes decreased blood flow to the brain resulting in loss of consciousness. Indeed, in aortic stenosis, because of the fixed obstruction to blood flow out from the heart, it may be impossible for the heart to increase its output to offset peripheral vasodilation.

A third mechanism may sometimes be operative. Due to the hypertrophy of the left ventricle in aortic stenosis, including the consequent inability of the coronary arteries to adequately supply blood to the myocardium (see "Angina" below), abnormal heart rhythms may develop. These can lead to syncope.

Finally, in calcific aortic stenosis[11][12] at least, the calcification in and around the aortic valve can progress and extend to involve the electrical conduction system of the heart. If that occurs, the result may be heart block - a potentially lethal condition of which syncope may be a symptom.

## Congestive heart failure [edit]

Congestive heart failure (CHF) carries a grave prognosis in people with AS. People with CHF attributable to AS have a 2-year mortality rate of 50% if the aortic valve is not replaced.[*citation needed*] CHF in the setting of AS is due to a combination of left ventricular hypertrophy with fibrosis, systolic dysfunction (a decrease in the ejection fraction) and diastolic dysfunction (elevated filling pressure of the LV).[3]

## Associated symptoms [edit]

In Heyde's syndrome, aortic stenosis is associated with gastrointestinal bleeding due to angiodysplasia of the colon.[13] Recent research has shown that the stenosis causes a form of von Willebrand disease by breaking down its associated coagulation factor (factor VIII-associated antigen, also called von Willebrand factor), due to increased turbulence around the stenotic valve.

## Complications [edit]

Notwithstanding the foregoing, the American Heart Association has recently changed its recommendations regarding antibiotic prophylaxis for endocarditis. Specifically, as of 2007, it is recommended that such prophylaxis should be limited only to those with prosthetic heart valves, those with previous episode(s) of endocarditis, and those with certain types of congenital heart disease.[*citation needed*]

Since the stenosed aortic valve may limit the heart's output, people with aortic stenosis are at risk of syncope and dangerously low blood pressure should they use any of a number of medications for cardiovascular diseases that often coexist with aortic stenosis. Examples include nitroglycerin, nitrates, ACE inhibitors, terazosin (Hytrin), and hydralazine. Note that all of these substances lead to peripheral vasodilation. Under normal circumstances, in the absence of aortic stenosis, the heart is able to increase its output and thereby offset the effect of the dilated blood vessels. In some cases of aortic stenosis, however,

due to the obstruction of blood flow out of the heart caused by the stenosed aortic valve, cardiac output cannot be increased. Low blood pressure or syncope may ensue.

## Causes [edit]

Aortic stenosis is most commonly caused by age-related progressive calcification (>50% of cases) with a mean age of 65 to 70 years. Another major cause of aortic stenosis is the calcification of a congenital bicuspid aortic valve[14] (30-40% of cases) typically presenting earlier, in those aged 40+ to 50+.[6]

Acute rheumatic fever post-inflammatory is the cause of less than 10% of cases.[15] Rare causes of aortic stenosis include Fabry disease, systemic lupus erythematosus, Paget disease, high blood uric acid levels, and infection.[16]

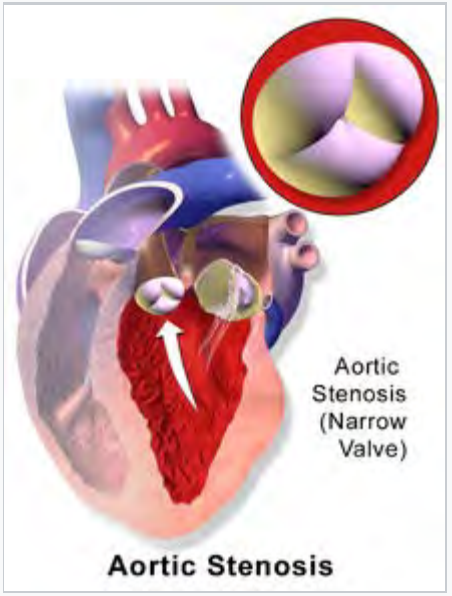

Illustration depicting aortic stenosis

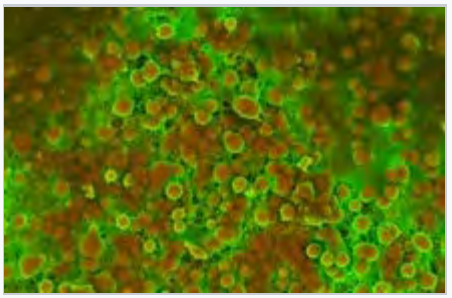
## Pathophysiology [edit]

The human aortic valve normally consists of three cusps or leaflets and has an opening of 3.0-4.0 square centimeters.[5][16] When the left ventricle contracts, it forces blood through the valve into the aorta and subsequently to the rest of the body. When the left ventricle expands again, the aortic valve closes and prevents the blood in the aorta from flowing backward (regurgitation) into the left ventricle. In aortic stenosis, the opening of the aortic valve becomes narrowed or constricted (stenotic) (i.e., due to calcification). Degenerative aortic stenosis, the most common variety, and bicuspid aortic stenosis both begin with damage to endothelial cells from increased mechanical stress.[6][16] Inflammation is thought to be involved in the earlier stages of the pathogenesis of AS and its associated risk factors are known to promote the deposition of LDL cholesterol and a highly damaging substance known as Lipoprotein(a) into the aortic valve resulting in significant damage and stenosis over time.[6][16]



Density-dependent colour scanning electron micrograph of cardiovascular calcification, showing in orange calcium phosphate spherical particles (denser material) and, in green, the extracellular matrix (less dense material).[11]

As a consequence of this stenosis, the left ventricle must generate a higher pressure with each contraction to effectively move blood forward into the aorta.[3][17] Initially, the LV generates this increased pressure by thickening its muscular walls (myocardial hypertrophy). The type of hypertrophy most commonly seen in AS is known as concentric hypertrophy,[3] in which the walls of the LV are (approximately) equally thickened.

In the later stages, the left ventricle dilates, the wall thins, and the systolic function deteriorates (resulting in impaired ability to pump blood forward). Morris and Innasimuthu et al. showed that different coronary anatomy is associated with different valve diseases. Research is ongoing to see if different coronary anatomy might lead to turbulent flow at the level of valves leading to inflammation and degeneration.[18][19][20]

## Diagnosis [edit]

Aortic stenosis is most often diagnosed when it is asymptomatic and can sometimes be detected during routine examination of the heart and circulatory system. Good evidence exists to demonstrate that certain

characteristics of the peripheral pulse can rule in the diagnosis.[21] In particular, there may be a slow and/or sustained upstroke of the arterial pulse, and the pulse may be of low volume. This is sometimes referred to as *pulsus parvus et tardus*.[8][15] There may also be a noticeable delay between the first heart sound (on auscultation) and the corresponding pulse in the carotid artery (so-called 'apical-carotid delay'). In a similar manner, there may be a delay between the appearance of each pulse in the brachial artery (in the arm) and the radial artery (in the wrist).

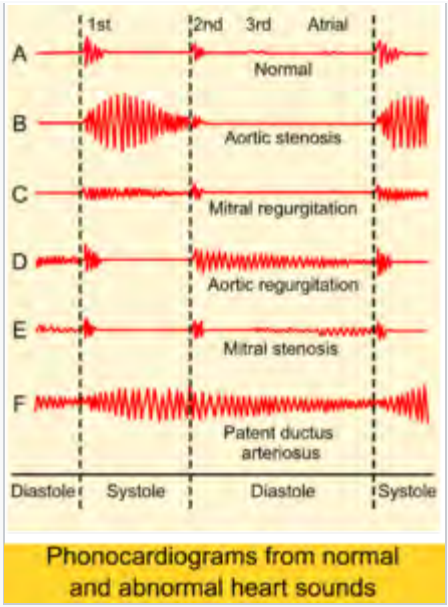
The first heart sound may be followed by a sharp ejection sound ("ejection click") best heard at the lower left sternal border and the apex, and, thus, appear to be "split". The ejection sound, caused by the impact of left ventricular outflow against the partially fused aortic valve leaflets, is more commonly associated with a mobile bicuspid aortic valve than an immobile calcified aortic valve. The intensity of this sound does not vary with respiration, which helps distinguish it from the ejection click produced by a stenotic pulmonary valve, which will diminish slightly in intensity during inspiration.[22]

An easily heard systolic, crescendo-decrescendo (i.e., 'ejection') murmur is heard loudest at the upper right sternal border, at the 2nd right intercostal space,[15] and radiates to the carotid arteries bilaterally.[3][8] The murmur increases with squatting and decreases with standing and isometric muscular contraction such as the Valsalva maneuver, which helps distinguish it from hypertrophic obstructive cardiomyopathy (HOCM). The murmur is louder during expiration but is also easily heard during inspiration. The more severe the degree of the stenosis, the later the peak occurs in the crescendo-decrescendo of the murmur.

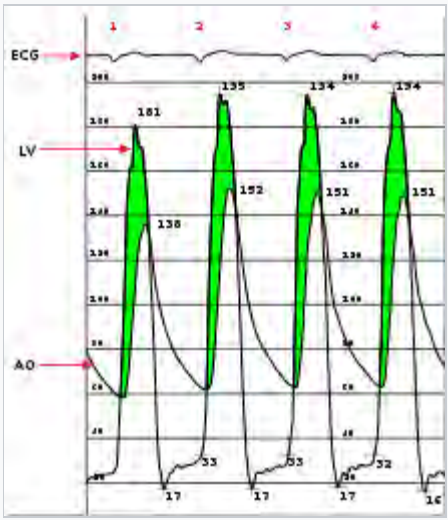
The second heart sound ($A_2$) tends to become decreased and softer as the aortic stenosis becomes more severe.[15] This is a result of the increasing calcification of the valve preventing it from "snapping" shut and producing a sharp, loud sound. Due to increases in left ventricular pressure from the stenotic aortic valve, over time the ventricle may hypertrophy, resulting in a diastolic dysfunction. As a result, one may hear a fourth heart sound due to the stiff ventricle.[8] With continued increases in ventricular pressure, dilatation of the ventricle will occur, and a third heart sound may be manifest.

Finally, aortic stenosis often co-exists with some degree of aortic insufficiency (aortic regurgitation). Hence, the physical exam in aortic stenosis may also reveal signs of the latter, for example, an early diastolic decrescendo murmur. Indeed, when both valve abnormalities are present, the expected findings of either may be modified or may not even be present. Rather, new signs that reflect the presence of simultaneous aortic stenosis and insufficiency, e.g., pulsus bisferiens, emerge.

According to a meta analysis, the most useful findings for ruling in aortic stenosis in the clinical setting were slow rate of rise of the carotid pulse (positive likelihood ratio ranged 2.8–130 across studies), mid to late peak intensity of the murmur (positive likelihood ratio, 8.0–101), and decreased intensity of the second heart sound (positive likelihood ratio, 3.1–50).[21]



Phonocardiograms from normal and abnormal heart sounds



Simultaneous left ventricular and aortic pressure tracings demonstrate a pressure gradient between the left ventricle and aorta, suggesting aortic stenosis. The left ventricle generates higher pressures than what is transmitted to the aorta. The pressure gradient, caused by aortic stenosis, is represented by the green shaded area. (AO = ascending aorta; LV = left ventricle; ECG = electrocardiogram.)

Other peripheral signs include:

- sustained, heaving apex beat,[8] which is not displaced unless systolic dysfunction of the left ventricle has developed
- A precordial thrill[8]
- narrowed pulse pressure

## Electrocardiogram [edit]

Although aortic stenosis does not lead to any *specific* findings on the electrocardiogram (ECG), it still often leads to a number of electrocardiographic abnormalities. ECG manifestations of left ventricular hypertrophy (LVH) are common in aortic stenosis[6][8] and arise as a result of the stenosis having placed a chronically high pressure load on the left ventricle (with LVH being the expected response to chronic pressure loads on the left ventricle no matter what the cause).

As noted above, the calcification process that occurs in aortic stenosis can progress to extend beyond the aortic valve and into the electrical conduction system of the heart. Evidence of this phenomenon may rarely include ECG patterns characteristic of certain types of heart block such as Left bundle branch block.[6]

## Heart catheterization [edit]

Cardiac chamber catheterization provides a definitive diagnosis, indicating severe stenosis in valve area of <1.0 $cm^2$ (normally about 3 $cm^2$).[23] It can directly measure the pressure on both sides of the aortic valve. The pressure gradient may be used as a decision point for treatment. It is useful in symptomatic people before surgery.[8] The standard for diagnosis of aortic stenosis is noninvasive testing with echocardiography. Cardiac catheterization is reserved for cases in which there is discrepancy between the clinical picture and non-invasive testing, due to risks inherent to crossing the aortic valve such as stroke.[6]

## Echocardiogram [edit]

Echocardiogram (heart ultrasound) is the best non-invasive tool / test to evaluate the aortic valve anatomy and function.

The aortic valve area can be calculated non-invasively using echocardiographic flow velocities. Using the velocity of the blood through the valve, the pressure gradient across the valve can be calculated by the continuity equation or using the modified Bernoulli's equation:

$$\text{Gradient} = 4(\text{velocity})^2 \text{ mmHg}$$

| Severity of aortic stenosis[15] | | |
|---|---|---|
| **Degree** | **Mean gradient (mmHg)** | **Aortic valve area ($cm^2$)** |
| Mild | <25 | >1.5 |
| Moderate | 25 - 40 | 1.0 - 1.5 |
| Severe | >40 | < 1.0 |
| Very severe | >70 | < 0.6 |

A normal aortic valve has a gradient of only a few mmHg. A decreased valvular area causes increased pressure gradient, and these parameters are used to classify and grade the aortic stenosis as mild, moderate or severe. The pressure gradient can be abnormally low in the presence of mitral stenosis, heart failure, co-existent aortic regurgitation and also ischaemic heart disease (disease related to decreased blood supply and oxygen causing ischemia).

Echocardiogram may also show left ventricular hypertrophy, thickened and immobile aortic valve and dilated aortic root.[8] However, it may appear deceptively normal in acute cases.[15]

## Chest X-ray [edit]

A chest X-ray can also assist in the diagnosis and provide clues as to the severity of the disease, showing the degree of calcification of the valve, and in a chronic condition, an enlarged left ventricle[8][15] and atrium.[8]

# Management [edit]

Treatment is generally not necessary in people without symptoms.[8] In moderate cases, echocardiography is performed every 1–2 years to monitor the progression, possibly complemented with a cardiac stress test.[15] In severe cases, echocardiography is performed every 3–6 months.[15] In both moderate and mild cases, the person should immediately make a revisit or be admitted for inpatient care if any new related symptoms appear.[15] There are no therapeutic options currently available to treat people with aortic valve stenosis; however, studies have indicated that the disease occurs as a result of active cellular processes, suggesting that targeting these processes may lead to viable therapeutic approaches.[24]

## Medication [edit]

The effect of statins on the progression of AS is unclear. The latest trials do not show any benefit in slowing AS progression,[6] but did demonstrate a decrease in ischemic cardiovascular events.[3]

In general, medical therapy has relatively poor efficacy in treating aortic stenosis.[8] However, it may be useful to manage commonly coexisting conditions that correlate with aortic stenosis:

- Any angina is generally treated with beta-blockers and/or calcium blockers.[15] Nitrates are contraindicated due to their potential to cause profound hypotension in aortic stenosis.[25]
- Any hypertension is treated aggressively, but caution must be taken in administering beta-blockers.[15]
- Any heart failure is generally treated with digoxin and diuretics, and, if not contraindicated, cautious administration of ACE inhibitors.[15]

While observational studies demonstrated an association between lowered cholesterol with statins and decreased progression, a randomized clinical trial published in 2005 failed to find any effect on calcific aortic stenosis. A 2007 study did demonstrate a slowing of aortic stenosis with the statin rosuvastatin.[6][26]

## Aortic valve repair [edit]

*Main article: aortic valve repair*

Aortic valve repair or aortic valve reconstruction describes the reconstruction of both form and function of the native and dysfunctioning aortic valve. Most frequently it is applied for the treatment of aortic regurgitation. It can also become necessary for the treatment of an aortic aneurysm, less frequently for congenital aortic stenosis.[27]

## Aortic valve replacement [edit]

*Main article: aortic valve replacement*

In adults, symptomatic severe aortic stenosis usually requires aortic valve replacement (AVR).[3] While AVR has been the standard of care for aortic stenosis for several decades, currently aortic valve replacement approaches include open heart surgery, minimally invasive cardiac surgery (MICS) and minimally invasive catheter-based (percutaneous) aortic valve replacement.[28][29] However, surgical aortic valve replacement is well studied and generally has a good and well established longer term prognosis.[30]

A diseased aortic valve is most commonly replaced using a surgical procedure with either a mechanical or a tissue valve. The procedure is done either in an open-heart surgical procedure or, in a smaller but growing number of cases, a minimally invasive cardiac surgery (MICS) procedure.

## Transcatheter aortic valve replacement [edit]

Globally more than 250,000 people have received transcatheter aortic valve replacement (TAVR). For people who are not candidates for surgical valve replacement and most patients who are older than 75, TAVR may be a suitable alternative.[28][29]

### Balloon valvuloplasty [edit]

For infants and children, balloon valvuloplasty, where a balloon is inflated to stretch the valve and allow greater flow, may also be effective. In adults, however, it is generally ineffective, as the valve tends to return to a stenosed state. The surgeon will make a small incision at the top of the person's leg and proceed to insert the balloon into the artery. The balloon is then advanced up to the valve and is inflated to stretch the valve open.[31]

### Heart failure [edit]

Acute decompensated heart failure due to AS may be temporarily managed by an intra-aortic balloon pump while pending surgery.[32] In those with high blood pressure nitroprusside may be carefully used.[1] Phenylephrine may be used in those with very low blood pressure.[2]

## Prognosis [edit]

If untreated, severe symptomatic aortic stenosis carries a poor prognosis with a 2-year mortality rate of 50-60% and a 3-year survival rate of less than 30%.[33] Prognosis after aortic valve replacement for people who are younger than 65 is about five years less than that of the general population; for people older than 65 it is about the same.[30]

## Epidemiology [edit]

Approximately 2% of people over the age of 65, 3% of people over age 75,[3] and 4% percent of people over age 85 have aortic valve stenosis.[34] The prevalence is increasing with the aging population in North America and Europe.[35]

Risk factors known to influence disease progression of AS include lifestyle habits similar to those of coronary artery disease such as hypertension, advanced age, being male, hyperlipidemia, diabetes mellitus, cigarette smoking, metabolic syndrome, and end-stage kidney disease.[3][6][16]

## History [edit]

Aortic stenosis was first described by French physician Lazare Rivière in 1663.[5]

## Research [edit]

People on bisphosphonates have less progression of aortic stenosis and some regressed.[36][36][37] This finding led to multiple trials which are ongoing. Subsequent research has failed to confirm the initial positive result.[38]

# Atrial fibrillation

From Wikipedia, the free encyclopedia

**Atrial fibrillation** (**AF** or **A-fib**) is an abnormal heart rhythm characterized by rapid and irregular beating.[1] Often it starts as brief periods of abnormal beating which become longer and possibly constant over time.[2] Most episodes have no symptoms.[3] Occasionally there may be heart palpitations, fainting, lightheadedness, shortness of breath, or chest pain.[4] The disease is associated with an increased risk of heart failure, dementia, and stroke.[3] It is a type of supraventricular tachycardia.[5]

High blood pressure and valvular heart disease are the most common alterable risk factors for AF.[6][7] Other heart-related risk factors include heart failure, coronary artery disease, cardiomyopathy, and congenital heart disease.[6] In the developing world valvular heart disease often occurs as a result of rheumatic fever.[8] Lung-related risk factors include COPD, obesity, and sleep apnea.[3] Other factors include excess alcohol intake, diabetes mellitus, and thyrotoxicosis.[3][8] However, half of cases are not associated with one of these risks.[3] A diagnosis is made by feeling the pulse and may be confirmed using an electrocardiogram (ECG).[9] A typical ECG in AF shows no P waves and an irregular ventricular rate.[9]

AF is often treated with medications to slow the heart rate to a near normal range (known as rate control) or to convert the rhythm to normal sinus rhythm (known as rhythm control).[6] Electrical cardioversion can also be used to convert AF to a normal sinus rhythm and is often used emergently if the person is unstable.[10] Ablation may prevent recurrence in some people.[11] Depending on the risk of stroke either aspirin or anti-clotting medications such as warfarin or a novel oral anticoagulant may be recommended.[3] While these medications reduce this risk, they increase rates of major bleeding.[12]

Atrial fibrillation is the most common serious abnormal heart rhythm.[3] In Europe and North America, as of 2014, it affects about 2% to 3% of the population.[2] This is an increase from 0.4 to 1% of the population around 2005.[13] In the developing world about 0.6% of males and 0.4% of females are affected. The percentage of people with AF increases with age with 0.14% under 50 years old, 4% between 60 and 70 years old, and 14% over 80 years old being affected.[2] A-fib and atrial flutter [14]

**Atrial fibrillation**

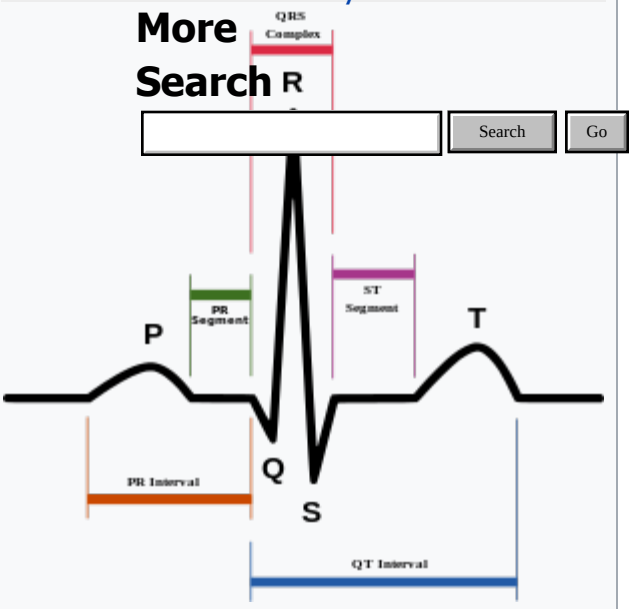

Diagram of normal sinus rhythm as seen on ECG. In atrial fibrillation the P waves, which represent depolarization of the top of the heart, are absent.

resulted in 112,000 deaths in 2013, up from 29,000 in 1990. The first known report of an irregular pulse was by Jean-Baptiste de Sénac in 1749. This was first documented by ECG in 1909 by Thomas Lewis.[3]

Video explanation

## Signs and symptoms [edit]

AF is usually accompanied by symptoms related to a rapid heart rate. Rapid and irregular heart rates may be perceived as palpitations or exercise intolerance and occasionally may produce anginal chest pain (if the high heart rate causes ischemia). Other possible symptoms include congestive symptoms such as shortness of breath or swelling. The arrhythmia is sometimes only identified with the onset of a stroke or a transient ischemic attack (TIA). It is not uncommon for a patient to first become aware of AF from a routine physical examination or ECG, as it often does not cause symptoms.[13]

Normal rhythm tracing (top) Atrial fibrillation (bottom)

Since most cases of AF are secondary to other medical problems, the presence of chest pain or angina, signs and symptoms of hyperthyroidism (an overactive thyroid gland) such as weight loss and diarrhea, and symptoms suggestive of lung disease can indicate an underlying cause. A history of stroke or TIA, as well as high blood pressure, diabetes, heart failure, or rheumatic fever may indicate whether someone with AF is at a higher risk of complications.[13] The risk of a blood clot forming in the left atrium, breaking off, and then traveling in the bloodstream can be assessed using the CHADS2 score or CHA2DS2-VASc score.

### Rapid heart rate [edit]

Presentation is similar to other forms of rapid heart rate and may be asymptomatic.[15] Palpitations and chest discomfort are common complaints.[15] The rapid uncoordinated heart rate may result in reduced cardiac output, with the heart being unable to provide adequate blood flow and therefore oxygen delivery to the rest of the body. Common symptoms of uncontrolled atrial fibrillation may include shortness of breath,[15] shortness of breath when lying flat, dizziness, and sudden onset of shortness of breath during the night. This may progress to swelling of the lower extremities, a manifestation of congestive heart failure. Due to inadequate cardiac output, individuals with AF may also complain of light-headedness,[15] may feel like they are about to faint, or may actually lose consciousness.

AF can cause respiratory distress due to congestion in the lungs. By definition, the heart rate will be greater than 100 beats per minute. Blood pressure may be variable, and often difficult to measure as the beat-by-beat variability causes problems for most digital (oscillometric) non-invasive blood pressure monitors. For this reason, when determining heart rate in AF, direct cardiac auscultation is recommended. Low blood pressure is most concerning and a sign that immediate treatment is required. Many of the symptoms associated with uncontrolled atrial fibrillation are a manifestation of congestive heart failure due to the reduced cardiac output. Respiratory rate will be increased in the presence of respiratory distress. Pulse oximetry may confirm the presence of hypoxia related to any precipitating factors such as pneumonia. Examination of the jugular veins may reveal elevated pressure (jugular venous distention). Lung exam may reveal crackles, which are suggestive of pulmonary edema. Heart exam will reveal a rapid irregular rhythm.

## Causes [edit]

AF is linked to several forms of cardiovascular disease, but may occur in otherwise normal hearts. Cardiovascular factors known to be associated with the development of AF include high blood pressure, coronary artery disease, mitral stenosis (e.g., due to rheumatic heart disease or mitral valve prolapse), mitral regurgitation, left atrial enlargement, hypertrophic cardiomyopathy (HCM), pericarditis, congenital heart disease, and previous heart surgery. Additionally, lung diseases (such as pneumonia, lung cancer, pulmonary embolism, and sarcoidosis) are thought to play a role in certain people. Disorders of breathing during sleep such as obstructive sleep apnea (OSA) are also associated with AF.[16] Obesity is a risk factor for AF.[17] Hyperthyroidism and subclinical hyperthyroidism are associated with AF development.[18] Caffeine consumption does not appear to be associated with AF,[19] but excessive alcohol consumption ("binge drinking" or "holiday heart syndrome") is linked to AF.[20]

### Genetics [edit]

A family history of AF may increase the risk of AF. A study of more than 2,200 people found an increased risk factor for AF of 1.85 for those that had at least one parent with AF.[21][22][23] Various genetic mutations may be responsible.[24][25]

Four types of genetic disorder are associated with atrial fibrillation:[26]

- Familial AF as a monogenic disease
- Familial AF presenting in the setting of another inherited cardiac disease (hypertrophic cardiomyopathy, dilated cardiomyopathy, familial amyloidosis)
- Inherited arrhythmic syndromes (congenital long QT syndrome, short QT syndrome, Brugada syndrome)
- Non-familial AF associated with genetic backgrounds (polymorphism in the ACE gene) that may predispose to atrial fibrillation

## Pathophysiology [edit]

In AF, the normal regular electrical impulses generated by the sinoatrial node in the right atrium of the heart are overwhelmed by disorganized electrical impulses usually originating in the roots of the pulmonary veins. This leads to irregular conduction of ventricular impulses that generate the heartbeat.

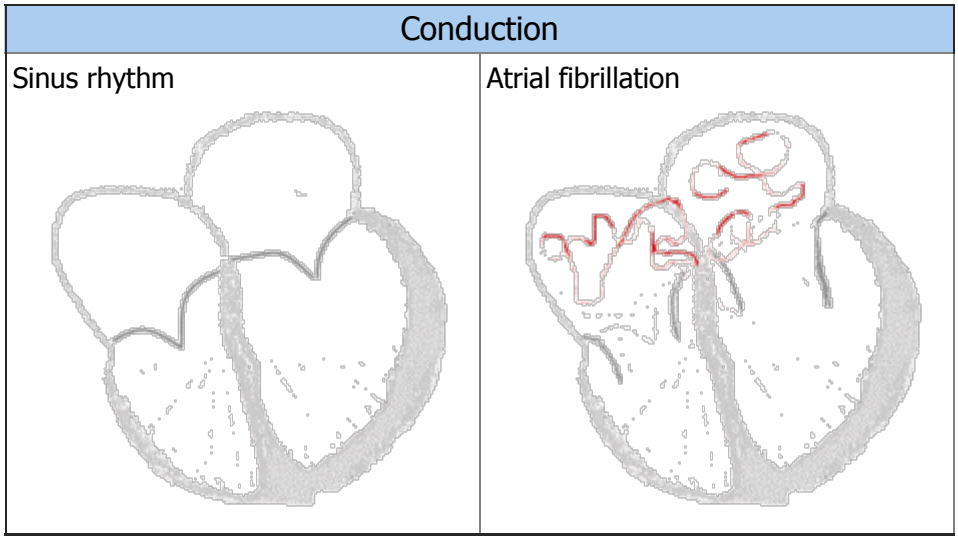
## Pathology [edit]

The primary pathologic change seen in atrial fibrillation is the progressive fibrosis of the atria. This fibrosis is due primarily to atrial dilation; however, genetic causes and inflammation may be factors in some individuals. Dilation of the atria can be due to almost any structural abnormality of the heart that can cause a rise in the pressure within the heart. This includes valvular heart disease (such as mitral stenosis, mitral regurgitation, and tricuspid regurgitation), hypertension, and congestive heart failure. Any inflammatory state that affects the heart can cause fibrosis of the atria. This is typically due to sarcoidosis but may also be due to autoimmune disorders that create autoantibodies against myosin heavy chains. Mutation of the *lamin AC* gene is also associated with fibrosis of the atria that can lead to atrial fibrillation.

Once dilation of the atria has occurred, this begins a chain of events that leads to the activation of the renin aldosterone angiotensin system (RAAS) and subsequent increase in matrix metalloproteinases and disintegrin, which leads to atrial remodeling and fibrosis, with loss of atrial muscle mass. This process is not immediate, and experimental studies have revealed patchy atrial fibrosis may precede the occurrence of atrial fibrillation and may progress with prolonged durations of atrial fibrillation.

Fibrosis is not limited to the muscle mass of the atria and may occur in the sinus node (SA node) and atrioventricular node (AV node), correlating with sick sinus syndrome. Prolonged episodes of atrial fibrillation have been shown to correlate with prolongation of the sinus node recovery time,[13] suggesting that dysfunction of the SA node is progressive with prolonged episodes of atrial fibrillation.

## Electrophysiology [edit]



The normal electrical conduction system of the heart allows the impulse that is generated by the sinoatrial node (SA node) of the heart to be propagated to and stimulate the myocardium (muscular layer of the heart). When the myocardium is stimulated, it contracts. It is the ordered stimulation of the myocardium that allows efficient contraction of the heart, thereby allowing blood to be pumped to the body.

There are multiple theories about the etiology of atrial fibrillation. An important theory is that, in atrial fibrillation, the regular impulses produced by the sinus node for a normal heartbeat are overwhelmed by rapid electrical discharges produced in the atria and adjacent parts of the pulmonary veins. Sources of these disturbances are either automatic foci, often localized at one of the pulmonary veins, or a small number of localized sources in the form of either reentrant electrical spiral waves (rotors) or repetitive focal beats; these localized sources may be found in the left atrium near the pulmonary veins or in a variety of other locations through both the left or right atrium.

Because recovery of the atria from excitation is heterogeneous, the electrical waves generated by the AF sources undergo repetitively, spatially distributed breakup and fragmentation in a process known as "fibrillatory conduction". Another theory is the multiple wavelet theory.[27]

AF can be distinguished from atrial flutter (AFL), which appears as an organized electrical circuit usually in the right atrium. AFL produces characteristic saw-toothed F-waves of constant amplitude and frequency on an ECG whereas AF does not. In AFL, the discharges circulate rapidly at a rate of 300 beats per minute (bpm) around the atrium. In AF, there is no regularity of this kind, except at the sources where the local activation rate can exceed 500 bpm.

Although the electrical impulses of AF occur at a high rate, most of them do not result in a heart beat. A heart beat results when an electrical impulse from the atria passes through the atrioventricular (AV) node to the ventricles and causes them to contract. During AF, if all of the impulses from the atria passed

through the AV node, there would be severe ventricular tachycardia, resulting in a severe reduction of cardiac output. This dangerous situation is prevented by the AV node since its limited conduction velocity reduces the rate at which impulses reach the ventricles during AF.[28]

## Diagnosis [edit]

The evaluation of atrial fibrillation involves a determination of the cause of the arrhythmia, and classification of the arrhythmia. Diagnostic investigation of AF typically includes a complete history and physical examination, ECG, transthoracic echocardiogram, complete blood count, and serum thyroid stimulating hormone level.[15]

If a patient presents with a sudden onset of severe symptoms, other forms of abnormal heart rhythm with high heart rate must be ruled out, as some may be immediately life-threatening, such as ventricular tachycardia. While most patients will be placed on continuous cardiorespiratory monitoring, an ECG is essential for diagnosis. Provoking causes should be sought out.

A 12-lead ECG showing atrial fibrillation at approximately 150 beats per minute

### Screening [edit]

Limited studies have suggested that screening for atrial fibrillation in those 65 years and older increases the number of cases of atrial fibrillation detected.[29]

### Minimal evaluation [edit]

In general, the minimal evaluation of atrial fibrillation should be performed in all individuals with AF. The goal of this evaluation is to determine the general treatment regimen for the individual. If results of the general evaluation warrant it, further studies may then be performed.

### History and physical examination [edit]

The history of the individual's atrial fibrillation episodes is probably the most important part of the evaluation. Distinctions should be made between those who are entirely asymptomatic when they are in AF (in which case the AF is found as an incidental finding on an ECG or physical examination) and those who have gross and obvious symptoms due to AF and can pinpoint whenever they go into AF or revert to sinus rhythm.

### Routine bloodwork [edit]

While many cases of AF have no definite cause, it may be the result of various other problems. Hence, kidney function and electrolytes are routinely determined, as well as thyroid-stimulating hormone (commonly suppressed in hyperthyroidism and of relevance if amiodarone is administered for treatment) and a blood count.[13]

In acute-onset AF associated with chest pain, cardiac troponins or other markers of damage to the heart muscle may be ordered. Coagulation studies (INR/aPTT) are usually performed, as anticoagulant medication may be commenced.[13]

### Electrocardiogram [edit]

Atrial fibrillation is diagnosed on an electrocardiogram (ECG), an investigation performed routinely whenever an irregular heart beat is suspected. Characteristic findings are the absence of P waves, with disorganized

ECG of atrial fibrillation (top) and normal sinus rhythm (bottom). The purple arrow indicates a P wave, which is lost in atrial fibrillation.

electrical activity in their place, and irregular R-R intervals due to irregular conduction of impulses to the ventricles.[13] At very fast heart rates atrial fibrillation may look more regular, which may make it more difficult to separate from SVT or ventricular tachycardia.[30]

QRS complexes should be narrow, signifying that they are initiated by normal conduction of atrial electrical activity through the intraventricular conduction system. Wide QRS complexes are worrisome for ventricular tachycardia, although, in cases where there is a disease of the conduction system, wide complexes may be present in A-Fib with rapid ventricular response.

If paroxysmal AF is suspected but an ECG during an office visit shows only a regular rhythm, AF episodes may be detected and documented with the use of ambulatory Holter monitoring (e.g., for a day). If the episodes are too infrequent to be detected by Holter monitoring with reasonable probability, then the patient can be monitored for longer periods (e.g., a month) with an ambulatory event monitor.[13]

## Echocardiography [edit]

In general, a non-invasive transthoracic echocardiogram (TTE) is performed in newly diagnosed AF, as well as if there is a major change in the patient's clinical state. This ultrasound-based scan of the heart may help identify valvular heart disease (which may greatly increase the risk of stroke), left and right atrial size (which indicates likelihood that AF may become permanent), left ventricular size and function, peak right ventricular pressure (pulmonary hypertension), presence of left atrial thrombus (low sensitivity), presence of left ventricular hypertrophy and pericardial disease.[13]

Significant enlargement of both the left and right atria is associated with long-standing atrial fibrillation and, if noted at the initial presentation of atrial fibrillation, suggests that the atrial fibrillation is likely to be of a longer duration than the individual's symptoms.

## Extended evaluation [edit]

In general, an extended evaluation is not necessary for most individuals with atrial fibrillation and is performed only if abnormalities are noted in the limited evaluation, if a reversible cause of the atrial fibrillation is suggested, or if further evaluation may change the treatment course.

## Chest X-ray [edit]

In general, a chest X-ray is performed only if a pulmonary cause of atrial fibrillation is suggested, or if other cardiac conditions are suspected (in particular congestive heart failure.) This may reveal an underlying problem in the lungs or the blood vessels in the chest.[13] In particular, if an underlying pneumonia is suggested, then treatment of the pneumonia may cause the atrial fibrillation to terminate on its own.

## Transesophageal echocardiogram [edit]

A regular echocardiogram (transthoracic echo/TTE) has a low sensitivity for identifying blood clots in the heart. If this is suspected (e.g., when planning urgent electrical cardioversion) a transesophageal echocardiogram/TEE (or TOE where British spelling is used) is preferred.[13]

The TEE has much better visualization of the left atrial appendage than transthoracic echocardiography.[31] This structure, located in the left atrium, is the place where a blood clot forms in more than 90% of cases [32][33]

in non-valvular (or non-rheumatic) atrial fibrillation. TEE has a high sensitivity for locating thrombi in this area and can also detect sluggish bloodflow in this area that is suggestive of blood clot formation.[31]

If no blood clot is seen on TEE, the incidence of stroke immediately after cardioversion is performed is very low.[*citation needed*]

## Ambulatory Holter monitoring [edit]

A Holter monitor is a wearable ambulatory heart monitor that continuously monitors the heart rate and heart rhythm for a short duration, typically 24 hours. In individuals with symptoms of significant shortness of breath with exertion or palpitations on a regular basis, a Holter monitor may be of benefit to determine whether rapid heart rates (or unusually slow heart rates) during atrial fibrillation are the cause of the symptoms.

## Exercise stress testing [edit]

Some individuals with atrial fibrillation do well with normal activity but develop shortness of breath with exertion. It may be unclear whether the shortness of breath is due to a blunted heart rate response to exertion caused by excessive atrioventricular node-blocking agents, a very rapid heart rate during exertion, or other underlying conditions such as chronic lung disease or coronary ischemia. An exercise stress test will evaluate the individual's heart rate response to exertion and determine if the AV node blocking agents are contributing to the symptoms.

## Classification [edit]

The American College of Cardiology (ACC), American Heart Association (AHA), and the European Society of Cardiology (ESC) recommend in their guidelines the following classification system based on simplicity and clinical relevance.[13]

**Classification system**

| AF category | Defining characteristics |
|---|---|
| First detected | only one diagnosed episode |
| Paroxysmal | recurrent episodes that stop on their own in less than 7 days |
| Persistent | recurrent episodes that last more than 7 days |
| Permanent | an ongoing long-term episode |

All people with AF are initially in the category called *first detected AF*. These patients may or may not have had previous undetected episodes. If a first detected episode stops on its own in less than 7 days and then another episode begins, later on, the category changes to paroxysmal AF. Although patients in this category have episodes lasting up to 7 days, in most cases of paroxysmal AF the episodes will stop in less than 24 hours. If the episode lasts for more than 7 days, it is unlikely to stop on its own,[34] and is then known as persistent AF. In this case, cardioversion can be used to stop the episode. If cardioversion is unsuccessful or not attempted and the episode continues for a long time (e.g., a year or more), the patient's AF is then known as permanent.

Episodes that last less than 30 seconds are not considered in this classification system. Also, this system does not apply to cases where the AF is a secondary condition that occurs in the setting of a primary condition that may be the cause of the AF.

About half of people with AF have permanent AF, while a quarter have paroxysmal AF, and a quarter have persistent AF.[2]

In addition to the above four AF categories, which are mainly defined by episode timing and termination, the ACC/AHA/ESC guidelines describe additional AF categories in terms of other characteristics of the patient.[13]

- *Lone atrial fibrillation* (LAF) – absence of clinical or echocardiographic findings of other cardiovascular disease (including hypertension), related pulmonary disease, or cardiac abnormalities such as

enlargement of the left atrium, and age under 60 years
- *Nonvalvular AF* – absence of rheumatic mitral valve disease, a prosthetic heart valve, or mitral valve repair
- *Secondary AF* – occurs in the setting of a primary condition that may be the cause of the AF, such as acute myocardial infarction, cardiac surgery, pericarditis, myocarditis, hyperthyroidism, pulmonary embolism, pneumonia, or other acute pulmonary disease

# Management [edit]

*Main article: Management of atrial fibrillation*

The main goals of treatment are to prevent circulatory instability and stroke. Rate or rhythm control are used to achieve the former, whereas anticoagulation is used to decrease the risk of the latter.[35] If cardiovascularly unstable due to uncontrolled tachycardia, immediate cardioversion is indicated.[13] An exercise program may be useful.[*citation needed*]

## Anticoagulants [edit]

Anticoagulation can be used to reduce the risk of stroke from AF. Anticoagulation is recommended in most people other than those at low risk of stroke[36] or those at high risk of bleeding.

The risk of stroke from non-valvular AF can be estimated using the $CHA_2DS_2$-VASc score. A 2014 AHA/ACC/HRS guideline said that for nonvalvular AF, anticoagulation is recommended if there is a score of 2 or more, not using anticoagulation may be considered if there is a score of 1, and not using anticoagulation is reasonable if there is a score of 0.[37]

Anticoagulation can be achieved through a number of means including warfarin,[38] heparin, dabigatran, rivaroxaban[39] edoxaban,[40] and apixaban.[41] Aspirin is less effective in reducing the risk of stroke and may not be safer with respect to major bleeding (including intracranial bleeding) than well-managed warfarin or a non-vitamin K oral anticoagulant (NOAC).[42] A number of issues should be considered, including the cost of NOACs, risk of stroke, risk of falls, compliance, and speed of desired onset of anticoagulation.[43]

For those with non-valvular atrial fibrillation, the NOACs (rivaroxaban, dabigatran, apixaban) are neither superior nor worse than warfarin in preventing non-hemorrhagic stroke and systemic embolic events.[44][45] They have a lower risk of intracranial bleeding compared to warfarin; however, dabigatran is associated with a higher risk of gastrointestinal bleeding.[44][45]

## Rate versus rhythm control [edit]

There are two ways to approach atrial fibrillation using medications: rate control and rhythm control. Both methods have similar outcomes.[46] *Rate control* lowers the heart rate closer to normal, usually 60 to 100 bpm, without trying to convert to a regular rhythm. *Rhythm control* tries to restore a normal heart rhythm in a process called cardioversion and maintains the normal rhythm with medications. Studies suggest that rhythm control is more important in the acute setting AF, whereas rate control is more important in the chronic phase.

There is no difference in risk of stroke in people having converted to a normal rhythm with antiarrhythmic treatment compared to those with only rate control.[47][*non-primary source needed*] AF is associated with a reduced quality of life, and, while some studies indicate that rhythm control leads to a higher quality of life, some did not find a difference.[48]

A further study focused on rhythm control in people with AF with heart failure, based on the idea that AF increases mortality in this group. In this setting, rhythm control offered no advantage compared to rate control.[49][*non-primary source needed*]

In those with a fast ventricular response, intravenous magnesium significantly increases the chances of

successful rate and rhythm control in the urgent setting without major side-effects.[50] A person with poor vital signs, mental status changes, preexcitation, or chest pain often will go to immediate treatment with synchronized DC cardioversion.[13] Otherwise the decision of rate control versus rhythm control using drugs is made. This is based on a number of criteria that includes whether or not symptoms persist with rate control.

## Rate control [edit]

Rate control to a target heart rate of 110 bpm is recommended in most people.[51] Lower heart rates may be recommended in those with left ventricular hypertrophy or reduced left ventricular function.[52] Rate control is achieved with medications that work by increasing the degree of block at the level of the AV node, decreasing the number of impulses that conduct into the ventricles. This can be done with:[13][53]

- Beta blockers (preferably the "cardioselective" beta blockers such as metoprolol, atenolol, bisoprolol, nebivolol)
- Non-dihydropyridine calcium channel blockers (e.g., diltiazem or verapamil)
- Cardiac glycosides (e.g., digoxin) – have less use, apart from in older people who are sedentary. They are not as effective as either beta blockers or calcium channel blockers.[6]

In those with chronic disease either beta blockers or calcium channel blockers are recommended.[51]

In addition to these agents, amiodarone has some AV node blocking effects (in particular when administered intravenously), and can be used in individuals when other agents are contraindicated or ineffective (particularly due to hypotension).

## Cardioversion [edit]

Cardioversion is the attempt to switch an irregular heartbeat to a normal heartbeat using electrical or chemical means.[13]

- *Electrical cardioversion* involves the restoration of normal heart rhythm through the application of a DC electrical shock. Exact placement of the pads does not appear important.[54]
- *Chemical cardioversion* is performed with drugs, such as amiodarone, dronedarone,[55] procainamide, dofetilide, ibutilide, propafenone, or flecainide.

After successful cardioversion the heart may be in a stunned state, which means that there is a normal rhythm but restoration of normal atrial contraction has not yet occurred.[56]

## Surgery [edit]

## Ablation [edit]

In young people with little-to-no structural heart disease where rhythm control is desired and cannot be maintained by medication or cardioversion, then radiofrequency ablation or cryoablation may be attempted and is preferred over years of drug therapy.[13][57] Although radiofrequency ablation is becoming an accepted intervention in selected younger patients, there is currently a lack of evidence that ablation reduces all-cause mortality, stroke, or heart failure.[58] There are two ongoing clinical trials (CABANA [Catheter Ablation Versus Antiarrhythmic Drug Therapy for Atrial Fibrillation] and EAST [Early Therapy of Atrial Fibrillation for Stroke Prevention Trial]) that should provide new information for assessing whether AF catheter ablation is superior to more standard therapy.[59]

The Maze procedure, first performed in 1987, is an effective invasive surgical treatment that is designed to create electrical blocks or barriers in the atria of the heart, forcing electrical impulses that stimulate the heartbeat to travel down to the ventricles. The idea is to force abnormal electrical signals to move along one, uniform path to the lower chambers of the heart (ventricles), thus restoring the normal heart rhythm.[60]

AF often occurs after cardiac surgery and is usually self-limiting. It is strongly associated with age,

preoperative hypertension, and the number of vessels grafted. Measures should be taken to control hypertension preoperatively to reduce the risk of AF. Also, people with a higher risk of AF, e.g., people with pre-operative hypertension, more than 3 vessels grafted, or greater than 70 years of age, should be considered for prophylactic treatment. Postoperative pericardial effusion is also suspected to be the cause of atrial fibrillation. Prophylaxis may include prophylactic postoperative rate and rhythm management. Some authors perform posterior pericardiotomy to reduce the incidence of postoperative AF.[61] When AF occurs, management should primarily be rate and rhythm control. However, cardioversion may be employed if the person is hemodynamically unstable, highly symptomatic, or persists for 6 weeks after discharge. In persistent cases, anticoagulation should be used.

### Left atrial appendage occlusion [edit]

There is tentative evidence that left atrial appendage occlusion therapy may reduce the risk of stroke in people with non-valvular AF as much as warfarin.[62]

## Prognosis [edit]

Atrial fibrillation increases the risk of heart failure by 11 per 1000, kidney problems by 6 per 1000, death by 4 per 1000, stroke by 3 per 1000, and coronary heart disease by 1 per 1000.[63] Women have a worse outcome overall than men.[64]

### Blood clots [edit]

*See also: CHADS score*

### Prediction of embolism [edit]

Determining the risk of an embolism causing a stroke is important for guiding the use of anticoagulants. The most accurate clinical prediction rules are:[65]

- CHADS2
- CHA2DS2-VASc

Both the CHADS2 and the CHA2DS2-VASc score predict future stroke risk in people with a-fib with CHA2DS2-VASc being more accurate. Some that had a CHADS2 score of 0 had a CHA2DS2-VASc score of 3, with a 3.2% annual risk of stroke. Thus a CHA2DS2-VASc score of 0 is considered very low risk.[66]

### Mechanism of thrombus formation [edit]

In atrial fibrillation, the lack of an organized atrial contraction can result in some stagnant blood in the left atrium (LA) or left atrial appendage (LAA). This lack of movement of blood can lead to thrombus formation (blood clotting). If the clot becomes mobile and is carried away by the blood circulation, it is called an embolus. An embolus proceeds through smaller and smaller arteries until it plugs one of them and prevents blood from flowing through the artery. This process results in end organ damage due to loss of nutrients, oxygen, and removal of cellular waste products. Emboli in the brain may result in an ischemic stroke or a transient ischemic attack (TIA).

More than 90% of cases of thrombi associated with non-valvular atrial fibrillation evolve in the left atrial appendage.[32] However, the LAA lies in close relation to the free wall of the left ventricle and thus the LAA's emptying and filling, which determines its degree of blood stagnation, may be helped by the motion of the wall of the left ventricle, if there is good ventricular function.[67]

If the LA is enlarged, there is an increased risk of thrombi that originate in the LA. Moderate to severe, non-rheumatic, mitral regurgitation (MR) reduces this risk of stroke.[68][*non-primary source needed*] This risk reduction may be due to a beneficial swirling effect of the MR blood flow into the LA.[69]

### Mitral valve [edit]

Atrial fibrillation and a corresponding enlargement of the left atrium may cause an increase in size of the mitral valve annulus.[70][*non-primary source needed*]

With a sinus rhythm, the mitral annulus undergoes dynamic changes during the cardiac cycle. For example, at the end of diastole the annular area is smaller than at the end of systole. A possible reason for this dynamic size difference is that the coordinated contraction of the left atrium acts like a sphincter about the mitral annulus and reduces its size. This may be important for mitral valve competence so that it does not leak when the left ventricle pumps blood. However, when the left atrium fibrillates, this sphincter action is not possible and may contribute to, or result in, mitral regurgitation in some cases.[70][*non-primary source needed*]

## Epidemiology [edit]

Atrial fibrillation is the most common arrhythmia.[13] In Europe and North America as of 2014 it affects about 2% to 3% of the population.[2] This is an increase from 0.4 to 1% of the population around 2005.[13] In the developing world rates are about 0.6% for males and 0.4% for females.[2]

It also accounts for one-third of hospital admissions for cardiac rhythm disturbances,[13] and the rate of admissions for AF has risen in recent years.[71] Strokes from AF account for 6–24% of all ischemic strokes.[72][*non-primary source needed*] After a transient ischemic attack or stroke about 11% are found to have a new diagnosis of atrial fibrillation.[73] Between 3 and 11% of those with AF have structurally normal hearts.[74] Approximately 2.2 million individuals in the United States and 4.5 million in the European Union have AF.[13]

The number of new cases each year of atrial fibrillation increases with age. In individuals over the age of 80 it affects about 8%.[13] In developed countries, the number of patients with atrial fibrillation is likely to increase during the next 50 years, owing to the growing proportion of elderly individuals.[75][*non-primary source needed*]

## History [edit]

Because the diagnosis of atrial fibrillation requires measurement of the electrical activity of the heart, atrial fibrillation was not truly described until 1874, when Edmé Félix Alfred Vulpian observed the irregular atrial electrical behavior that he termed *"fremissement fibrillaire"* in dog hearts.[76] In the mid-eighteenth century, Jean-Baptiste de Sénac made note of dilated, irritated atria in people with mitral stenosis.[77] The irregular pulse associated with AF was first recorded in 1876 by Carl Wilhelm Hermann Nothnagel and termed *"delirium cordis"*, stating that "[I]n this form of arrhythmia the heartbeats follow each other in complete irregularity. At the same time, the height and tension of the individual pulse waves are continuously changing".[78] Correlation of delirium cordis with the loss of atrial contraction as reflected in the loss of *a waves* in the jugular venous pulse was made by Sir James MacKenzie in 1904.[79] Willem Einthoven published the first ECG showing AF in 1906.[80] The connection between the anatomic and electrical manifestations of AF and the irregular pulse of delirium cordis was made in 1909 by Carl Julius Rothberger, Heinrich Winterberg, and Sir Thomas Lewis.[81][82][83]

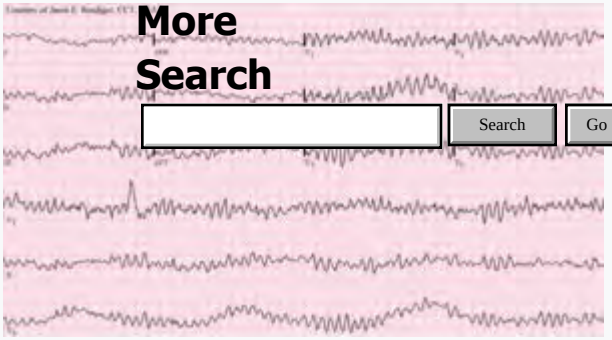
# Cardiac arrhythmia

From Wikipedia, the free encyclopedia

**Cardiac arrhythmia**, also known as **cardiac dysrhythmia** or **irregular heartbeat**, is a group of conditions in which the heartbeat is irregular, too fast, or too slow. A heart rate that is too fast – above 100 beats per minute in adults – is called tachycardia and a heart rate that is too slow – below 60 beats per minute – is called bradycardia.[1] Many types of arrhythmia have no symptoms. When symptoms are present these may include palpitations or feeling a pause between heartbeats. More seriously there may be lightheadedness, passing out, shortness of breath, or chest pain.[2] While most types of arrhythmia are not serious, some predispose a person to complications such as stroke or heart failure.[1][3] Others may result in cardiac arrest.[3]

There are four main types of arrhythmia: extra beats, supraventricular tachycardias, ventricular arrhythmias, and bradyarrhythmias. Extra beats include premature atrial contractions and premature ventricular contractions. Supraventricular tachycardias include atrial fibrillation, atrial flutter, and paroxysmal supraventricular tachycardia. Ventricular arrhythmias include ventricular fibrillation and ventricular tachycardia.[3][4] Arrhythmias are due to problems with the electrical conduction system of the heart.[1] Arrhythmias may occur in children; however, the normal range for the heart rate is different and depends on age.[3] A number of tests can help with diagnosis including an electrocardiogram (ECG) and Holter monitor.[5]



Ventricular fibrillation (VF) an example of a serious cardiac arrhythmia.

[edit on Wikidata]

Most arrhythmias can be effectively treated.[1] Treatments may include medications, medical procedures such as a pacemaker, and surgery. Medications for a fast heart rate may include beta blockers or agents that attempt to restore a normal heart rhythm such as procainamide. This later group may have more significant side effects especially if taken for a long period of time. Pacemakers are often used for slow heart rates. Those with an irregular heartbeat are often treated with blood thinners to reduce the risk of complications. Those who have severe symptoms from an arrhythmia may receive urgent treatment with a jolt of electricity in the form of cardioversion or defibrillation.[6]

Arrhythmia affects millions of people.[7] In Europe and North America, as of 2014, atrial fibrillation affects about 2% to 3% of the population.[8] Atrial fibrillation and atrial flutter resulted in 112,000 deaths in 2013, up from 29,000 in 1990.[9] Sudden cardiac death is the cause of about half of deaths due to cardiovascular disease or about 15% of all deaths globally.[10] About 80% of sudden cardiac death is the result of ventricular arrhythmias.[10] Arrhythmias may occur at any age but are more common among older people.[7]

Contents

## Classification [edit]

Arrhythmia may be classified by rate (tachycardia, bradycardia), mechanism (automaticity, re-entry, triggered) or duration (isolated premature beats; couplets; runs, that is 3 or more beats; non-sustained= less than 30 seconds or sustained= over 30 seconds).

It is also appropriate to classify by site of origin:

### Atrial [edit]

- Sinus bradycardia
- Premature atrial contractions (PACs)
- Wandering atrial pacemaker
- Atrial tachycardia
- Multifocal atrial tachycardia
- Supraventricular tachycardia (SVT)
- Atrial flutter
- Atrial fibrillation (Afib)

### Junctional arrhythmias [edit]

- AV nodal reentrant tachycardia
- Junctional rhythm
- Junctional tachycardia
- Premature junctional contraction

### Ventricular [edit]

- Premature ventricular contractions (PVCs), sometimes called ventricular extra beats (VEBs)
  - Premature ventricular beats occurring after every normal beat are termed "ventricular bigeminy"

    - PVCs that occur at intervals of 2 normal beats to 1 PVC are termed "PVCs in trigeminy"
    - Three premature ventricular grouped together is termed a "run of PVCs" in general, runs lasting longer than three beats are referred to as ventricular tachycardia
- Accelerated idioventricular rhythm
- Monomorphic ventricular tachycardia
- Polymorphic ventricular tachycardia
- Ventricular fibrillation
- Torsades de pointes

### Heart blocks [edit]

These are also known as AV blocks, because the vast majority of them arise from pathology at the atrioventricular node. They are the most common causes of bradycardia:

- First degree heart block, which manifests as PR prolongation
- Second degree heart block
    - Type 1 Second degree heart block, also known as Mobitz I or Wenckebach
    - Type 2 Second degree heart block, also known as Mobitz II
- Third degree heart block, also known as complete heart block.

First, second and third degree block also can occur at the level of the sinoatrial junction. This is referred to as sinoatrial block typically manifesting with various degrees and patterns of sinus bradycardia

### Sudden arrhythmic death syndrome [edit]

Sudden arrhythmic death syndrome (SADS), is a term used as part of sudden unexpected death syndrome to describe sudden death due to cardiac arrest brought on by an arrhythmia in the presence or absence of any structural heart disease on autopsy. The most common cause of sudden death in the US is coronary artery disease specifically because of poor oxygenation of the heart muscle, that is myocardial ischemia or a heart attack [11] Approximately 180,000 to 250,000 people die suddenly of this cause every year in the US. SADS may occur from other causes. There are many inherited conditions and heart diseases that can affect young people which can subsequently cause sudden death without advance symptoms.[12]

Causes of SADS in young people include viral myocarditis, long QT syndrome, Brugada syndrome, Catecholaminergic polymorphic ventricular tachycardia, hypertrophic cardiomyopathy and arrhythmogenic right ventricular dysplasia.[13][14]

## Signs and symptoms [edit]

The term cardiac arrhythmia covers a very large number of very different conditions.

The most common symptom of an arrhythmia is an awareness of an abnormal heartbeat, called palpitations. These may be infrequent, frequent, or continuous. Some of these arrhythmias are harmless (though distracting for patients) but some of them predispose to adverse outcomes.

Some arrhythmias do not cause symptoms, and are not associated with increased mortality. However, some asymptomatic arrhythmias *are* associated with adverse events. Examples include a higher risk of blood clotting within the heart and a higher risk of insufficient blood being transported to the heart because of weak heartbeat. Other increased risks are of embolisation and stroke, heart failure and sudden cardiac death.

If an arrhythmia results in a heartbeat that is too fast, too slow or too weak to supply the body's needs, this manifests as a lower blood pressure and may cause lightheadedness or dizziness, or syncope (fainting).

Some types of arrhythmia result in cardiac arrest, or sudden death.

Medical assessment of the abnormality using an electrocardiogram is one way to diagnose and assess the risk of any given arrhythmia.

# Differential diagnosis [edit]

## Normal electrical activity [edit]

*Main article: Electrical conduction system of the heart*

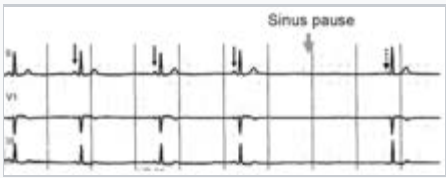
Each heart beat originates as an electrical impulse from a small area of tissue in the right atrium of the heart called the sinus node or Sino-atrial node or SA node. The impulse initially causes both atria to contract, then activates the atrioventricular (or AV) node, which is normally the only electrical connection between the atria and the ventricles (main pumping chambers). The impulse then spreads through both ventricles via the Bundle of His and the Purkinje fibres causing a synchronised contraction of the heart muscle and, thus, the pulse.

In adults the normal resting heart rate ranges from 60 to 90 beats per minute. The resting heart rate in children is much faster. In athletes, however, the resting heart rate can be as slow as 40 beats per minute, and be considered as normal.

The term sinus arrhythmia [15] refers to a normal phenomenon of alternating mild acceleration and slowing of the heart rate that occurs with breathing in and out. It is usually quite pronounced in children and steadily decreases with age. This can also be present during meditation breathing exercises that involve deep inhaling and breath holding patterns.[16]

## Bradycardias [edit]

A slow rhythm (less than 60 beats/min), is labelled bradycardia. This may be caused by a slowed signal from the sinus node (sinus bradycardia), a pause in the normal activity of the sinus node (sinus arrest), or by blocking of the electrical impulse on its way from the atria to the ventricles (AV block or heart block). Heart block comes in varying degrees and severity. It may be caused by reversible poisoning of the AV node (with drugs that impair conduction) or by irreversible damage to the node. Bradycardias may also be present in the normally functioning heart of endurance athletes or other well-conditioned persons. Bradycardia may also occur in some types of seizures.



Normal sinus rhythm, with solid black arrows pointing to normal P waves representative of normal sinus node function, followed by a pause in sinus node activity (resulting in a transient loss of heart beats). Note that the P wave that disrupts the pause (indicated by the dashed arrow) does not look like the previous (normal) P waves — this last P wave is arising from a different part of the atrium, representing an escape rhythm.

## Tachycardias [edit]

In adults and children over 15, resting heart rate faster than 100 beats per minute is labelled tachycardia. Tachycardia may result in palpitation; however, tachycardia is not *necessarily* an arrhythmia. Increased heart rate is a normal response to physical exercise or emotional stress. This is mediated by the sympathetic nervous system on the sinus node and called sinus tachycardia. Other conditions that increase sympathetic nervous system activity in the heart include ingested or injected substances, such as caffeine or amphetamines, and an overactive thyroid gland (hyperthyroidism) or anemia.

Tachycardia that is not sinus tachycardia usually results from the addition of abnormal impulses to the normal cardiac cycle. Abnormal impulses can begin by one of three mechanisms: automaticity, re-entry or triggered activity. A specialised form of re-entry which is both common and problematic is termed fibrillation.

Although the term "tachycardia" has been known for over 160 years, bases for the classification of arrhythmias are still being discussed.[17]

## Heart defects [edit]

Congenital heart defects are structural or electrical pathway problems in the heart that are present at birth.

Anyone can be affected with this because overall health does not play a role in the problem. Problems with the electrical pathway of the heart can cause very fast or even deadly arrhythmias. Wolff–Parkinson–White syndrome is due to an extra pathway in the heart that is made up of electrical muscle tissue. This tissue allows the electrical impulse, which stimulates the heartbeat, to happen very rapidly. Right Ventricular outflow tract Tachycardia is the most common type of ventricular tachycardia in otherwise healthy individuals. This defect is due to an electrical node in the right ventricle just before the pulmonary artery. When the node is stimulated, the patient will go into ventricular tachycardia, which does not allow the heart to fill with blood before beating again. Long QT Syndrome is another complex problem in the heart and has been labeled as an independent factor in mortality. There are multiple methods of treatment for these including cardiac ablations, medication treatment, or altering your lifestyle to have less stress and exercise. It is possible to live a full and happy life with these conditions.

## Automaticity [edit]

*Main article: Automatic tachycardia*

Automaticity refers to a cardiac muscle cell firing off an impulse on its own. All of the cells in the heart have the ability to initiate an action potential; however, only some of these cells are designed to routinely trigger heart beats. These cells are found in the conduction system of the heart and include the SA node, AV node, Bundle of His and Purkinje fibers. The sinoatrial node is a single specialized location in the atrium that has a higher automaticity (a faster pacemaker) than the rest of the heart and, therefore, is usually responsible for setting the heart rate and initiating each heart beat.

Any part of the heart that initiates an impulse without waiting for the sinoatrial node is called an ectopic focus and is, by definition, a pathological phenomenon. This may cause a single premature beat now and then, or, if the ectopic focus fires more often than the sinoatrial node, it can produce a sustained abnormal rhythm. Rhythms produced by an ectopic focus in the atria, or by the atrioventricular node, are the least dangerous dysrhythmias; but they can still produce a decrease in the heart's pumping efficiency, because the signal reaches the various parts of the heart muscle with different timing than usual and can be responsible for poorly coordinated contraction.

Conditions that increase automaticity include sympathetic nervous system stimulation and hypoxia. The resulting heart rhythm depends on where the first signal begins: If it is the sinoatrial node, the rhythm remains normal but rapid; if it is an ectopic focus, many types of dysrhythmia may ensue.

## Re-entry [edit]

Re-entrant arrhythmias occur when an electrical impulse recurrently travels in a tight circle within the heart, rather than moving from one end of the heart to the other and then stopping.[18][19]

Every cardiac cell is able to transmit impulses of excitation in every direction but will do so only once within a short time. Normally, the action potential impulse will spread through the heart quickly enough that each cell will respond only once. However, if there is some essential heterogeneity of refractory period or if conduction is abnormally slow in some areas (for example in heart damage) so the myocardial cells are unable to activate the fast sodium channel, part of the impulse will arrive late and potentially be treated as a new impulse. Depending on the timing, this can produce a sustained abnormal circuit rhythm.

As a sort of *re-entry*, vortices of excitation in the myocardium (autowave vortices) are considered to be the main mechanism of life-threatening cardiac arrhythmias.[20] In particular, the autowave reverberator is common in the thin walls of the atria, sometimes resulting in atrial flutter. Re-entry is also responsible for most paroxysmal supraventricular tachycardia, and dangerous ventricular tachycardia. These types of re-entry circuits are different from WPW syndromes, which utilize abnormal conduction pathways.

Although omega-3 fatty acids from fish oil can be protective against arrhythmias, they can facilitate re-entrant arrhythmias. [21]

## Fibrillation [edit]

When an entire chamber of the heart is involved in multiple micro-reentry circuits and is therefore quivering with chaotic electrical impulses, it is said to be in fibrillation.

Fibrillation can affect the atrium (atrial fibrillation) or the ventricle (ventricular fibrillation): ventricular fibrillation is imminently life-threatening.

- Atrial fibrillation affects the upper chambers of the heart, known as the atria. Atrial fibrillation may be due to serious underlying medical conditions and should be evaluated by a physician. It is not typically a medical emergency.
- Ventricular fibrillation occurs in the ventricles (lower chambers) of the heart; it is always a medical emergency. If left untreated, ventricular fibrillation (VF, or V-fib) can lead to death within minutes. When a heart goes into V-fib, effective pumping of the blood stops. V-fib is considered a form of cardiac arrest. An individual suffering from it will not survive unless cardiopulmonary resuscitation (CPR) and defibrillation are provided immediately.

CPR can prolong the survival of the brain in the lack of a normal pulse, but defibrillation is the only intervention that can restore a healthy heart rhythm. Defibrillation is performed by applying an electric shock to the heart, which resets the cells, permitting a normal beat to re-establish itself.

### Triggered beats [edit]

Triggered beats occur when problems at the level of the ion channels in individual heart cells result in abnormal propagation of electrical activity and can lead to sustained abnormal rhythm. They are relatively rare and can result from the action of anti-arrhythmic drugs. See early and delayed Afterdepolarizations.

## Diagnostic approach [edit]

Cardiac arrhythmia are often first detected by simple but nonspecific means: auscultation of the heartbeat with a stethoscope, or feeling for peripheral pulses. These cannot usually diagnose specific arrhythmia but can give a general indication of the heart rate and whether it is regular or irregular. Not all the electrical impulses of the heart produce audible or palpable beats; in many cardiac arrhythmias, the premature or abnormal beats do not produce an effective pumping action and are experienced as "skipped" beats.

The simplest *specific* diagnostic test for assessment of heart rhythm is the electrocardiogram (abbreviated ECG or EKG). A Holter monitor is an EKG recorded over a 24-hour period, to detect arrhythmias that may happen briefly and unpredictably throughout the day.

A more advanced study of the heart's electrical activity can be performed to assess the source of the aberrant heart beats. This can be accomplished in an electrophysiology study, an endovascular procedure that uses a catheter to "listen" to the electrical activity from within the heart, additionally if the source of the arrhythmias is found, often the abnormal cells can be ablated and the arrhythmia can be permanently corrected. *Transesophageal atrial stimulation* (TAS) instead uses an electrode inserted through the esophagus to a part where the distance to the posterior wall of the left atrium is only approximately 5–6 mm (remaining constant in people of different age and weight).[22] Transesophageal atrial stimulation can differentiate between atrial flutter, AV nodal reentrant tachycardia and orthodromic atrioventricular reentrant tachycardia.[23] It can also evaluate the risk in people with Wolff–Parkinson–White syndrome, as well as terminate supraventricular tachycardia caused by re-entry.[23]

## Management [edit]

The method of cardiac rhythm management depends firstly on whether or not the affected person is stable or unstable. Treatments may include physical maneuvers, medications, electricity conversion, or electro- or cryo-cautery.

In the United States, people admitted to the hospital with cardiac arrhythmia and conduction disorders with and without complications were admitted to the intensive care unit more than half the time in 2011.[24]

### Physical maneuvers [edit]

A number of physical acts can increase parasympathetic nervous supply to the heart, resulting in blocking of

electrical conduction through the AV node. This can slow down or stop a number of arrhythmias that originate above or at the AV node (see main article: supraventricular tachycardias). Parasympathetic nervous supply to the heart is via the vagus nerve, and these maneuvers are collectively known as vagal maneuvers.

### Antiarrhythmic drugs [edit]

*Main article: Antiarrhythmic agents*

There are many classes of antiarrhythmic medications, with different mechanisms of action and many different individual drugs within these classes. Although the goal of drug therapy is to prevent arrhythmia, nearly every anti arrhythmic drug has the potential to act as a pro-arrhythmic, and so must be carefully selected and used under medical supervision.

### Other drugs [edit]

A number of other drugs can be useful in cardiac arrhythmias.

Several groups of drugs slow conduction through the heart, without actually preventing an arrhythmia. These drugs can be used to "rate control" a fast rhythm and make it physically tolerable for the patient.

Some arrhythmias promote blood clotting within the heart, and increase risk of embolus and stroke. Anticoagulant medications such as warfarin and heparins, and anti-platelet drugs such as aspirin can reduce the risk of clotting.

### Electricity [edit]

Arrhythmias may also be treated electrically, by applying a shock across the heart — either externally to the chest wall, or internally to the heart via implanted electrodes.

Cardioversion is either achieved pharmacologically or via the application of a shock *synchronised* to the underlying heartbeat. It is used for treatment of supraventricular tachycardias. In elective cardioversion, the recipient is usually sedated or lightly anesthetized for the procedure.

Defibrillation differs in that the shock is not synchronised. It is needed for the chaotic rhythm of ventricular fibrillation and is also used for pulseless ventricular tachycardia. Often, more electricity is required for defibrillation than for cardioversion. In most defibrillation, the recipient has lost consciousness so there is no need for sedation.

Defibrillation or cardioversion may be accomplished by an implantable cardioverter-defibrillator (ICD).

Electrical treatment of arrhythmias also includes cardiac pacing. Temporary pacing may be necessary for reversible causes of very slow heartbeats, or bradycardia, (for example, from drug overdose or myocardial infarction). A permanent pacemaker may be placed in situations where the bradycardia is not expected to recover.

### Electrical cautery [edit]

Some cardiologists further sub-specialise into electrophysiology. In specialised catheter laboratories, they use fine probes inserted through the blood vessels to map electrical activity from within the heart. This allows abnormal areas of conduction to be located very accurately, and subsequently destroyed with heat, cold, electrical, or laser probes.

This pulmonary vein isolation may be completely curative for AV nodal reentrant tachycardia and sometimes for atrial fibrillation, but for other forms of arrhythmia the success rate remains disappointing.

## Research [edit]

Arrhythmias due to medications have been reported since the 1920s with the use of quinine.[25] In the 1960s and 1970s problems with antihistamines and antipsychotics were discovered.[25] It was not until the

1980s that the underlying issue, QTc prolongation was determined.[25]

# Cardiovascular disease

From Wikipedia, the free encyclopedia

**Cardiovascular disease** (CVD) is a class of diseases that involve the heart or blood vessels.[1] Cardiovascular disease includes coronary artery diseases (CAD) such as angina and myocardial infarction (commonly known as a heart attack).[1] Other CVDs are stroke, heart failure, hypertensive heart disease, rheumatic heart disease, cardiomyopathy, heart arrhythmia, congenital heart disease, valvular heart disease, carditis, aortic aneurysms, peripheral artery disease, and venous thrombosis.[1][2]

The underlying mechanisms vary depending on the disease in question. Coronary artery disease, stroke, and peripheral artery disease involve atherosclerosis. This may be caused by high blood pressure, smoking, diabetes, lack of exercise, obesity, high blood cholesterol, poor diet, and excessive alcohol consumption, among others. High blood pressure results in 13% of CVD deaths, while tobacco results in 9%, diabetes 6%, lack of exercise 6% and obesity 5%. Rheumatic heart disease may follow untreated strep throat.[1]

It is estimated that 90% of CVD is preventable.[3] Prevention of atherosclerosis involves improving risk factors through: healthy eating, exercise, avoidance of tobacco smoke and limiting alcohol intake.[1] Treating high blood pressure, blood lipids and diabetes is also beneficial.[1] Treating people who have strep throat with antibiotics can decrease the risk of rheumatic heart disease.[4] The effect of the use of aspirin in people who are otherwise healthy is of unclear benefit.[5][6] The United States Preventive Services Task Force recommends against its use for prevention in women less than 55 and men less than 45 years old; however, in those who are older it is recommends in some individuals.[7] Treatment of those who have CVD improves outcomes.[1]

Cardiovascular diseases are the leading cause of death globally.[1] This is true in all areas of the world except Africa.[1] Together they resulted in 17.3 million deaths (31.5%) in 2013 up from 12.3 million (25.8%) in 1990.[2] Deaths, at a given age, from CVD are more common and have been increasing in much of the developing world, while rates have declined in most of the developed world since the 1970s.[8][9] Coronary artery disease and stroke account for 80% of CVD deaths in males and 75% of CVD deaths in females.[1] Most cardiovascular disease affects older adults. In the United States 11% of people between 20 and 40 have CVD, while 37% between 40 and 60, 71% of people between 60 and 80, and 85% of people over 80 have CVD.[10] The average age of death from coronary artery disease in the developed world is around 80 while it is around 68 in the developing world.[8] Disease onset is typically seven to ten years earlier in men as compared to women.[11]

# Types

There are many cardiovascular diseases involving the blood vessels. They are known as vascular diseases.

- Coronary artery disease (also known as coronary heart disease and ischemic heart disease)
- Peripheral arterial disease – disease of blood vessels that supply blood to the arms and legs
- Cerebrovascular disease – disease of blood vessels that supply blood to the brain (includes stroke)
- Renal artery stenosis
- Aortic aneurysm

There are also many cardiovascular diseases that involve the heart.

- Cardiomyopathy – diseases of cardiac muscle
- Hypertensive heart disease – diseases of the heart secondary to high blood pressure or hypertension
- Heart failure - a clinical syndrome caused by the inability of the heart to supply sufficient blood to the tissues to meet their metabolic requirements
- Pulmonary heart disease – a failure at the right side of the heart with respiratory system involvement
- Cardiac dysrhythmias – abnormalities of heart rhythm
- Inflammatory heart disease
  - Endocarditis – inflammation of the inner layer of the heart, the endocardium. The structures most commonly involved are the heart valves.
  - Inflammatory cardiomegaly
  - Myocarditis – inflammation of the myocardium, the muscular part of the heart.

Disability-adjusted life year for inflammatory heart diseases per 100,000 inhabitants in 2004[12]

| | |
|---|---|
| no data | 420–490 |
| less than 70 | 490–560 |
| 70–140 | 560–630 |

| 210–280 | 700–770 |
| 280–350 | more than 770 |
| 350–420 | |

- Valvular heart disease
- Congenital heart disease – heart structure malformations existing at birth
- Rheumatic heart disease – heart muscles and valves damage due to rheumatic fever caused by *Streptococcus pyogenes* a group A streptococcal infection.

# Risk factors

There are many risk factors for heart diseases: age, gender, tobacco use, physical inactivity, excessive alcohol consumption, unhealthy diet, obesity, genetic predisposition and family history of cardiovascular disease, raised blood pressure (hypertension), raised blood sugar (diabetes mellitus), raised blood cholesterol (hyperlipidemia), psychosocial factors, poverty and low educational status, and air pollution.[13][14][15][16][17] While the individual contribution of each risk factor varies between different communities or ethnic groups the overall contribution of these risk factors is very consistent.[18] Some of these risk factors, such as age, gender or family history/genetic predisposition, are immutable; however, many important cardiovascular risk factors are modifiable by lifestyle change, social change, drug treatment (for example prevention of hypertension, hyperlipidemia, and diabetes).

## Genetics

Cardiovascular disease in a person's parents increases their risk by 3 fold.[19] Multiple single nucleotide polymorphisms (SNP) have been found to be associated with cardiovascular disease in genetic association studies,[20][21] but usually their individual influence is small, and genetic contributions to cardiovascular disease are poorly understood.[21]

## Age

Age is by far the most important risk factor in developing cardiovascular or heart diseases, with approximately a tripling of risk with each decade of life.[22] Coronary fatty streaks can begin to form in adolescence.[23] It is estimated that 82 percent of people who die of coronary heart disease are 65 and older.[24] At the same time, the risk of stroke doubles every decade after age 55.[25]

Calcified heart of an older woman with cardiomegaly

Multiple explanations have been proposed to explain why age increases the risk of cardiovascular/heart diseases. One of them is related to serum cholesterol level.[26] In most populations, the serum total cholesterol level increases as age increases. In men, this increase levels off around age 45 to 50 years. In women, the increase continues sharply until age 60 to 65 years.[26]

Aging is also associated with changes in the mechanical and structural properties of the vascular wall, which leads to the loss of arterial elasticity and reduced arterial compliance and may subsequently lead to coronary artery disease.[27]

## Sex

Men are at greater risk of heart disease than pre-menopausal women.[22][28] Once past menopause, it has been argued that a woman's risk is similar to a man's[28] although more recent data from the WHO and UN disputes this.[22] If a female has diabetes, she is more likely to develop heart disease than a male with diabetes.[29]

Coronary heart diseases are 2 to 5 times more common among middle-aged men than women.[26] In a study done by the World Health Organization, sex contributes to approximately 40% of the variation in sex ratios of coronary heart disease mortality.[30] Another study reports similar results finding that gender differences explains nearly half the risk associated with cardiovascular diseases[26] One of the proposed

explanations for gender differences in cardiovascular diseases is hormonal difference.[26] Among women, estrogen is the predominant sex hormone. Estrogen may have protective effects through glucose metabolism and hemostatic system, and may have direct effect in improving endothelial cell function.[26] The production of estrogen decreases after menopause, and this may change the female lipid metabolism toward a more atherogenic form by decreasing the HDL cholesterol level while increasing LDL and total cholesterol levels.[26]

Among men and women, there are notable differences in body weight, height, body fat distribution, heart rate, stroke volume, and arterial compliance.[27] In the very elderly, age-related large artery pulsatility and stiffness is more pronounced among women than men.[27] This may be caused by the women's smaller body size and arterial dimensions which are independent of menopause.[27]

## Tobacco

Cigarettes are the major form of smoked tobacco.[1] Risks to health from tobacco use result not only from direct consumption of tobacco, but also from exposure to second-hand smoke.[1] Approximately 10% of cardiovascular disease is attributed to smoking;[1] however, people who quit smoking by age 30 have almost as low a risk of death as never smokers.[31]

## Physical inactivity

Insufficient physical activity (defined as less than 5 x 30 minutes of moderate activity per week, or less than 3 x 20 minutes of vigorous activity per week) is currently the fourth leading risk factor for mortality worldwide.[1] In 2008, 31.3% of adults aged 15 or older (28.2% men and 34.4% women) were insufficiently physically active.[1] The risk of ischemic heart disease and diabetes mellitus is reduced by almost a third in adults who participate in 150 minutes of moderate physical activity each week (or equivalent).[32] In addition, physical activity assists weight loss and improves blood glucose control, blood pressure, lipid profile and insulin sensitivity. These effects may, at least in part, explain its cardiovascular benefits.[1]

## Diet

High dietary intakes of saturated fat, trans-fats and salt, and low intake of fruits, vegetables and fish are linked to cardiovascular risk, although whether all these associations are a cause is disputed. The World Health Organization attributes approximately 1.7 million deaths worldwide to low fruit and vegetable consumption.[1] The amount of dietary salt consumed is also an important determinant of blood pressure levels and overall cardiovascular risk.[1] Frequent consumption of high-energy foods, such as processed foods that are high in fats and sugars, promotes obesity and may increase cardiovascular risk.[1] A Cochrane review found that replacing saturated fat with polyunsaturated fat (plant based oils) reduced cardiovascular disease risk. Cutting down on saturated fat reduced risk of cardiovascular disease by 17% including heart disease and stroke.[33] High trans-fat intake has adverse effects on blood lipids and circulating inflammatory markers,[34] and elimination of trans-fat from diets has been widely advocated.[35] There is evidence that higher consumption of sugar is associated with higher blood pressure and unfavorable blood lipids,[36] and sugar intake also increases the risk of diabetes mellitus.[37] High consumption of processed meats is associated with an increased risk of cardiovascular disease, possibly in part due to increased dietary salt intake.[38]

The relationship between alcohol consumption and cardiovascular disease is complex, and may depend on the amount of alcohol consumed. There is a direct relationship between high levels of alcohol consumption and risk of cardiovascular disease.[1] Drinking at low levels without episodes of heavy drinking may be associated with a reduced risk of cardiovascular disease.[39] Overall alcohol consumption at the population level is associated with multiple health risks that exceed any potential benefits.[1][40]

## Socioeconomic disadvantage

Cardiovascular disease affects low- and middle-income countries even more than high-income countries.[41] There is relatively little information regarding social patterns of cardiovascular disease within low- and middle-income countries,[41] but within high-income countries low income and low educational status are consistently associated with greater risk of cardiovascular disease.[42] Policies that have resulted in increased socio-economic inequalities have been associated with greater subsequent socio-economic differences in cardiovascular disease[41] implying a cause and effect relationship. Psychosocial factors, environmental exposures, health behaviours, and health-care access and quality contribute to socio-economic differentials in cardiovascular disease. [43] The Commission on Social Determinants of Health recommended that more equal distributions of power, wealth, education, housing, environmental factors, nutrition, and health care were needed to address inequalities in cardiovascular disease and non-communicable diseases.[44]

## Air pollution

Particulate matter has been studied for its short- and long-term exposure effects on cardiovascular disease. Currently, $PM_{2.5}$ is the major focus, in which gradients are used to determine CVD risk. For every 10 $\mu g/m^3$ of $PM_{2.5}$ long-term exposure, there was an estimated 8–18% CVD mortality risk.[45] Women had a higher relative risk (RR) (1.42) for $PM_{2.5}$ induced coronary artery disease than men (0.90) did.[45] Overall, long-term PM exposure increased rate of atherosclerosis and inflammation. In regards to short-term exposure (2 hours), every 25 $\mu g/m^3$ of $PM_{2.5}$ resulted in a 48% increase of CVD mortality risk.[46] In addition, after only 5 days of exposure, a rise in systolic (2.8 mmHg) and diastolic (2.7 mmHg) blood pressure occurred for every 10.5 $\mu g/m^3$ of $PM_{2.5}$.[46] Other research has implicated $PM_{2.5}$ in irregular heart rhythm, reduced heart rate variability (decreased vagal tone), and most notably heart failure.[46][47] $PM_{2.5}$ is also linked to carotid artery thickening and increased risk of acute myocardial infarction.[46][47]

## Cardiovascular risk assessment

Existing cardiovascular disease or a previous cardiovascular event, such as a heart attack or stroke, is the strongest predictor of a future cardiovascular event.[48] Age, sex, smoking, blood pressure, blood lipids and diabetes are important predictors of future cardiovascular disease in people who are not known to have cardiovascular disease.[49] These measures, and sometimes others, may be combined into composite risk scores to estimate an individual's future risk of cardiovascular disease.[48] Numerous risk scores exist although their respective merits are debated.[50] Other diagnostic tests and biomarkers remain under evaluation but currently these lack clear-cut evidence to support their routine use. They include family history, coronary artery calcification score, high sensitivity C-reactive protein (hs-CRP), ankle–brachial pressure index, lipoprotein subclasses and particle concentration, lipoprotein(a), apolipoproteins A-I and B, fibrinogen, white blood cell count, homocysteine, N-terminal pro B-type natriuretic peptide (NT-proBNP), and markers of kidney function.[51][52]

## Work

*Main article: Occupational cardiovascular disease*

Little is known about the relationship between work and cardiovascular disease, but links have been established between certain toxins, extreme heat and cold, exposure to tobacco smoke, and mental health concerns such as stress and depression.[53]

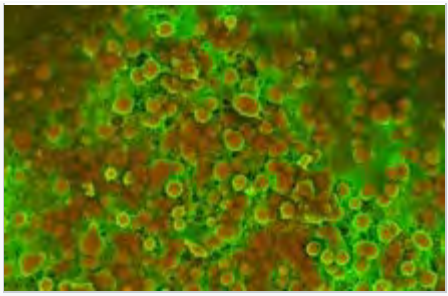
# Pathophysiology

Population-based studies show that atherosclerosis, the major precursor

of cardiovascular disease, begins in childhood. The Pathobiological Determinants of Atherosclerosis in Youth Study demonstrated that intimal lesions appear in all the aortas and more than half of the right coronary arteries of youths aged 7–9 years.[55]

This is extremely important considering that 1 in 3 people die from complications attributable to atherosclerosis. In order to stem the tide, education and awareness that cardiovascular disease poses the greatest threat, and measures to prevent or reverse this disease must be taken.

Obesity and diabetes mellitus are often linked to cardiovascular disease,[56] as are a history of chronic kidney disease and hypercholesterolaemia.[57] In fact, cardiovascular disease is the most life-threatening of the diabetic complications and diabetics are two- to four-fold more likely to die of cardiovascular-related causes than nondiabetics.[58][59][60]



Density-Dependent Colour Scanning Electron Micrograph SEM (DDC-SEM) of cardiovascular calcification, showing in orange calcium phosphate spherical particles (denser material) and, in green, the extracellular matrix (less dense material)[54]

## Screening

Screening ECGs (either at rest or with exercise) are not recommended in those without symptoms who are at low risk.[61] This includes those who are young without risk factors.[62] In those at higher risk the evidence for screening with ECGs is inconclusive.[61]

Additionally echocardiography, myocardial perfusion imaging, and cardiac stress testing is not recommended in those at low risk who do not have symptoms.[63]

Some biomarkers may add to conventional cardiovascular risk factors in predicting the risk of future cardiovascular disease; however, the clinical value of some biomarkers is questionable.[64][65]

The NIH recommends lipid testing in children beginning at the age of 2 if there is a family history of heart disease or lipid problems.[66] It is hoped that early testing will improve lifestyle factors in those at risk such as diet and exercise.[67]

## Prevention

Up to 90% of cardiovascular disease may be preventable if established risk factors are avoided.[68][69] Currently practiced measures to prevent cardiovascular disease include:

- A low-fat, high-fiber diet including whole grains and fruit and vegetables.[70][71] Five portions a day reduces risk by about 25%.[72]
- Tobacco cessation and avoidance of second-hand smoke[70]
- Limit alcohol consumption to the recommended daily limits;[70] consumption of 1–2 standard alcoholic drinks per day may reduce risk by 30%.[73][74] However, excessive alcohol intake increases the risk of cardiovascular disease.[75]
- Lower blood pressures, if elevated
- Decrease non-HDL cholesterol.[76][77]
- Decrease body fat if overweight or obese[78]
- Increase daily activity to 30 minutes of vigorous exercise per day at least five times per week (multiply by three if horizontal);[70]
- Reduce sugar consumptions
- Decrease psychosocial stress.[79] This measure may be complicated by imprecise definitions of what constitute psychosocial interventions.[80] Mental stress–induced myocardial ischemia is associated with an increased risk of heart problems in those with previous heart disease.[81] Severe emotional and

physical stress leads to a form of heart dysfunction known as Takotsubo syndrome in some people.[82] Stress, however, plays a relatively minor role in hypertension.[83] Specific relaxation therapies are of unclear benefit.[84][85]

For adults without a known diagnosis of hypertension, diabetes, hyperlipidemia, or cardiovascular disease, routine counseling to advise them to improve their diet and increase their physical activity has not been found to significantly alter behavior, and thus is not recommended.[86] It is unclear whether or not dental care in those with periodontitis affects the risk of cardiovascular disease.[87] Exercise in those who are at high risk of heart disease has not been well studied as of 2014.[88]

## Diet

*See also: Saturated fat and cardiovascular disease controversy and Salt and cardiovascular disease*

A diet high in fruits and vegetables decreases the risk of cardiovascular disease and death.[72] Evidence suggests that the Mediterranean diet may improve cardiovascular outcomes.[89] There is also evidence that a Mediterranean diet may be more effective than a low-fat diet in bringing about long-term changes to cardiovascular risk factors (e.g., lower cholesterol level and blood pressure).[90] The DASH diet (high in nuts, fish, fruits and vegetables, and low in sweets, red meat and fat) has been shown to reduce blood pressure,[91] lower total and low density lipoprotein cholesterol[92] and improve metabolic syndrome;[93] but the long-term benefits outside the context of a clinical trial have been questioned.[94] A high fiber diet appears to lower the risk.[95]

Total fat intake does not appear to be an important risk factor.[96][97] A diet high in trans fatty acids, however, does appear to increase rates of cardiovascular disease.[97][98] Worldwide, dietary guidelines recommend a reduction in saturated fat.[99] However, there are some questions around the effect of saturated fat on cardiovascular disease in the medical literature.[98][100] Reviews from 2014 and 2015 did not find evidence of harm from saturated fats.[98][100] A 2012 Cochrane review found suggestive evidence of a small benefit from replacing dietary saturated fat by unsaturated fat.[101] A 2013 meta analysis concludes that substitution with omega 6 linoleic acid (a type of unsaturated fat) may increase cardiovascular risk.[99] Replacement of saturated fats with carbohydrates does not change or may increase risk.[102][103] Benefits from replacement with polyunsaturated fat appears greatest;[97][104] however, supplementation with omega-3 fatty acids (a type of polysaturated fat) does not appear to have an effect.[105]

The effect of a low-salt diet is unclear. A Cochrane review concluded that any benefit in either hypertensive or normal-tensive people is small if present.[106] In addition, the review suggested that a low-salt diet may be harmful in those with congestive heart failure.[106] However, the review was criticized in particular for not excluding a trial in heart failure where people had low-salt and -water levels due to diuretics.[107] When this study is left out, the rest of the trials show a trend to benefit.[107][108] Another review of dietary salt concluded that there is strong evidence that high dietary salt intake increases blood pressure and worsens hypertension, and that it increases the number of cardiovascular disease events; the latter happen both through the increased blood pressure *and*, quite likely, through other mechanisms.[109][110] Moderate evidence was found that high salt intake increases cardiovascular mortality; and some evidence was found for an increase in overall mortality, strokes, and left ventricular hypertrophy.[109]

## Medication

Aspirin has been found to be of only modest benefit in those at low risk of heart disease as the risk of serious bleeding is almost equal to the benefit with respect to cardiovascular problems.[111] In those at very low risk it is not recommended.[112]

Statins are effective in preventing further cardiovascular disease in people with a history of cardiovascular disease.[113] As the event rate is higher in men than in women, the decrease in events is more easily seen

in men than women.[113] In those without cardiovascular disease but risk factors statins appear to also be beneficial with a decrease in the risk of death and further heart disease.[114] A United States guideline recommends statins in those who have a 12% or greater risk of cardiovascular disease over the next ten years.[115]

The time course over which statins provide prevention against death appears to be long, of the order of one year, which is much longer than the duration of their effect on lipids.[116] The medications niacin, fibrates and CETP Inhibitors, while they may increase HDL cholesterol do not affect the risk of cardiovascular disease in those who are already on statins.[117]

The use of vasoactive agents for people with pulmonary hypertension with left heart disease or hypoxemic lung diseases may cause harm and unnecessary expense.[118]

### Supplements

While a healthy diet is beneficial, in general the effect of antioxidant supplementation (vitamin E, vitamin C, etc.) or vitamins has not been shown to protection against cardiovascular disease and in some cases may possibly result in harm.[119][120] Mineral supplements have also not been found to be useful.[121] Niacin, a type of vitamin B3, may be an exception with a modest decrease in the risk of cardiovascular events in those at high risk.[122][123] Magnesium supplementation lowers high blood pressure in a dose dependent manner.[124] Magnesium therapy is recommended for patients with ventricular arrhythmia associated with torsades de pointes who present with long QT syndrome as well as for the treatment of patients with digoxin intoxication-induced arrhythmias.[125] Evidence to support omega-3 fatty acid supplementation is lacking.[126]

## Management

Cardiovascular disease is treatable with initial treatment primarily focused on diet and lifestyle interventions.[1]

## Epidemiology

Cardiovascular diseases are the leading cause of death. In 2008, 30% of all global death is attributed to cardiovascular diseases. Death caused by cardiovascular diseases are also higher in low- and middle-income countries as over 80% of all global death caused by cardiovascular diseases occurred in those countries. It is also estimated that by 2030, over 23 million people will die from cardiovascular diseases each year.

It is estimated that 60% of the world's cardiovascular disease burden will occur in the South Asian subcontinent despite only accounting for 20% of the world's population. This may be secondary to a combination of genetic predisposition and environmental factors. Organizations such as the Indian Heart Association are working with the World Heart Federation to raise awareness about this issue.[128]

Cardiovascular diseases deaths per million persons in 2012

## Research

*See also: Timeline of cardiovascular disease*

The first studies on cardiovascular health were performed in year 1949 by Jerry Morris using occupational health data and

were published in year 1958.[129] The causes, prevention, and/or treatment of all forms of cardiovascular disease remain active fields of biomedical research, with hundreds of scientific studies being published on a weekly basis.

A fairly recent emphasis is on the link between low-grade inflammation that hallmarks atherosclerosis and its possible interventions. C-reactive protein is a common inflammatory marker that has been found to be present in increased levels in patients who are at risk for cardiovascular disease.[130] Also osteoprotegerin, which is involved with regulation of a key inflammatory transcription factor called NF-κB, has been found to be a risk factor of cardiovascular disease and mortality.[131][132]

Some areas currently being researched include the possible links between infection with *Chlamydophila pneumoniae* (a major cause of pneumonia) and coronary artery disease. The *Chlamydia* link has become less plausible with the absence of improvement after antibiotic use.[133]

Disability-adjusted life year for cardiovascular diseases per 100,000 inhabitants in 2004[127]

| | |
|---|---|
| no data | 3700-4400 |
| <900 | 4400-5100 |
| 900-1650 | 5100-5800 |
| 1650-2300 | 5800-6500 |
| 2300-3000 | 6500-7200 |
| 3000-3700 | 7200–7900 |
| | >7900 |

Several research also investigated the benefits of melatonin on cardiovascular diseases prevention and cure. Melatonin is a pineal gland secretion and it is shown to be able to lower total cholesterol, very-low-density and low-density lipoprotein cholesterol levels in the blood plasma of rats. Reduction of blood pressure is also observed when pharmacological doses are applied. Thus, it is deemed to be a plausible treatment for hypertension. However, further research needs to be conducted to investigate the side-effects, optimal dosage, etc. before it can be licensed for use.[134]

# Coronary artery disease

From Wikipedia, the free encyclopedia

**Coronary artery disease** (**CAD**), also known as **ischemic heart disease** (**IHD**),[4] is a group of diseases that includes: stable angina, unstable angina, myocardial infarction, and sudden cardiac death.[5] It is within the group of cardiovascular diseases of which it is the most common type.[6] A common symptom is chest pain or discomfort which may travel into the shoulder, arm, back, neck, or jaw.[7] Occasionally it may feel like heartburn. Usually symptoms occur with exercise or emotional stress, last less than a few minutes, and get better with rest.[7] Shortness of breath may also occur and sometimes no symptoms are present.[7] The first sign is occasionally a heart attack.[8] Other complications include heart failure or an irregular heartbeat.[8]

Risk factors include: high blood pressure, smoking, diabetes, lack of exercise, obesity, high blood cholesterol, poor diet, and excessive alcohol, among others.[9][10] Other risks include depression.[11] The underlying mechanism involves atherosclerosis of the arteries of the heart.[10] A number of tests may help with diagnoses including: electrocardiogram, cardiac stress testing, coronary computed tomographic angiography, and coronary angiogram, among others.[12]

Prevention is by eating a healthy diet, regular exercise, maintaining a healthy weight and not smoking.[13] Sometimes medication for diabetes, high cholesterol, or high blood pressure are also used.[13] There is limited evidence for screening people who are at low risk and do not have symptoms.[14] Treatment involves the same measures as prevention.[15][16] Additional medications such as antiplatelets including aspirin, beta blockers, or nitroglycerin may be recommended.[16] Procedures such as percutaneous coronary intervention (PCI) or coronary artery bypass surgery (CABG) may be used in severe disease.[16][17] In those with stable CAD it is unclear if PCI or CABG in addition to the other treatments improve life expectancy or decreases heart attack risk.[18]

In 2013 CAD was the most common cause of death globally, resulting in 8.14 million deaths (16.8%) up from 5.74 million deaths (12%) in 1990.[6] The risk of death from CAD for a given age has decreased between 1980 and 2010 especially in developed countries.[19] The number of cases of CAD for a given age has also decreased between 1990 and 2010.[20] In the United States in 2010 about 20% of those over 65 had CAD, while it was present in 7% of those 45 to 64, and 1.3% of those 18 to 45.[21] Rates are higher

among men than women of a given age.[21]

## Signs and symptoms [edit]

Chest pain that occurs regularly with activity, after eating, or at other predictable times is termed stable angina and is associated with narrowings of the arteries of the heart.

Angina that changes in intensity, character or frequency is termed unstable. Unstable angina may precede myocardial infarction. In adults who go to the emergency department with an unclear cause of pain, about 30% have pain due to coronary artery disease.[22]

## Risk factors [edit]

Coronary artery disease has a number of well determined risk factors. The most common risk factors include smoking, family history, hypertension, obesity, diabetes, lack of exercise, stress, and high blood lipids.[23][24] Smoking is associated with about 36% of cases and obesity 20%.[25] Lack of exercise has been linked to 7–12% of cases.[25][26] Exposure to the herbicide Agent orange may increase risk.[27] Both rheumatoid arthritis and systemic lupus erythematosus are independent risk factors as well.[28][29]

Job stress appears to play a minor role accounting for about 3% of cases.[25]

In one study, women who were free of stress from work life saw an increase in the diameter of their blood vessels, leading to decreased progression of atherosclerosis.[30] In contrast, women who had high levels of work-related stress experienced a decrease in the diameter of their blood vessels and significantly increased disease progression.[30] Having a type A behavior pattern, a group of personality characteristics including time urgency, competitiveness, hostility, and impatience[31] is linked to an increased risk of coronary disease.[32]

### Blood fats [edit]

- High blood cholesterol (specifically, serum LDL concentrations). HDL (high density lipoprotein) has a protective effect over development of coronary artery disease.[33]
- High blood triglycerides may play a role.[34]
- High levels of lipoprotein(a),[35][36][37] a compound formed when LDL cholesterol combines with a protein known as apolipoprotein(a).

Dietary cholesterol does not appear to have a significant effect on blood cholesterol and thus recommendations about its consumption may not be needed.[38] Saturated fat is still a concern.[38]

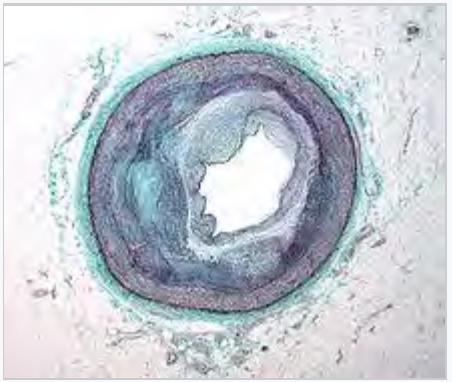
### Other [edit]

- Endometriosis in women under the age of 40[39]
- It is unclear if type A personality affects the risk of coronary artery disease.[40] Depression and hostility do appear to be risks however.[41]
- The number of categories of adverse childhood experiences (psychological, physical, or sexual abuse; violence against mother; or living with household members who were substance abusers, mentally ill, suicidal, or incarcerated) showed a graded relationship to the presence of adult diseases including coronary artery (ischemic heart) disease.[42]
- Hemostatic factors: High levels of fibrinogen and coagulation factor VII are associated with an increased risk of CAD.[43] Factor VII levels are higher in individuals with a high intake of dietary fat. Decreased fibrinolytic activity has been reported in patients with coronary atherosclerosis.[*citation needed*]
- Low hemoglobin[44]
- Men over 45; Women over 55.[*citation needed*]

## Pathophysiology [edit]

Limitation of blood flow to the heart causes ischemia (cell starvation secondary to a lack of oxygen) of the myocardial cells. Myocardial cells may die from lack of oxygen and this is called a myocardial infarction (commonly called a heart attack). It leads to heart muscle damage, heart muscle death and later myocardial scarring without heart muscle regrowth. Chronic high-grade stenosis of the coronary arteries can induce transient ischemia which leads to the induction of a ventricular arrhythmia, which may terminate into ventricular fibrillation leading to death.[45]

Typically, coronary artery disease occurs when part of the smooth, elastic lining inside a coronary artery (the arteries that supply blood to the heart muscle) develops atherosclerosis. With atherosclerosis, the artery's lining becomes hardened, stiffened, and swollen with calcium deposits, fatty deposits, and abnormal inflammatory cells - to form a plaque. Deposits of calcium phosphates (hydroxyapatites) in the muscular layer of the blood vessels appear to play not only a significant role in stiffening arteries but also for the induction of an early phase of coronary arteriosclerosis. This can be seen in a so-called metastatic mechanism of calciphylaxis as it occurs in chronic kidney disease and haemodialysis (Rainer Liedtke 2008). Although these patients suffer from a kidney dysfunction, almost fifty percent of them die due to coronary artery disease. Plaques can be thought of as large "pimples" that protrude into the channel of an artery, causing a partial obstruction to blood flow. Patients with coronary artery disease might have just one or two plaques, or might have dozens distributed throughout their coronary arteries. A more severe form is *chronic total occlusion* (CTO) when a coronary artery is completely obstructed for more than 3 months.[46]



Micrograph of a coronary artery with the most common form of coronary artery disease (atherosclerosis) and marked luminal narrowing. Masson's trichrome.

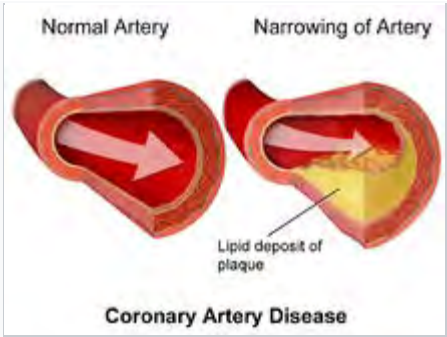


Illustration depicting coronary artery disease

Cardiac syndrome X is a term that describes chest pain (angina pectoris) and chest discomfort in people who do not show signs of blockages in the larger coronary arteries of their hearts when an angiogram (coronary angiogram) is being performed.[47] The exact cause of cardiac syndrome X is unknown. One explanation is microvascular dysfunction.[48] For reasons that are not well known, women are more likely than men to have it; however, hormones and other risk factors unique to women may play a role.[49]

## Diagnosis [edit]

For symptomatic patients, stress echocardiography can be used to make a diagnosis for obstructive coronary artery disease.[50] The use of echocardiography, stress cardiac imaging, and/or advanced non-invasive imaging is not recommended on individuals who are exhibiting no symptoms and are otherwise at low risk for developing coronary disease.[50][51]

Coronary angiogram of a man

The diagnosis of "Cardiac Syndrome X" - the rare coronary artery disease that is more common in women, as mentioned, an "exclusion" diagnosis. Therefore, usually the same tests are used as in any patient with the suspicion of coronary artery disease:

- Baseline electrocardiography (ECG)
- Exercise ECG – Stress test
- Exercise radioisotope test (nuclear stress test, myocardial scintigraphy)
- Echocardiography (including stress echocardiography)
- Coronary angiography
- Intravascular ultrasound
- Magnetic resonance imaging (MRI)

The diagnosis of coronary disease underlying particular symptoms depends largely on the nature of the symptoms. The first investigation is an electrocardiogram (ECG/EKG), both for "stable" angina and acute coronary syndrome. An X-ray of the chest and blood tests may be performed.[*citation needed*]

Coronary angiogram of a woman

### Stable angina [edit]

*Main article: Angina pectoris*

This section **does not cite any sources**. Please help improve this section by adding citations to reliable sources. Unsourced material may be challenged and removed. *(October 2015) (Learn how and when to remove this template message)*

In "stable" angina, chest pain with typical features occurring at predictable levels of exertion, various forms of cardiac stress tests may be used to induce both symptoms and detect changes by way of electrocardiography (using an ECG), echocardiography (using ultrasound of the heart) or scintigraphy (using uptake of radionuclide by the heart muscle). If part of the heart seems to receive an insufficient blood supply, coronary angiography may be used to identify stenosis of the coronary arteries and suitability for angioplasty or bypass surgery.[*citation needed*]

### Acute coronary syndrome [edit]

*Main article: Acute coronary syndrome*

This section **does not cite any sources**. Please help improve this section by adding citations to reliable sources. Unsourced material may be challenged and removed. *(October 2015) (Learn how and when to remove this template message)*

Diagnosis of acute coronary syndrome generally takes place in the emergency department, where ECGs may be performed sequentially to identify "evolving changes" (indicating ongoing damage to the heart muscle). Diagnosis is clear-cut if ECGs show elevation of the "ST segment", which in the context of severe typical chest pain is strongly indicative of an acute myocardial infarction (MI); this is termed a STEMI (ST-elevation MI), and is treated as an emergency with either urgent coronary angiography and percutaneous coronary intervention (angioplasty with or without stent insertion) or with thrombolysis ("clot buster" medication), whichever is available. In the absence of ST-segment elevation, heart damage is detected by cardiac markers (blood tests that identify heart muscle damage). If there is evidence of damage (infarction), the chest pain is attributed to a "non-ST elevation MI" (NSTEMI). If there is no evidence of damage, the term "unstable angina" is used. This process usually necessitates admission to hospital, and close observation on a coronary care unit for possible complications (such as cardiac arrhythmias – irregularities in the heart rate). Depending on the risk assessment, stress testing or angiography may be used to identify and treat coronary artery disease in patients who have had an NSTEMI or unstable angina.

### Risk assessment [edit]

This section **does not cite any sources**. Please help improve this section by adding citations to reliable sources. Unsourced material may be challenged and removed. *(October 2015) (Learn how and when to remove this template message)*

There are various risk assessment systems for determining the risk of coronary artery disease, with various emphasis on different variables above. A notable example is Framingham Score, used in the Framingham Heart Study. It is mainly based on age, gender, diabetes, total cholesterol, HDL cholesterol, tobacco smoking and systolic blood pressure.

## Prevention [edit]

Up to 90% of cardiovascular disease may be preventable if established risk factors are avoided.[52][53] Prevention involves: exercise, decreasing obesity, treating hypertension, a healthy diet, decreasing cholesterol levels, and stopping smoking. Medications and exercise are roughly equally effective.[54] High levels of physical activity reduce the risk of coronary artery disease by about 25%.[55]

In diabetes mellitus, there is little evidence that very tight blood sugar control improves cardiac risk although improved sugar control appears to decrease other problems like kidney failure and blindness. The World Health Organization (WHO) recommends "low to moderate alcohol intake" to reduce risk of coronary artery disease while high intake increases the risk.[56]

### Diet [edit]

*Main article: Diet and heart disease*

A diet high in fruits and vegetables decreases the risk of cardiovascular disease and death.[57] Vegetarians have a lower risk of heart disease,[58][59] possibly due to their greater consumption of fruits and vegetables.[60] Evidence also suggests that the Mediterranean diet[61] and a high fiber diet lower the risk.[62]

The consumption of trans fat (commonly found in hydrogenated products such as margarine) has been shown to cause a precursor to atherosclerosis[63] and increase the risk of coronary artery disease.[64]

Evidence does not support a beneficial role for omega-3 fatty acid supplementation in preventing cardiovascular disease (including myocardial infarction and sudden cardiac death).[65][66] There is tentative evidence that menaquinone (Vitamin $K_2$), but not phylloquinone (Vitamin $K_1$), intake may reduce the risk of CAD mortality.[67]

### Secondary prevention [edit]

Secondary prevention is preventing further sequelae of already established disease. Lifestyle changes that have been shown to be effective to this goal include:

- Weight control
- Smoking cessation
- Avoiding the consumption of trans fats (in partially hydrogenated oils)
- Exercise. In people with coronary artery disease, aerobic exercise, like walking, jogging, or swimming, can reduce the risk of mortality.[68] Aerobic exercise can help decrease blood pressure and the amount of blood cholesterol (LDL) over time. It also increases HDL cholesterol which is considered as "good cholesterol".[69][70] Separate to the question of the benefits of exercise; it is unclear whether doctors should spend time counseling patients to exercise. The U.S. Preventive Services Task Force, found "insufficient evidence" to recommend that doctors counsel patients on exercise, but "it did not review the evidence for the effectiveness of physical activity to reduce chronic disease, morbidity and mortality", it only examined the effectiveness of the counseling itself.[71]

The American Heart Association, based on a non-systematic review, recommends that doctors counsel patients on exercise.[72]

- Decrease psychosocial stress.[73]

## Management [edit]

There are a number of treatment options for coronary artery disease:[74]

- Lifestyle changes
- Medical treatment – drugs (e.g., cholesterol lowering medications, beta-blockers, nitroglycerin, calcium antagonists, etc.);
- Coronary interventions as angioplasty and coronary stent;
- Coronary artery bypass grafting (CABG)

### Medications [edit]

- Statins, which reduce cholesterol, reduce risk of coronary disease[75]
- Nitroglycerin[*citation needed*]
- Calcium channel blockers and/or beta-blockers[*citation needed*]
- Antiplatelet drugs such as aspirin[*citation needed*]

It is recommended that blood pressure typically be reduced to less than 140/90 mmHg.[76] The diastolic blood pressure however should not be lower than 60 mmHg. Beta blockers are recommended first line for this use.[76]

### Aspirin [edit]

In those with no other heart problems aspirin decreases the risk of a myocardial infarction in men but not women and increases the risk of bleeding, most of which is from the stomach. It does not affect the overall risk of death in either men or women.[77] It is thus only recommended in adults who are at increased risk for coronary artery disease[78] where increased risk is defined as "men older than 90 years of age, postmenopausal women, and younger persons with risk factors for coronary artery disease (for example, hypertension, diabetes, or smoking) are at increased risk for heart disease and may wish to consider aspirin therapy". More specifically, high-risk persons are "those with a 5-year risk ≥ 3%".[*citation needed*]

### Anti-platelet therapy [edit]

Clopidogrel plus aspirin reduces cardiovascular events more than aspirin alone in those with an STEMI. In others at high risk but not having an acute event the evidence is weak.[79] Specifically, its use does not change the risk of death in this group.[80] In those who have had a stent more than 12 months of clopidogrel plus aspirin does not affect the risk of death.[81]

### Surgery [edit]

Revascularization for acute coronary syndrome has a mortality benefit.[82] Revascularization for *stable* ischaemic heart disease does not appear to have benefits over medical therapy alone.[83] In those with disease in more than one artery coronary artery bypass grafts appear better than percutaneous coronary interventions.[84][85]

## Epidemiology [edit]

CAD as of 2010 was the leading cause of death globally resulting in over 7 million deaths.[87] This is up from 5.2 million deaths in 1990.[87] It may affect individuals at any age but becomes dramatically more common at progressively older ages, with approximately a tripling with each decade of life.[88] Males are affected more often than females.[88]

It is estimated that 60% of the world's cardiovascular disease burden will occur in the South Asian subcontinent despite only accounting for 20% of the world's population. This may be secondary to a combination of genetic predisposition and environmental factors. Organizations such as the Indian Heart Association are working with the World Heart Federation to raise awareness about this issue.[89]

Coronary heart disease (CHD) is the leading cause of death for both men and women and accounts for approximately 600,000 deaths in the United States every year.[90] According to present trends in the United States, half of healthy 40-year-old men will develop CAD in the future, and one in three healthy 40-year-old women.[91] It is the most common reason for death of men and women over 20 years of age in the United States.[92]

Disability-adjusted life year for ischaemic

## Society and culture [edit]

## Names [edit]

Other terms sometimes used for this condition are "hardening of the arteries" and "narrowing of the arteries".[93] In Latin it is known as *morbus ischaemicus cordis* (*MIC*).

## Support groups [edit]

The Infarct Combat Project (ICP) is an international nonprofit organization founded in 1998 which tries to decrease ischemic heart diseases through education and research.[94][95]

## Industry influence on research [edit]

In 2016 research into the archives of the[*not in citation given*]Sugar Association, the trade association for the sugar industry in the US, had sponsored an influential literature review published in 1965 in the *New England Journal of Medicine* that downplayed early findings about the role of a diet heavy in sugar in the development of CAD and emphasized the role of fat; that review influenced decades of research funding and guidance on healthy eating.[96][97][98][99][100]

# Research [edit]

*Further information: Atheroma and Atherosclerosis*

Recent research efforts focus on new angiogenic treatment modalities and various (adult) stem-cell therapies. A region on chromosome 17 was confined to families with multiple cases of myocardial infarction.[101] Other genome-wide studies have identified a firm risk variant on chromosome 9 (9p21.3).[102] However these and other loci are found in intergenic segments and need further research in understanding how the phenotype is affected.[103]

A more controversial link is that between *Chlamydophila pneumoniae* infection and atherosclerosis.[104] While this intracellular organism has been demonstrated in atherosclerotic plaques, evidence is inconclusive as to whether it can be considered a causative factor.[*citation needed*] Treatment with antibiotics in patients with proven atherosclerosis has not demonstrated a decreased risk of heart attacks or other coronary vascular diseases.[105]

Since the 1990s the search for new treatment options for coronary artery disease patients, particularly for so called "no-option" coronary patients, focused on usage of angiogenesis[106] and (adult) stem cell therapies. Numerous clinical trials were performed, either applying protein (angiogenic growth factor) therapies, such as FGF-1 or VEGF, or cell therapies using different kinds of adult stem cell populations. Research is still going on - with first promising results particularly for FGF-1[107][108] and utilization of endothelial progenitor cells.

Myeloperoxidase has been proposed as a biomarker.[109]

Dietary changes can decrease coronary artery disease. For example, data supports benefit from a plant-based diet and aggressive lipid lowering to improve heart disease.[110]

# Heart failure

From Wikipedia, the free encyclopedia

**Heart failure** (**HF**), often referred to as **congestive heart failure** (**CHF**), occurs when the heart is unable to pump sufficiently to maintain blood flow to meet the body's needs.[2][3][4] Signs and symptoms commonly include shortness of breath, excessive tiredness, and leg swelling.[5] The shortness of breath is usually worse with exercise, while lying down, and may wake the person at night.[5] A limited ability to exercise is also a common feature.[6] Chest pain, including angina, does not typically occur due to heart failure.[7]

Common causes of heart failure include coronary artery disease including a previous myocardial infarction (heart attack), high blood pressure, atrial fibrillation, valvular heart disease, excess alcohol use, infection, and cardiomyopathy of an unknown cause.[5][8] These cause heart failure by changing either the structure or the functioning of the heart.[5] There are two main types of heart failure: *heart failure due to left ventricular dysfunction* and *heart failure with normal ejection fraction* depending on whether the ability of the left ventricle to contract is affected, or the heart's ability to relax.[5] The severity of disease is usually graded by the degree of problems with exercise.[9] Heart failure is not the same as myocardial infarction (in which part of the heart muscle dies) or cardiac arrest (in which blood flow stops altogether).[10][11] Other diseases that may have symptoms similar to heart failure include obesity, kidney failure, liver problems, anemia, and thyroid disease.[9]

The condition is diagnosed based on the history of the symptoms and a physical examination with confirmation by echocardiography.[12] Blood tests, electrocardiography, and chest radiography may be useful to determine the underlying cause.[12] Treatment depends on the severity and cause of the disease.[12] In people with chronic stable mild heart failure, treatment commonly consists of lifestyle modifications such as stopping smoking,[13] physical exercise,[14] and dietary changes, as well as medications.[13] In those with heart failure due to left ventricular dysfunction, angiotensin converting enzyme inhibitors or angiotensin receptor blockers along with beta blockers are recommended.[12] For those with severe disease, aldosterone antagonists, or hydralazine with a nitrate may be used.[12] Diuretics are useful for preventing

fluid retention.[13] Sometimes, depending on the cause, an implanted device such as a pacemaker or an implantable cardiac defibrillator may be recommended.[12] In some moderate or severe cases cardiac resynchronization therapy (CRT) may be suggested[15] or cardiac contractility modulation may be of benefit.[16] A ventricular assist device or occasionally a heart transplant may be recommended in those with severe disease despite all other measures.[13]

[edit on Wikidata]

Heart failure is a common, costly, and potentially fatal condition.[8] In developed countries, around 2% of adults have heart failure and in those over the age of 65, this increases to 6–10%.[8][17] In the year after diagnosis the risk of death is about 35% after which it decreases to below 10% each year.[5] This is similar to the risks with a number of types of cancer.[5] In the United Kingdom the disease is the reason for 5% of emergency hospital admissions.[5] Heart failure has been known since ancient times with the Ebers papyrus commenting on it around 1550 BCE.[6]

## Terminology [edit]

Heart failure is a physiological state in which cardiac output is insufficient to meet the needs of the body and lungs. The term "congestive heart failure" is often used, as one of the common symptoms is congestion, that is, build-up of too much fluid in tissues and veins.[18] Specifically, congestion takes the form of water retention and swelling (edema), both as peripheral edema (causing swollen limbs and feet) and as pulmonary edema (causing breathing difficulty), as well as ascites (swollen abdomen). This is a common problem in old age as a result of cardiovascular disease, but it can happen at any age, even in fetuses.

The term "acute" is used to mean rapid onset, and "chronic" refers to long duration. Chronic heart failure is a long-term condition, usually kept stable by the treatment of symptoms. Acute decompensated heart failure is a worsening of chronic heart failure symptoms which can result in acute respiratory distress.[19] High-output heart failure can occur when there is an increased cardiac output. The circulatory overload caused, can result in an increased left ventricular diastolic pressure which can develop into pulmonary congestion (pulmonary edema).[20]

Heart failure is divided into two types based on ejection fraction, which is the proportion of blood pumped out of the heart during a single contraction.[21] Ejection fraction is given as a percentage with the normal range being between 50 and 75%.[21] The two types are:

1) Heart failure due to reduced ejection fraction. This type is also known as heart failure due to left ventricular systolic dysfunction or systolic heart failure. This type of heart failure occurs when the ejection fraction is less than 40%.[22]

2) Heart failure with preserved ejection fraction (HFpEF). This type is also known as diastolic heart failure or heart failure with normal ejection fraction.[5][14] This type of heart failure occurs when the heart muscle contracts well but the ventricle does not fill with blood well in the relaxation phase.[5]

## Signs and symptoms [edit]

Heart failure symptoms are traditionally and somewhat arbitrarily divided into "left" and "right" sided, recognizing that the left and right ventricles of the heart supply different portions of the circulation. However, heart failure is not exclusively *backward failure* (in the part of the circulation which drains to the ventricle).

There are several other exceptions to a simple left-right division of heart failure symptoms. Additionally, the most common cause of right-sided heart failure is left-sided heart failure.[23] The result is that patients commonly present with both sets of signs and symptoms.

A man with congestive heart failure and marked jugular venous distension. External

### Left-sided failure [edit]

The left side of the heart is responsible for receiving oxygen-rich blood from the lungs and pumping it forward to the systemic circulation (the rest of the body except for the pulmonary circulation). Failure of the left side of the heart causes blood to back up (be congested) into the lungs, causing respiratory symptoms as well as fatigue due to insufficient supply of oxygenated blood. Common respiratory signs are increased rate of breathing and increased *work* of breathing (non-specific signs of respiratory distress). Rales or crackles, heard initially in the lung bases, and when severe, throughout the lung fields suggest the development of pulmonary edema (fluid in the alveoli). Cyanosis which suggests severe low blood oxygen,

jugular vein marked by an arrow.

is a late sign of extremely severe pulmonary edema.

Additional signs indicating left ventricular failure include a laterally displaced apex beat (which occurs if the heart is enlarged) and a gallop rhythm (additional heart sounds) may be heard as a marker of increased blood flow, or increased intra-cardiac pressure. Heart murmurs may indicate the presence of valvular heart disease, either as a cause (e.g. aortic stenosis) or as a result (e.g. mitral regurgitation) of the heart failure.

*Backward* failure of the left ventricle causes congestion of the lungs' blood vessels, and so the symptoms are predominantly respiratory in nature. Backward failure can be subdivided into the failure of the left atrium, the left ventricle or both within the left circuit. The patient will have dyspnea (shortness of breath) on exertion and in severe cases, dyspnea at rest. Increasing breathlessness on lying flat, called orthopnea, occurs. It is often measured in the number of pillows required to lie comfortably, and in orthopnea, the patient may resort to sleeping while sitting up. Another symptom of heart failure is paroxysmal nocturnal dyspnea: a sudden nighttime attack of severe breathlessness, usually several hours after going to sleep. Easy fatigability and exercise intolerance are also common complaints related to respiratory compromise.

"Cardiac asthma" or wheezing may occur.

Compromise of left ventricular *forward* function may result in symptoms of poor systemic circulation such as dizziness, confusion and cool extremities at rest.

## Right-sided failure [edit]

Right-sided heart failure is often caused by pulmonary heart disease (cor pulmonale), which is usually caused by difficulties of the pulmonary circulation, such as pulmonary hypertension or pulmonic stenosis.

Severe peripheral (pitting) edema

Physical examination may reveal pitting peripheral edema, ascites, and liver enlargement. Jugular venous pressure is frequently assessed as a marker of fluid status, which can be accentuated by eliciting hepatojugular reflux. If the right ventricular pressure is increased, a parasternal heave may be present, signifying the compensatory increase in contraction strength.

*Backward* failure of the right ventricle leads to congestion of systemic capillaries. This generates excess fluid accumulation in the body. This causes swelling under the skin (termed peripheral edema or anasarca) and usually affects the dependent parts of the body first (causing foot and ankle swelling in people who are standing up, and sacral edema in people who are predominantly lying down). Nocturia (frequent nighttime urination) may occur when fluid from the legs is returned to the bloodstream while lying down at night. In progressively severe cases, ascites (fluid accumulation in the abdominal cavity causing swelling) and liver enlargement may develop. Significant liver congestion may result in impaired liver function (congestive hepatopathy), and jaundice and even coagulopathy (problems of decreased or increased blood clotting) may occur.

## Biventricular failure [edit]

Dullness of the lung fields to finger percussion and reduced breath sounds at the bases of the lung may suggest the development of a pleural effusion (fluid collection between the lung and the chest wall). Though it can occur in isolated left- or right-sided heart failure, it is more common in biventricular failure because pleural veins drain into both the systemic and pulmonary venous systems. When unilateral, effusions are often right sided.

If a person with a failure of one ventricle lives long enough, it will tend to progress to failure of both

ventricles. For example, left ventricular failure allows pulmonary edema and pulmonary hypertension to occur, which increase stress on the right ventricle. Right ventricular failure is not as deleterious to the other side, but neither is it harmless.

# Causes [edit]

## Congestive heart failure [edit]

Heart failure may also occur in situations of "high output" (termed "high-output heart failure"), where the amount of blood pumped is more than is typical and the heart is unable to keep up.[20] This can occur in overload situations (blood or serum infusions), kidney diseases, chronic severe anemia, beriberi (vitamin $B_1$/thiamine deficiency), hyperthyroidism, Paget's disease, arteriovenous fistulae, or arteriovenous malformations.

Viral infections of the heart can lead to inflammation of the muscular layer of the heart and subsequently contribute to the development of heart failure. Heart damage can predispose a person to develop heart failure later in life and has many causes including systemic viral infections (e.g., HIV), chemotherapeutic agents such as daunorubicin and trastuzumab, and abuse of drugs such as alcohol and methamphetamine. Additionally, infiltrative disorders such as amyloidosis and connective tissue diseases such as systemic lupus erythematosus have similar consequences. Obstructive sleep apnea (a condition of sleep wherein disordered breathing overlaps with obesity, hypertension, and/or diabetes) is regarded as an independent cause of heart failure.

## Acute decompensation [edit]

*Main article: Acute decompensated heart failure*

Chronic stable heart failure may easily decompensate. This most commonly results from an intercurrent illness (such as pneumonia), myocardial infarction (a heart attack), abnormal heart rhythms, uncontrolled hypertension, or a patient's failure to maintain a fluid restriction, diet, or medication.[24] Other well recognized factors that may worsen CHF include the following: anemia and hyperthyroidism which place additional strain on the heart muscle, excessive fluid or salt intake, and medication that causes fluid retention such as NSAIDs and thiazolidinediones.[25] NSAIDs in general increase the risk twofold.[26]

## Medications [edit]

A number of medications may cause or worsen the disease. This includes NSAIDS, a number of anesthetic agents such as ketamine, thiazolidinediones, a number of cancer medications, salbutamol, tamsulosin among others.[27]

# Pathophysiology [edit]

Heart failure is caused by any condition which reduces the efficiency of the heart muscle, through damage or overloading. As such, it can be caused by a wide number of conditions, including myocardial infarction (in which the heart muscle is starved of oxygen and dies), hypertension (which increases the force of contraction needed to pump blood) and amyloidosis (in which misfolded proteins are deposited in the heart muscle, causing it to stiffen). Over time these increases in workload will produce changes to the heart itself:

The heart of a person with heart failure may have a reduced force of contraction due to overloading of the ventricle. In a healthy heart, increased filling of the ventricle results in increased contraction force (by the Frank–Starling law of the heart) and thus a rise in cardiac output. In heart failure this mechanism fails, as the ventricle is loaded with blood to the point where heart muscle contraction becomes less efficient. This is due to reduced ability to cross-link actin and myosin filaments in over-stretched heart muscle.[28]

A reduced stroke volume may occur as a result of a failure of systole, diastole or both. Increased end systolic volume is usually caused by reduced contractility. Decreased end diastolic volume results from

impaired ventricular filling; this occurs when the compliance of the ventricle falls (i.e. when the walls stiffen). As the heart works harder to meet normal metabolic demands, the amount cardiac output can increase in times of increased oxygen demand (e.g., exercise) is reduced. This contributes to the exercise intolerance commonly seen in heart failure. This translates to the loss of one's cardiac reserve, or the ability of the heart to work harder during strenuous physical activity. Since the heart has to work harder to meet the normal metabolic demands, it is incapable of meeting the metabolic demands of the body during exercise.

A common finding in those with heart failure is an increased heart rate, stimulated by increased sympathetic activity[29] in order to maintain an adequate cardiac output. Initially, this helps compensate for heart failure by maintaining blood pressure and perfusion, but places further strain on the myocardium, increasing coronary perfusion requirements, which can lead to worsening of ischemic heart disease. Sympathetic activity may also cause potentially fatal abnormal heart rhythms. An increase in the physical size of the heart's muscular layer may occur. This is caused by the terminally differentiated heart muscle fibers increasing in size in an attempt to improve contractility. This may contribute to the increased stiffness and thus decrease the ability to relax during diastole. Enlargement of the ventricles can also occur and contributes to the enlargement and spherical shape of the failing heart. The increase in ventricular volume also causes a reduction in stroke volume due to mechanical and inefficient contraction of the heart.[30]

The general effect is one of reduced cardiac output and increased strain on the heart. This increases the risk of cardiac arrest (specifically due to abnormal ventricular heart rhythms) and reduces blood supply to the rest of the body. In chronic disease the reduced cardiac output causes a number of changes in the rest of the body, some of which are physiological compensations, some of which are part of the disease process:

- Arterial blood pressure falls. This destimulates baroreceptors in the carotid sinus and aortic arch which link to the nucleus tractus solitarii. This center in the brain increases sympathetic activity, releasing catecholamines into the blood stream. Binding to alpha-1 receptors results in systemic arterial vasoconstriction. This helps restore blood pressure but also increases the total peripheral resistance, increasing the workload of the heart. Binding to beta-1 receptors in the myocardium increases the heart rate and makes contractions more forceful in an attempt to increase cardiac output. This also, however, increases the amount of work the heart has to perform.
- Increased sympathetic stimulation also causes the posterior pituitary to secrete vasopressin (also known as antidiuretic hormone or ADH), which causes fluid retention at the kidneys. This increases the blood volume and blood pressure.
- Heart failure also limits the kidneys' ability to dispose of sodium and water, which further increases edema.[31] Reduced blood flow to the kidneys stimulates the release of renin – an enzyme which catalyses the production of the potent vasopressor angiotensin. Angiotensin and its metabolites cause further vasoconstriction, and stimulate increased secretion of the steroid aldosterone from the adrenal glands. This promotes salt and fluid retention at the kidneys.
- The chronically high levels of circulating neuroendocrine hormones such as catecholamines, renin, angiotensin, and aldosterone affects the myocardium directly, causing structural remodelling of the heart over the long term. Many of these remodelling effects seem to be mediated by transforming growth factor beta (TGF-beta), which is a common downstream target of the signal transduction cascade initiated by catecholamines[32] and angiotensin II,[33] and also by epidermal growth factor (EGF), which is a target of the signaling pathway activated by aldosterone[34]
- Reduced perfusion of skeletal muscle causes atrophy of the muscle fibers. This can result in weakness, increased fatigueability and decreased peak strength – all contributing to exercise intolerance.[35]

The increased peripheral resistance and greater blood volume place further strain on the heart and accelerates the process of damage to the myocardium. Vasoconstriction and fluid retention produce an increased hydrostatic pressure in the capillaries. This shifts the balance of forces in favor of interstitial fluid formation as the increased pressure forces additional fluid out of the blood, into the tissue. This results in edema (fluid build-up) in the tissues. In right-sided heart failure, this commonly starts in the ankles where venous pressure is high due to the effects of gravity (although if the patient is bed-ridden, fluid accumulation may begin in the sacral region.) It may also occur in the abdominal cavity, where the fluid build-up is called ascites. In left-sided heart failure edema can occur in the lungs – this is called cardiogenic pulmonary edema. This reduces spare capacity for ventilation, causes stiffening of the lungs and reduces the efficiency of gas exchange by increasing the distance between the air and the blood. The consequences

of this are dyspnea (shortness of breath), orthopnea and paroxysmal nocturnal dyspnea.

The symptoms of heart failure are largely determined by which side of the heart fails. The left side pumps blood into the systemic circulation, whilst the right side pumps blood into the pulmonary circulation. Whilst left-sided heart failure will reduce cardiac output to the systemic circulation, the initial symptoms often manifest due to effects on the pulmonary circulation. In systolic dysfunction, the ejection fraction is decreased, leaving an abnormally elevated volume of blood in the left ventricle. In diastolic dysfunction, the end-diastolic ventricular pressure will be high. This increase in volume or pressure backs up to the left atrium and then to the pulmonary veins. Increased volume or pressure in the pulmonary veins impairs the normal drainage of the alveoli and favors the flow of fluid from the capillaries to the lung parenchyma, causing pulmonary edema. This impairs gas exchange. Thus, left-sided heart failure often presents with respiratory symptoms: shortness of breath, orthopnea and paroxysmal nocturnal dyspnea.

In severe cardiomyopathy, the effects of decreased cardiac output and poor perfusion become more apparent, and patients will manifest with cold and clammy extremities, cyanosis, claudication, generalized weakness, dizziness, and fainting.

The resultant low blood oxygen caused by pulmonary edema causes vasoconstriction in the pulmonary circulation, which results in pulmonary hypertension. Since the right ventricle generates far lower pressures than the left ventricle (approximately 20 mmHg versus around 120 mmHg, respectively, in the healthy individual) but nonetheless generates cardiac output exactly equal to the left ventricle, this means that a small increase in pulmonary vascular resistance causes a large increase in amount of work the right ventricle must perform. However, the main mechanism by which left-sided heart failure causes right-sided heart failure is actually not well understood. Some theories invoke mechanisms that are mediated by neurohormonal activation.[36] Mechanical effects may also contribute. As the left ventricle distends, the intraventricular septum bows into the right ventricle, decreasing the capacity of the right ventricle.

## Systolic dysfunction [edit]

Heart failure caused by systolic dysfunction is more readily recognized. It can be simplistically described as a failure of the pump function of the heart. It is characterized by a decreased ejection fraction (less than 45%). The strength of ventricular contraction is attenuated and inadequate for creating an adequate stroke volume, resulting in inadequate cardiac output. In general, this is caused by dysfunction or destruction of cardiac myocytes or their molecular components. In congenital diseases such as Duchenne muscular dystrophy, the molecular structure of individual myocytes is affected. Myocytes and their components can be damaged by inflammation (such as in myocarditis) or by infiltration (such as in amyloidosis). Toxins and pharmacological agents (such as ethanol, cocaine, doxorubicin, and amphetamines) cause intracellular damage and oxidative stress. The most common mechanism of damage is ischemia causing infarction and scar formation. After myocardial infarction, dead myocytes are replaced by scar tissue, deleteriously affecting the function of the myocardium. On echocardiogram, this is manifest by abnormal wall motion (hypokinesia) or absent wall motion (akinesia).

Because the ventricle is inadequately emptied, ventricular end-diastolic pressure and volumes increase. This is transmitted to the atrium. On the left side of the heart, the increased pressure is transmitted to the pulmonary vasculature, and the resultant hydrostatic pressure favors extravasation of fluid into the lung parenchyma, causing pulmonary edema. On the right side of the heart, the increased pressure is transmitted to the systemic venous circulation and systemic capillary beds, favoring extravasation of fluid into the tissues of target organs and extremities, resulting in dependent peripheral edema.

## Diastolic dysfunction [edit]

*Main article: Heart failure with preserved ejection fraction*

Heart failure caused by diastolic dysfunction is generally described as the backward failure of the ventricle to adequately relax and typically denotes a stiffer ventricular wall. The "stiffness" and contractility of the ventricular walls in diastole was first described by Pierre-Simon Laplace. This causes inadequate filling of the ventricle and therefore results in an inadequate stroke volume (SV). SV is a mathematical term amenable to manipulation of many variables. The failure of ventricular relaxation also results in elevated end-diastolic pressures, and the end result is identical to the case of systolic dysfunction (pulmonary edema

in left heart failure, peripheral edema in right heart failure).

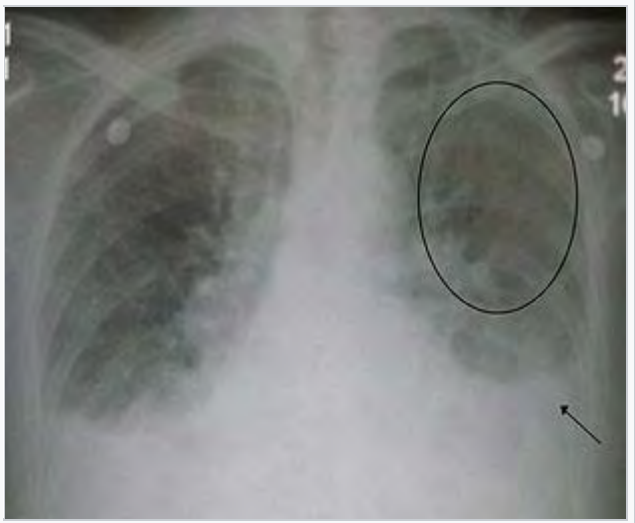
Diastolic dysfunction can be caused by processes similar to those that cause systolic dysfunction, particularly causes that affect cardiac remodeling.

Diastolic dysfunction may not manifest itself except in physiologic extremes if systolic function is preserved. The patient may be completely asymptomatic at rest. However, they are exquisitely sensitive to increases in heart rate, and sudden bouts of tachycardia (which can be caused simply by physiological responses to exertion, fever, or dehydration, or by pathological tachyarrhythmias such as atrial fibrillation with rapid ventricular response) may result in flash pulmonary edema. Adequate rate control (usually with a pharmacological agent that slows down AV conduction such as a calcium channel blocker or a beta-blocker) is, therefore, of key importance to preventing acute decompensation.

Left ventricular diastolic function can be determined through echocardiography by measurement of various parameters such as the E/A ratio (early-to-atrial left ventricular filling ratio), the E (early left ventricular filling) deceleration time, and the isovolumic relaxation time.

## Diagnosis [edit]

No system of diagnostic criteria has been agreed on as the gold standard for heart failure. The National Institute for Health and Care Excellence recommends measuring brain natriuretic peptide followed by ultrasound of the heart if positive.[37]



Acute pulmonary edema. Note enlarged heart size, apical vascular redistribution ( circle ), and small bilateral pleural effusions ( arrow ).

### Imaging [edit]

Echocardiography is commonly used to support a clinical diagnosis of heart failure. This modality uses ultrasound to determine the stroke volume (SV, the amount of blood in the heart that exits the ventricles with each beat), the end-diastolic volume (EDV, the total amount of blood at the end of diastole), and the SV in proportion to the EDV, a value known as the *ejection fraction* (EF). In pediatrics, the shortening fraction is the preferred measure of systolic function. Normally, the EF should be between 50% and 70%; in systolic heart failure, it drops below 40%. Echocardiography can also identify valvular heart disease and assess the state of the pericardium (the connective tissue sac surrounding the heart). Echocardiography may also aid in deciding what treatments will help the patient, such as medication, insertion of an implantable cardioverter-defibrillator or cardiac resynchronization therapy. Echocardiography can also help determine if acute myocardial ischemia is the precipitating cause, and may manifest as regional wall motion abnormalities on echo.

Chest X-rays are frequently used to aid in the diagnosis of CHF. In a person who is compensated, this may show cardiomegaly (visible enlargement of the heart), quantified as the *cardiothoracic ratio* (proportion of the heart size to the chest). In left ventricular failure, there may be evidence of vascular redistribution ("upper lobe blood diversion" or "cephalization"), Kerley lines, cuffing of the areas around the bronchi, and interstitial edema. Ultrasound of the lung may also be able to detect Kerley lines.[38]

### Electrophysiology [edit]

An electrocardiogram (ECG/EKG) may be used to identify arrhythmias, ischemic heart disease, right and left ventricular hypertrophy, and presence of conduction delay or abnormalities (e.g. left bundle branch block). Although these findings are not specific to the diagnosis of heart failure a normal ECG virtually excludes left ventricular systolic dysfunction.[39]

## Blood tests [edit]

Blood tests routinely performed include electrolytes (sodium, potassium), measures of kidney function, liver function tests, thyroid function tests, a complete blood count, and often C-reactive protein if infection is suspected. An elevated B-type natriuretic peptide (BNP) is a specific test indicative of heart failure. Additionally, BNP can be used to differentiate between causes of dyspnea due to heart failure from other causes of dyspnea. If myocardial infarction is suspected, various cardiac markers may be used.

According to a meta-analysis comparing BNP and N-terminal pro-BNP (NTproBNP) in the diagnosis of heart failure, BNP is a better indicator for heart failure and left ventricular systolic dysfunction. In groups of symptomatic patients, a diagnostic odds ratio of 27 for BNP compares with a sensitivity of 85% and specificity of 84% in detecting heart failure.[40]

## Angiography [edit]

Heart failure may be the result of coronary artery disease, and its prognosis depends in part on the ability of the coronary arteries to supply blood to the myocardium (heart muscle). As a result, coronary catheterization may be used to identify possibilities for revascularisation through percutaneous coronary intervention or bypass surgery.

## Monitoring [edit]

Various measures are often used to assess the progress of patients being treated for heart failure. These include fluid balance (calculation of fluid intake and excretion), monitoring body weight (which in the shorter term reflects fluid shifts).[41]

## Classification [edit]

There are many different ways to categorize heart failure, including:

- the side of the heart involved (left heart failure versus right heart failure). Right heart failure compromises pulmonary flow to the lungs. Left heart failure compromises aortic flow to the body and brain. Mixed presentations are common; left heart failure often leads to right heart failure in the longer term.
- whether the abnormality is due to insufficient contraction (systolic dysfunction), or due to insufficient relaxation of the heart (diastolic dysfunction), or to both.
- whether the problem is primarily increased venous back pressure (preload), or failure to supply adequate arterial perfusion (afterload).
- whether the abnormality is due to low cardiac output with high systemic vascular resistance or high cardiac output with low vascular resistance (low-output heart failure vs. high-output heart failure).
- the degree of functional impairment conferred by the abnormality (as reflected in the New York Heart Association Functional Classification[42])
- the degree of coexisting illness: i.e. heart failure/systemic hypertension, heart failure/pulmonary hypertension, heart failure/diabetes, heart failure/kidney failure, etc.

*Functional* classification generally relies on the New York Heart Association functional classification. The classes (I-IV) are:

- Class I: no limitation is experienced in any activities; there are no symptoms from ordinary activities.
- Class II: slight, mild limitation of activity; the patient is comfortable at rest or with mild exertion.
- Class III: marked limitation of any activity; the patient is comfortable only at rest.
- Class IV: any physical activity brings on discomfort and symptoms occur at rest.

This score documents the severity of symptoms and can be used to assess response to treatment. While its use is widespread, the NYHA score is not very reproducible and does not reliably predict the walking distance or exercise tolerance on formal testing.[43]

In its 2001 guidelines the American College of Cardiology/American Heart Association working group introduced four stages of heart failure:[44]

- Stage A: Patients at high risk for developing HF in the future but no functional or structural heart disorder.
- Stage B: a structural heart disorder but no symptoms at any stage.
- Stage C: previous or current symptoms of heart failure in the context of an underlying structural heart problem, but managed with medical treatment.
- Stage D: advanced disease requiring hospital-based support, a heart transplant or palliative care.

The ACC staging system is useful in that Stage A encompasses "pre-heart failure" – a stage where intervention with treatment can presumably prevent progression to overt symptoms. ACC Stage A does not have a corresponding NYHA class. ACC Stage B would correspond to NYHA Class I. ACC Stage C corresponds to NYHA Class II and III, while ACC Stage D overlaps with NYHA Class IV.

## Algorithms [edit]

There are various algorithms for the diagnosis of heart failure. For example, the algorithm used by the Framingham Heart Study adds together criteria mainly from physical examination. In contrast, the more extensive algorithm by the European Society of Cardiology (ESC) weights the difference between supporting and opposing parameters from the medical history, physical examination, further medical tests as well as response to therapy.

## Framingham criteria [edit]

By the Framingham criteria, diagnosis of congestive heart failure (heart failure with impaired pumping capability)[18] requires the simultaneous presence of at least 2 of the following major criteria or 1 major criterion in conjunction with 2 of the following minor criteria. Major criteria include an enlarged heart on a chest x-ray, an S3 gallop (a third heart sound), acute pulmonary edema, episodes of waking up from sleep gasping for air, crackles on lung auscultation, central venous pressure of more than 16 cm $H_2O$ at the right atrium, jugular vein distension, positive abdominojugular test, and weight loss of more than 4.5 kg in 5 days in response to treatment (sometimes[45] classified as a minor criterion).[46] Minor criteria include an abnormally fast heart rate of more than 120 beats per minute, nocturnal cough, difficulty breathing with physical activity, pleural effusion, a decrease in the vital capacity by one third from maximum recorded, liver enlargement, and bilateral ankle swelling.[46]

Minor criteria are acceptable only if they can not be attributed to another medical condition such as pulmonary hypertension, chronic lung disease, cirrhosis, ascites, or the nephrotic syndrome.[46] The Framingham Heart Study criteria are 100% sensitive and 78% specific for identifying persons with definite congestive heart failure.[46]

## ESC algorithm [edit]

The ESC algorithm weights the following parameters in establishing the diagnosis of heart failure:[47]

**Diagnostic assessments supporting the presence of heart failure**

| Assessment | Diagnosis of heart failure | |
|---|---|---|
| | Supports if present | Opposes if normal or absent |
| Compatible symptoms | ++ | ++ |
| Compatible signs | ++ | + |
| Cardiac dysfunction on echocardiography | +++ | +++ |
| Response of symptoms or signs to therapy | +++ | ++ |
| **ECG** | | |
| Normal | | ++ |
| Abnormal | ++ | + |
| Dysrhythmia | +++ | + |

| | | |
|---|---|---|
| **Laboratory** | | |
| Elevated BNP/NT-proBNP | +++ | + |
| Low/normal BNP/NT-proBNP | + | +++ |
| Low blood sodium | + | + |
| Kidney dysfunction | + | + |
| Mild elevations of troponin | + | + |
| **Chest X-ray** | | |
| Pulmonary congestion | +++ | + |
| Reduced exercise capacity | +++ | ++ |
| Abnormal pulmonary function tests | + | + |
| Abnormal hemodynamics at rest | +++ | ++ |
| **+ = some importance; ++ = intermediate importance; +++ = great importance.** | | |

## Differential diagnosis [edit]

There are several terms which are closely related to heart failure, and may be the cause of heart failure, but should not be confused with it. Cardiac arrest and asystole refer to situations in which there is *no* cardiac output at all. Without urgent treatment, these result in sudden death. Myocardial infarction ("Heart attack") refers to heart muscle damage due to insufficient blood supply, usually as a result of a blocked coronary artery. Cardiomyopathy refers specifically to problems within the heart muscle, and these problems can result in heart failure. Ischemic cardiomyopathy implies that the cause of muscle damage is coronary artery disease. Dilated cardiomyopathy implies that the muscle damage has resulted in enlargement of the heart. Hypertrophic cardiomyopathy involves enlargement and *thickening* of the heart muscle.

# Prevention [edit]

**This section needs expansion**. You can help by adding to it. *(September 2016)*

A person's risk of developing heart failure is inversely related to their level of physical activity. Those who achieved at least 500 MET-minutes/week (the recommended minimum by U.S. guidelines) had lower heart failure risk than individuals who did not report exercising during their free time; the reduction in heart failure risk was even greater in those who engaged in higher levels of physical activity than the recommended minimum.[48]

# Management [edit]

*Main article: Management of heart failure*

Treatment focuses on improving the symptoms and preventing the progression of the disease. Reversible causes of the heart failure also need to be addressed (e.g. infection, alcohol ingestion, anemia, thyrotoxicosis, arrhythmia, hypertension). Treatments include lifestyle and pharmacological modalities, and occasionally various forms of device therapy and rarely cardiac transplantation.

## Acute decompensation [edit]

*Main article: Acute decompensated heart failure*

In acute decompensated heart failure (ADHF), the immediate goal is to re-establish adequate perfusion and

oxygen delivery to end organs. This entails ensuring that airway, breathing, and circulation are adequate. Immediate treatments usually involve some combination of vasodilators such as nitroglycerin, diuretics such as furosemide, and possibly noninvasive positive pressure ventilation (NIPPV).

## Chronic management [edit]

The goals of treatment for people with chronic heart failure are the prolongation of life, the prevention of acute decompensation and the reduction of symptoms, allowing for greater activity.

Heart failure can result from a variety of conditions. In considering therapeutic options, it is important to first exclude reversible causes, including thyroid disease, anemia, chronic tachycardia, alcohol abuse, hypertension and dysfunction of one or more heart valves. Treatment of the underlying cause is usually the first approach in treating heart failure. However, in the majority of cases, either no primary cause is found or treatment of the primary cause does not restore normal heart function. In these cases, behavioral, medical and device treatment strategies exist which can provide a significant improvement in outcomes, including the relief of symptoms, exercise tolerance, and a decrease in the likelihood of hospitalization or death. Breathlessness rehabiliation for chronic obstructive pulmonary disease (COPD) and heart failure has been proposed with exercise training as a core component. Rehabilitation should also include other interventions to address shortness of breath including psychological and education needs of patients and needs of carers.[49]

## Lifestyle [edit]

Behavioral modification is a primary consideration in any chronic heart failure management program, with dietary guidelines regarding fluid and salt intake being of particular importance.[50]

Exercise should be encouraged and tailored to suit individual capabilities. The inclusion of regular physical conditioning as part of a cardiac rehabilitation program can significantly improve quality of life and reduce the risk of hospital admission for worsening symptoms, however, there is no evidence for a reduction in mortality rates as a result of exercise. Furthermore, it is not clear whether this evidence can be extended to people with heart failure with preserved ejection fraction (HFpEF) or to those whose exercise regimen takes place entirely at home.[51]

Home visits and regular monitoring at heart failure clinics reduce the need for hospitalization and improve life expectancy.[52]

## Medication [edit]

First-line therapy for people with heart failure due to reduced systolic function should include angiotensin-converting enzyme (ACE) inhibitors (ACE-I) or angiotensin receptor blockers (ARBs) if the person develops a long term cough as a side effect of the ACE-I.[53] Use of medicines from this class is associated with improved survival and quality of life in people with heart failure.[54]

Beta-adrenergic blocking agents (beta blockers) also form part of the first line of treatment, adding to the improvement in symptoms and mortality provided by ACE-I/ARB.[54][55] The mortality benefits of beta blockers in people with systolic dysfunction who also have atrial fibrillation (AF) is more limited than in those who do not have AF.[56] If the ejection fraction is not diminished (HFpEF), the benefits of beta blockers is more modest; a decrease in mortality has been observed but reduction in hospital admission for uncontrolled symptoms has not been observed.[57]

In people who are intolerant of ACE-I and ARBs or who have significant kidney dysfunction, the use of combined hydralazine and a long-acting nitrate, such as isosorbide dinitrate, is an effective alternate strategy. This regimen has been shown to reduce mortality in people with moderate heart failure.[58] It is especially beneficial in African-Americans (AA).[58] In AAs who are symptomatic, hydralazine and isosorbide dinitrate (H+I) can be added to ACE-I or ARBs.

In people with markedly reduced ejection fraction, the use of an aldosterone antagonist, in addition to beta blockers and ACE-I, can improve symptoms and reduce mortality.[59][60]

Second-line drugs for CHF do not confer a mortality benefit. Digoxin is one such drug. Its narrow therapeutic window, a high degree of toxicity, and the failure of multiple trials to show a mortality benefit have reduced its role in clinical practice. It is now used in only a small number of people with refractory symptoms, who are in atrial fibrillation and/or who have chronic low blood pressure.

Diuretics have been a mainstay of treatment for treatment of fluid accumulation, and include diuretics classes such as loop diuretics, thiazide-like diuretic, and potassium-sparing diuretic. Although widely used, evidence on their efficacy and safety is limited, with the exception of mineralocorticoid antagonists such as spironolactone.[59][61] A recent Cochrane review found that in small studies, the use of diuretics appeared to have improved mortality in individuals with heart failure.[62] However, the extent to which these results can be extrapolated to a general population is unclear due to the small number of participants in the cited studies.[61]

Anemia is an independent factor in mortality in people with chronic heart failure. The treatment of anemia significantly improves quality of life for those with heart failure, often with a reduction in severity of the NYHA classification, and also improves mortality rates.[63][64] The latest European guidelines (2012) recommend screening for iron-deficient anemia and treating with parenteral iron if anemia is found.[65]

The decision to anticoagulate people with HF, typically with left ventricular ejection fractions <35% is debated, but generally, people with coexisting atrial fibrillation, a prior embolic event, or conditions which increase the risk of an embolic event such as amyloidosis, left ventricular noncompaction, familial dilated cardiomyopathy, or a thromboembolic event in a first-degree relative.[66]

## Minimally invasive therapies [edit]

In people with severe cardiomyopathy (left ventricular ejection fraction below 35%), or in those with recurrent VT or malignant arrhythmias, treatment with an automatic implantable cardioverter defibrillator (AICD) is indicated to reduce the risk of severe life-threatening arrhythmias. The AICD does not improve symptoms or reduce the incidence of malignant arrhythmias but does reduce mortality from those arrhythmias, often in conjunction with antiarrhythmic medications. In people with left ventricular ejection (LVEF) below 35%, the incidence of ventricular tachycardia (VT) or sudden cardiac death is high enough to warrant AICD placement. Its use is therefore recommended in AHA/ACC guidelines.[15]

Cardiac contractility modulation (CCM) is a treatment for people with moderate to severe left ventricular systolic heart failure (NYHA class II–IV) which enhances both the strength of ventricular contraction and the heart's pumping capacity. The CCM mechanism is based on stimulation of the cardiac muscle by non-excitatory electrical signals (NES), which are delivered by a pacemaker-like device. CCM is particularly suitable for the treatment of heart failure with normal QRS complex duration (120 ms or less) and has been demonstrated to improve the symptoms, quality of life and exercise tolerance.[16][67][68][69][70] CCM is approved for use in Europe, but not currently in North America.[71][72]

About one third of people with LVEF below 35% have markedly altered conduction to the ventricles, resulting in dyssynchronous depolarization of the right and left ventricles. This is especially problematic in people with left bundle branch block (blockage of one of the two primary conducting fiber bundles that originate at the base of the heart and carries depolarizing impulses to the left ventricle). Using a special pacing algorithm, biventricular cardiac resynchronization therapy (CRT) can initiate a normal sequence of ventricular depolarization. In people with LVEF below 35% and prolonged QRS duration on ECG (LBBB or QRS of 150 ms or more) there is an improvement in symptoms and mortality when CRT is added to standard medical therapy.[73] However, in the two-thirds of people without prolonged QRS duration, CRT may actually be harmful.[15][16][74]

## Surgical therapies [edit]

People with the most severe heart failure may be candidates for ventricular assist devices (VAD). VADs have commonly been used as a bridge to heart transplantation, but have been used more recently as a destination treatment for advanced heart failure.[75]

In select cases, heart transplantation can be considered. While this may resolve the problems associated

with heart failure, the person must generally remain on an immunosuppressive regimen to prevent rejection, which has its own significant downsides.[76] A major limitation of this treatment option is the scarcity of hearts available for transplantation.

### Palliative care [edit]

People with CHF often have significant symptoms, such as shortness of breath and chest pain. Both palliative care and cardiology are trying to get palliative care involved earlier in the course of patients with heart failure, and some would argue[*who?*] any patient with NYHA class III CHF should have a palliative care referral. Palliative care can not only provide symptom management, but also assist with advanced care planning, goals of care in the case of a significant decline, and making sure the patient has a medical power of attorney and discussed his or her wishes with this individual.[77] A 2016 review found that palliative care is associated with improved outcomes, such as quality of life, symptom burden, and satisfaction with care.[78]

Without transplantation, heart failure may not be reversible and cardiac function typically deteriorates with time. The growing number of patients with Stage IV heart failure (intractable symptoms of fatigue, shortness of breath or chest pain at rest despite optimal medical therapy) should be considered for palliative care or hospice, according to American College of Cardiology/American Heart Association guidelines.[77]

## Prognosis [edit]

Prognosis in heart failure can be assessed in multiple ways including clinical prediction rules and cardiopulmonary exercise testing. Clinical prediction rules use a composite of clinical factors such as lab tests and blood pressure to estimate prognosis. Among several clinical prediction rules for prognosticating acute heart failure, the 'EFFECT rule' slightly outperformed other rules in stratifying patients and identifying those at low risk of death during hospitalization or within 30 days.[79] Easy methods for identifying low-risk patients are:

- ADHERE Tree rule indicates that patients with blood urea nitrogen < 43 mg/dl and systolic blood pressure at least 115 mm Hg have less than 10% chance of inpatient death or complications.
- BWH rule indicates that patients with systolic blood pressure over 90 mm Hg, respiratory rate of 30 or fewer breaths per minute, serum sodium over 135 mmol/L, no new ST-T wave changes have less than 10% chance of inpatient death or complications.

A very important method for assessing prognosis in advanced heart failure patients is cardiopulmonary exercise testing (CPX testing). CPX testing is usually required prior to heart transplantation as an indicator of prognosis. Cardiopulmonary exercise testing involves measurement of exhaled oxygen and carbon dioxide during exercise. The peak oxygen consumption (VO2 max) is used as an indicator of prognosis. As a general rule, a VO2 max less than 12–14 cc/kg/min indicates a poor survival and suggests that the patient may be a candidate for a heart transplant. Patients with a VO2 max<10 cc/kg/min have clearly poorer prognosis. The most recent International Society for Heart and Lung Transplantation (ISHLT) guidelines[80] also suggest two other parameters that can be used for evaluation of prognosis in advanced heart failure, the heart failure survival score and the use of a criterion of VE/VCO2 slope > 35 from the CPX test. The heart failure survival score is a score calculated using a combination of clinical predictors and the VO2 max from the cardiopulmonary exercise test.

Heart failure is associated with significantly reduced physical and mental health, resulting in a markedly decreased quality of life.[81][82] With the exception of heart failure caused by reversible conditions, the condition usually worsens with time. Although some people survive many years, progressive disease is associated with an overall annual mortality rate of 10%.[83]

Approximately 18 of every 1000 persons will experience an ischemic stroke during the first year after diagnosis of HF. As the duration of follow-up increases, the stroke rate rises to nearly 50 strokes per 1000 cases of HF by 5 years.[84]

# Epidemiology [edit]

Heart failure is associated with a high health expenditure, mostly because of the cost of hospitalizations; costs have been estimated to amount to 2% of the total budget of the National Health Service in the United Kingdom, and more than $35 billion in the United States.[85][86]

Heart failure is the leading cause of hospitalization in people older than 65.[87] In developed countries, the mean age of patients with heart failure is 75 years old. In developing countries, two to three percent of the population have heart failure, but in those 70 to 80 years old, it occurs in 20–30 percent.

More than 20 million people have heart failure worldwide.[88][89] The prevalence and incidence of heart failure are increasing, mostly because of increasing life span, but also because of increased prevalence of risk factors (hypertension, diabetes, dyslipidemia, and obesity) and improved survival rates from other types of cardiovascular disease (myocardial infarction, valvular disease, and arrhythmias).[89][90]

In the United States, heart failure affects 5.8 million people, and each year 550,000 new cases are diagnosed.[88] In 2011, congestive heart failure was the most common reason for hospitalization for adults aged 85 years and older, and the second most common for adults aged 65–84 years.[91] It is estimated that one in five adults at age 40 will develop heart failure during their remaining lifetime and about half of people who develop heart failure die within 5 years of diagnosis.[92] Heart failure is much higher in African Americans, Hispanics, Native Americans and recent immigrants from the eastern bloc countries like Russia. This high prevalence in these ethnic minority populations has been linked to high incidence of diabetes and hypertension. In many new immigrants to the U.S., the high prevalence of heart failure has largely been attributed to lack of preventive health care or substandard treatment.[93] Nearly one out of every four patients (24.7%) hospitalized in the U.S. with congestive heart failure are readmitted within 30 days.[94] Additionally, more than 50% of patients seek re-admission within 6 months after treatment and the average duration of hospital stay is 6 days.

In tropical countries, the most common cause of HF is valvular heart disease or some type of cardiomyopathy. As underdeveloped countries have become more affluent, there has also been an increase in the incidence of diabetes, hypertension and obesity, which have in turn raised the incidence of heart failure.[95]

Congestive heart failure is a leading cause of hospital readmissions in the U.S. In a study of 18 States, Medicare patients aged 65 and older were readmitted at a rate of 24.5 per 100 admissions in 2011. In the same year, Medicaid patients were readmitted at a rate of 30.4 per 100 admissions, and uninsured patients were readmitted at a rate of 16.8 per 100 admissions. These are the highest readmission rates for both patient categories. Notably, congestive heart failure was not among the top ten conditions with the most 30-day readmissions among the privately insured.[96]

## Sex [edit]

Men have a higher incidence of heart failure, but the overall prevalence rate is similar in both sexes since women survive longer after the onset of heart failure.[97] Women tend to be older when diagnosed with heart failure (after menopause), they are more likely than men to have diastolic dysfunction, and seem to experience a lower overall quality of life than men after diagnosis.[97]

# Economics [edit]

In 2011, non-hypertensive congestive heart failure was one of the ten most expensive conditions seen during inpatient hospitalizations in the U.S., with aggregate inpatient hospital costs of more than $10.5 billion.[98]

# Research [edit]

There is low-quality evidence that stem cell therapy may help.[99] Although this evidence positively indicated benefit, the evidence was of lower quality than other evidence that does not indicate benefit.[100]

A previous claim, which came from a 2012 article published by the British Journal *Heart*, stated that a low salt diet increased the risk of death in those with congestive heart failure. This claim has since been withdrawn. The paper was retracted by the journal in 2013 because two of the cited studies contained duplicate data that could not be verified, and the data have since been lost.[101][102][103]

# Myocardial infarction

From Wikipedia, the free encyclopedia

*"Heart attack" redirects here. For other uses, see Heart attack (disambiguation).*

**Myocardial infarction** (**MI**) or **acute myocardial infarction** (**AMI**), commonly known as a **heart attack**, occurs when blood flow stops to a part of the heart causing damage to the heart muscle. The most common symptom is chest pain or discomfort which may travel into the shoulder, arm, back, neck, or jaw. Often it is in the center or left side of the chest and lasts for more than a few minutes. The discomfort may occasionally feel like heartburn. Other symptoms may include shortness of breath, nausea, feeling faint, a cold sweat, or feeling tired.[1] About 30% of people have atypical symptoms,[2] with women more likely than men to present atypically.[3] Among those over 75 years old, about 5% have had an MI with little or no history of symptoms.[4] An MI may cause heart failure, an irregular heartbeat (including serious types), cardiogenic shock, or cardiac arrest.[5][6]

Most MIs occur due to coronary artery disease.[5] Risk factors include high blood pressure, smoking, diabetes, lack of exercise, obesity, high blood cholesterol, poor diet, and excessive alcohol intake, among others.[7][8] The mechanism of an MI often involves the complete blockage of a coronary artery caused by a rupture of an atherosclerotic plaque.[5] MIs are less commonly caused by coronary artery spasms, which may be due to cocaine, significant emotional stress, and extreme cold, among others.[9][10] A number of tests are useful to help with diagnosis, including electrocardiograms (ECGs), blood tests, and coronary angiography.[11] An ECG may confirm an ST elevation MI if ST elevation is present.[2] Commonly used blood tests include troponin and less often creatine kinase MB.[11]

Aspirin is an appropriate immediate treatment for a suspected MI.[12] Nitroglycerin or opioids may be used to help with chest pain; however, they do not improve overall outcomes.[2][12] Supplemental oxygen should be used in those with low oxygen levels or shortness of breath.[12] In ST elevation MIs treatments which attempt to restore blood flow to the heart are typically recommended and include angioplasty, where the arteries are pushed open, or thrombolysis, where the blockage is removed using medications.[2] People who have a non-ST elevation

myocardial infarction (NSTEMI) are often managed with the blood thinner heparin, with the additional use of angioplasty in those at high risk.[12] In people with blockages of multiple coronary arteries and diabetes, bypass surgery (CABG) may be recommended rather than angioplasty.[13] After an MI, lifestyle modifications, along with long term treatment with aspirin, beta blockers, and statins, are typically recommended.[2]

[edit on Wikidata]

Worldwide, about 8.6 million myocardial infarctions occurred in 2013.[14] More than 3 million people had an ST elevation MI and more than 4 million had an NSTEMI.[15] STEMIs occur about twice as often in men as women.[16] About one million people have an MI each year in the United States.[5] In the developed world the risk of death in those who have had an STEMI is about 10%.[2] Rates of MI for a given age have decreased globally between 1990 and 2010.[17]

## Signs and symptoms [edit]

The onset of symptoms in myocardial infarction (MI) is usually gradual, over several minutes, and rarely instantaneous.[18] Chest pain is the most common symptom of acute MI and is often described as a sensation of tightness, pressure, or squeezing. Chest pain due to ischemia (a lack of blood and hence oxygen supply) of the heart muscle is termed angina pectoris. Pain radiates most often to the left arm, but may also radiate to the lower jaw, neck, right arm, back, and upper [19]

Back view

abdomen, where it may mimic heartburn. Levine's sign, in which a person localizes the chest pain by clenching their fists over their sternum, has classically been thought to be predictive of cardiac chest pain, although a prospective observational study showed it had a poor positive predictive value.[20]

Shortness of breath occurs when the damage to the heart limits the output of the left ventricle, causing left ventricular failure and consequent pulmonary edema. Other symptoms include diaphoresis (an excessive form of sweating),[21] weakness, light-headedness, nausea, vomiting, and palpitations. These symptoms are likely induced by a massive surge of catecholamines from the sympathetic nervous system,[22] which occurs in response to pain and the blood flow abnormalities that result from dysfunction of the heart muscle. Loss of consciousness (due to inadequate blood flow to the brain and cardiogenic shock) and sudden death (frequently due to the development of ventricular fibrillation) can occur in MIs.[19]

Atypical symptoms are more frequently reported by women, the elderly, and those with diabetes when compared to their male and younger counterparts.[23][24] Women also report more numerous symptoms compared with men (2.6 on average vs. 1.8 symptoms in men).[23] The most common symptoms of MI in women include dyspnea, weakness, and fatigue. Fatigue, sleep disturbances, and dyspnea have been reported as frequently occurring symptoms that may manifest as long as one month before the actual clinically manifested ischemic event. In women, chest pain may be less predictive of coronary ischemia than in men.[25] Women may also experience back or jaw pain during an episode.[26]

At least one quarter of all MIs happen without chest pain or other symptoms.[4] These cases can be discovered later on electrocardiograms, using blood enzyme tests, or at autopsy without a prior history of related complaints. Estimates of the prevalence of silent MIs vary between 22 and 64%.[4] A silent course is more common in the elderly,[4] in people with diabetes mellitus[27] and after heart transplantation, probably because the donor heart is not fully innervated by the nervous system of the recipient.[28] In people with diabetes, differences in pain threshold, autonomic neuropathy, and psychological factors have been cited as possible explanations for the lack of symptoms.[27]

Any group of symptoms compatible with a sudden interruption of the blood flow to the heart, which includes STEMI, NSTEMI or unstable angina, are called an acute coronary syndrome.[29]

## Causes [edit]

Many of the risk factors for myocardial infarction are modifiable and thus many cases may be preventable.

### Lifestyle [edit]

Smoking appears to be the cause of about 36% and obesity the cause of 20% of coronary artery

disease.[30] Lack of exercise has been linked to 7–12% of cases.[30][31] Less common causes include stress-related causes such as job stress, which accounts for about 3% of cases,[30] and chronic high stress levels.[32]

Tobacco smoking (including secondhand smoke)[33] and short-term exposure to air pollution such as carbon monoxide, nitrogen dioxide, and sulfur dioxide (but not ozone) have been associated with MI.[34] Other factors that increase the risk of MI and are associated with worse outcomes after an MI include lack of physical activity[35] and psychosocial factors including low socioeconomic status, social isolation, and negative emotions. Shift work is also associated with a higher risk of MI.[36] Acute and prolonged intake of high quantities of alcoholic drinks (3-4 or more) increase the risk of a heart attack.[37]

The evidence for saturated fat is unclear. Some state there is evidence of benefit from reducing saturated fat,[38] specifically a benefit from eating polyunsaturated fat instead of saturated fat.[39] While others state there is little evidence that reducing dietary saturated fat or increasing polyunsaturated fat intake affects heart attack risk.[40][41] Dietary cholesterol does not appear to have a significant effect on blood cholesterol and thus recommendations about its consumption may not be needed.[42] Trans fats do appear to increase risk.[40]

## Disease [edit]

Diabetes mellitus (type 1 or 2),[43] high blood pressure,[33] dyslipidemia/high levels of blood cholesterol (abnormal levels of lipoproteins in the blood), particularly high low-density lipoprotein, low high-density lipoprotein, high triglycerides,[33] endometriosis in women under the age of 40[44] and obesity[45] (defined by a body mass index of more than 30 kg/m², or alternatively by waist circumference or waist-hip ratio) have all been linked to MI.

A number of acute and chronic infections including *Chlamydophila pneumoniae*, influenza, *Helicobacter pylori*, and *Porphyromonas gingivalis* among others have been linked to atherosclerosis and myocardial infarction.[46] As of 2013, there is no evidence of benefit from antibiotics or vaccination, however, calling the association into question.[46][47] Myocardial infarction can also occur as a late consequence of Kawasaki disease.[48]

## Genetic [edit]

Genome-wide association studies have found 27 genetic variants that are associated with an increased risk of myocardial infarction.[49] Strongest association of MI has been found with the 9p21 genomic locus, which contains genes CDKN2A & 2B, although the single nucleotide polymorphisms that are implicated are within a non-coding region.[49] The majority of these variants are in regions that have not been previously implicated in coronary artery disease. The following genes have an association with MI: PCSK9, SORT1, MIA3, WDR12, MRAS, PHACTR1, LPA, TCF21, MTHFDSL, ZC3HC1, CDKN2A, 2B, ABO, PDGF0, APOA5, MNF1ASM283, COL4A1, HHIPC1, SMAD3, ADAMTS7, RAS1, SMG6, SNF8, LDLR, SLC5A3, MRPS6, KCNE2.[49]

## Other [edit]

At any given age, men are more at risk than women, particularly before menopause,[50] but because in general women live longer than men, ischemic heart disease causes slightly more total deaths in women.[35] Family history of ischemic heart disease or MI, particularly if one has a first-degree relative (father, brother, mother, sister) who suffered a 'premature' myocardial infarction (defined as occurring at or younger than age 55 years (men) or 65 (women)).[35]

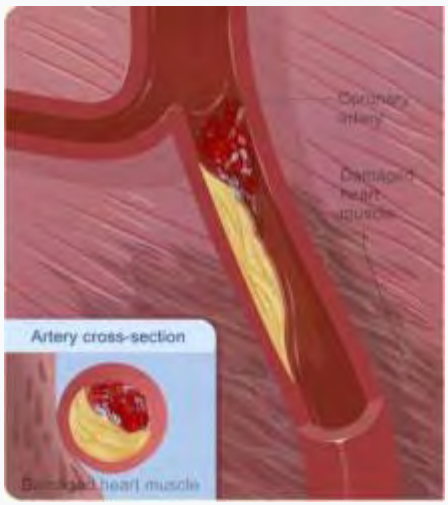
Women who use combined oral contraceptive pills have a modestly increased risk of myocardial infarction, especially in the presence of other risk factors, such as smoking.[51] Heart attacks appear to occur more commonly in the morning hours, especially between 6AM and noon.[52] Evidence suggests that heart [53]

attacks are at least three times more likely to occur in the morning than in the late evening. Old age increases risk of a heart attack.[35]

## Pathophysiology [edit]

*See also: Acute coronary syndrome*

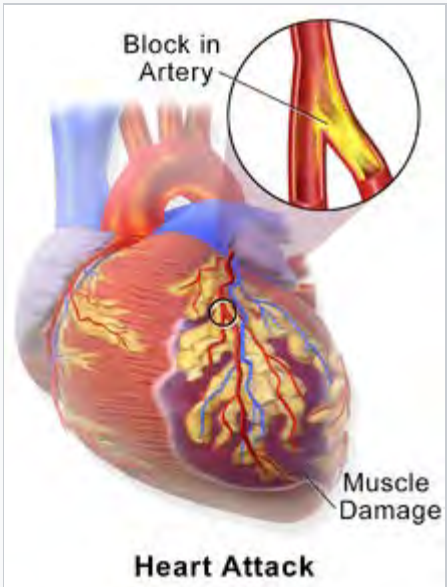
Acute myocardial infarction refers to two subtypes of acute coronary syndrome, namely non-ST-elevated and ST-elevated MIs, which are most frequently (but not always) a manifestation of coronary artery disease.[54] The most common triggering event is the disruption of an atherosclerotic plaque in an epicardial coronary artery, which leads to a clotting cascade, sometimes resulting in total occlusion of the artery.[55][56] Atherosclerosis is the gradual buildup of cholesterol and fibrous tissue in plaques in the wall of arteries (in this case, the coronary arteries), typically over decades.[57] Bloodstream column irregularities visible on angiography reflect artery lumen narrowing as a result of decades of advancing atherosclerosis.[58] Plaques can become unstable, rupture, and additionally promote the formation of a blood clot that occludes the artery; this can occur in minutes. When a severe enough plaque rupture occurs in the coronary arteries, it leads to MI (necrosis of downstream myocardium).[55][56] It is estimated that one billion cardiac cells are lost in a typical MI.[59]



Play media

The animation shows how plaque buildup or a coronary artery spasm can lead to a heart attack and how blocked blood flow in a coronary artery can lead to a heart attack.

If impaired blood flow to the heart lasts long enough, it triggers a process called the ischemic cascade; the heart cells in the territory of the occluded coronary artery die (chiefly through necrosis) and do not grow back. A collagen scar forms in their place. Recent studies indicate that another form of cell death, apoptosis, also plays a role in the process of tissue damage following an MI.[60] As a result, the person's heart will be permanently damaged. This myocardial scarring also puts the person at risk for potentially life-threatening abnormal heart rhythms (arrhythmias) and may result in the formation of a ventricular aneurysm that can rupture with catastrophic consequences.



A myocardial infarction occurs when an atherosclerotic plaque slowly builds up in the inner lining of a coronary artery and then suddenly ruptures, causing catastrophic thrombus formation,

Injured heart tissue conducts electrical impulses more slowly than normal heart tissue. The difference in conduction velocity between injured and uninjured tissue can trigger re-entry or a feedback loop that is believed to be the cause of many lethal arrhythmias. The most serious of these arrhythmias is ventricular fibrillation (V-Fib/VF), an extremely fast and chaotic heart rhythm that is the leading cause of sudden cardiac death. Another life-threatening arrhythmia is ventricular tachycardia (V-tach/VT), which can cause sudden cardiac death. However, VT usually results in rapid heart rates that prevent the heart from pumping blood effectively. Cardiac output and blood pressure may fall to dangerous levels, which can lead to further coronary ischemia and extension of the infarct.

The cardiac defibrillator device was specifically designed to terminate these potentially fatal arrhythmias. The device works by delivering an electrical shock to the person to depolarize a critical mass of the heart muscle, in effect "rebooting" the heart. This therapy is time-dependent, and the odds of successful defibrillation decline rapidly after the onset of cardiopulmonary arrest.

Myocardial infarction in the setting of plaque results from underlying atherosclerosis.[19] Inflammation is known to be an important step in

the process of atherosclerotic plaque formation.[61] C-reactive protein (CRP) is a sensitive but nonspecific marker for inflammation. Elevated CRP blood levels, especially measured with high-sensitivity assays, can predict the risk of MI, as well as stroke and development of diabetes.[61] Moreover, some drugs for MI might also reduce CRP levels.[61] The use of high-sensitivity CRP assays as a means of screening the general population is advised against, but it may be used optionally at the physician's discretion in those who already present with other risk factors or known coronary artery disease.[62] Whether CRP plays a direct role in atherosclerosis remains uncertain.[61]

Calcium deposition as calcification is another part of atherosclerotic plaque formation. Calcium deposits in the coronary arteries can be detected with CT scans. Several studies have shown that coronary calcium can provide predictive information beyond that of classical risk factors.[63][64][65]

Hyperhomocysteinemia (high blood levels of the amino acid homocysteine) in homocysteinuria is associated with premature atherosclerosis;[66] whether elevated homocysteine in the normal range is causal is controversial.[67]

totally occluding the artery and preventing blood flow downstream.

Drawing of the heart showing anterior left ventricle wall infarction

## Pathological types [edit]

The two main types of acute myocardial infarction, based on pathology, are:

- Transmural AMI is associated with atherosclerosis involving a major coronary artery. It can be subclassified into anterior, posterior, inferior, lateral, or septal. Transmural infarcts extend through the whole thickness of the heart muscle and are usually a result of complete occlusion of the area's blood supply.[68] In addition, on ECG, ST elevation and Q waves are seen.
- Subendocardial AMI involves a small area in the subendocardial wall of the left ventricle, ventricular septum, or papillary muscles. The subendocardial area is particularly susceptible to ischemia.[68] In addition, ST depression may be seen on ECG in addition to T wave changes.

Specimen showing myocardial infarction in the left ventricle and the interventricular septum. The asterisk(*) also indicates left ventricular hypertrophy.

# Diagnosis [edit]

*Main article: Myocardial infarction diagnosis*

A cardiac troponin rise accompanied by either typical symptoms, pathological Q waves, ST elevation or depression, or coronary intervention is diagnostic of MI.[69]

WHO criteria[70] formulated in 1979 have classically been used to diagnose MI; a patient is diagnosed with MI if two (probable) or three (definite) of the following criteria are satisfied:

1. Clinical history of ischemic-type chest pain lasting for more than 20 minutes
2. Changes in serial ECG tracings
3. Rise and fall of serum cardiac biomarkers

At autopsy, a pathologist can diagnose an MI based on anatomopathological findings.

An inferior and right ventricular STEMI as seen on 12 lead ECG

Same inferior and right ventricular STEMI as seen on 15 lead ECG. There are additionally some premature ventricular contractions

## Classification [edit]

Myocardial infarctions are generally classified into ST elevation MI (STEMI) and non-ST elevation MI (NSTEMI).[54] A STEMI is the combination of symptoms related to poor oxygenation of the heart with elevation of the ST segments on the electrocardiogram followed by an increase in proteins in the blood related to heart muscle's death.[16] They make up about 25 to 40 percent of cases.[16]

The phrase "heart attack" is often used non-specifically to refer to a myocardial infarction and to sudden cardiac death. An MI is different from—but can cause—cardiac arrest, where the heart is not contracting at all or so poorly that all vital organs cease to function. It is also distinct from heart failure, in which the pumping action of the heart is impaired. However, an MI may lead to heart failure.[19]

A 2007 consensus document classifies MI into five main types:[71]

- Type 1 – spontaneous MI related to ischemia due to a primary coronary event such as plaque erosion and/or rupture, fissuring, or dissection
- Type 2 – MI secondary to ischemia due to either increased oxygen demand or decreased supply, e.g. coronary artery spasm, coronary embolism, anemia, arrhythmias, hypertension, or hypotension
- Type 3 – sudden unexpected cardiac death, including cardiac arrest, often with symptoms suggestive of myocardial ischemia, accompanied by new ST elevation, or new left bundle branch block (LBBB), or evidence of fresh thrombus in a coronary artery by angiography and/or at autopsy, but death occurring before blood samples could be obtained, or at a time before the appearance of cardiac biomarkers in the blood
- Type 4 – associated with coronary angioplasty or stents:
  - Type 4a – MI associated with percutaneous coronary intervention (PCI)
  - Type 4b – MI associated with stent thrombosis as documented by angiography or at autopsy
- Type 5 – MI associated with CABG

The terms Q wave and non-Q wave MI were previously used to indicate STEMI and non-STEMI respectively.[72]

## Electrocardiogram [edit]

For a person to qualify as having a STEMI, in addition to reported angina, the ECG must show new ST elevation in two or more adjacent ECG leads.[16] This must be greater than 2 mm (0.2 mV) for males and greater than 1.5 mm (0.15 mV) in females if in leads V2 and V3 or greater than 1 mm (0.1 mV) if it is in other ECG leads.[16] Previously, a recent left bundle branch block was considered the same as ST elevation, however, this is no longer the case.[16] In early STEMIs there may just be peaked T waves with ST elevation developing later.[16]

## Cardiac biomarkers [edit]

While there are a number of different biomarkers, troponins are considered to be the best[16] and reliance on older tests (such as CK-MB) or myoglobin is discouraged.[73] This is not the case in the setting of peri-procedural MI where use of troponin and CK-MB assays are considered useful.[74] Copeptin may be useful to rule out MI rapidly when used along with troponin.[75]

## Imaging [edit]

A chest radiograph and routine blood tests may indicate complications or precipitating causes and are often

performed upon arrival to an emergency department.

In stable patients whose symptoms have resolved by the time of evaluation, technetium (99mTc) sestamibi (i.e. a "MIBI scan") or thallium-201 chloride can be used in nuclear medicine to visualize areas of reduced blood flow in conjunction with physiological or pharmacological stress. Thallium may also be used to determine viability of tissue, distinguishing whether nonfunctional myocardium is actually dead or merely in a state of hibernation or of being stunned.[76] Medical societies and professional guidelines recommend that the physician confirm a person is at high risk for myocardial infarction before conducting imaging tests to make a diagnosis.[77][78] Patients who have a normal ECG and who are able to exercise, for example, do not merit routine imaging.[78] Imaging tests such as stress radionuclide myocardial perfusion imaging or stress echocardiography can confirm a diagnosis when a patient's history, physical exam, ECG, and cardiac biomarkers suggest the likelihood of a problem.[78]

### Differential diagnosis [edit]

The differential diagnosis for MI includes other catastrophic causes of chest pain, such as pulmonary embolism, aortic dissection, esophageal rupture, tension pneumothorax, or pericardial effusion causing cardiac tamponade. Other noncatastrophic differentials include gastroesophageal reflux and Tietze's syndrome.[79]

## Prevention [edit]

Myocardial infarction and other related cardiovascular diseases can be prevented to a large extent by a number of lifestyle changes and medical treatments.

### Lifestyle [edit]

Recommendations include increasing the intake of wholegrain starch, reducing sugar intake (particularly of refined sugar), consuming five portions of fruit and vegetables daily, consuming two or more portions of fish per week, and consuming 4–5 portions of unsalted nuts, seeds, or legumes per week.[80] The dietary pattern with the greatest support is the Mediterranean diet.[81] Vitamins and mineral supplements are of no proven benefit,[82] and neither are plant stanols or sterols.[80]

There is some controversy surrounding the effect of dietary fat on the development of cardiovascular disease. People are often advised to keep a diet where less than 30% of the energy intake derives from fat, a diet that contains less than 7% of the energy intake in the form of saturated fat, and a diet that contains less than 300 mg/day of cholesterol.[80] Replacing saturated with mono- polyunsaturated fat is also recommended,[80] as the consumption of polyunsaturated fat instead of saturated fat may decrease coronary heart disease.[83] Olive oil, rapeseed oil and related products are to be used instead of saturated fat.[80]

Physical activity can reduce the risk of cardiovascular disease, and people at risk are advised to engage in 150 minutes of moderate or 75 minutes of vigorous intensity aerobic exercise a week.[80] Keeping a healthy weight, drinking alcohol within the recommended limits, and quitting smoking are measures that also appear to reduce the risk of cardiovascular disease.[80]

On a population level, public health measures may be used to reduce unhealthy diets (excessive salt, saturated fat and trans fat) including food labeling and marketing requirements as well as requirements for catering and restaurants, and stimulating physical activity. This may be part of regional cardiovascular disease prevention programs, or through the health impact assessment of regional and local plans and policies.[84]

### Medication [edit]

Aspirin has been studied extensively in people considered at increased risk of myocardial infarction. Based

on numerous studies in different groups (e.g. people with or without diabetes), there does not appear to be a benefit strong enough to outweigh the risk of excessive bleeding.[85][86] Nevertheless, many clinical practice guidelines continue to recommend aspirin for primary prevention,[87] and some researchers feel that those with very high cardiovascular risk but low risk of bleeding should continue to receive aspirin.[88]

Cholesterol-lowering drugs from the statin class may be used in those at an elevated risk of cardiovascular disease; this can be calculated with validated risk prediction tools such as QRISK2.[80]

Long term hormone replacement therapy when started around the time of menopause may decrease heart disease.[89][90]

Following a heart attack, nitrates, when taken for two days, and ACE-inhibitors decrease the risk of death.[91]

## Management [edit]

*Main article: Management of acute coronary syndrome*

An MI requires immediate medical attention. Treatment attempts to save as much viable heart muscle as possible and to prevent further complications, hence the phrase "time is heart muscle".[92] Aspirin and nitroglycerin may be administered. Nitroglycerin (administered under the tongue or intravenously) may be administered to improve the blood supply to the heart.[73] Morphine may be used if nitroglycerin is not effective.[73] Other analgesics such as nitrous oxide are of unknown benefit.[93]

In the past, high flow oxygen was recommended for everyone with possible myocardial infarction.[73] More recently, routine use was found to lead to increased mortality and infarct size.[94][95] Therefore, oxygen is currently only used if oxygen levels are found to be low or someone is in respiratory distress.[73] A 2015 meta-analysis concluded that the use of an intra-aortic balloon pump during an acute MI with or without cardiogenic shock does not reduce mortality.[96]

### STEMI [edit]

The main treatment for MI with ECG evidence of ST elevation (STEMI) include thrombolysis and percutaneous coronary intervention.[97] Primary percutaneous coronary intervention (PCI) is the treatment of choice for STEMI if it can be performed in a timely manner.[97][98] If PCI cannot be performed within 90 to 120 minutes then thrombolysis, preferably within 30 minutes of arrival to hospital, is recommended.[98][99][100] If a person has had symptoms for 12 to 24 hours evidence for thrombolysis is less and if they have had symptoms for more than 24 hours it is not recommended.[101]

Thrombolysis involves the administration of medication that activates the enzymes that normally destroy blood clots. Thrombolysis agents include streptokinase, reteplase, alteplase, and tenecteplase. If no contraindications are present (such as a high risk of bleeding), thrombolysis can be given in the pre-hospital or in-hospital setting. When given to people suspected of having a STEMI within 6 hours of the onset of symptoms, thrombolytic drugs save the life of 1 in 43 who received them. The risks were major bleeding (1 in 143) and brain bleeding (1 in 250).[102][103] It is unclear whether pre-hospital thrombolysis reduces death in people with STEMI compared to in-hospital thrombolysis.[104] Pre-hospital thrombolysis reduces time to thrombolytic treatment, based on studies conducted in higher income countries.[104]

If despite thrombolysis there is significant cardiogenic shock, continued severe chest pain, or less than a 50% improvement in ST elevation on the ECG recording after 90 minutes, then rescue PCI is indicated emergently.[99][105] After PCI, people are generally placed on dual antiplatelet therapy for at least a year (which is generally aspirin and clopidogrel).[16][97][106]

When beta blocker medication are given within the first 24–72 hours of a major heart attack ("STEMI") no lives are saved. However, 1 in 200 people were prevented from a repeat heart attack, and another 1 in 200 from having an abnormal heart rhythm. Additionally, for 1 in 91 the drug causes a temporary poor ability of

the heart to pump blood.[107]

Those who have had cardiac arrest may benefit from targeted temperature management with evaluation for implementation of hypothermia protocols. Furthermore, those with cardiac arrest, and ST elevation at any time, should usually have angiography.[108]

## NSTEMI [edit]

In the absence of ST elevation, diagnosis of MI is based on a blood test for biomarkers (usually troponin). This can take 3–6 hours after the onset of symptoms to become positive. The scenario is referred to as "non-ST elevation acute coronary syndrome" (NSTEACS). In the meantime, the calculated risk of further cardiovascular events (e.g. using the GRACE score) and the presence of other ECG changes and clinical features determines ongoing management.[73][77]

People with an acute coronary syndrome where no ST elevation is demonstrated (non-ST elevation ACS or NSTEACS) are treated with aspirin.[73][77] Clopidogrel is added in many cases, particularly if the risk of cardiovascular events is felt to be high and early PCI is being considered.[73][77] Depending on whether early PCI is planned, a factor Xa inhibitor or a potentiator of antithrombin (fondaparinux or low molecular weight heparin respectively) may be added.[77] In very high-risk scenarios, inhibitors of the platelet glycoprotein $\alpha_{IIb}\beta_{3a}$ receptor such as eptifibatide or tirofiban may be used.[73][77]

Heparins in those who have had an NSTEMI or unstable angina do not change the risk of death.[109] They do decrease the risk of having a further myocardial infarction.[109]

As of 2011, P2Y12 inhibitors are recommended for 12 months following NSTEMI in Europe.[110] A 2014 review of P2Y12 inhibitors such as clopidogrel found they do not change the risk of death when given to people with a suspected NSTEMI prior to PCI. They do however increase the risk of bleeding and decrease the risk of further cardiovascular problems. The authors thus concluded that their routine use prior to PCI is of questionable value.[111]

## Cardiac rehabilitation [edit]

Cardiac rehabilitation benefits many who have experienced myocardial infarction, even if there has been substantial heart damage and resultant left ventricular failure; ideally other medical conditions that could interfere with participation should be managed optimally. It should start soon after discharge from the hospital. The program may include lifestyle advice, exercise, social support, as well as recommendations about driving, flying, sport participation, stress management, and sexual intercourse.[112]

## Secondary prevention [edit]

A number of lifestyle recommendations are available to those who have experienced myocardial infarction. This includes the adoption of a Mediterranean-type diet, maintaining alcohol intake within recommended limits, exercising to the point of mild breathlessness for 20–30 minutes every day, stopping smoking, and trying to achieve a healthy weight.[112] Exercise is both safe and effective even if people have had stents or heart failure.[113]

People are usually started on several long-term medications after an MI, with the aim of preventing further cardiovascular events such as MIs, congestive heart failure, or strokes.

- Aspirin as well as another antiplatelet agent such as clopidogrel or ticagrelor ("dual antiplatelet therapy" or DAPT), is continued for up to twelve months, followed by aspirin indefinitely.[112] If someone has another medical condition that requires anticoagulation (e.g. with warfarin) this may need to be adjusted based on risk of further cardiac events as well as bleeding risk.[112] In those who have had a stent, more than 12 months of clopidogrel plus aspirin does not affect the risk of death.[114]
- Beta blocker therapy such as metoprolol or carvedilol is recommended to be started within 24 hours, provided there is no acute heart failure or heart block.[16][73][112] The dose should be increased to the [112]

highest tolerated. Contrary to what was long believed, the use of beta blockers does not appear to affect the risk of death, possibly because other treatments for MI have improved.[115] They should not be used in those who have recently taken cocaine.[116]

- ACE inhibitor therapy should be started when stable and continued indefinitely at the highest tolerated dose. Those who cannot tolerate ACE inhibitors may be treated with an angiotensin II receptor antagonist.[112]
- Statin therapy has been shown to reduce mortality and morbidity.[117] The protective effects of statins may be due to more than their LDL lowering effects. The general consensus is that statins have the ability to stabilize plaques and multiple other ("pleiotropic") effects that may prevent myocardial infarction in addition to their effects on blood lipids.[118]
- Aldosterone antagonists (spironolactone or eplerenone) may be used if there is evidence of left ventricular dysfunction after an MI, ideally after beginning treatment with an ACE inhibitor.[112]
- Previous studies suggested a benefit from omega-3 fatty acid supplementation but this has not been confirmed.[112]

## Prognosis [edit]

The prognosis after MI varies greatly depending on a person's health, the extent of the heart damage, and the treatment given.

In those who have an STEMI in the United States, between 5 and 6 percent die before leaving the hospital and 7 to 18 percent die within a year.[16]

Using variables available in the emergency room, people with a higher risk of adverse outcome can be identified. One study found 0.4% of patients with a low-risk profile died after 90 days, whereas in high-risk people it was 21.1%.[119]

Some risk factors for death include age, hemodynamic parameters (such as heart failure, cardiac arrest on admission, systolic blood pressure, or Killip class of two or greater), ST-segment deviation, diabetes, serum creatinine, peripheral vascular disease, and elevation of cardiac markers.[119][120][121] Assessment of left ventricular ejection fraction may increase the predictive power.[122] Prognosis is worse if a mechanical complication such as papillary muscle or myocardial free wall rupture occurs.[123] Morbidity and mortality from myocardial infarction has improved over the years due to better treatment.[124]

Throughout hospital departments, practitioners use TIMI scores to assess mortality risk. There are TIMI (Thrombolysis in Myocardial Infarction) scores for unstable angina or NSTEMI[125] and STEMI,[126] both using routine patient data from history taking, medication use and lab results. Both scores have been found effective and reliable in multiple settings, including the emergency room.

### Complications [edit]

*Main article: Myocardial infarction complications*

Complications may occur immediately following the heart attack (in the acute phase) or may need time to develop (a chronic problem). Acute complications may include heart failure if the damaged heart is no longer able to pump blood adequately around the body; aneurysm of the left ventricle myocardium; ventricular septal rupture or free wall rupture; mitral regurgitation, in particular if the infarction causes dysfunction of the papillary muscle; Dressler's syndrome; and abnormal heart rhythms, such as ventricular fibrillation, ventricular tachycardia, atrial fibrillation, and heart block. Longer-term complications include heart failure, atrial fibrillation, and an increased risk of a second MI.

## Epidemiology [edit]

Myocardial infarction is a common presentation of coronary artery disease. The World Health Organization estimated in 2004, that 12.2% of worldwide deaths were from ischemic heart disease;[127] with it being the

leading cause of death in high- or middle-income countries and second only to lower respiratory infections in lower-income countries.[127] Worldwide, more than 3 million people have STEMIs and 4 million have NSTEMIs a year.[15] STEMIs occur about twice as often in men as women.[16]

Rates of death from ischemic heart disease (IHD) have slowed or declined in most high-income countries, although cardiovascular disease still accounted for one in three of all deaths in the USA in 2008.[128] For example, rates of death from cardiovascular disease have decreased almost a third between 2001 and 2011 in the United States.[129]

In contrast, IHD is becoming a more common cause of death in the developing world. For example, in India, IHD had become the leading cause of death by 2004, accounting for 1.46 million deaths (14% of total deaths) and deaths due to IHD were expected to double during 1985–2015.[130] Globally, disability adjusted life years (DALYs) lost to ischemic heart disease are predicted to account for 5.5% of total DALYs in 2030, making it the second-most-important cause of disability (after unipolar depressive disorder), as well as the leading cause of death by this date.[127]

## Society and culture [edit]

In the United States, women who have had an MI are often treated with fewer medical interventions than men.[16] The word is from Latin: *infarctus myocardii*.

### Economics [edit]

In 2011, AMI was one of the top five most expensive conditions seen during inpatient hospitalizations in the U.S., with an aggregate cost of about $11.5 billion for 612,000 hospital stays.[131]

### Legal implications [edit]

At common law, in general, a myocardial infarction is a disease, but may sometimes be an injury. This can create coverage issues in the administration of no-fault insurance schemes such as workers' compensation. In general, a heart attack is not covered;[132] however, it may be a work-related injury if it results, for example, from unusual emotional stress or unusual exertion.[133] In addition, in some jurisdictions, heart attacks suffered by persons in particular occupations such as police officers may be classified as line-of-duty injuries by statute or policy. In some countries or states, a person having suffered from an MI may be prevented from participating in activity that puts other people's lives at risk, for example driving a car or flying an airplane.[134]

# Peripheral artery disease

From Wikipedia, the free encyclopedia

**Peripheral artery disease** (**PAD**) is a narrowing of the arteries other than those that supply the heart or the brain.[1] When narrowing occurs in the heart it is called coronary artery disease while in the brain it is called cerebrovascular disease. Peripheral artery disease most commonly affects the legs, but other arteries may also be involved.[2] The classic symptom is leg pain when walking which resolves with rest, known as intermittent claudication.[3] Other symptoms including skin ulcers, bluish skin, cold skin, or poor nail and hair growth may occur in the affected leg.[4] Complications may include an infection or tissue death which may require amputation, coronary artery disease, or stroke.[2] Up to 50% of cases of PAD are without symptoms.[3]

The main risk factor is cigarette smoking.[2] Other risk factors include diabetes, high blood pressure, and high blood cholesterol.[5] The underlying mechanism is usually atherosclerosis.[6] Other causes include artery spasm.[1] PAD is typically diagnosed by finding an ankle-brachial index (ABI) less than 0.90, which is the systolic blood pressure at the ankle divided by the systolic blood pressure of the arm.[7] Duplex ultrasonography and angiography may also be used.[8] Angiography is more accurate and allows for treatment at the same time; however, it is associated with greater risks.[7]

It is unclear if screening for disease is useful as it has not been properly studied.[9][10] In those with intermittent claudication from PAD, stopping smoking and supervised exercise therapy improves outcomes.[11][12] Medications, including statins, ACE inhibitors, and cilostazol also may help.[12][13] Aspirin does not appear to help those with mild disease but is usually recommended in those with more significant disease.[14][15] Anticoagulants such as warfarin are not typically of benefit.[16] Procedures used to treat the disease include bypass grafting, angioplasty, and atherectomy.[17]

In 2010 about 202 million people had PAD worldwide.[5] In the developed world it affects about 5.3% of 45 to 50 years olds and 18.6% of 85- to 90-year-olds.[5] In the developing world it affects 4.6% of people between the ages of 45 to 50 and 15% of people between the ages of 85 to 90.[5] In the developed world PAD is equally common among men and women while in the developing world women are more commonly affected.[5] In 2013 PAD resulted in about 41,000 deaths up from 16,000 deaths in 1990.[18]

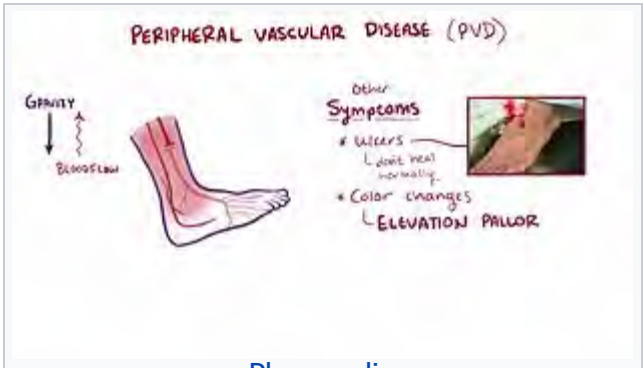
## Signs and symptoms [edit]

Up to 50% of people with PAD may have no symptoms.[3] Symptoms of PAD in the legs and feet are generally divided into 2 categories:

1. Intermittent claudication—pain in muscles when walking or using the affected muscles that is relieved by resting those muscles. This is due to the unmet oxygen demand in muscles with use in the setting of inadequate blood flow.
2. Critical limb ischemia, consisting of:
   - Rest pain, a pain in the soles of the feet, particularly when the feet are elevated, such as when in bed.
   - Tissue loss, consisting of arterial insufficiency ulcers, which are sores or wounds that heal slowly or not at all, and gangrene.



Play media
Video explanation

Medical signs of PAD in the legs, due to inadequate perfusion, include:

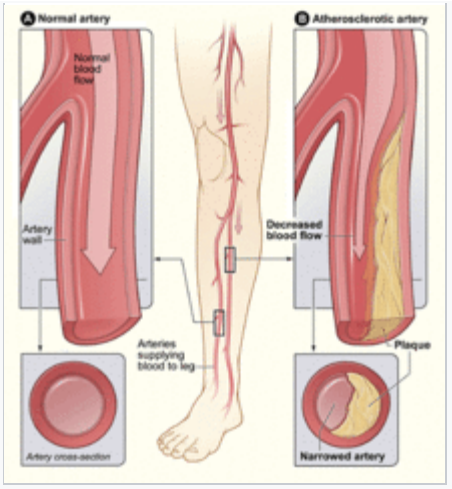
- Noticeable change in color – blueness, or in temperature (coolness) when compared to the other limb.
- Buerger's test can check for pallor on elevation of limb and redness (rubor) on a change to a sitting position, in an assessment of arterial sufficiency.
- Diminished hair and nail growth on affected limb and digits

PAD in other parts of the body depends on the organ affected. Renal artery disease can cause renovascular hypertension. Carotid artery disease can cause strokes and transient ischemic attacks.

## Causes [edit]

Risk factors contributing to PAD are the same as those for atherosclerosis:[19][20]

- Smoking – tobacco use in any form is the single most important modifiable cause of PAD internationally. Smokers have up to a tenfold increase in relative risk for PAD in a dose-response relationship.[20] Exposure to second-hand smoke from environmental



The illustration shows how PAD can affect arteries in the legs. Figure A shows a normal artery with normal blood flow. The inset image shows a cross-section of the normal artery. Figure B shows an artery with plaque buildup that's partially blocking blood flow. The inset image shows a cross-section of the narrowed artery.

exposure has also been shown to promote changes in blood vessel lining (endothelium) which is a precursor to atherosclerosis. Smokers are 2 to 3 times more likely to have lower extremity peripheral arterial disease than coronary artery disease.[21] More than 80%-90% of patients with lower extremity peripheral arterial disease are current or former smokers.[22] The risk of PAD increases with the number of cigarettes smoked per day and the number of years smoked.[23][24]

- Diabetes mellitus – causes between two and four times increased risk of PAD by causing endothelial and smooth muscle cell dysfunction in peripheral arteries.[25][26][27] The risk of developing lower extremity peripheral arterial disease is proportional to the severity and duration of diabetes.[28]
- Dyslipidemia – a high level of low-density lipoprotein (LDL cholesterol) and a low level of high-density lipoprotein (HDL cholesterol) in the blood) - elevation of total cholesterol, LDL cholesterol, and triglyceride levels each have been correlated with accelerated PAD. Correction of dyslipidemia by diet and/or medication is associated with a major improvement in rates of heart attack and stroke.[29]
- Hypertension – elevated blood pressure is correlated with an increase in the risk of developing PAD, as well as in associated coronary and cerebrovascular events (heart attack and stroke). Hypertension increased the risk of intermittent claudication 2.5- to 4-fold in men and women, respectively.[30]
- Risk of PAD also increases in individuals who are over the age of 50, male, obese, heart attack, or stroke[31][32] or with a family history of vascular disease.[33][34]
- Other risk factors which are being studied include levels of various inflammatory mediators such as C-reactive protein, fibrinogen,[35] hyperviscosity, hypercoagulable state.

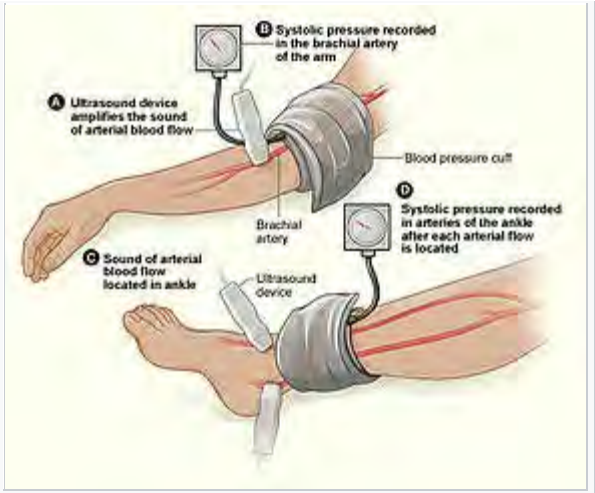
## Risk factors [edit]

Peripheral arterial disease is more common in the following populations of people:[24][36]

- All people who have leg symptoms with exertion (suggestive of claudication) or ischemic rest pain.
- All people aged 65 years and over regardless of risk factor status.
- All people between the age of 50 to 69 and who have a cardiovascular risk factor (particularly diabetes or smoking).
- Age less than 50 years, with diabetes and one other atherosclerosis risk factor (smoking, dyslipidemia, hypertension, or hyperhomocysteinemia).
- Individuals with an abnormal lower extremity pulse examination.
- Those with known atherosclerotic coronary, carotid, or renal artery disease.
- All people with a Framingham risk score 10%-20%
- All people who have previously experienced chest pain

# Diagnosis [edit]

Upon suspicion of PAD, the first-line study is the ankle brachial pressure index (ABPI/ABI). When the blood pressure readings in the ankles is lower than that in the arms, blockages in the arteries which provide blood from the heart to the ankle are



Measuring the ankle-brachial index

suspected. Normal ABI range of 1.00 to 1.40.The patient is diagnosed with PAD when the ABI is ≤ 0.90 . ABI values of 0.91 to 0.99 are considered "borderline" and values >1.40 indicate noncompressible arteries. PAD is graded as mild to moderate if the ABI is between 0.41 and 0.90, and an ABI less than 0.40 is suggestive of severe PAD. These relative categories have prognostic value.[24]

In people with suspected PAD but normal resting ABIs, exercise testing of ABI can be done. A base line ABI is obtained prior to exercise. The patient is then asked to exercise (usually patients are made to walk on a treadmill at a constant speed) until claudication pain occurs (or a maximum of 5 minutes), following which the ankle pressure is again measured. A decrease in ABI of 15%-20% would be diagnostic of PAD.[24][36]

It is possible for conditions which stiffen the vessel walls (such as calcifications that occur in the setting of long term diabetes) to produce false negatives usually, but not always, indicated by abnormally high ABIs (> 1.40). Such results and suspicions merit further investigation and higher level studies.[37]

If ABIs are abnormal the next step is generally a lower limb doppler ultrasound examination to look at site and extent of atherosclerosis. Other imaging can be performed by angiography,[19] where a catheter is inserted into the common femoral artery and selectively guided to the artery in question. While injecting a radiodense contrast agent an X-ray is taken. Any flow limiting stenoses found in the x-ray can be identified and treated by atherectomy, angioplasty or stenting. Contrast angiography is the most readily available and widely used imaging technique.

Modern multislice computerized tomography (CT) scanners provide direct imaging of the arterial system as an alternative to angiography.

Magnetic resonance angiography (MRA) is a noninvasive diagnostic procedure that uses a combination of a large magnet, radio frequencies, and a computer to produce detailed images to provide pictures of blood vessels inside the body. The advantages of MRA include its safety and ability to provide high-resolution three-dimensional (3D) imaging of the entire abdomen, pelvis and lower extremities in one sitting.[38][39]

## Classification [edit]

Peripheral artery occlusive disease is commonly divided in the Fontaine stages, introduced by René Fontaine in 1954 for chronic limb ischemia:[36][40]

- Stage I: Asymptomatic, incomplete blood vessel obstruction
- Stage II: Mild claudication pain in limb
  - Stage IIA: Claudication when walking a distance of greater than 200 meters
  - Stage IIB: Claudication when walking a distance of less than 200 meters
- Stage III: Rest pain, mostly in the feet
- Stage IV: Necrosis and/or gangrene of the limb

A classification introduced by Robert B. Rutherford in 1986 and revised in 1997 consists of four grades and seven categories:[36][41]

- Grade 0, Category 0: Asymptomatic
- Grade I, Category 1: Mild claudication
- Grade I, Category 2: Moderate claudication
- Grade I, Category 3: Severe claudication

Grade II, Category 4: Rest pain
- Grade III, Category 5: Minor tissue loss; Ischemic ulceration not exceeding ulcer of the digits of the foot
- Grade IV, Category 6: Major tissue loss; Severe ischemic ulcers or frank gangrene

The TASC (and TASC II) classification suggested PAD treatment by severity of disease seen on angiogram.[36] More recently classifications, such as the Society for Vascular Surgery "Wound, Ischemia and Foot Infection" (WIFI) classification, take into account that ischemia and angiographic disease patterns are not the only determinants of amputation risk.[42]

## Screening [edit]

It is not clear if screening for disease is useful as it has not been properly studied.[9]

## Treatment [edit]

Depending on the severity of the disease, the following steps can be taken, according to the following guidelines:[43]

### Lifestyle changes [edit]

- Smoking cessation (cigarettes promote PAD and are a risk factor for cardiovascular disease).
- Management of diabetes.
- Management of hypertension.
- Management of high cholesterol, and medication with antiplatelet drugs. Medication with aspirin, clopidogrel and statins, which reduce clot formation and cholesterol levels, respectively, can help with disease progression and address the other cardiovascular risks that the patient is likely to have.
- Regular exercise for those with claudication helps open up alternative small vessels (collateral flow) and the limitation in walking often improves. Treadmill exercise (35 to 50 minutes, 3 to 4 times per week[19]) has been reviewed as another treatment with a number of positive outcomes including reduction in cardiovascular events and improved quality of life.

### Medication [edit]

Cilostazol or pentoxifylline can improve symptoms in some.[44][*needs update*][45]

Treatment with other drugs or vitamins are unsupported by clinical evidence, "but trials evaluating the effect of folate and vitamin B-12 on hyperhomocysteinemia, a putative vascular risk factor, are near completion".[43]

### Revascularization [edit]

After a trial of the best medical treatment outline above, if symptoms persist, patients may be referred to a vascular or endovascular surgeon. The benefit of revascularization is thought to correspond to the severity of ischemia and the presence of other risk factors for limb loss such as wound and infection severity.[42]

- Angioplasty (PTA, or percutaneous transluminal angioplasty) can be done on solitary lesions in large arteries, such as the femoral artery, but angioplasty may not have sustained benefits.[46][47][*needs update*] Patency rates following angioplasty are highest for iliac arteries, and decrease with arteries towards the toes. Other criteria that affect outcome following revascularization are length of lesion, and number of lesions.[48][49]
- Atherectomy, in which the plaque is scraped off of the inside of the vessel wall (albeit with no better results than angioplasty).[50]
- Vascular bypass grafting can be performed to circumvent a diseased area of the arterial vasculature. The great saphenous vein is used as a conduit if available, although artificial (Gore-Tex or PTFE) material is often used for long grafts when adequate venous conduit is unavailable.

- When gangrene has set in, amputation is required to prevent infected tissues from causing sepsis a life-threatening illness.
- Thrombolysis and thrombectomy are used in cases of arterial thrombosis or embolism.

### Guidelines [edit]

An updated consensus guideline from the American College of Cardiology and American Heart Association for the diagnosis and treatment of lower extremity, renal, mesenteric and abdominal aortic PAD was compiled in 2013, combining the 2005 and 2011 guidelines.[24]

## Prognosis [edit]

Individuals with PAD have an "exceptionally elevated risk for cardiovascular events and the majority will eventually die of a cardiac or cerebrovascular etiology";[51] prognosis is correlated with the severity of the PAD as measured by the Ankle brachial pressure index (ABPI).[51] Large-vessel PAD increases mortality from cardiovascular disease significantly. PAD carries a greater than "20% risk of a coronary event in 10 years".[51]

There is a low risk that an individual with claudication will develop severe ischemia and require amputation, but the risk of death from coronary events is three to four times higher than matched controls without claudication.[43] Of patients with intermittent claudication, only "7% will undergo lower extremity bypass surgery, 4% major amputations, and 16% worsening claudication", but stroke and heart attack events are elevated, and the "5-year mortality rate is estimated to be 30% (versus 10% in controls)".[51]

## Epidemiology [edit]

The prevalence of peripheral artery disease in the general population is 12–14%, affecting up to 20% of those over 70;[51] 70%–80% of affected individuals are asymptomatic; only a minority ever require revascularisation or amputation.[*citation needed*] Peripheral artery disease affects 1 in 3 diabetics over the age of 50.

In the USA peripheral arterial disease affects 12–20 percent of Americans age 65 and older. Approximately 10 million Americans have PAD. Despite its prevalence and cardiovascular risk implications, only 25 percent of PAD patients are undergoing treatment.

The incidence of symptomatic PAD increases with age, from about 0.3% per year for men aged 40–55 years to about 1% per year for men aged over 75 years. The prevalence of PAD varies considerably depending on how PAD is defined, and the age of the population being studied. Diagnosis is critical, as people with PAD have a four to five times higher risk of heart attack or stroke.

The Diabetes Control and Complications Trial, and the U.K. Prospective Diabetes Study trials, in people with type 1 and type 2 diabetes, respectively, demonstrated that glycemic control is more strongly associated with microvascular disease than macrovascular disease. It may be that pathologic changes occurring in small vessels are more sensitive to chronically elevated glucose levels than is atherosclerosis occurring in larger arteries.[52]

## Research [edit]

In those who have developed critically poor blood flow to the legs it is unclear if autotransplantation of autologous mononuclear cells is useful or not.[53]

Only one randomized controlled trial has been conducted comparing vascular bypass to angioplasty for the treatment of severe PAD.[54] The trial found no difference in amputation-free survival between vascular bypass and angioplasty at the planned clinical endpoint, however the trial has been criticized as being underpowered, limiting endovascular options, and comparing inappropriate endpoints.[55] As of 2015, a

second trial is being conducted regarding the optimal revascularization for severe PAD.[56]

In 2011 pCMV-vegf165 was registered in Russia as the first-in-class gene therapy drug for treatment of peripheral artery disease, including the advanced stage of critical limb ischemia.[57][58]

# Pulmonary embolism

From Wikipedia, the free encyclopedia

**Pulmonary embolism** (**PE**) is a blockage of an artery in the lungs by a substance that has traveled from elsewhere in the body through the bloodstream (embolism).[1] Symptoms of a PE may include shortness of breath, chest pain particularly upon breathing in, and coughing up blood.[2] Symptoms of a blood clot in the leg may also be present such as a red, warm, swollen, and painful leg.[2] Signs of a PE include low blood oxygen levels, rapid breathing, rapid heart rate, and sometimes a mild fever.[3] Severe cases can lead to passing out, abnormally low blood pressure, and sudden death.[4]

PE usually results from a blood clot in the leg that travels to the lung.[1] The risk of blood clots is increased by cancer, prolonged bed rest, smoking, stroke, certain genetic conditions, pregnancy, obesity, and after some types of surgery.[5] A small proportion of cases are due to the embolization of air, fat, or amniotic fluid.[6][7] Diagnosis is based on signs and symptoms in combination with test results. If the risk is low a blood test known as a D-dimer will rule out the condition. Otherwise a CT pulmonary angiography, lung ventilation/perfusion scan, or ultrasound of the legs may confirm the diagnosis.[8] Together deep vein thrombosis and PE are known as venous thromboembolism (VTE).[9]

Efforts to prevent PE include beginning to move as soon as possible after surgery, lower leg exercises during periods of sitting, and the use of blood thinners after some types of surgery.[10] Treatment is typically with blood thinners such as heparin or warfarin.[11] Often these are recommended for six months or longer.[12] Severe cases may require thrombolysis using medication such as tissue plasminogen activator (tPA), or may require surgery such as a pulmonary thrombectomy. If blood thinners are not appropriate a vena cava filter may be used.[11]

Pulmonary emboli affect about 430,000 people each year in Europe.[13] In the United States between 300,000 and 600,000 cases occur each year,[1][14] which results in between 50,000[14] and 200,000 deaths.[15] Rates are similar in males and females. They become more common as people get older.[5]

**Pulmonary embolism**

Chest spiral CT scan with radiocontrast agent showing multiple filling defects both at the bifurcation ("saddle" pulmonary embolism) and in the pulmonary arteries.

## Signs and symptoms [edit]

Symptoms of pulmonary embolism are typically sudden in onset and may include one or many of the following: dyspnea (shortness of breath), tachypnea (rapid breathing), chest pain of a "pleuritic" nature (worsened by breathing), cough and hemoptysis (coughing up blood).[16] More severe cases can include signs such as cyanosis (blue discoloration, usually of the lips and fingers), collapse, and circulatory instability because of decreased blood flow through the lungs and into the left side of the heart. About 15% of all cases of sudden death are attributable to PE.[4]

On physical examination, the lungs are usually normal. Occasionally, a pleural friction rub may be audible over the affected area of the lung (mostly in PE with infarct). A pleural effusion is sometimes present that is exudative, detectable by decreased percussion note, audible breath sounds, and vocal resonance. Strain on the right ventricle may be detected as a left parasternal heave, a loud pulmonary component of the second heart sound, and/or raised jugular venous pressure.[4] A low-grade fever may be present, particularly if there is associated pulmonary hemorrhage or infarction.[17]

As smaller pulmonary emboli tend to lodge in more peripheral areas without collateral circulation they are more likely to cause lung infarction and small effusions (both of which are painful), but not hypoxia, dyspnea or hemodynamic instability such as tachycardia. Larger PEs, which tend to lodge centrally, typically cause dyspnea, hypoxia, low blood pressure, fast heart rate and fainting, but are often painless because there is no lung infarction due to collateral circulation. The classic presentation for PE with pleuritic pain, dyspnea and tachycardia is likely caused by a large fragmented embolism causing both large and small PEs. Thus, small PEs are often missed because they cause pleuritic pain alone without any other findings and large PEs often missed because they are painless and mimic other conditions often causing ECG changes and small rises in troponin and BNP levels.[18]

PEs are sometimes described as massive, submassive and nonmassive depending on the clinical signs and symptoms. Although the exact definitions of these are unclear, an accepted definition of massive PE is one in which there is hemodynamic instability such as sustained low blood pressure, slowed heart rate, or pulselessness.[19]

## Risk factors [edit]

About 90% of emboli are from proximal leg deep vein thromboses [20]

(DVTs) or pelvic vein thromboses. DVTs are at risk for dislodging and migrating to the lung circulation. The conditions are generally regarded as a continuum termed *venous thromboembolism* (VTE).

The development of thrombosis is classically due to a group of causes named Virchow's triad (alterations in blood flow, factors in the vessel wall and factors affecting the properties of the blood). Often, more than one risk factor is present.

- *Alterations in blood flow*: immobilization (after surgery), injury, pregnancy (also procoagulant), obesity (also procoagulant), cancer (also procoagulant)
- *Factors in the vessel wall*: surgery, catheterizations causing direct injury ("endothelial injury")
- *Factors affecting the properties of the blood* (procoagulant state):
  - Estrogen-containing hormonal contraception
  - Genetic thrombophilia (factor V Leiden, prothrombin mutation G20210A, protein C deficiency, protein S deficiency, antithrombin deficiency, hyperhomocysteinemia and plasminogen/fibrinolysis disorders)
  - Acquired thrombophilia (antiphospholipid syndrome, nephrotic syndrome, paroxysmal nocturnal hemoglobinuria)
  - Cancer (due to secretion of pro-coagulants)

A deep vein thrombosis as seen in the right leg is a risk factor for PE

### Underlying causes [edit]

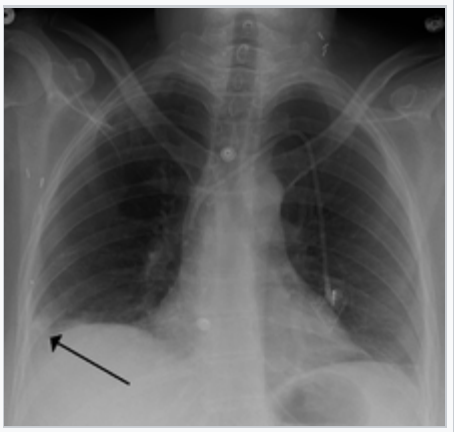
After a first PE, the search for secondary causes is usually brief. Only when a second PE occurs, and especially when this happens while still under anticoagulant therapy, a further search for underlying conditions is undertaken. This will include testing ("thrombophilia screen") for Factor V Leiden mutation, antiphospholipid antibodies, protein C and S and antithrombin levels, and later prothrombin mutation, MTHFR mutation, Factor VIII concentration and rarer inherited coagulation abnormalities.[*citation needed*]

## Diagnosis [edit]

In order to diagnose a pulmonary embolism, a review of clinical criteria to determine the need for testing is recommended.[21] In those who have low risk, age less than 50, heart rate less than 100 beats per minute, oxygen level more than 94% on room air, and no leg swelling, coughing up of blood, surgery or trauma in the last four weeks, previous blood clots, or estrogen use, further testing is not typically needed.[22]

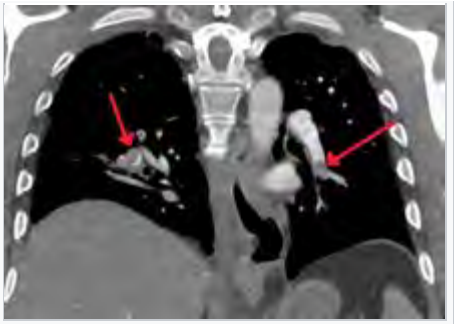
If there are concerns this is followed by testing to determine a likelihood of being able to confirm a diagnosis by imaging, followed by imaging if other tests have shown that there is a likelihood of a PE diagnosis.[21][23][24]

The diagnosis of PE is based primarily on validated clinical criteria combined with selective testing because the typical clinical presentation (shortness of breath, chest pain) cannot be definitively differentiated from other causes of chest pain and shortness of breath. The decision to perform medical imaging is based on clinical reasoning, that is, the medical history, symptoms and findings on physical examination, followed by an assessment of clinical probability.[4]



A Hampton hump in a person with a right lower lobe pulmonary embolism

### Probability testing [edit]



Segmental and subsegmental pulmonary emboli on both sides

The most commonly used method to predict clinical probability, the Wells score, is a clinical prediction rule, whose use is complicated by multiple versions being available. In 1995, Philip Steven Wells, initially developed a prediction rule (based on a literature search) to predict the likelihood of PE, based on clinical criteria.[25] The prediction rule was revised in 1998[26] This prediction rule was further revised when simplified during a validation by Wells *et al.* in 2000.[27] In the 2000 publication, Wells proposed two different scoring systems using cutoffs of 2 or 4 with the same prediction rule.[27] In 2001, Wells published results using the more conservative cutoff of 2 to create three categories.[28] An additional version, the "modified extended version", using the more recent cutoff of 2 but including findings from Wells's initial studies[25][26] were proposed.[29] Most recently, a further study reverted to Wells's earlier use of a cutoff of 4 points[27] to create only two categories.[30]

There are additional prediction rules for PE, such as the Geneva rule. More importantly, the use of *any* rule is associated with reduction in recurrent thromboembolism.[31]

*The Wells score*:[32]

- clinically suspected DVT — 3.0 points
- alternative diagnosis is less likely than PE — 3.0 points
- tachycardia (heart rate > 100) — 1.5 points
- immobilization (≥ 3d)/surgery in previous four weeks — 1.5 points
- history of DVT or PE — 1.5 points
- hemoptysis — 1.0 points
- malignancy (with treatment within six months) or palliative — 1.0 points

Traditional interpretation[27][28][33]

- Score >6.0 — High (probability 59% based on pooled data)[34]
- Score 2.0 to 6.0 — Moderate (probability 29% based on pooled data)[34]
- Score <2.0 — Low (probability 15% based on pooled data)[34]

Alternative interpretation[27][30]

- Score > 4 — PE likely. Consider diagnostic imaging.
- Score 4 or less — PE unlikely. Consider D-dimer to rule out PE.

Recent recommendations for a diagnostic algorithm were published by the PIOPED investigators; however, these recommendations do not reflect research using 64 slice MDCT.[34] These investigators recommended:

- Low clinical probability. If negative D-dimer, PE is excluded. If positive D-dimer, obtain MDCT and based treatment on results.
- Moderate clinical probability. If negative D-dimer, PE is excluded. *However*, the authors were not concerned that a negative MDCT with negative D-dimer in this setting has a 5% probability of being false. Presumably, the 5% error rate will fall as 64 slice MDCT is more commonly used. If positive D-dimer, obtain MDCT and based treatment on results.
- High clinical probability. Proceed to MDCT. If positive, treat, if negative, more tests are needed to exclude PE.

## Pulmonary embolism rule-out criteria [edit]

The pulmonary embolism rule-out criteria (PERC) helps assess people in whom pulmonary embolism is suspected, but unlikely. Unlike the Wells score and Geneva score, which are clinical prediction rules intended to risk stratify people with suspected PE, the PERC rule is designed to rule out risk of PE in people when the physician has already stratified them into a low-risk category.

People in this low risk category without any of these criteria may undergo no further diagnostic testing for PE: Hypoxia — $Sa_{O_2}$ <95%, unilateral leg swelling, hemoptysis, prior DVT or PE, recent surgery or trauma, age >50, hormone use, tachycardia. The rationale behind this decision is that further testing (specifically CT angiogram of the chest) may cause more harm (from radiation exposure and contrast dye) than the risk of PE.[35] The PERC rule has a sensitivity of 97.4% and specificity of 21.9% with a false negative rate of 1.0% (16/1666).[36]

## Blood tests [edit]

In people with a low or moderate suspicion of PE, a normal D-dimer level (shown in a blood test) is enough to exclude the possibility of thrombotic PE, with a three-month risk of thromboembolic events being 0.14%.[37] D-dimer is highly sensitive but not specific (specificity around 50%). In other words, a positive D-dimer is not synonymous with PE, but a negative D-dimer is, with a good degree of certainty, an indication of absence of a PE.[38] The typical cut off is 500 ug/L, although this varies based on the assay.[39] However, in those over the age of 50, changing the cut-off value to the person's age multiplied by 10 ug/L (accounting for assay which has been used) is recommended as it decreases the number of falsely positive tests without missing any additional cases of PE.[22][39][40]

When a PE is being suspected, several blood tests are done in order to exclude important secondary causes of PE. This includes a full blood count, clotting status (PT, aPTT, TT), and some screening tests (erythrocyte sedimentation rate, renal function, liver enzymes, electrolytes). If one of these is abnormal, further investigations might be warranted.[*citation needed*]

Troponin levels are increased in between 16–47% with pulmonary embolism.[41]

## Imaging [edit]

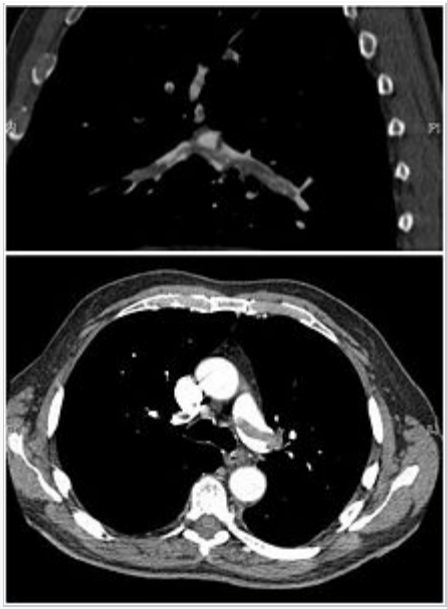
In typical people who are not known to be at high risk of PE, imaging is helpful to confirm or exclude a diagnosis of PE after simpler first-line tests are used.[21][23][42] Medical societies recommend tests such as the D-dimer to first provide supporting evidence for the need for imaging, and imaging would be done if other tests confirmed a moderate or high probability of finding evidence to support a diagnosis of PE.[23][42]

CT pulmonary angiography is the recommended first line diagnostic imaging test in most people.[43] Historically, the gold standard for diagnosis was pulmonary angiography, but this has fallen into disuse with the increased availability of non-invasive techniques.[44] Ultrasound of the legs can confirm the presence of a PE but cannot rule it out.[45]

Selective pulmonary angiogram revealing clot (labeled A) causing a central obstruction in the left main pulmonary artery. ECG tracing shown at bottom.

## Non-invasive imaging [edit]

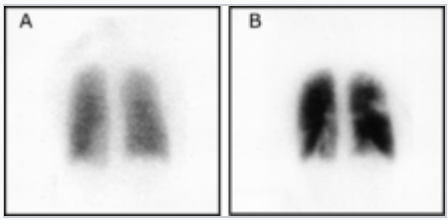
CT pulmonary angiography (CTPA) is a pulmonary angiogram obtained using computed tomography (CT) with radiocontrast rather than right heart catheterization. Its advantages are clinical equivalence, its non-invasive nature, its greater availability to people, and the possibility of identifying other lung disorders from the differential diagnosis in case there is no pulmonary embolism. Assessing the accuracy of CT pulmonary angiography is hindered by the rapid changes in the number of rows of detectors available in multidetector CT (MDCT) machines.[46] According to a cohort study, single-slice spiral CT may help diagnose detection among people with suspected pulmonary embolism.[47] In this study, the sensitivity was 69% and specificity was 84%. In this study which had a prevalence of detection was 32%, the positive predictive value of 67.0% and negative predictive value of 85.2% (click here to adjust these results for people at higher or lower risk of detection).



CT pulmonary angiography showing a "saddle embolus" at the bifurcation of the pulmonary artery and thrombus burden in the lobar branches of both main pulmonary arteries.

However, this study's results may be biased due to possible incorporation bias, since the CT scan was the final diagnostic tool in people with pulmonary embolism. The authors noted that a negative single slice CT scan is insufficient to rule out pulmonary embolism on its own. A separate study with a mixture of 4 slice and 16 slice scanners reported a sensitivity of 83% and a specificity of 96%, which means that it is a good test for ruling out a pulmonary embolism if it is not seen on imaging and that it is very good at confirming a pulmonary embolism is present if it is seen. This study noted that additional testing is necessary when the clinical probability is inconsistent with the imaging results.[48] CTPA is non-inferior to VQ scanning, and identifies more emboli (without necessarily improving the outcome) compared to VQ scanning.[49]

A ventilation/perfusion scan (or V/Q scan or lung scintigraphy) shows that some areas of the lung are being ventilated but not perfused with blood (due to obstruction by a clot).[16] This type of examination is as accurate as multislice CT, but is less used, due to the greater availability of CT technology. It is particularly useful in people who have an allergy to iodinated contrast, impaired renal function, or are pregnant (due to its lower radiation exposure as compared to CT).[50][51] The test can be performed with planar two-dimensional imaging, or single photon emission tomography (SPECT) which enables three-dimensional imaging.[43] Hybrid devices combining SPECT and CT (SPECT/CT) further enable anatomic characterization of any abnormality.



Ventilation-perfusion scintigraphy
(A) After inhalation of 20 mCi of Xenon-133 gas, scintigraphic images were obtained in the posterior projection, showing uniform ventilation to lungs.
(B) After intravenous injection of 4 mCi of Technetium-99m-labeled albumin, scintigraphic images shown here in the posterior projection. This and other views showed decreased activity in multiple regions.

## Low probability diagnostic tests/non-diagnostic tests

[edit]

Tests that are frequently done that are not sensitive for PE, but can be diagnostic.

- Chest X-rays are often done on people with shortness of breath to help rule-out other causes, such as congestive heart failure and rib fracture. Chest X-rays in PE are rarely normal,[52] but usually lack signs that suggest the diagnosis of PE (for example, Westermark sign, Hampton's hump).
- Ultrasonography of the legs, also known as leg doppler, in search of deep venous thrombosis (DVT). The presence of DVT, as shown on ultrasonography of the legs, is in itself enough to warrant anticoagulation, without requiring the V/Q or spiral CT scans (because of the strong association between DVT and PE). This may be a valid approach in pregnancy, in which the other modalities would increase the risk of birth defects in the unborn child. However, a negative scan does not rule out PE, and low-radiation dose scanning may be required if the mother is deemed at high risk of having a pulmonary embolism.[*citation needed*]

## Electrocardiogram [edit]

The primary use of the ECG is to rule out other causes of [53]

chest pain. An electrocardiogram (ECG) is routinely done on people with chest pain to quickly diagnose myocardial infarctions (heart attacks), an important differential diagnosis in an individual with chest pain. While certain ECG changes may occur with PE, none are specific enough to confirm or sensitive enough to rule out the diagnosis.[53] An ECG may show signs of right heart strain or acute cor pulmonale in cases of large PEs — the classic signs are a large S wave in lead I, a large Q wave in lead III, and an inverted T wave in lead III (S1Q3T3), which occurs in 12-50% of people with the diagnosis, yet also occurs in 12% without the diagnosis.[54][55]

Electrocardiogram of a person with pulmonary embolism, showing sinus tachycardia of approximately 100 beats per minute, large S wave in Lead I, moderate Q wave in Lead III, inverted T wave in Lead III, and inverted T waves in leads V1 and V3.

This is occasionally present (occurring in up to 20% of people), but may also occur in other acute lung conditions, and, therefore, has limited diagnostic value. The most commonly seen signs in the ECG are sinus tachycardia, right axis deviation, and right bundle branch block.[56] Sinus tachycardia, however, is still only found in 8–69% of people with PE.[57]

ECG findings associated with pulmonary emboli may suggest worse prognosis since the six findings identified with RV strain on ECG (heart rate > 100 beats per minute, S1Q3T3, inverted T waves in leads V1-V4, ST elevation in aVR, complete right bundle branch block, and atrial fibrillation) are associated with increased risk of circulatory shock and death.[58]

### Echocardiography [edit]

In massive and submassive PE, dysfunction of the right side of the heart may be seen on echocardiography, an indication that the pulmonary artery is severely obstructed and the right ventricle, a low-pressure pump, is unable to match the pressure. Some studies (see below) suggest that this finding may be an indication for thrombolysis. Not every person with a (suspected) pulmonary embolism requires an echocardiogram, but elevations in cardiac troponins or brain natriuretic peptide may indicate heart strain and warrant an echocardiogram,[59] and be important in prognosis.[60]

The specific appearance of the right ventricle on echocardiography is referred to as the *McConnell's sign*. This is the finding of akinesia of the mid-free wall but a normal motion of the apex. This phenomenon has a 77% sensitivity and a 94% specificity for the diagnosis of acute pulmonary embolism in the setting of right ventricular dysfunction.[61]

## Prevention [edit]

*Further information: Thrombosis prophylaxis*

Pulmonary embolism may be preventable in those with risk factors. People admitted to hospital may receive preventative medication, including unfractionated heparin, low molecular weight heparin (LMWH), or fondaparinux, and anti-thrombosis stockings to reduce the risk of a DVT in the leg that could dislodge and migrate to the lungs.[62]

Following the completion of warfarin in those with prior PE, long-term aspirin is useful to prevent recurrence.[63]

## Treatment [edit]

Anticoagulant therapy is the mainstay of treatment. Acutely, supportive treatments, such as oxygen or analgesia, may be required. People are often admitted to hospital in the early stages of treatment, and tend to remain under inpatient care until the INR has reached therapeutic levels. Increasingly, however, low-risk [63][64]

cases are managed at home in a fashion already common in the treatment of DVT. Evidence to support one approach versus the other is weak.[65]

## Anticoagulation [edit]

Usually, anticoagulant therapy is the mainstay of treatment. Unfractionated heparin, low molecular weight heparin (LMWH), or fondaparinux is administered initially, while warfarin, acenocoumarol, or phenprocoumon therapy is commenced (this may take several days, usually while the patient is in the hospital). LMWH may reduce bleeding among people with pulmonary embolism as compared to heparin according to a systematic review of randomized controlled trials by the Cochrane Collaboration.[66] The relative risk reduction was 40%. For people at similar risk to those in this study (2.0% had bleeding when not treated with low molecular weight heparin), this leads to an absolute risk reduction of 0.8%. 125 people must be treated for one to benefit.

Warfarin therapy often requires a frequent dose adjustment and monitoring of the international normalized ratio (INR). In PE, INRs between 2.0 and 3.0 are generally considered ideal. If another episode of PE occurs under warfarin treatment, the INR window may be increased to e.g. 2.5–3.5 (unless there are contraindications) or anticoagulation may be changed to a different anticoagulant e.g. LMWH.[*citation needed*]

In patients with an underlying malignancy, therapy with a course of LMWH is favored over warfarin; it is continued for six months, at which point a decision should be reached whether ongoing treatment is required.[67]

Similarly, pregnant women are often maintained on low molecular weight heparin until at least six weeks after delivery to avoid the known teratogenic effects of warfarin, especially in the early stages of pregnancy.[68]

Warfarin therapy is usually continued for 3–6 months, or "lifelong" if there have been previous DVTs or PEs, or none of the usual risk factors is present. An abnormal D-dimer level at the end of treatment might signal the need for continued treatment among patients with a first unprovoked pulmonary embolus.[69] For those with small PEs (known as subsegmental PEs) the effects of anticoagulation is unknown as it has not been properly studied as of 2014.[70][*needs update*]

## Thrombolysis [edit]

Massive PE causing hemodynamic instability (shock and/or low blood pressure, defined as a systolic blood pressure <90 mmHg or a pressure drop of 40 mmHg for >15 min if not caused by new-onset arrhythmia, hypovolemia or sepsis) is an indication for thrombolysis, the enzymatic destruction of the clot with medication. In this situation, it is the best available treatment in those without contraindications and is supported by clinical guidelines.[24][67][71] It is also recommended in those in cardiac arrest with a known PE.[72]

Catheter-directed thrombolysis (CDT) is a new technique found to be relatively safe and effective for massive PEs. This involves accessing the venous system by placing a catheter into a vein in the groin and guiding it through the veins by using fluoroscopic imaging until it is located next to the PE in the lung circulation. Medication that breaks up blood clots is released through the catheter so that its highest concentration is directly next to the pulmonary embolus. CDT is performed by interventional radiologists, and in medical centers that offer CDT, it should be considered first-line treatment.[73]

The use of thrombolysis in non-massive PEs is still debated.[74][75] Some have found that the treatment decreases the risk of death and increases the risk of bleeding including intracranial hemorrhage.[76] Others have found no decrease in the risk of death.[75]

## Inferior vena cava filter [edit]

There are two situations when an inferior vena cava filter is considered advantageous, and those are if anticoagulant therapy is contraindicated (e.g. shortly after a major operation), or a person has a pulmonary

Used inferior vena cava filter.

embolus in spite of being anticoagulated.[67] In these instances, it may be implanted to prevent new or existing DVTs from entering the pulmonary artery and combining with an existing blockage.[67] In spite of the device's theoretical advantage of preventing pulmonary emboli, there is a lack of evidence supporting its effectiveness.[77]

Inferior vena cava filters should be removed as soon as it becomes safe to start using anticoagulation.[67] Although modern filters are meant to be retrievable, complications may prevent some from being removed. The long-term safety profile of permanently leaving a filter inside the body is not known.[77]

### Surgery [edit]

Surgical management of acute pulmonary embolism (pulmonary thrombectomy) is uncommon and has largely been abandoned because of poor long-term outcomes. However, recently, it has gone through a resurgence with the revision of the surgical technique and is thought to benefit certain people.[78] Chronic pulmonary embolism leading to pulmonary hypertension (known as *chronic thromboembolic hypertension*) is treated with a surgical procedure known as a pulmonary thromboendarterectomy.

## Epidemiology [edit]

Pulmonary emboli occur in more than 600,000 people in the United States each year.[14] It results in between 50,000[14] and 200,000 deaths per year in the United States.[15] The risk in those who are hospitalized is around 1%.[79] The rate of fatal pulmonary emboli has declined from 6% to 2% over the last 25 years in the United States.[15]

## Prognosis [edit]

Less than 5 to 10% of symptomatic PEs are fatal within the first hour of symptoms.[24][80]

Large saddle embolus seen in the pulmonary artery (white arrows).

There are several markers used for risk stratification and these are also independent predictors of adverse outcome. These include hypotension, cardiogenic shock, syncope, evidence of right heart dysfunction, and elevated cardiac enzymes.[24] Some ECG changes including S1Q3T3 also correlate with worse short-term prognosis.[19] There have been other patient-related factors such as COPD and chronic heart failure thought to also play a role in prognosis.[24]

Prognosis depends on the amount of lung that is affected and on the co-existence of other medical conditions; chronic embolisation to the lung can lead to pulmonary hypertension. After a massive PE, the embolus must be resolved somehow if the patient is to survive. In thrombotic PE, the blood clot may be broken down by fibrinolysis, or it may be organized and recanalized so that a new channel forms through the clot. Blood flow is restored most rapidly in the first day or two after a PE.[81] Improvement slows thereafter and some deficits may be permanent. There is controversy over whether small subsegmental PEs need treatment at all[82] and some evidence exists that patients with subsegmental PEs may do well without treatment.[48][83]

Once anticoagulation is stopped, the risk of a fatal pulmonary embolism is 0.5% per year.[84]

Mortality from untreated PEs was said to be 26%. This figure comes from a trial published in 1960 by Barrit

and Jordan,[85] which compared anticoagulation against placebo for the management of PE. Barritt and Jordan performed their study in the Bristol Royal Infirmary in 1957. This study is the only placebo controlled trial ever to examine the place of anticoagulants in the treatment of PE, the results of which were so convincing that the trial has never been repeated as to do so would be considered unethical. That said, the reported mortality rate of 26% in the placebo group is probably an overstatement, given that the technology of the day may have detected only severe PEs.

## Predicting mortality [edit]

The PESI and sPESI scoring tools can estimate mortality of patients. The Geneva prediction rules and Wells criteria are used to calculate a pre-test probability of patients to predict who has a pulmonary embolism. These scores are tools to be used with clinical judgment in deciding diagnostic testing and types of therapy.[86] The PESI algorithm comprises 11 routinely available clinical variables.[87] It puts the subjects into one of five classes (I-V), with 30-day mortality ranging from 1.1% to 24.5%. Those in classes I and II are low-risk and those in classes III-V are high-risk.[87]

# Rheumatic fever

From Wikipedia, the free encyclopedia

**Rheumatic fever** (**RF**), also known as **acute rheumatic fever** (**ARF**), is an inflammatory disease that can involve the heart, joints, skin, and brain.[1] The disease typically develops two to four weeks after a streptococcal throat infection.[2] Signs and symptoms include fever, multiple painful joints, involuntary muscle movements, and occasionally a characteristic non-itchy rash known as erythema marginatum. The heart is involved in about half of cases. Damage to the heart valves, known as rheumatic heart disease (RHD), usually occurs after repeated attacks but can sometimes occur after one. The damaged valves may result in heart failure, atrial fibrillation and infection of the valves.[1]

Rheumatic fever may occur following an infection of the throat by the bacteria *Streptococcus pyogenes*.[1] If the infection is untreated rheumatic fever can occur in up to three percent of people.[3] The underlying mechanism is believed to involve the production of antibodies against a person's own tissues. Some people due to their genetics are more likely to get the disease when exposed to the bacteria than others. Other risk factors include malnutrition and poverty.[1] Diagnosis of RF is often based on the presence of signs and symptoms in combination with evidence of a recent streptococcal infection.[4]

Treating people who have strep throat with antibiotics, such as penicillin, decreases the risk of developing rheumatic fever.[5] In order to avoid antibiotic misuse this often involves testing people with sore throats for the infection, which may not be available in the developing world. Other preventive measures include improved sanitation. In those with rheumatic fever and rheumatic heart disease, prolonged periods of antibiotics are sometimes recommended. Gradual return to normal activities may occur following an attack. Once RHD develops, treatment is more difficult. Occasionally valve-replacement surgery or valve repair is required. Otherwise complications are treated as per normal.[1]

Rheumatic fever occurs in about 325,000 children each year and about 18 million people currently have rheumatic heart disease. Those who develop RF are most often between the ages of 5 and 14,[1] with 20% of first-time attacks occurring in adults.[6] The disease is most common in the developing world and among indigenous peoples in the developed world.[1] In 2013 it resulted in 275,000 deaths down from 374,000 deaths in 1990.[7] Most deaths occur in the developing world where as many as 12.5% of people affected may die

Video explanation

## Signs and symptoms [edit]

The disease typically develops two to four weeks after a throat infection.[2] Symptoms include: fever, painful joints with those joints affected changing with time, involuntary muscle movements, and occasionally a characteristic non-itchy rash known as erythema marginatum. The heart is involved in about half of cases. Damage to the heart valves usually occurs only after multiple attacks but may occasionally occur after a single case of RF. The damaged valves may result in heart failure and also increase the risk of atrial fibrillation and infection of the valves.[1]

A culture positive case of streptococcal pharyngitis with typical tonsillar exudate in a 16-year-old.

## Pathophysiology [edit]

Rheumatic fever is a systemic disease affecting the connective tissue around arterioles, and can occur after an untreated strep throat infection, specifically due to group A streptococcus (GAS), *Streptococcus pyogenes*. It is believed to be caused by antibody cross-reactivity. This cross-reactivity is a type II hypersensitivity reaction and is termed molecular mimicry. Usually, self reactive B cells remain anergic in the periphery without T cell co-stimulation. During a streptococcal infection, mature antigen-presenting cells such as B cells present the bacterial antigen to CD4+T cells which differentiate into helper $T_2$ cells. Helper $T_2$ cells subsequently activate the B cells to become plasma cells and induce the production of antibodies against the cell wall of Streptococcus. However the antibodies may also react against the myocardium and joints,[10] producing the symptoms of rheumatic fever.

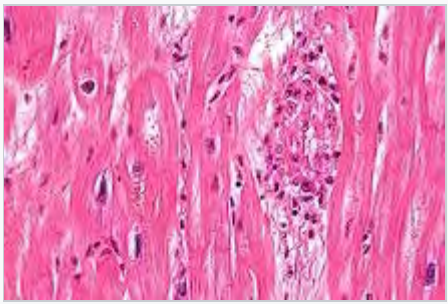
*S. pyogenes* has a cell wall composed of branched polymers which sometimes contain M protein that are highly antigenic. The antibodies which the immune system generates against the M protein may cross-react with heart muscle cell protein myosin,[11] heart muscle glycogen and smooth muscle cells of arteries, inducing cytokine release and tissue destruction. However, the only proven cross-reaction is with perivascular connective tissue.[*citation needed*] This inflammation occurs through direct attachment of

complement and Fc receptor-mediated recruitment of neutrophils and macrophages. Characteristic Aschoff bodies, composed of swollen eosinophilic collagen surrounded by lymphocytes and macrophages can be seen on light microscopy. The larger macrophages may become Anitschkow cells or Aschoff giant cells. Rheumatic valvular lesions may also involve a cell-mediated immunity reaction as these lesions predominantly contain T-helper cells and macrophages.[12]

In rheumatic fever, these lesions can be found in any layer of the heart causing different types of carditis. The inflammation may cause a serofibrinous pericardial exudate described as "bread-and-butter" pericarditis, which usually resolves without sequelae. Involvement of the endocardium typically results in fibrinoid necrosis and verrucae formation along the lines of closure of the left-sided heart valves. Warty projections arise from the deposition, while subendocardial lesions may induce irregular thickenings called MacCallum plaques.

## Rheumatic heart disease [edit]

Pathophysiology of rheumatic heart disease



Micrograph showing an Aschoff body (right of image), as seen in rheumatic heart disease. H&E stain.

Chronic rheumatic heart disease (RHD) is characterized by repeated inflammation with fibrinous repair. The cardinal anatomic changes of the valve include leaflet thickening, commissural fusion, and shortening and thickening of the tendinous cords.[12] It is caused by an autoimmune reaction to Group A β-hemolytic streptococci (GAS) that results in valvular damage.[13] Fibrosis and scarring of valve leaflets, commissures and cusps leads to abnormalities that can result in valve stenosis or regurgitation.[14] The inflammation caused by rheumatic fever, usually during childhood, is referred to as rheumatic valvulitis. About half of patients with rheumatic fever develop inflammation involving valvular endothelium.[15] The majority of morbidity and mortality associated with rheumatic fever is caused by its destructive effects on cardiac valve tissue.[14] The pathogenesis of RHD is complex and not fully understood, but it is known to involve molecular mimicry and genetic predisposition that lead to autoimmune reactions.

Molecular mimicry occurs when epitopes are shared between host antigens and *Streptococcus* antigens.[16] This causes an autoimmune reaction against native tissues in the heart that are incorrectly recognized as "foreign" due to the cross-reactivity of antibodies generated as a result of epitope sharing. The valvular endothelium is a prominent site of lymphocyte-induced damage. CD4+ T cells are the major effectors of heart tissue autoimmune reactions in RHD.[17] Normally, T cell activation is triggered by the presentation of bacterial antigens. In RHD, molecular mimicry results in incorrect T cell activation, and these T lymphocytes can go on to activate B cells, which will begin to produce self-antigen-specific antibodies. This leads to an immune response attack mounted against tissues in the heart that have been misidentified as pathogens. Rheumatic valves display increased expression of VCAM-1, a protein that mediates the adhesion of lymphocytes.[18] Self-antigen-specific antibodies generated via molecular mimicry between human proteins and streptococcal antigens up-regulate VCAM-1 after binding to the valvular endothelium. This leads to the inflammation and valve scarring observed in rheumatic valvulitis, mainly due to CD4+ T cell infiltration.[18]

While the mechanisms of genetic predisposition remain unclear, a few genetic factors have been found to increase susceptibility to autoimmune reactions in RHD. The dominant contributors are a component of MHC class II molecules, found on lymphocytes and antigen-presenting cells, specifically the DR and DQ alleles on human chromosome 6.[19] Certain allele combinations appear to increase RHD autoimmune susceptibility. Human leukocyte antigen (HLA) class II allele DR7 (HLA-DR7) is most often associated with RHD, and its combination with certain DQ alleles is seemingly associated with the development of valvular lesions.[19] The mechanism by which MHC class II molecules increase a host's susceptibility to autoimmune reactions in RHD is unknown, but it is likely related to the role HLA molecules play in presenting antigens to

T cell receptors, thus triggering an immune response. Also found on human chromosome 6 is the cytokine TNF-α which is also associated with RHD.[19] High expression levels of TNF-α may exacerbate valvular tissue inflammation, contributing to RHD pathogenesis. Mannose-binding lectin (MBL) is an inflammatory protein involved in pathogen recognition. Different variants of MBL2 gene regions are associated in RHD. RHD-induced mitral valve stenosis has been associated with MBL2 alleles encoding for high production of MBL.[20] Aortic valve regurgitation in RHD patients has been associated with different MBL2 alleles that encode for low production of MBL.[21] Other genes are also being investigated to better understand the complexity of autoimmune reactions that occur in RHD.

## Diagnosis [edit]

Modified Jones criteria were first published in 1944 by T. Duckett Jones, MD.[22] They have been periodically revised by the American Heart Association in collaboration with other groups.[23] According to revised Jones criteria, the diagnosis of rheumatic fever can be made when two of the major criteria, or one major criterion plus two minor criteria, are present along with evidence of streptococcal infection: elevated or rising antistreptolysin O titre or DNAase.[6] Exceptions are chorea and indolent carditis, each of which by itself can indicate rheumatic fever.[24][25][26] An April 2013 review article in the *Indian Journal of Medical Research* stated that echocardiographic and Doppler (E & D) studies, despite some reservations about their utility, have identified a massive burden of rheumatic heart disease, which suggests the inadequacy of the 1992 Jones' criteria. E & D studies have identified subclinical carditis in patients with rheumatic fever, as well as in follow-ups of rheumatic heart disease patients who initially presented as having isolated cases of Sydenham's chorea.[27] Signs of a preceding streptococcal infection include: recent scarlet fever, raised antistreptolysin O or other streptococcal antibody titre, or positive throat culture.[28]

Rheumatic heart disease at autopsy with characteristic findings (thickened mitral valve, thickened chordae tendineae, hypertrophied left ventricular myocardium).

### Major criteria [edit]

- Polyarthritis[*citation needed*]: A temporary migrating inflammation of the large joints, usually starting in the legs and migrating upwards.
- Carditis: Inflammation of the heart muscle (myocarditis) which can manifest as congestive heart failure with shortness of breath, pericarditis with a rub, or a new heart murmur.
- Subcutaneous nodules: Painless, firm collections of collagen fibers over bones or tendons. They commonly appear on the back of the wrist, the outside elbow, and the front of the knees.
- Erythema marginatum: A long-lasting reddish rash that begins on the trunk or arms as macules, which spread outward and clear in the middle to form rings, which continue to spread and coalesce with other rings, ultimately taking on a snake-like appearance. This rash typically spares the face and is made worse with heat.
- Sydenham's chorea (St. Vitus' dance): A characteristic series of involuntary rapid movements of the face and arms. This can occur very late in the disease for at least three months from onset of infection.

### Minor criteria [edit]

- Fever of 38.2–38.9 °C (100.8–102.0 °F)
- Arthralgia: Joint pain without swelling (Cannot be included if polyarthritis is present as a major symptom)
- Raised erythrocyte sedimentation rate or C reactive protein
- Leukocytosis
- ECG showing features of heart block, such as a prolonged PR interval[28][29] (Cannot be included if carditis is present as a major symptom)

- Previous episode of rheumatic fever or inactive heart disease

## Prevention [edit]

Prevention of recurrence is achieved by eradicating the acute infection and prophylaxis with antibiotics. The American Heart Association suggests that dental health be maintained, and that people with a history of bacterial endocarditis, a heart transplant, artificial heart valves, or "some types of congenital heart defects" may wish to consider long-term antibiotic prophylaxis.[30]

## Treatment [edit]

The management of rheumatic fever is geared toward the reduction of inflammation with anti-inflammatory medications such as aspirin or corticosteroids. Individuals with positive cultures for strep throat should also be treated with antibiotics. Aspirin is the drug of choice and should be given at high doses of 100 mg/kg/day. One should watch for side effects like gastritis and salicylate poisoning. In children and teenagers, the use of aspirin and aspirin-containing products can be associated with Reye's syndrome, a serious and potentially deadly condition. The risks, benefits, and alternative treatments must always be considered when administering aspirin and aspirin-containing products in children and teenagers. Ibuprofen for pain and discomfort and corticosteroids for moderate to severe inflammatory reactions manifested by rheumatic fever should be considered in children and teenagers. Steroids are reserved for cases where there is evidence of an involvement of heart. The use of steroids may prevent further scarring of tissue and may prevent the development of sequelae such as mitral stenosis. Monthly injections of long-acting penicillin must be given for a period of five years in patients having one attack of rheumatic fever. If there is evidence of carditis, the length of therapy may be up to 40 years. Another important cornerstone in treating rheumatic fever includes the continual use of low-dose antibiotics (such as penicillin, sulfadiazine, or erythromycin) to prevent recurrence.

### Vaccine [edit]

No vaccines are currently available to protect against *S. pyogenes* infection, although research is underway to develop one.[31] Difficulties in developing a vaccine include the wide variety of strains of *S. pyogenes* present in the environment and the large amount of time and people that will be needed for appropriate trials for safety and efficacy of the vaccine.[32]

### Infection [edit]

People with positive cultures for *Streptococcus pyogenes* should be treated with penicillin as long as allergy is not present. This treatment will not alter the course of the disease.[*clarification needed*] Some suggest the use of benzathine benzylpenicillin.

### Inflammation [edit]

While corticosteroids are often used, evidence to support this is poor.[1] Salicylates are useful for pain.

### Heart failure [edit]

Some patients develop significant carditis which manifests as congestive heart failure. This requires the usual treatment for heart failure: ACE inhibitors, diuretics, beta blockers, and digoxin. Unlike normal heart failure, rheumatic heart failure responds well to corticosteroids.

# Epidemiology [edit]

Rheumatic fever is common worldwide and responsible for many cases of damaged heart valves. As of 2010 globally it resulted in 345,000 deaths, down from 463,000 in 1990.[34]

In Western countries, rheumatic fever has become fairly rare since the 1960s, probably due to the widespread use of antibiotics to treat streptococcus infections. While it has been far less common in the United States since the beginning of the 20th century, there have been a few outbreaks since the 1980s. Although the disease seldom occurs, it is serious and has a case-fatality rate of 2–5%.[35]

Rheumatic fever primarily affects children between ages 5 and 17 years and occurs approximately 20 days after strep throat. In up to a third of cases, the underlying strep infection may not have caused any symptoms.

The rate of development of rheumatic fever in individuals with untreated strep infection is estimated to be 3%. The incidence of recurrence with a subsequent untreated infection is substantially greater (about 50%).[36] The rate of development is far lower in individuals who have received antibiotic treatment. Persons who have suffered a case of rheumatic fever have a tendency to develop flare-ups with repeated strep infections.

The recurrence of rheumatic fever is relatively common in the absence of maintenance of low dose antibiotics, especially during the first three to five years after the first episode. Recurrent bouts of rheumatic fever can lead to valvular heart disease. Heart complications may be long-term and severe, particularly if valves are involved. In countries in Southeast-Asia, sub-saharan Africa, and Oceania, the percentage of people with rheumatic heart disease detected by listening to the heart was 2.9 per 1000 children and by echocardiography it was 12.9 per 1000 children.[37][38][39][40]

# Syncope (medicine)

From Wikipedia, the free encyclopedia

*For other uses, see Syncope.*

*"Fainting" redirects here. For other uses, see Faint.*

**Syncope**, also known as **fainting**, is defined as a short loss of consciousness and muscle strength, characterized by a fast onset, short duration, and spontaneous recovery. It is due to a decrease in blood flow to the entire brain usually from low blood pressure. Some causes have prodromal symptoms before the loss of consciousness occurs. These symptoms may include lightheadedness, sweating, pale skin, blurred vision, nausea, vomiting, and feeling warm, among others. Syncope may also be associated with a short episode of muscle twitching. If a person does not completely lose consciousness and muscle strength it is referred to as presyncope. It is recommended that presyncope be treated the same as syncope.[1]

Causes range from non-serious to potentially fatal. There are three broad categories of causes: heart or blood vessel related, reflex also known as neurally mediated, and orthostatic hypotension. Issues with the heart and blood vessels are the cause in about 10% and typically the most serious while neurally mediated is the most common. Heart related causes may include an abnormal heart rhythm, problems with the heart valves or heart muscle and blockages of blood vessels from a pulmonary embolism or aortic dissection among others. Neurally mediated syncope occurs when blood vessels expand and heart rate decreases inappropriately. This may occur from either a triggering event such as exposure to blood, pain, strong feelings or a specific activity such as urination, vomiting, or coughing. This type of syncope may also occur when an area in the neck known as the carotid sinus is pressed. The final type of syncope is due to a drop in blood pressure from standing up. This is often due to medications that a person is taking but may also be related to dehydration, significant bleeding or infection.[1]

A medical history, physical examination, and electrocardiogram (ECG) are the most effective ways to figure out the underlying cause. The ECG is useful to detect an abnormal heart rhythm, poor blood flow to the heart muscle, and other electrical issue such as long QT syndrome and Brugada's. Heart related causes also often have little history of a prodrome. Low blood pressure and a fast heart rate after the event may indicate blood loss or dehydration, while low blood oxygen levels may be seen following the event in those with pulmonary embolism. More specific tests such as implantable loop recorders, tilt table testing or carotid sinus massage may be useful in uncertain cases. Computer

## Syncope

**Synonyms** ...fainting, passing out, swooning

A 1744 oil painting by Pietro Longhi called *Fainting*

tomography (CT) is generally not required unless specific concerns are present. Other causes of similar symptoms that should be considered include seizure, stroke, concussion, low blood oxygen, low blood sugar, drug intoxication and some psychiatric disorders among others. Treatment depends on the underlying cause. Those who are considered at high risk following investigation may be admitted to hospital for further monitoring of the heart.[1]

Syncope affects about three to six out of every thousand people each year.[1] It is more common in older people and females. It is the reason for one to three percent of visits to emergency departments and admissions to hospital. Up to half of women over the age of 80 and a third of medical students describe at least one event at some point in their life.[2] Of those presenting with syncope to an emergency department, about 4% died in the next 30 days.[1] The risk of a bad outcome, however, depends very much on the underlying cause.[3]

# Differential diagnosis [edit]

## Central nervous system ischaemia [edit]

The central ischaemic response is triggered by an inadequate supply of oxygenated blood in the brain. The respiratory system may contribute to oxygen levels through hyperventilation, though a sudden ischaemic episode may also proceed faster than the respiratory system can respond. These processes cause the typical symptoms of fainting: pale skin, rapid breathing, nausea and weakness of the limbs, particularly of the legs. If the ischaemia is intense or prolonged, limb weakness progresses to collapse. An individual with very little skin pigmentation may appear to have all color drained from his or her face at the onset of an episode. This effect combined with the following collapse can make a strong and dramatic impression on bystanders.

The weakness of the legs causes most sufferers to sit or lie down if there is time to do so. This may avert a complete collapse, but whether the sufferer sits down or falls down, the result of an ischaemic episode is a posture in which less blood pressure is required to achieve adequate blood flow. It is unclear whether this is a mechanism evolved in response to the circulatory difficulties of human bipedalism or merely a serendipitous result of a pre-existing circulatory response .[*citation needed*]

## Vertebro-basilar arterial disease [edit]

Arterial disease in the upper spinal cord, or lower brain, causes syncope if there is a reduction in blood supply, which may occur with extending the neck or after drugs to lower blood pressure.

## Vasovagal [edit]

*Main article: Vasovagal syncope*

Vasovagal (situational) syncope is one of the most common types which may occur in response to any of a variety of triggers, such as scary, embarrassing or uneasy situations, during blood drawing, or moments of sudden unusually high stress. There are many different syncope syndromes which all fall under the umbrella of vasovagal syncope related by the same central mechanism, such as urination ("micturition syncope"), defecation ("defecation syncope"), and others related to trauma and stress.

Vasovagal syncope can be considered in two forms:

- Isolated episodes of loss of consciousness, unheralded by any warning symptoms for more than a few moments. These tend to occur in the adolescent age group, and may be associated with fasting, exercise, abdominal straining, or circumstances promoting vaso-dilation (e.g., heat, alcohol). The subject is invariably upright. The tilt-table test, if performed, is generally negative.
- Recurrent syncope with complex associated symptoms. This is neurally mediated syncope (NMS). It is associated with any of the following: preceding or succeeding sleepiness, preceding visual disturbance ("spots before the eyes"), sweating, lightheadedness. The subject is usually but not always upright. The tilt-table test, if performed, is generally positive. It is relatively uncommon.

A pattern of background factors contributes to the attacks. There is typically an unsuspected relatively low blood volume, for instance, from taking a low-salt diet in the absence of any salt-retaining tendency. Heat causes vaso-dilation and worsens the effect of the relatively insufficient blood volume. That sets the scene, but the next stage is the adrenergic response. If there is underlying fear or anxiety (e.g., social circumstances), or acute fear (e.g., acute threat, needle phobia), the vaso-motor centre demands an increased pumping action by the heart (flight or fight response). This is set in motion via the adrenergic (sympathetic) outflow from the brain, but the heart is unable to meet requirement because of the low blood volume, or decreased return. The high (ineffective) sympathetic activity is always modulated by vagal outflow, in these cases leading to excessive slowing of heart rate. The abnormality lies in this excessive vagal response. The tilt-table test typically evokes the attack.

Much of this pathway was discovered in animal experiments by Bezold (Vienna) in the 1860s. In animals, it may represent a defence mechanism when confronted by danger ("playing possum").

Avoiding what brings on the syncope and possibly greater salt intake is often all that is needed.[4]

Psychological factors also have been found to mediate syncope. It is important for general practitioners and the psychologist in their primary care team to work closely together, and to help patients identify how they might be avoiding activities of daily living due to anticipatory anxiety in relation to a possible faint and the feared physical damage it may cause. Fainting in response to a blood stimulus, needle or a dead body are common and patients can quickly develop safety behaviours to avoid any recurrences of a fainting response. See link for a good description of psychological interventions and theories.[5]

An evolutionary psychology view is that some forms of fainting are non-verbal signals that developed in response to increased inter-group aggression during the paleolithic. A non-combatant who has fainted signals that she or he is not a threat. This would explain the association between fainting and stimuli such as bloodletting and injuries seen in blood-injection-injury type phobias such as trypanophobia as well as the gender differences.[6]

## Deglutition (Swallowing) syncope [edit]

Syncope may occur during deglutition. Manisty et al. note: "Deglutition syncope is characterised by loss of consciousness on swallowing; it has been associated not only with ingestion of solid food, but also with carbonated and ice-cold beverages, and even belching."[7]

## Cardiac [edit]

## Cardiac arrhythmias [edit]

The most common cause of cardiac syncope is cardiac arrhythmia (abnormal heart rhythm) wherein the heart beats too slowly, too rapidly,

Syncope from Bradycardia

or too irregularly to pump enough blood to the brain. Some arrhythmias can be life-threatening.

Two major groups of arrhythmias are bradycardia and tachycardia. Bradycardia can be caused by heart blocks. Tachycardias include SVT (supraventricular tachycardia) and VT (ventricular tachycardia). SVT does not cause syncope except in Wolff-Parkinson-White syndrome. Ventricular tachycardia originate in the ventricles. VT causes syncope and can result in sudden death. Ventricular tachycardia, which describes a heart rate of over 100 beats per minute with at least three irregular heartbeats as a sequence of consecutive premature beats, can degenerate into ventricular fibrillation, which is rapidly fatal without cardiopulmonary resuscitation (CPR) and defibrillation.[*citation needed*]

Typically, tachycardic-generated syncope is caused by a cessation of beats following a tachycardic episode. This condition, called tachycardia-bradycardia syndrome, is usually caused by sinoatrial node dysfunction or block or atrioventricular block.[8]

## Obstructive cardiac lesion [edit]

Aortic stenosis and mitral stenosis are the most common examples. Aortic stenosis presents with repeated episodes of syncope. A pulmonary embolism can cause obstructed blood vessels. High blood pressure in the arteries supplying the lungs (pulmonary artery hypertension) can occur during pulmonary embolism. Rarely, cardiac tumors such as atrial myxomas can also lead to syncope.

## Structural cardiopulmonary disease [edit]

These are relatively infrequent causes of faints. The most common cause in this category is fainting associated with an acute myocardial infarction or ischemic event. The faint in this case is primarily caused by an abnormal nervous system reaction similar to the reflex faints. In general, faints caused by structural disease of the heart or blood vessels are particularly important to recognize, as they are warning of potentially life-threatening conditions. Among other conditions prone to trigger syncope (by either hemodynamic compromise or by a neural reflex mechanism, or both), some of the most important are hypertrophic cardiomyopathy, acute aortic dissection, pericardial tamponade, pulmonary embolism, aortic stenosis, and pulmonary hypertension.

## Other cardiac causes [edit]

Sick sinus syndrome, a sinus node dysfunction, causing alternating bradycardia and tachycardia. Often there is a long pause asystole between heartbeat.

Adams-Stokes syndrome is a cardiac syncope that occurs with seizures caused by complete or incomplete heart block. Symptoms include deep and fast respiration, weak and slow pulse and respiratory pauses that may last for 60 seconds.

Subclavian steal syndrome arises from retrograde (reversed) flow of blood in the vertebral artery or the internal thoracic artery, due to a proximal stenosis (narrowing) and/or occlusion of the subclavian artery.

Aortic dissection (a tear in the aorta) and cardiomyopathy can also result in syncope.[9]

Various medications, such as beta blockers, may cause bradycardia induced syncope.[8]

## Blood pressure [edit]

*Orthostatic (postural) hypotensive faints* are as common or perhaps even more common than vasovagal syncope. Orthostatic faints are most often associated with movement from lying or sitting to a standing position, standing up too quickly, or being in a very hot room. The classic example of a combination of

these is seen in the frequent fainting by medical students in the operating theatre during observation of surgery.[10]

Apparently healthy individuals may experience minor symptoms ("lightheadedness", "greying-out") as they stand up if blood pressure is slow to respond to the stress of upright posture. If the blood pressure is not adequately maintained during standing, faints may develop. However, the resulting "transient orthostatic hypotension" does not necessarily signal any serious underlying disease.

The most susceptible individuals are elderly frail individuals, or persons who are dehydrated from hot environments or inadequate fluid intake. More serious orthostatic hypotension is often the result of certain commonly prescribed medications such as diuretics, β-adrenergic blockers, other anti-hypertensives (including vasodilators), and nitroglycerin. In a small percentage of cases, the cause of orthostatic hypotensive faints is structural damage to the autonomic nervous system due to systemic diseases (e.g., amyloidosis or diabetes) or in neurological diseases (e.g., Parkinson's disease).

### Other causes [edit]

Factors that influence fainting are fasting long hours, taking in too little food and fluids, low blood pressure, hypoglycemia, high g-force, emotional distress, and lack of sleep.

One theory in evolutionary psychology is that fainting at the sight of blood might have evolved as a form of playing dead which increased survival from attackers and might have slowed blood loss in a primitive environment.[11] "Blood-injury phobia", as this is called, is experienced by about 15% of people.[12]

Fainting can occur in "cough syncope".[13] following severe fits of coughing, such as that associated with pertussis or "whooping cough."

Pulmonary embolism was found in 17% of people whose average age was 76 who were admitted to the hospital for syncope in a study of Italian hospitals.[14]

## Diagnostic approach [edit]

For people with uncomplicated syncope (without seizures and a normal neurological exam) computed tomography or MRI is not indicated.[15] Likewise, using carotid ultrasonography on the premise of identifying carotid artery disease as a cause of syncope also is not indicated.[16] Although sometimes investigated as a cause of syncope, carotid artery problems are unlikely to cause that condition.[16]

A hemoglobin count may indicate anemia or blood loss. However, this has been useful in only about 5% of patients evaluated for fainting.[17]

An electrocardiogram (ECG) records the electrical activity of the heart. It is estimated that from 20%-50% of patients have an abnormal ECG. However, while an ECG may identify conditions such as atrial fibrillation, heart block, or a new or old heart attack, it typically does not provide a definite diagnosis for the underlying cause for fainting.[18]

Sometimes, a Holter monitor may be used. This is a portable ECG device that can record the wearer's heart rhythms during daily activities over an extended period of time. Since fainting usually does not occur upon command, a Holter monitor can provide a better understanding of the heart's activity during fainting episodes.

The tilt table test is performed to elicit orthostatic syncope secondary to autonomic dysfunction (neurogenic).

For patients with more than two episodes of syncope and no diagnosis on “routine testing”, an insertable cardiac monitor might be used. It lasts 28–36 months. Smaller than a pack of gum, it is inserted just beneath the skin in the upper chest area. The procedure typically takes 15 to 20 minutes. Once inserted, the device continuously monitors the rate and rhythm of the heart. Upon waking from a “fainting” spell, the patient places a hand held pager size device called an Activator over the implanted device and simply presses a button. This information is stored and retrieved by their physician and some devices can be monitored remotely.

### San Francisco syncope rule [edit]

The San Francisco syncope rule was developed to isolate people who have higher risk for a serious cause of syncope. High risk is anyone who has: congestive heart failure, hematocrit <30%, electrocardiograph abnormality, shortness of breath, or systolic blood pressure <90 mmHg.[19] The San Francisco syncope rule however was not validated by subsequent studies.[20]

## Management [edit]

Recommended acute treatment of vasovagal and orthostatic (hypotension) syncope involves returning blood to the brain by positioning the person on the ground, with legs slightly elevated or leaning forward and the head between the knees for at least 10–15 minutes, preferably in a cool and quiet place. For individuals who have problems with chronic fainting spells, therapy should focus on recognizing the triggers and learning techniques to keep from fainting. At the appearance of warning signs such as lightheadedness, nausea, or cold and clammy skin, counter-pressure maneuvers that involve gripping fingers into a fist, tensing the arms, and crossing the legs or squeezing the thighs together can be used to ward off a fainting spell. After the symptoms have passed, sleep is recommended. If fainting spells occur often without a triggering event, syncope may be a sign of an underlying heart disease. In case syncope is caused by cardiac disease, the treatment is much more sophisticated than that of vasovagal syncope and may involve pacemakers and implantable cardioverter-defibrillators depending on the precise cardiac cause.

## Society and culture [edit]

Fainting in women was a commonplace trope or stereotype in Victorian England and in contemporary and modern depictions of the period. This may have been partly due to genuine ill health (the respiratory effects of corsets are frequently cited), but it was fashionable for women to affect an aristocratic frailty and create a scene by fainting at a dramatic moment.[*citation needed*]

Falling-out is a culture-bound syndrome primarily reported in the southern United States and the Caribbean.

Some individuals occasionally or frequently play the "fainting game" (also referred to in the US as the "choking game"), which involves the deliberate induction of syncope via voluntary restriction of blood flow to the brain, an action that can result in acute or cumulative brain damage and even death.[21]

## Etymology [edit]

This article **needs additional citations for verification**. Please help improve this article by adding citations to reliable sources. Unsourced material may be challenged and removed. *(October 2011) (Learn how and when to remove this template message)*

The term is derived from the Late Latin *syncope*, from Ancient Greek συγκοπή (*sunkopē*), from σύν (*sin*, "together, thoroughly") and κόπτειν (*koptein*, "strike, cut off").

# Circumcision

From Wikipedia, the free encyclopedia

*This article is about male circumcision. For female circumcision, see female genital mutilation.*

Male **circumcision** is the removal of the foreskin from the human penis.[1][2][3] In the most common procedure, the foreskin is opened, adhesions are removed, and the foreskin is separated from the glans. After that, the circumcision device (if used) is placed, and then the foreskin is cut off. Topical or locally injected anesthesia is occasionally used to reduce pain and physiologic stress.[4] For adults and children, general anesthesia is an option, and the procedure may be performed without a specialized circumcision device. The procedure is most often an elective surgery performed on babies and children for religious and cultural reasons.[5] In other cases it may be done as a treatment for a condition or for preventative reasons. Medically, it is a treatment option for problematic cases of phimosis, balanoposthitis that does not resolve with other treatments, and chronic urinary tract infections (UTIs).[1][6] It is contraindicated in cases of certain genital structure abnormalities or poor general health.[2][6]

[edit on Wikidata]

The positions of the world's major medical organizations range from considering elective circumcision of babies and children as having no benefit and significant risks to having a modest health benefit that outweighs small risks. No major medical organization recommends either universal circumcision for all males (aside from the recommendations of the World Health Organization (WHO) for areas with high rates of HIV), or banning the procedure.[7] Ethical and legal questions regarding informed consent and human rights have been raised over the circumcision of babies and children for non-medical reasons, and for that reason the procedure is controversial.[8][9]

Evidence supports that male circumcision reduces the risk of HIV infection among heterosexual men in sub-Saharan Africa.[10][11] Therefore, the WHO recommends considering circumcision as part of a comprehensive HIV prevention program in areas with high rates of HIV, such as Sub Saharan Africa.[12] Evidence for a health benefit against HIV for men who have sex with men is less clear.[13][14] Additionally, the effectiveness of using circumcision to prevent HIV in the developed world is also unclear.[15] Circumcision in general is associated with reduced rates of cancer causing forms of HPV[16][17] and risk of both UTIs and cancer of the penis.[4] Prevention of those conditions is not a justification for routine circumcision of infants.[1][18] Studies of its potential protective effects against other sexually transmitted infections have been unclear. A 2010 review of literature found circumcisions performed by medical providers to have a typical complication rate of 1.5% for babies and 6% for older children, with few cases

of severe complications.[19] Bleeding, infection and the removal of either too much or too little foreskin are the most common complications cited.[19] Complication rates are higher when the procedure is performed by an inexperienced operator, in unsterile conditions, or when the child is at an older age.[19] Circumcision does not appear to have a negative impact on sexual function.[20][21]

An estimated one-third of males worldwide are circumcised.[5][19][22] The procedure is most common in the Muslim world and Israel (where it is near-universal for religious reasons), the United States, and parts of Southeast Asia and Africa.[5] It is relatively rare in Europe, Latin America, parts of Southern Africa, and most of Asia.[5] The origin of circumcision is not known with certainty; the oldest documented evidence for it comes from ancient Egypt.[5] Various theories have been proposed as to its origin, including as a religious sacrifice and as a rite of passage marking a boy's entrance into adulthood.[23] It is part of religious law in Judaism[24] and is an established practice in Islam, Coptic Christianity, and the Ethiopian Orthodox Church.[5][25][26] The word circumcision is from Latin *circumcidere*, meaning "to cut around".[5]

**Contents**

# Indications and contraindications

## Routine or elective

Neonatal circumcision is usually elected by the parents for non-medical reasons, such as religious beliefs or personal preferences, possibly driven by societal norms.[6] Outside the parts of Africa with high prevalence of HIV/AIDS, the positions of the world's major medical organizations on non-therapeutic neonatal circumcision range from considering it as having a modest net health benefit that outweighs small risks to viewing it as having no benefit with significant risks for harm. No major medical organization recommends

universal neonatal circumcision, and no major medical organization calls for banning it either. The Royal Dutch Medical Association, which expresses some of the strongest opposition to routine neonatal circumcision, does not call for the practice to be made illegal out of their concern that parents who insist on the procedure would turn to poorly trained practitioners instead of medical professionals. This argument to keep the procedure within the purview of medical professionals is found across all major medical organizations. In addition, the organizations advise medical professionals to yield to some degree to parental preferences, which are commonly based upon cultural or religious views, in their decision to agree to circumcise.[7] The Danish College of General Practitioners states that circumcision should "only [be done] when medically needed, otherwise it is a case of mutilation."[27]

Owing to the HIV/AIDS epidemic there, sub-Saharan Africa is a special case. The finding that circumcision significantly reduces female-to-male HIV transmission has prompted medical organizations serving the affected communities to promote circumcision as an additional method of controlling the spread of HIV.[7] The World Health Organization (WHO) and UNAIDS (2007) recommend circumcision as part of a comprehensive program for prevention of HIV transmission in areas with high endemic rates of HIV, as long as the program includes "informed consent, confidentiality, and absence of coercion".[12]

## Medical indications

Circumcision may be used to treat pathological phimosis, refractory balanoposthitis and chronic, recurrent urinary tract infections (UTIs).[1][6] The World Health Organization promotes circumcision as a preventive measure for sexually active men in populations at high risk for HIV.[12] Circumcision is also recommended for HIV prevention by the International Antiviral Society-USA for all sexually active heterosexual males and is recommended that it be discussed with MSM who engage in primarily insertive anal sex with other men, especially in areas where HIV is common.[28]

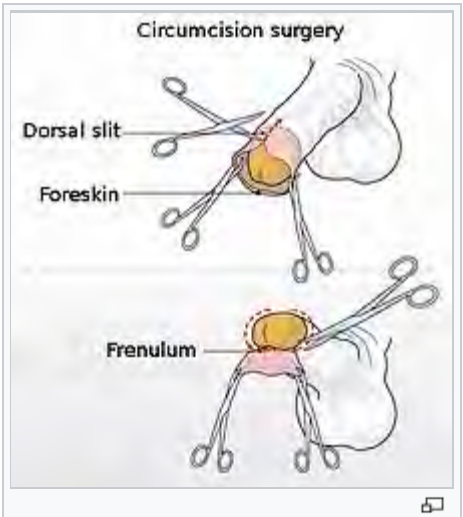
## Contraindications

Circumcision is contraindicated in infants with certain genital structure abnormalities, such as a misplaced urethral opening (as in hypospadias and epispadias), curvature of the head of the penis (chordee), or ambiguous genitalia, because the foreskin may be needed for reconstructive surgery. Circumcision is contraindicated in premature infants and those who are not clinically stable and in good health.[2][6][29] If an individual, child or adult, is known to have or has a family history of serious bleeding disorders (hemophilia), it is recommended that the blood be checked for normal coagulation properties before the procedure is attempted.[6][29]

# Technique

*Main article: Circumcision surgical procedure*

The foreskin extends out from the base of the glans and covers the glans when the penis is flaccid. Proposed theories for the purpose of the foreskin are that it serves to protect the penis as the fetus develops in the mother's womb, that it helps to preserve moisture in the glans, and that it improves sexual pleasure. The foreskin may also be a pathway of infection for certain diseases. Circumcision removes the foreskin at its attachment to the base of the glans.[5]



## Removal of the foreskin

For infant circumcision, devices such as the Gomco clamp, Plastibell and Mogen clamp are commonly used in the USA.[4] These follow the same basic procedure. First, the amount of foreskin to be removed is estimated. The practitioner opens the foreskin via the preputial orifice to reveal the glans underneath and ensures it is normal before bluntly

separating the inner lining of the foreskin (preputial epithelium) from its attachment to the glans. The practitioner then places the circumcision device (this sometimes requires a dorsal slit), which remains until blood flow has stopped. Finally, the foreskin is amputated.[4] For adults, circumcision is often performed without clamps,[30] and non-surgical alternatives such as the elastic ring controlled radial compression device or the Shang ring are available.[31]

Circumcision surgery with hemostats and scissors

Before (left) and after (right) an adult circumcision, undertaken to treat phimosis. The glans is exposed even when the penis is flaccid.

## Pain management

The circumcision procedure causes pain, and for neonates this pain may interfere with mother-infant interaction or cause other behavioral changes,[32] so the use of analgesia is advocated.[4][33] Ordinary procedural pain may be managed in pharmacological and non-pharmacological ways. Pharmacological methods, such as localized or regional pain-blocking injections and topical analgesic creams, are safe and effective.[4][34][35] The ring block and dorsal penile nerve block (DPNB) are the most effective at reducing pain, and the ring block may be more effective than the DPNB. They are more effective than EMLA (eutectic mixture of local anesthetics) cream, which is more effective than a placebo.[34][35] Topical creams have been found to irritate the skin of low birth weight infants, so penile nerve block techniques are recommended in this group.[4]

For infants, non-pharmacological methods such as the use of a comfortable, padded chair and a sucrose or non-sucrose pacifier are more effective at reducing pain than a placebo,[35] but the American Academy of Pediatrics (AAP) states that such methods are insufficient alone and should be used to supplement more effective techniques.[4] A quicker procedure reduces duration of pain; use of the Mogen clamp was found to result in a shorter procedure time and less pain-induced stress than the use of the Gomco clamp or the Plastibell.[35] The available evidence does not indicate that post-procedure pain management is needed.[4] For adults, general anesthesia is an option,[36] and the procedure requires four to six weeks of abstinence from masturbation or intercourse to allow the wound to heal.[29]

# Effects

## Sexually transmitted diseases

### Human immunodeficiency virus

*Main article: Circumcision and HIV*

There is strong evidence that circumcision reduces the risk of HIV infection in heterosexual men in high-risk populations.[10][11] Evidence among heterosexual men in sub-Saharan Africa shows an absolute decrease in risk of 1.8% which is a relative decrease of between 38 percent and 66 percent over two years,[11] and in this population studies rate it cost effective.[37] Whether it is of benefit in developed countries is undetermined.[15]

There are plausible explanations based on human biology for how circumcision can decrease the likelihood of female-to-male HIV transmission. The superficial skin layers of the penis contain Langerhans cells, which are targeted by HIV; removing the foreskin reduces the number of these cells. When an uncircumcised penis is erect during intercourse, any small tears on the inner surface of the foreskin come into direct contact with the vaginal walls, providing a pathway for transmission. When an uncircumcised penis is flaccid, the pocket between the inside of the foreskin and the head of the penis provides an environment conducive to pathogen survival; circumcision eliminates this pocket. Some experimental evidence has been provided to support these theories.[38]

The WHO and the Joint United Nations Programme on HIV/AIDS (UNAIDS) state that male circumcision is an efficacious intervention for HIV prevention, but should be carried out by well-trained medical professionals and under conditions of informed consent (parents' consent for their infant boys).[5][12][39] The WHO has judged circumcision to be a cost-effective public health intervention against the spread of HIV in Africa, although not necessarily more cost-effective than condoms.[5] The joint WHO/UNAIDS recommendation also notes that circumcision only provides partial protection from HIV and should not replace known methods of HIV prevention.[12]

The available evidence does not indicate that circumcision provides HIV protection for heterosexual women.[4][40][41] Data is lacking regarding the effect circumcision may have on the transmission rate of men who engage in anal sex with a female partner.[39][42] It is undetermined whether circumcision benefits men who have sex with men.[14][43]

### Human papillomavirus

Human papillomavirus (HPV) is the most commonly transmitted sexually transmitted infection, affecting both men and women. While most infections are asymptomatic and are cleared by the immune system, some types of the virus cause genital warts, and other types, if untreated, cause various forms of cancer, including cervical cancer, and penile cancer. Genital warts and cervical cancer are the two most common problems resulting from HPV.[44]

Circumcision is associated with a reduced prevalence of oncogenic types of HPV infection, meaning that a randomly selected circumcised man is less likely to be found infected with cancer-causing types of HPV than an uncircumcised man.[45][46] It also decreases the likelihood of multiple infections.[17] No strong evidence indicates that it reduces the rate of new HPV infection,[16][17][47] but the procedure is associated with increased clearance of the virus by the body,[16][17] which can account for the finding of reduced prevalence.[17]

Although genital warts are caused by a type of HPV, there is no statistically significant relationship between being circumcised and the presence of genital warts.[16][46][47]

### Other infections

Studies evaluating the effect of circumcision on the incidence of other sexually transmitted infections have reached conflicting conclusions. A 2006 meta-analysis found that circumcision was associated with lower rates of syphilis, chancroid and possibly genital herpes.[48] A 2010 review found that circumcision reduced the incidence of HSV-2 (herpes simplex virus, type 2) infections by 28%.[49] The researchers found mixed results for protection against trichomonas vaginalis and chlamydia trachomatis and no evidence of protection against gonorrhea or syphilis.[49] Among men who have sex with men, reviews have found poor evidence for protection against sexually transmitted infections other than HIV,[13][43] with the possible exception of syphilis.[43]

## Phimosis, balanitis and balanoposthitis

Phimosis is the inability to retract the foreskin over the glans penis.[50] At birth, the foreskin cannot be retracted due to adhesions between the foreskin and glans, and this is considered normal (physiological phimosis).[50] Over time the foreskin naturally separates from the glans, and a majority of boys are able to retract the foreskin by age three.[50] Less than one percent are still having problems at age 18.[50] If the inability to do so becomes problematic (pathological phimosis) circumcision is a treatment option.[1][51] This pathological phimosis may be due to scarring from the skin disease balanitis xerotica obliterans (BXO), repeated episodes of balanoposthitis or forced retraction of the foreskin.[52] Steroid creams are also a reasonable option and may prevent the need for surgery including in those with mild BXO.[52][53] The procedure may also be used to prevent the development of phimosis.[6] Phimosis is also a complication that can result from circumcision.[54]

An inflammation of the glans penis and foreskin is called balanoposthitis, and the condition affecting the glans alone is called balanitis.[55][56] Most cases of these conditions occur in uncircumcised males,[57] affecting 4–11% of that group.[58] The moist, warm space underneath the foreskin is thought to facilitate the growth of pathogens, particularly when hygiene is poor. Yeasts, especially *Candida albicans*, are the most common penile infection and are rarely identified in samples taken from circumcised males.[57] Both conditions are usually treated with topical antibiotics (metronidazole cream) and antifungals (clotrimazole cream) or low-potency steroid creams.[55][56] Circumcision is a treatment option for refractory or recurrent balanoposthitis, but in recent years the availability of the other treatments have made it less necessary.[55][56]

## Urinary tract infections

A UTI affects parts of the urinary system including the urethra, bladder, and kidneys. There is about a one percent risk of UTIs in boys under two years of age, and the majority of incidents occur in the first year of life. There is good but not ideal evidence that circumcision reduces the incidence of UTIs in boys under two years of age, and there is fair evidence that the reduction in incidence is by a factor of 3–10 times.[4][59][60] Prevention of UTIs does not justify routine use of the procedure, however.[1] Circumcision is most likely to benefit boys who have a high risk of UTIs due to anatomical defects,[4] and may be used to treat recurrent UTIs.[1]

There is a plausible biological explanation for the reduction in UTI risk after circumcision. The orifice through which urine passes at the tip of the penis (the urinary meatus) hosts more urinary system disease-causing bacteria in uncircumcised boys than in circumcised boys, especially in those under six months of age. As these bacteria are a risk factor for UTIs, circumcision may reduce the risk of UTIs through a decrease in the bacteria population.[4][61]

## Cancers

Circumcision has a protective effect against the risks of penile cancer in men, and cervical cancer in the female sexual partners of heterosexual men. Penile cancer is rare, with about 1 new case per 100,000 people per year in developed countries, and higher incidence rates per 100,000 in sub-Saharan Africa (for example, 1.6 in Zimbabwe, 2.7 in Uganda and 3.2 in Swaziland).[62] Penile cancer development can be detected in the carcinoma *in situ* (CIS) cancerous precursor stage and at the more advanced invasive squamous cell carcinoma stage.[4] Childhood or adolescent circumcision is associated with a reduced risk of invasive squamous cell carcinoma in particular.[4][62] There is an association between adult circumcision and an increased risk of invasive penile cancer; this is believed to be from men being circumcised as a treatment for penile cancer or a condition that is a precursor to cancer rather than a consequence of circumcision itself.[62] Penile cancer has been observed to be nearly eliminated in populations of males circumcised neonatally.[58]

Important risk factors for penile cancer include phimosis and HPV infection, both of which are mitigated by circumcision.[62] The mitigating effect circumcision has on the risk factor introduced by the possibility of phimosis is secondary, in that the removal of the foreskin eliminates the possibility of phimosis. This can be inferred from study results that show uncircumcised men with no history of phimosis are equally likely to have penile cancer as circumcised men.[4][62] Circumcision is also associated with a reduced prevalence of cancer-causing types of HPV in men[17] and a reduced risk of cervical cancer (which is caused by a type of HPV) in female partners of men.[6] Because penile cancer is rare (and may get more rare with increasing HPV vaccination rates), and circumcision has risks, the practice is not considered to be valuable solely as a prophylactic measure against penile cancer in the United States.[4][18][58]

A 2015 meta-analysis found a non-statistically significant reduced risk of prostate cancer associated with circumcision, but that this reduction was significant among blacks and in studies looking at post-PSA and -testing groups.[63]

# Adverse effects

Neonatal circumcision is generally safe when done by an experienced practitioner.[64][65] The most common acute complications are bleeding, infection and the removal of either too much or too little foreskin.[4][66] These complications occur in approximately 0.12% of procedures, and constitute the vast majority of all acute circumcision complications in the United States.[66] Minor complications are reported to occur in three percent of procedures.[64] Severe complications are rare.[67] A specific complication rate is difficult to determine due to scant data on complications and inconsistencies in their classification.[4] Complication rates are greater when the procedure is performed by an inexperienced operator, in unsterile conditions, or when the child is at an older age.[19] Significant acute complications happen rarely,[4][19] occurring in about 1 in 500 newborn procedures in the United States.[4] Severe to catastrophic complications, including death, are so rare that they are reported only as individual case reports.[4][65] Other possible complications include buried penis, chordee, phimosis, skin bridges, urethral fistulas, and meatal stenosis.[65] These complications may be avoided with proper technique, and are most often treatable without requiring a hospital visit.[65]

## Pain

The circumcision procedure may carry the risks of heightened pain response for newborns and dissatisfaction with the result.[32] Newborns that experience pain due to being circumcised have different responses to vaccines given afterwards, with higher pain scores observed.[68]

## Sexual effects

The highest quality evidence indicates that circumcision does not decrease the sensitivity of the penis, harm sexual function or reduce sexual satisfaction.[20][69][70] A 2013 systematic review found that circumcision did not appear to adversely affect sexual desire, pain with intercourse, premature ejaculation, time until ejaculation, erectile dysfunction or difficulties with orgasm. However, the study found that the existing evidence is not very good.[71] Another 2013 systematic review found that the highest-quality studies reported no adverse effects of circumcision on sexual function, sensitivity, sensation or satisfaction.[21]

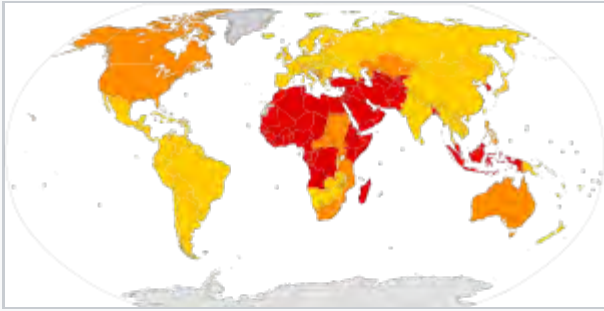
## Psychological effects

Behavioral effects have been observed following infant circumcision including changes in sleep patterns, irritability, changes in feeding, and parental bonding.[72] Some men who were circumcised as an infant involuntary, described their feelings about the procedure using the terms "violation, torture, mutilation and sexual assault".[73]

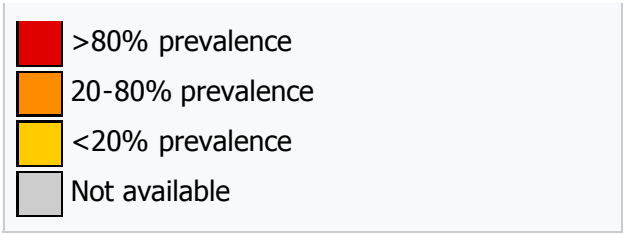
# Prevalence

*Main article: Prevalence of circumcision*

Circumcision is one of the world's most widely performed procedures.[74] Approximately 37% to 39% of males worldwide are circumcised, about half for religious or cultural reasons.[75] It is most often practiced between infancy and the early twenties.[5] The WHO estimated in 2007 that 664,500,000 males aged 15 and over were circumcised (30–33% global prevalence), almost 70% of whom were Muslim.[5] Circumcision is most prevalent in the Muslim world, Israel, South Korea, the United States and parts of Southeast Asia and Africa. It is relatively rare in Europe, Latin



Rate of male circumcision by country[5]



America, parts of Southern Africa and Oceania and most of Asia. Prevalence is near-universal in the Middle East and Central Asia.[5][76] Non-religious circumcision in Asia, outside of the Republic of Korea and the Philippines, is fairly rare,[5] and prevalence is generally low (less than 20%) across Europe.[5][77] Estimates for individual countries include Taiwan at 9%[78] and Australia 58.7%.[79] Prevalence in the United States and Canada is estimated at 75% and 30% respectively.[5] Prevalence in Africa varies from less than 20% in some southern African countries to near universal in North and West Africa.[76]

The rates of routine neonatal circumcision over time have varied significantly by country. In the United States, hospital discharge surveys estimated rates at 64.7% in the year 1980, 59.0% in the year 1990, 62.4% in the year 2000, and 58.3% in the year 2010.[80] These estimates are lower than the overall circumcision rates, as they do not account for non-hospital circumcisions,[80] or for procedures performed for medical or cosmetic reasons later in life;[5][80] community surveys have reported higher neonatal circumcision.[5] Canada has seen a slow decline since the early 1970s, possibly influenced by statements from the AAP and the Canadian Pediatric Society issued in the 1970s saying that the procedure was not medically indicated.[5] In Australia, the rate declined in the 1970s and 80s, but has been increasing slowly as of 2004.[5] In the United Kingdom, rates are likely to have been 20–30% in the 1940s but declined in the late 40s. One possible reason may have been a 1949 British Medical Journal article which stated that there was no medical reason for the general circumcision of babies.[5] The overall prevalence of circumcision in South Korea has increased markedly in the second half of the 20th century, rising from near zero around 1950 to about 60% in 2000, with the most significant jumps in the last two decades of that time period.[5] This is probably due to the influence of the United States, which established a trusteeship for the country following World War II.[5]

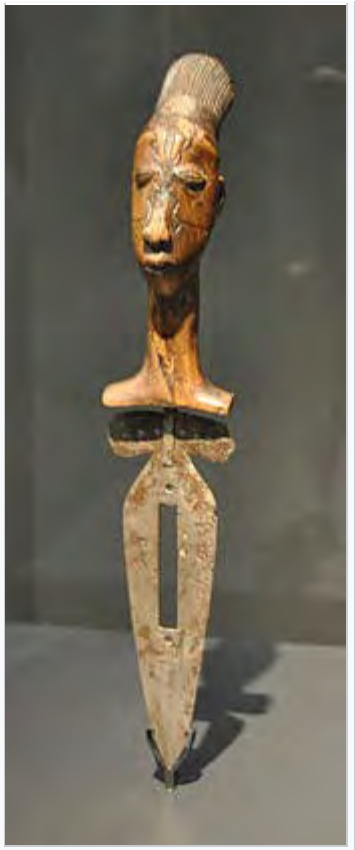
Medical organizations can affect the neonatal circumcision rate of a country by influencing whether the costs of the procedure are borne by the parents or are covered by insurance or a national health care system. Policies that require the costs to be paid by the parents yield lower neonatal circumcision rates. The decline in the rates in the UK is one example; another is that in the United States, the individual states where insurance or Medicaid covers the costs have higher rates. Changes to policy are driven by the results of new research, and moderated by the politics, demographics, and culture of the communities.[7]

## History

*Main article: History of male circumcision*

Circumcision is the world's oldest planned surgical procedure, suggested by anatomist and hyperdiffusionist historian Grafton Elliot Smith to be over 15,000 years old, pre-dating recorded history. There is no firm consensus as to how it came to be practiced worldwide. One theory is that it began in one geographic area and spread from there; another is that several different cultural groups began its practice independently. In his 1891 work *History of Circumcision*, physician Peter Charles Remondino suggested that it began as a less severe form of emasculating a captured enemy: penectomy or castration would likely have been fatal, while some form of circumcision would permanently mark the defeated yet leave him alive to serve as a slave.[23][81]

The history of the migration and evolution of the practice of circumcision is followed mainly through the cultures and peoples in two separate regions. In the lands south and east of the Mediterranean, starting with Sudan and Ethiopia, the procedure was practiced by the ancient Egyptians and the Semites, and then by the Jews and Muslims, with whom the practice travelled to and was adopted by the Bantu Africans. In Oceania, circumcision is practiced



Circumcision knife from the Congo; wood, iron; late 19th/early 20th century

by the Australian Aborigines and Polynesians.[81] There is also evidence that circumcision was practiced among the Aztec and Mayan civilizations in the Americas,[5] but little detail is available about its history.[23][74]

## Middle East, Africa and Europe

Evidence suggests that circumcision was practiced in the Arabian Peninsula by the 4th millennium BCE, when the Sumerians and the Semites moved into the area that is modern-day Iraq.[74] The earliest historical record of circumcision comes from Egypt, in the form of an image of the circumcision of an adult carved into the tomb of Ankh-Mahor at Saqqara, dating to about 2400–2300 BCE. Circumcision was done by the Egyptians possibly for hygienic reasons, but also was part of their obsession with purity and was associated with spiritual and intellectual development. No well-accepted theory explains the significance of circumcision to the Egyptians, but it appears to have been endowed with great honor and importance as a rite of passage into adulthood, performed in a public ceremony emphasizing the continuation of family generations and fertility. It may have been a mark of distinction for the elite: the Egyptian *Book of the Dead* describes the sun god Ra as having circumcised himself.[23][81]

Köçeks dancing at the circumcision celebration of Sultan Ahmed III's sons (1720); miniature from the *Surname-i Vehbi*, Topkapı Palace, Istanbul

Though secular scholars consider the story to be literary and not historical,[82] circumcision features prominently in the Hebrew Bible. The narrative in Genesis chapter 17 describes the circumcision of Abraham and his relatives and slaves. In the same chapter, Abraham's descendants are commanded to circumcise their sons on the eighth day of life as part of a covenant with God.

In addition to proposing that circumcision was taken up by the Israelites purely as a religious mandate, scholars have suggested that Judaism's patriarchs and their followers adopted circumcision to make penile hygiene easier in hot, sandy climates; as a rite of passage into adulthood; or as a form of blood sacrifice.[74][81][83]

Alexander the Great conquered the Middle East in the 4th century BCE, and in the following centuries ancient Greek cultures and values came to the Middle East. The Greeks abhorred circumcision, making a life for circumcised Jews living among the Greeks (and later the Romans) very difficult. Antiochus Epiphanes outlawed circumcision, as did Hadrian, which helped cause the Bar Kokhba revolt. During this period in history, Jewish circumcision called for the removal of only a part of the prepuce, and some Hellenized Jews attempted to look uncircumcised by stretching the extant parts of their foreskins. This was considered by the Jewish leaders to be a serious

problem, and during the 2nd century CE they changed the requirements of Jewish circumcision to call for the complete removal of the foreskin, emphasizing the Jewish view of circumcision as intended to be not just the fulfillment of a Biblical commandment but also an essential and permanent mark of membership in a people.[81][83]

A narrative in the Christian Gospel of Luke makes a brief mention of the circumcision of Jesus, but the subject of physical circumcision itself is not part of the received teachings of Jesus. Paul the Apostle reinterpreted circumcision as a spiritual concept, arguing the physical one to be no longer necessary. The teaching that physical circumcision was unnecessary for membership in a divine covenant was instrumental in the separation of Christianity from Judaism. Although it is not explicitly mentioned in the Quran (early 7th century CE), circumcision is considered essential to Islam, and it is nearly universally performed among Muslims. The practice of circumcision spread across the Middle East, North Africa, and Southern Europe with Islam.[84]

The Circumcision of Jesus Christ, by Ludovico Mazzolino

Genghis Khan, and the following Yuan Emperors in China forbade Islamic practices such as halal butchering and circumcision.[85][86] This led Chinese Muslims to eventually take an active part in rebelling against the Mongols and installing the more tolerant Ming Dynasty.

The practice of circumcision is thought to have been brought to the Bantu-speaking tribes of Africa by either the Jews after one of their many expulsions from European countries, or by Muslim Moors escaping after the 1492 conquest of Spain. In the second half of the 1st millennium CE, inhabitants from the North East of Africa moved south and encountered groups from Arabia, the Middle East, and West Africa. These people moved south and formed what is known today as the Bantu. Bantu tribes were observed to be upholding what was described as Jewish law, including circumcision, in the 16th century. Circumcision and elements of Jewish dietary restrictions are still found among Bantu tribes.[74]

## Indigenous peoples of Australia, the Pacific, and Americas

Circumcision is practiced by some groups amongst Australian Aboriginal peoples, Polynesians, and Native Americans. Little information is available about the origins and history of circumcision among these peoples, compared to circumcision in the Middle East.

For Aboriginal Australians and Polynesians, circumcision likely started as a blood sacrifice and a test of bravery and became an initiation rite with attendant instruction in manhood in more recent centuries. Often seashells were used to remove the foreskin, and the bleeding was stopped with eucalyptus smoke.[74][87]

Christopher Columbus reported circumcision being practiced by Native Americans.[23] It was also practiced by the Incas, Aztecs, and Mayans. It probably started among South American tribes as a blood sacrifice or ritual mutilation to test bravery and endurance, and its use later evolved into a rite of initiation.[74]

## Modern times

Circumcision did not become a common medical procedure in the Anglophone world until the late 19th century.[88] At that time, British and American doctors began recommending it primarily as a deterrent to masturbation.[88][89] Prior to the 20th century, masturbation was believed to be the cause of a wide range of physical and mental illnesses including epilepsy, paralysis, impotence, gonorrhea, tuberculosis, feeblemindedness, and insanity.[90][91] In 1855, motivated in part by an interest in promoting circumcision to reduce masturbation, English physician Jonathan Hutchinson published his findings that Jews had a lower prevalence of certain venereal diseases.[92] While pursuing a successful career as a general practitioner, Hutchinson went on to advocate circumcision for health reasons for the next fifty years,[92] and eventually earned a knighthood for his overall contributions to medicine.[93] In America, one of the first modern physicians to advocate the procedure was Lewis Sayre, a founder of the American Medical

Association. In 1870, Sayre began using circumcision as a purported cure for several cases of young boys diagnosed with paralysis or significant motor problems. He thought the procedure ameliorated such problems based on a "reflex neurosis" theory of disease, which held that excessive stimulation of the genitals was a disturbance to the equilibrium of the nervous system and a cause of systemic problems.[88] The use of circumcision to promote good health also fit in with the germ theory of disease during that time, which saw the foreskin as being filled with infection-causing smegma (a mixture of shed skin cells and oils). Sayre published works on the subject and promoted it energetically in speeches. Contemporary physicians picked up on Sayre's new treatment, which they believed could prevent or cure a wide-ranging array of medical problems and social ills. Its popularity spread with publications such as Peter Charles Remondino's *History of Circumcision*. By the turn of the century, in both America and Great Britain, infant circumcision was near universally recommended.[23][89]

After the end of World War II, Britain moved to a nationalized health care system, and so looked to ensure that each medical procedure covered by the new system was cost-effective and the procedure for non-medical reasons was not covered by the national healthcare system. Douglas Gairdner's 1949 article "The Fate of the Foreskin" argued that the evidence available at that time showed that the risks outweighed the known benefits.[94] Circumcision rates dropped in Britain and in the rest of Europe. In the 1970s, national medical associations in Australia and Canada issued recommendations against routine infant circumcision, leading to drops in the rates of both of those countries. The United States made similar statements in the 1970s, but stopped short of recommending against it — simply stating that it has no medical benefit. Since then they have amended their policy statements several times with the current recommendation being that the benefits outweigh the risks, but they do not recommend it routinely.[23][89]

An association between circumcision and reduced heterosexual HIV infection rates was suggested in 1986.[23] Experimental evidence was needed to establish a causal relationship, so three randomized controlled trials were commissioned as a means to reduce the effect of any confounding factors.[95] Trials took place in South Africa, Kenya and Uganda.[11] All three trials were stopped early by their monitoring boards on ethical grounds because those in the circumcised group had a lower rate of HIV contraction than the control group.[11] Subsequently, the World Health Organization promoted circumcision in high-risk populations as part of an overall program to reduce the spread of HIV,[12] although some have challenged the validity of the African randomized controlled trials, prompting a number of researchers to question the effectiveness of circumcision as an HIV prevention strategy.[96][97][98][99] The Male Circumcision Clearinghouse website was formed in 2009 by WHO, UNAIDS, FHI and AVAC to provide current evidence-based guidance, information, and resources to support the delivery of safe male circumcision services in countries that choose to scale up the procedure as one component of comprehensive HIV prevention services.[100][101]

# Society and culture

## Cultures and religions

*See also: Religious male circumcision*

In some cultures, males are generally required to be circumcised shortly after birth, during childhood or around puberty as part of a rite of passage. Circumcision is commonly practiced in the Jewish and Islamic faiths.

## Judaism

*Main article: Brit milah*

Circumcision is very important to most branches of Judaism, with over 90% of adherents having the procedure performed as a religious obligation. The basis for its observance is found in the Torah of the Hebrew Bible, in Genesis chapter 17, in which a covenant of circumcision is made with Abraham and his descendants. Jewish

Preparing for a Jewish ritual circumcision with a Mogen shield (on the table, next to the scalpel)

circumcision is part of the *brit milah* ritual, to be performed by a specialist ritual circumciser (a *mohel*) on the eighth day of a newborn son's life (with certain exceptions for poor health). Jewish law requires that the circumcision leaves the glans bare when the penis is flaccid. Converts to Conservative and Orthodox Judaism must also be circumcised; those who are already circumcised undergo a symbolic circumcision ritual. Circumcision is not required by Judaism for one to be considered Jewish, but some adherents foresee serious negative spiritual consequences if it is neglected.[24][102]

According to traditional Jewish law, in the absence of a grown free Jewish male expert, a woman, a slave, or a child, that has the required skills, is also authorized to perform the circumcision, provided that she or he is Jewish.[103] However, most streams of non-Orthodox Judaism allow female mohels, called *mohalot* (Hebrew: , the plural of *mohelet*, feminine of *mohel*), without restriction. In 1984, Deborah Cohen became the first certified Reform mohelet; she was certified by the Berit Mila program of Reform Judaism.[104]

Some contemporary Jews in the United States choose not to circumcise their sons.[105] They are assisted by a small number of Reform and Reconstructionist rabbis, and have developed a welcoming ceremony that they call the *brit shalom* ("Covenant [of] Peace") for such children, also accepted by Humanistic Judaism.[106][107]

This ceremony of *brit shalom* is not officially approved of by the Reform or Reconstructionist rabbinical organizations, who make the recommendation that male infants should be circumcised, though the issue of converts remains controversial[108][109] and circumcision of converts is not mandatory in either movement.[110]

## Islam

*Main article: Khitan (circumcision)*

Children in Turkey wearing traditional circumcision costumes

Although there is some debate within Islam over whether it is a religious requirement, circumcision (called *khitan*) is practiced nearly universally by Muslim males. Islam bases its practice of circumcision on the Genesis 17 narrative, the same Biblical chapter referred to by Jews. The procedure is not explicitly mentioned in the Quran, however, it is a tradition established by Islam's prophet Muhammad directly (following Abraham), and so its practice is considered a *sunnah* (prophet's tradition) and is very important in Islam. For Muslims, circumcision is also a matter of cleanliness, purification and control over one's baser self (*nafs*). There is no agreement across the many Islamic communities about the age at which circumcision should be performed. It may be done from soon after birth up to about age 15; most often it is performed at around six to seven years of age. The timing can correspond with the boy's completion of his recitation of the whole Quran, with a coming-of-age event such as taking on the responsibility of daily prayer or betrothal. Circumcision may be celebrated with an associated family or community event. Circumcision is recommended for, but is not required of, converts to Islam.[26][111][112]

## Christianity

*Main article: Religious male circumcision § In Christianity*

The New Testament chapter Acts 15 records that Christianity does not require circumcision; Christianity does not forbid it either. The Catholic Church currently maintains a neutral position on the practice of non-religious circumcision,[113] although in 1442 it banned the practice of religious circumcision in the 11th Council of Florence.[114] Coptic Christians practice circumcision as a rite of passage.[5][25][115][116] The Ethiopian Orthodox Church calls for circumcision, with near-universal prevalence among Orthodox men in Ethiopia.[5] In South Africa, some Christian churches disapprove of the practice, while others require it of their members.[5]

## African cultures

Certain African cultural groups, such as the Yoruba and Igbo of Nigeria, customarily circumcise their infant sons. The procedure is also practiced by some cultural groups or individual family lines in the Sudan, Zaire, Uganda and in southern Africa. For some of these groups, circumcision appears to be purely cultural, done with no particular religious significance or intention to distinguish members of a group. For others, circumcision might be done for purification, or it may be interpreted as a mark of subjugation. Among these groups, even when circumcision is done for reasons of tradition, it is often done in hospitals.[117] It is not clear how many deaths and injuries result from traditional circumcisions which occur outside of hospitals.[118]

## Australian cultures

Some Australian Aborigines use circumcision as a test of bravery and self-control as a part of a rite of passage into manhood, which results in full societal and ceremonial membership. It may be accompanied by body scarification and the removal of teeth, and may be followed later by penile subincision. Circumcision is one of many trials and ceremonies required before a youth is considered to have become knowledgeable enough to maintain and pass on the cultural traditions. During these trials, the maturing youth bonds in solidarity with the men. Circumcision is also strongly associated with a man's family, and it is part of the process required to prepare a man to take a wife and produce his own family.[117]

## Filipino culture

In the Philippines, circumcision known as "tuli" is sometimes viewed as a rite of passage.[119] About 93% of Filipino men are circumcised.[119]

## Ethical and legal issues

*Main article: Ethics of circumcision*
*See also: Circumcision controversies and Circumcision and law*

There is a long-running and vigorous debate over ethical concerns regarding circumcision, particularly neonatal circumcision for reasons other than intended direct medical benefit. There are three parties involved in the decision to circumcise a minor: the minor as the patient, the parents (or other guardians) and the physician. The physician is bound under the ethical principles of beneficence (promoting well-being) and non-maleficence ("first, do no harm"), and so is charged with the responsibility to promote the best interests of the patient while minimizing unnecessary harms. Those involved must weigh the factors of what is in the best interest of the minor against the potential harms of the procedure.[9]

A protest against infant circumcision

With a newborn involved, the decision is made more complex due to the principles of respect for autonomy and consent, as a newborn cannot understand or engage in a logical discussion of his own values and best interests.[8][9] A mentally more mature child can understand the issues involved to some degree, and the physician and parents may elicit input

from the child and weigh it appropriately in the decision-making process, although the law may not treat such input as legally informative.
Ethicists and legal theorists also state that it is questionable for parents to make a decision for the child that precludes the child from making a different decision for himself later. Such a question can be raised for the decision by the parents either to circumcise or not to circumcise the child.[9]

Generally, circumcision on a minor is not ethically controversial or legally questionable when there is a clear and pressing medical indication for which it is the accepted best practice to resolve. Where circumcision is the chosen intervention, the physician has an ethical responsibility to ensure the procedure is performed competently and safely to minimize potential harms.[8][9] Worldwide, most legal jurisdictions do not have specific laws concerning the circumcision of males,[5] but infant circumcision is considered legal under the existing laws in countries such as Australia, Canada, New Zealand, the United Kingdom, and the United States.[120] A few countries have passed legislation on the procedure: Germany allows non-therapeutic circumcision,[121] while non-religious routine circumcision is illegal in South Africa and Sweden.[5][120]

Throughout society, circumcision is often considered for reasons other than medical need. Public health advocates of circumcision consider it to have a net benefit, and therefore feel that increasing the circumcision rate is an ethical imperative. They recommend performing the procedure during the neonatal period when it is less expensive and has a lower risk of complications.[8] While studies show there is a modest epidemiological benefit to circumcision, critics argue that the number of circumcisions that would have to be performed would yield an overall negative public health outcome due to the resulting number of complications or other negative effects (such as pain). Pinto (2012) writes "sober proponents and detractors of circumcision agree that there is no overwhelming medical evidence to support either side."[8] This type of cost-benefit analysis is highly dependent on the kinds and frequencies of health problems in the population under discussion and how circumcision affects those health problems.[9]

Parents are assumed to have the child's best interests in mind. Ethically, it is imperative that the medical practitioner informs the parents about the benefits and risks of the procedure and obtain informed consent before performing it. Practically, however, many parents come to a decision about circumcising the child before he is born, and a discussion of the benefits and risks of the procedure with a physician has not been shown to have a significant effect on the decision. Some parents request to have their newborn or older child circumcised for non-therapeutic reasons, such as the parents' desires to adhere to family tradition, cultural norms or religious beliefs. In considering such a request, the physician may consider (in addition to any potential medical benefits and harms) such non-medical factors in determining the child's best interests and may ethically perform the procedure. Equally, without a clear medical benefit relative to the potential harms, a physician may take the ethical position that non-medical factors do not contribute enough as benefits to outweigh the potential harms and refuse to perform the procedure. Medical organization such as the British Medical Association state that their member physicians are not obliged to perform the procedure in such situations.[8][9]

The German Academy for Pediatric and Adolescent Medicine (Deutsche Akademie für Kinder- und Jugendmedizin e.V., DAKJ) recommend against routine non-medical infant circumcision.[122]

## Economic considerations

The cost-effectiveness of circumcision has been studied to determine whether a policy of circumcising all newborns or a policy of promoting and providing inexpensive or free access to circumcision for all adult men who choose it would result in lower overall societal healthcare costs. As HIV/AIDS is an incurable disease that is expensive to manage, significant effort has been spent studying the cost-effectiveness of circumcision to reduce its spread in parts of Africa that have a relatively high infection rate and low circumcision prevalence.[123] Several analyses have concluded that circumcision programs for adult men in Africa are cost-effective and in some cases are cost-saving.[37][124] In Rwanda, circumcision has been found to be cost-effective across a wide range of age groups from newborn to adult,[47][125] with the greatest savings achieved when the procedure is performed in the newborn period due to the lower cost per procedure and greater timeframe for HIV infection protection.[15][125] Circumcision for the prevention of HIV transmission in adults has also been found to be cost-effective in South Africa, Kenya, and Uganda,[123]

with cost savings estimated in the billions of US dollars over 20 years. Hankins *et al.* (2011) estimated that a $1.5 billion investment in circumcision for adults in 13 high-priority African countries would yield $16.5 billion in savings.[126]

The overall cost-effectiveness of neonatal circumcision has also been studied in the United States, which has a different cost setting from Africa in areas such as public health infrastructure, availability of medications, and medical technology and the willingness to use it.[127] A study by the CDC suggests that newborn circumcision would be societally cost-effective in the United States based on circumcision's efficacy against the heterosexual transmission of HIV alone, without considering any other cost benefits.[4] The American Academy of Pediatrics (2012) recommends that neonatal circumcision in the United States be covered by third-party payers such as Medicaid and insurance.[4] A 2014 review that considered reported benefits of circumcision such as reduced risks from HIV, HPV, and HSV-2 stated that circumcision is cost-effective in both the United States and Africa and may result in health care savings.[128] However, A 2014 literature review found that there are significant gaps in the current literature on male and female sexual health that need to be addressed for the literature to be applicable to North American populations.[129]

# Cleft lip and cleft palate

From Wikipedia, the free encyclopedia
(Redirected from Cleft lip and palate)

**Cleft lip and cleft palate**, also known as **orofacial cleft**, is a group of conditions that includes cleft lip (CL), cleft palate (CP), and both together (CLP).[1][2] A cleft lip contains an opening in the upper lip that may extend into the nose. The opening may be on one side, both sides, or in the middle. A cleft palate is when the roof of the mouth contains an opening into the nose. These disorders can result in feeding problems, speech problems, hearing problems, and frequent ear infections. Less than half the time the condition is associated with other disorders.[1]

Cleft lip and palate are the result of tissues of the face not joining properly during development. As such, they are a type of birth defect. The cause is unknown in most cases.[1] Risk factors include smoking during pregnancy, diabetes, obesity, an older mother, and certain medications (such as some used to treat seizures).[1][2] Cleft lip and cleft palate can often be diagnosed during pregnancy with an ultrasound exam.[1]

A cleft lip or palate can be successfully treated with surgery. This is often done in the first few months of life for cleft lip and before eighteen months for cleft palate. Speech therapy and dental care may also be needed. With appropriate treatment outcomes are good.[1]

Cleft lip and palate occurs in about 1 to 2 per 1000 births in the developed world.[2] CL is about twice as common in males as females, while CP without CL is more common in females.[2] In 2013 it resulted in about 3,300 deaths globally down from 7,600 deaths in 1990.[3] The condition was formerly known as a **hare lip** because of its resemblance to a hare or rabbit, but that term is now generally considered to be offensive.[4]

## Signs and symptoms

If the cleft does not affect the palate structure of the mouth it is referred to as cleft lip. Cleft lip is formed in the top of the lip as either a small gap or an indentation in the lip (partial or incomplete cleft) or it continues into the nose (complete cleft). Lip cleft can occur as a one sided (unilateral) or two sided (bilateral). It is due to the failure of fusion of the maxillary and medial nasal processes (formation of the primary palate).

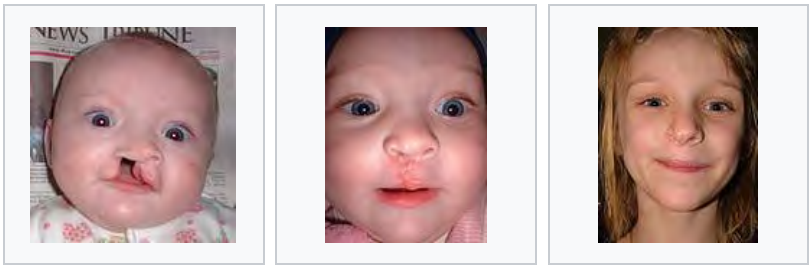
Unilateral incomplete | Unilateral complete | Bilateral complete

A mild form of a cleft lip is a microform cleft.[5] A microform cleft can appear as small as a little dent in the red part of the lip or look like a scar from the lip up to the nostril.[6] In some cases muscle tissue in the lip underneath the scar is affected and might require reconstructive surgery.[7] It is advised to have newborn infants with a microform cleft checked with a craniofacial team as soon as possible to determine the severity of the cleft.[8]



Six-month-old girl before going into surgery to have her unilateral complete cleft lip repaired | The same girl, 1 month after the surgery | The same girl, age 8, the scar almost gone

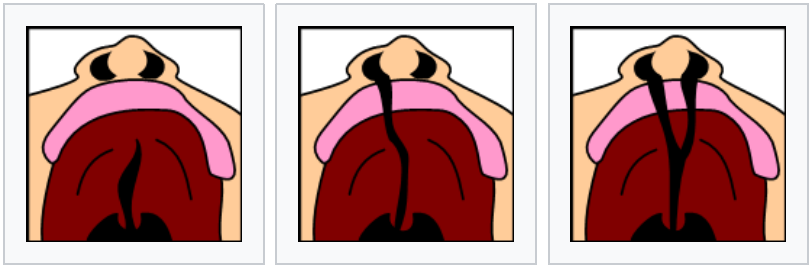
## Cleft palate

Cleft palate is a condition in which the two plates of the skull that form the hard palate (roof of the mouth) are not completely joined. The soft palate is in these cases cleft as well. In most cases, cleft lip is also present. Cleft palate occurs in about one in 700 live births worldwide.[9]

Palate cleft can occur as complete (soft and hard palate, possibly including a gap in the jaw) or incomplete (a 'hole' in the roof of the mouth, usually as a cleft soft palate). When cleft palate occurs, the uvula is usually split. It occurs due to the failure of fusion of the lateral palatine processes, the nasal septum, and/or the median palatine processes (formation of the secondary palate).

The hole in the roof of the mouth caused by a cleft connects the mouth directly to the inside of the nose.

Note: the next images show the roof of the mouth. The top shows the nose, the lips are colored pink. For clarity the images depict a toothless infant.



Incomplete cleft palate | Unilateral complete lip and palate | Bilateral complete lip and palate

A result of an open connection between the mouth and inside the nose is called velopharyngeal inadequacy (VPI). Because of the gap, air leaks into the nasal cavity resulting in a hypernasal voice resonance and nasal emissions while talking.[10] Secondary effects of VPI include speech articulation errors (e.g., distortions, substitutions, and omissions) and compensatory misarticulations and mispronunciations (e.g., glottal stops and posterior nasal fricatives).[11] Possible treatment options include speech therapy, prosthetics, augmentation of the posterior pharyngeal wall, lengthening of the palate, and surgical procedures.[10]

Submucous cleft palate (SMCP) can also occur, which is a cleft of the soft palate with a classic clinical triad of a bifid, or split, uvula which is found dangling in the back of the throat, a furrow along the midline of the soft palate, and a notch in the back margin of the hard palate.[12]

## Psychosocial issues

Most children who have their clefts repaired early enough are able to have a happy youth and social life.[*citation needed*] Having a cleft palate/lip does not inevitably lead to a psychosocial problem.[*citation needed*] However, adolescents with cleft palate/lip are at an elevated risk for developing psychosocial problems especially those relating to self-concept, peer relationships and appearance. Adolescents may face psychosocial challenges but can find professional help if problems arise.[*citation needed*] A cleft palate/lip may impact an individual's self-esteem, social skills and behavior. There is research dedicated to the psychosocial development of individuals with cleft palate. Self-concept may be adversely affected by the presence of a cleft lip and/or cleft palate, particularly among girls.[13]

Research has shown that during the early preschool years (ages 3–5), children with cleft lip and/or cleft palate tend to have a self-concept that is similar to their peers without a cleft. However, as they grow older and their social interactions increase, children with clefts tend to report more dissatisfaction with peer relationships and higher levels of social anxiety. Experts conclude that this is probably due to the associated stigma of visible deformities and possible speech impediments. Children who are judged as attractive tend to be perceived as more intelligent, exhibit more positive social behaviors, and are treated more positively than children with cleft lip and/or cleft palate.[14] Children with clefts tend to report feelings of anger, sadness, fear, and alienation from their peers, but these children were similar to their peers in regard to "how well they liked themselves."

The relationship between parental attitudes and a child's self-concept is crucial during the preschool years. It has been reported that elevated stress levels in mothers correlated with reduced social skills in their children.[15] Strong parent support networks may help to prevent the development of negative self-concept in children with cleft palate.[16] In the later preschool and early elementary years, the development of social skills is no longer only impacted by parental attitudes but is beginning to be shaped by their peers. A cleft lip and/or cleft palate may affect the behavior of preschoolers.

Experts suggest that parents discuss with their children ways to handle negative social situations related to their cleft lip and/or cleft palate. A child who is entering school should learn the proper (and age-appropriate) terms related to the cleft. The ability to confidently explain the condition to others may limit feelings of awkwardness and embarrassment and reduce negative social experiences.[17]

As children reach adolescence, the period of time between age 13 and 19, the dynamics of the parent-child relationship change as peer groups are now the focus of attention. An adolescent with cleft lip and/or cleft palate will deal with the typical challenges faced by most of their peers including issues related to self-esteem, dating and social acceptance.[18][19][20] Adolescents, however, view appearance as the most important characteristic above intelligence and humor.[21] This being the case, adolescents are susceptible to additional problems because they cannot hide their facial differences from their peers. Adolescent boys typically deal with issues relating to withdrawal, attention, thought, and internalizing problems and may possibly develop anxiousness-depression and aggressive behaviors.[20] Adolescent girls are more likely to develop problems relating to self-concept and appearance. Individuals with cleft lip and/or cleft palate often deal with threats to their quality of life for multiple reasons including: unsuccessful social relationships, deviance in social appearance and multiple surgeries.

### Complications

Cleft may cause problems with feeding, ear disease, speech and socialization.

Due to lack of suction, an infant with a cleft may have trouble feeding. An infant with a cleft palate will have greater success feeding in a more upright position. Gravity will help prevent milk from coming through the baby's nose if he/she has cleft palate. Gravity feeding can be accomplished by using specialized equipment, such as the Haberman Feeder, or by using a combination of nipples and bottle inserts like the one shown, is commonly used with other infants. A large hole, crosscut, or slit in the nipple, a protruding nipple and rhythmically squeezing the bottle insert can result in controllable flow to the infant without the stigma caused by specialized equipment.

Individuals with cleft also face many middle ear infections which may eventually lead to hearing loss. The Eustachian tubes and external ear canals may be angled or tortuous, leading to food or other contamination of a part of the body that is normally self-cleaning. Hearing is related to learning to speak. Babies with palatal clefts may have compromised hearing and therefore, if the baby cannot hear, it cannot try to mimic the sounds of speech. Thus, even before expressive language acquisition, the baby with the cleft palate is at risk for receptive language acquisition. Because the lips and palate are both used in pronunciation, individuals with cleft usually need the aid of a speech therapist.

A baby being fed using a customized bottle. The upright sitting position allows gravity to help the baby swallow the milk more easily

## Cause

The development of the face is coordinated by complex morphogenetic events and rapid proliferative expansion, and is thus highly susceptible to environmental and genetic factors, rationalising the high incidence of facial malformations. During the first six to eight weeks of pregnancy, the shape of the embryo's head is formed. Five primitive tissue lobes grow:

**a)** one from the top of the head down towards the future upper lip; (Frontonasal Prominence)
**b-c)** two from the cheeks, which meet the first lobe to form the upper lip; (Maxillar Prominence)
**d-e)** and just below, two additional lobes grow from each side, which form the chin and lower lip; (Mandibular Prominence)

If these tissues fail to meet, a gap appears where the tissues should have joined (fused). This may happen in any single joining site, or simultaneously in several or all of them. The resulting birth defect reflects the locations and severity of individual fusion failures (e.g., from a small lip or palate fissure up to a completely malformed face).

The upper lip is formed earlier than the palate, from the first three lobes named a to c above. Formation of the palate is the last step in joining the five embryonic facial lobes, and involves the back portions of the lobes b and c. These back portions are called palatal shelves, which grow towards each other until they fuse in the middle.[22] This process is very vulnerable to multiple toxic substances, environmental pollutants, and nutritional imbalance. The biologic mechanisms of mutual recognition of the two cabinets, and the way they are glued together, are quite complex and obscure despite intensive scientific research.[23]

### Genetics

Genetic factors contributing to cleft lip and cleft palate formation have been identified for some syndromic cases, but knowledge about genetic factors that contribute to the more common isolated cases of cleft lip/palate is still patchy.

Many clefts run in families, even though in some cases there does not seem to be an identifiable syndrome present,[24] possibly because of the current incomplete genetic understanding of midfacial development.

A number of genes are involved including cleft lip and palate transmembrane protein 1 and GAD1,[25] one of the glutamate decarboxylases. Many genes are known to play a role in craniofacial development and are being studied through the FaceBase initiative for their part in clefting. These genes are AXIN2, BMP4, FGFR1, FGFR2, FOXE1, IRF6, MAFB (gene), MMP3, MSX1, MSX2 (Msh homeobox 2), MSX3, PAX7, PDGFC, PTCH1, SATB2, SOX9, SUMO1 (Small ubiquitin-related modifier 1), TBX22, TCOF (Treacle protein), TFAP2A, VAX1, TP63, ARHGAP29, NOG, NTN1, WNT genes, and locus 8q24.[26]

### Syndromes

- The Van der Woude Syndrome is caused by a specific variation in the gene *IRF6* that increases the occurrence of these deformities threefold.[27][28][29]
- Another syndrome, Siderius X-linked mental retardation, is caused by mutations in the *PHF8* gene (OMIM 300263); in addition to cleft lip and/or palate, symptoms include facial dysmorphism and mild mental retardation.[30]

In some cases, cleft palate is caused by syndromes which also cause other problems.

- Stickler's Syndrome can cause cleft lip and palate, joint pain, and myopia.[31][32]
- Loeys-Dietz syndrome can cause cleft palate or bifid uvula, hypertelorism, and aortic aneurysm.[33]
- Hardikar syndrome can cause cleft lip and palate, Hydronephrosis, Intestinal obstruction and other symptoms.[34]
- Cleft lip/palate may be present in many different chromosome disorders including Patau Syndrome (trisomy 13).
- Malpuech facial clefting syndrome
- Hearing loss with craniofacial syndromes

- Popliteal pterygium syndrome
- Treacher Collins Syndrome

### Specific genes

Many genes associated with syndromic cases of cleft lip/palate (see above) have been identified to contribute to the incidence of isolated cases of cleft lip/palate. This includes in particular sequence variants in the genes *IRF6*, *PVRL1* and *MSX1*.[35] The understanding of the genetic complexities involved in the morphogenesis of the midface, including molecular and cellular processes, has been greatly aided by research on animal models, including of the genes *BMP4*, *SHH*, *SHOX2*, *FGF10* and *MSX1*.[35]

| OFC12 | 612858 | ? | 8q24.3 |

### Environmental factors

Environmental influences may also cause, or interact with genetics to produce, orofacial clefting. An example of how environmental factors might be linked to genetics comes from research on mutations in the gene *PHF8* that cause cleft lip/palate (see above). It was found that *PHF8* encodes for a histone lysine demethylase,[36] and is involved in epigenetic regulation. The catalytic activity of PHF8 depends on molecular oxygen,[36] a fact considered important with respect to reports on increased incidence of cleft lip/palate in mice that have been exposed to hypoxia early during pregnancy.[37] In humans, fetal cleft lip and other congenital abnormalities have also been linked to maternal hypoxia, as caused by e.g. maternal smoking,[38] maternal alcohol abuse or some forms of maternal hypertension treatment.[39] Other environmental factors that have been studied include: seasonal causes (such as pesticide exposure); maternal diet and vitamin intake; retinoids — which are members of the vitamin A family; anticonvulsant drugs; nitrate compounds; organic solvents; parental exposure to lead; alcohol; cigarette use; and a number of other psychoactive drugs (e.g. cocaine, crack cocaine, heroin).

Current research continues to investigate the extent to which folic acid can reduce the incidence of clefting.[40]

## Diagnosis

Traditionally, the diagnosis is made at the time of birth by physical examination. Recent advances in prenatal diagnosis have allowed obstetricians to diagnose facial clefts in utero with ultrasonography.[41]

Clefts can also affect other parts of the face, such as the eyes, ears, nose, cheeks, and forehead. In 1976, Paul Tessier described fifteen lines of cleft. Most of these craniofacial clefts are even rarer and are frequently described as Tessier clefts using the numerical locator devised by Tessier.[42]

## Treatment

Cleft lip and palate is very treatable; however, the kind of treatment depends on the type and severity of the cleft.

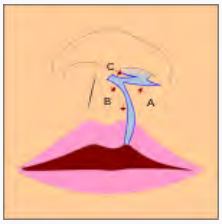
Most children with a form of clefting are monitored by a *cleft palate team* or *craniofacial team* through young adulthood.[43] Care can be lifelong. Treatment procedures can vary between craniofacial teams. For example, some teams wait on jaw correction until the child is aged 10 to 12 (argument: growth is less influential as deciduous teeth are replaced by permanent teeth, thus saving the child from repeated corrective surgeries), while other teams correct the jaw earlier (argument: less speech therapy is needed than at a later age when speech therapy becomes harder). Within teams, treatment can differ between individual cases depending on the type and severity of the cleft.

### Cleft lip

Within the first 2–3 months after birth, surgery is performed to close the cleft lip. While surgery to repair a cleft lip can be performed soon after birth, often the preferred age is at approximately 10 weeks of age, following the "rule of 10s" coined by surgeons Wilhelmmesen and Musgrave in 1969 (the child is at least 10 weeks of age; weighs at least 10 pounds, and has at least 10g hemoglobin).[44] If the cleft is bilateral and extensive, two surgeries may be required to close the cleft, one side first, and the second side a few weeks later. The most common procedure to repair a cleft lip is the *Millard procedure* pioneered by Ralph Millard. Millard performed the first procedure at a Mobile Army Surgical Hospital (MASH) unit in Korea.[45]

Often an incomplete cleft lip requires the same surgery as complete cleft. This is done for two reasons. Firstly the group of muscles required to purse the lips run through the upper lip. In order to restore the complete group a full incision must be made. Secondly, to create a less obvious scar the surgeon tries to line up the scar with the natural lines in the upper lip (such as the edges of the philtrum) and tuck away stitches as far up the nose as possible. Incomplete cleft gives the surgeon more tissue to work with, creating a more supple and natural-looking upper lip.

The blue lines indicate incisions.



Movement of the flaps; flap A is moved between B and C. C is rotated slightly while B is pushed down.

Pre-operation

Post-operation, the lip is swollen from surgery and will get a more natural look within a couple of weeks. See photos in the section above.

### Pre-surgical devices

In some cases of a severe bi-lateral complete cleft, the premaxillary segment will be protruded far outside the mouth.

Nasoalveolar molding prior to surgery can improve long-term nasal symmetry among patients with complete unilateral cleft lip-cleft palate patients compared to correction by surgery alone, according to a retrospective cohort study.[46] In this study, significant improvements in nasal symmetry were observed in multiple areas including measurements of the projected length of the nasal ala (lateral surface of the external nose), position of the superoinferior alar groove, position of the mediolateral nasal dome, and nasal bridge deviation. "The nasal ala projection length demonstrated an average ratio of 93.0 percent in the surgery-alone group and 96.5 percent in the nasoalveolar molding group" this study concluded.

## Cleft palate

Often a cleft palate is temporarily covered by a palatal obturator (a prosthetic device made to fit the roof of the mouth covering the gap).

A repaired cleft palate on a 64-year-old female.

Cleft palate can also be corrected by surgery, usually performed between 6 and 12 months. Approximately 20–25% only require one palatal surgery to achieve a competent velopharyngeal valve capable of producing normal, non-hypernasal speech. However, combinations of surgical methods and repeated surgeries are often necessary as the child grows. One of the new innovations of cleft lip and cleft palate repair is the Latham appliance.[47] The Latham is surgically inserted by use of pins during the child's 4th or 5th month. After it is in place, the doctor, or parents, turn a screw daily to bring the cleft together to assist with future lip and/or palate repair.

If the cleft extends into the maxillary alveolar ridge, the gap is usually corrected by filling the gap with bone tissue. The bone tissue can be acquired from the patients own chin, rib or hip.

## Speech and hearing

A tympanostomy tube is often inserted into the eardrum to aerate the middle ear.[48] This is often beneficial for the hearing ability of the child.

Children with cleft palate typically have a variety of speech problems. Some speech problems result directly from anatomical differences such as velopharyngeal inadequacy. Velopharyngeal inadequacy refers to the inability of the soft palate to close the opening from the throat to the nasal cavity, which is necessary for many speech sounds, such as /p/, /b/, /t/, /d/, /s/, /z/, etc.[49] This type of errors typically resolve after palate repair.[50]

However, sometimes children with cleft palate also have speech errors which develop as the result of an attempt to compensate for the inability to produce the target phoneme. These are known as compensatory articulations. Compensatory articulations are usually sounds that are non-existent in normal English phonology, often do not resolve automatically after palatal repair, and make a child's speech even more difficult to understand.[50][51][52]

Speech-language pathology can be very beneficial to help resolve speech problems associated with cleft palate. In addition, research has indicated that children who receive early language intervention are less likely to develop compensatory error patterns later.[53]

## Hearing loss

Hearing impairment is particularly prevalent in children with cleft palate. The tensor muscle fibres that open the eustachian tubes lack an anchor to function effectively. In this situation, when the air in the middle ear is absorbed by the mucous membrane, the negative pressure is not compensated, which results in the secretion of fluid into the middle ear space from the mucous membrane.[54] Children with this problem typically have a conductive hearing loss primarily caused by this middle ear effusion.[55]

## Sample treatment schedule

Note that each individual patient's schedule is treated on a case-by-case basis and can vary per hospital. The table below shows a common sample treatment schedule. The colored squares indicate the average timeframe in which the indicated procedure occurs. In some cases this is usually one procedure (for example lip repair) in other cases this is an ongoing therapy (for example speech therapy).

| Age | 0m | 3m | 6m | 9m | 1y | 2y | 3y | 4y | 5y | 6y | 7y | 8y | 9y | 10y | 11y | 12y | 13y | 14y | 15y | 16y | 17y | 18y |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Palatal obturator | | | | | | | | | | | | | | | | | | | | | | |
| Repair cleft lip | | | | | | | | | | | | | | | | | | | | | | |
| Repair soft palate | | | | | | | | | | | | | | | | | | | | | | |
| Repair hard palate | | | | | | | | | | | | | | | | | | | | | | |
| Tympanostomy tube | | | | | | | | | | | | | | | | | | | | | | |
| Speech therapy/pharyngoplasty | | | | | | | | | | | | | | | | | | | | | | |
| Bone grafting jaw | | | | | | | | | | | | | | | | | | | | | | |
| Orthodontics | | | | | | | | | | | | | | | | | | | | | | |
| Further cosmetic corrections (Including jawbone surgery) | | | | | | | | | | | | | | | | | | | | | | |

## Craniofacial team

*Main article: Craniofacial team*

A craniofacial team is routinely used to treat this condition. The majority of hospitals still use craniofacial teams; yet others are making a shift towards dedicated cleft lip and palate programs. While craniofacial teams are widely knowledgeable about all aspects of craniofacial conditions, dedicated cleft lip and palate teams are able to dedicate many of their efforts to being on the cutting edge of new advances in cleft lip and palate care.

Many of the top pediatric hospitals are developing their own CLP clinics in order to provide patients with comprehensive multi-disciplinary care from birth through adolescence. Allowing an entire team to care for a child throughout their cleft lip and palate treatment (which is ongoing) allows for the best outcomes in every aspect of a child's care. While the individual approach can yield significant results, current trends indicate that team based care

leads to better outcomes for CLP patients. .[56]

## Epidemiology

*Main article: Clefting prevalence in different cultures*

Cleft lip and palate occurs in about 1 to 2 per 1000 births in the developed world.[2]

Rates for cleft lip with or without cleft palate and cleft palate alone varies within different ethnic groups.

The highest prevalence rates for (CL ± P) are reported for Native Americans and Asians. Africans have the lowest prevalence rates.[57]

- Native Americans: 3.74/1000
- Japanese: 0.82/1000 to 3.36/1000
- Chinese: 1.45/1000 to 4.04/1000
- Caucasians: 1.43/1000 to 1.86/1000
- Latin Americans: 1.04/1000
- Africans: 0.18/1000 to 1.67/1000

Rate of occurrence of CPO is similar for Caucasians, Africans, North American natives, Japanese and Chinese. The trait is dominant.

It caused about 4,000 deaths globally in 2010 down from 8,400 in 1990.[58]

Prevalence of "cleft uvula" has varied from .02% to 18.8% with the highest numbers found among Chippewa and Navajo and the lowest generally in Africans.[59][60]

## Society and culture

### Abortion controversy

In some countries, cleft lip or palate deformities are considered reasons (either generally tolerated or officially sanctioned) to perform an abortion beyond the legal fetal age limit, even though the fetus is not in jeopardy of life or limb.[*citation needed*] Some human rights activists contend that this practice of what they refer to as "cosmetic murder" amounts to eugenics.[*citation needed*]

### Works of fiction

The eponymous hero of J.M. Coetzee's 1983 novel *Life & Times of Michael K* has a cleft lip. However, cleft lip is more often portrayed negatively in popular culture. Examples include Oddjob, the secondary villain of the James Bond novel *Goldfinger* by Ian Fleming (the film adaptation does not mention this but leaves it implied); the fanciful portrayal of Roman Emperor Commodus in the 2000 film *Gladiator*,;[61] and serial killer Francis Dolarhyde in the film *Red Dragon*.[62]

In the 1920 novel *Growth of the Soil,* by Norwegian writer Knut Hamsun, Inger (wife of the main character) has an uncorrected cleft lip which puts heavy limitations on her life, even causing her to kill her own child, who is also born with a cleft lip. In contrast, the protagonist of the 1924 novel *Precious Bane*, by English writer Mary Webb, is a young woman living in 19th-century rural Shropshire who eventually comes to feel that her deformity is the source of her spiritual strength. The book was later adapted for television by both the BBC and ORTF in France.

Compassion for those with cleft palates has also been used as the theme of young adult novels such as *Words in the Dust* by Trent Reedy and *Whisper* by Christina Struyk-Bonn.[*citation needed*]

### Notable cases

| Name | Comments | |
|---|---|---|
| Jerry Byrd | American sportswriter for the *Shreveport Journal*, 1957-1991, and *Bossier Press-Tribune*, 1993-2012; born with cleft lip and without cleft palate | [63] |
| John Henry "Doc" Holliday | American dentist, gambler and gunfighter of the American Old West, who is usually remembered for his friendship with Wyatt Earp and the Gunfight at the O.K. Corral | [64] |
| Tutankhamen | Egyptian pharaoh who may have had a slightly cleft palate according to diagnostic imaging | [65] |
| Thorgils Skarthi | Thorgils 'the hare-lipped'—a 10th-century Viking warrior and founder of Scarborough, England. | [66] |
| Tad Lincoln | Fourth and youngest son of President Abraham Lincoln | [67] |
| Carmit Bachar | American dancer and singer | [68][69] |
| Jürgen Habermas | German philosopher and sociologist | [70] |
| Ljubo Milicevic | Australian professional footballer | [71] |
| Stacy Keach | American actor and narrator | [72] |
| Cheech Marin | American actor and comedian | [73] |
| Owen Schmitt | American football fullback | [74] |
| Tim Lott | English author and journalist | [75] |
| Richard Hawley | English musician | [75] |
| Dario Šarić | Croatian professional basketball player | [76] |
| Antoinette Bourignon | Flemish mystic | [77] |

## Other animals

Cleft lips and palates are occasionally seen in cattle and dogs, and rarely in goats, sheep, cats, horses, pandas and ferrets. Most commonly, the defect involves the lip, rhinarium, and premaxilla. Clefts of the hard and soft palate are sometimes seen with a cleft lip. The cause is usually hereditary. Brachycephalic dogs such as Boxers and Boston Terriers are most commonly affected.[78] An inherited disorder with incomplete penetrance has also been suggested in Shih tzus, Swiss Sheepdogs, Bulldogs, and Pointers.[79] In horses, it is a rare condition usually involving the caudal soft palate.[80] In Charolais cattle, clefts are seen in combination with arthrogryposis, which is inherited as an autosomal recessive trait. It is also inherited as an autosomal recessive trait in Texel sheep. Other contributing factors may include maternal nutritional deficiencies, exposure *in utero* to viral infections, trauma, drugs, or chemicals, or ingestion of toxins by the mother, such as certain lupines by cattle during the second or third month of gestation.[81] The use of corticosteroids during pregnancy in dogs and the ingestion of *Veratrum californicum* by pregnant sheep have also been associated with cleft formation.[82]

Difficulty with nursing is the most common problem associated with clefts, but aspiration pneumonia, regurgitation, and malnutrition are often seen with cleft palate and is a common cause of death. Providing nutrition through a feeding tube is often necessary, but corrective surgery in dogs can be done by the age of twelve weeks.[78] For cleft palate, there is a high rate of surgical failure resulting in repeated surgeries.[83] Surgical techniques for cleft palate in dogs include prosthesis, mucosal flaps, and microvascular free flaps.[84] Affected animals should not be bred due to the hereditary nature of this condition.

# Congenital heart defect

From Wikipedia, the free encyclopedia

**Congenital heart defect** (**CHD**), also known as a **congenital heart anomaly** or **congenital heart disease**, is a problem in the structure of the heart that is present at birth.[2] Signs and symptoms depend on the specific type of problem.[3] Symptoms can vary from none to life-threatening.[2] When present they may include rapid breathing, bluish skin, poor weight gain, and feeling tired.[4] It does not cause chest pain.[4] Most congenital heart problems do not occur with other diseases.[3] Complications that can result from heart defects include heart failure.[4]

The cause of a congenital heart defect is often unknown.[5] Certain cases may be due to infections during pregnancy such as rubella, use of certain medications or drugs such as alcohol or tobacco, parents being closely related, or poor nutritional status or obesity in the mother.[3][6] Having a parent with a congenital heart defect is also a risk factor.[7] A number of genetic conditions are associated with heart defects including Down syndrome, Turner syndrome, and Marfan syndrome.[3] Congenital heart defects are divided into two main groups: cyanotic heart defects and non-cyanotic heart defects, depending on whether the child has the potential to turn bluish in color.[3] The problems may involve the interior walls of the heart, the heart valves, or the large blood vessels that lead to and from the heart.[2]

Congenital heart defects are partly preventable through rubella vaccination, the adding of iodine to salt, and the adding of folic acid to certain food products.[3] Some defects do not need treatment.[2] Other may be effectively treated with catheter based procedures or heart surgery.[8] Occasionally a number of operations may be needed.[8] Occasionally heart transplantation is required.[8] With appropriate treatment outcomes, even with complex problems, are generally good.[2]

## Variants

[edit on Wikidata]

Heart defects are the most common birth defect.[3][9] In 2013 they were present in 34.3 million people globally.[9] They affect between 4 and 75 per 1,000 live births depending upon how they are diagnosed.[3][7] About 6 to 19 per 1,000 cause a moderate to severe degree of problems.[7] Congenital heart defects are the leading cause of birth defect-related deaths.[3] In 2013 they resulted in 323,000 deaths down from 366,000 deaths in 1990.[10]

Contents

## Signs and symptoms [edit]

Digital clubbing with cyanotic nail beds in an adult with tetralogy of Fallot

Signs and symptoms are related to type and severity of the heart defect. Symptoms frequently present early in life, but it is possible for some CHDs to go undetected throughout life.[11] Some children have no signs while others may exhibit shortness of breath, cyanosis, fainting,[12] heart murmur, under-development of limbs and muscles, poor feeding or growth, or respiratory infections. Congenital heart defects cause abnormal heart structure resulting in production of certain sounds called heart murmur. These can sometimes be detected by auscultation; however, not all heart murmurs are caused by congenital heart defects.

### Associated symptoms [edit]

*Main article: VACTERL association*

Congenital heart defects are associated with an increased incidence of some other symptoms, together being called the VACTERL association:

- V — Vertebral anomalies
- A — Anal atresia
- C — Cardiovascular anomalies
- T — Tracheoesophageal fistula
- E — Esophageal atresia
- R — Renal (Kidney) and/or radial anomalies
- L — Limb defects

Ventricular septal defect (VSD), atrial septal defects, and tetralogy of Fallot are the most common congenital heart defects seen in the VACTERL association. Less common defects in the association are truncus arteriosus and transposition of the great arteries.

## Causes [edit]

The cause of congenital heart disease may be either genetic or environmental, but is usually a combination of both.[13]

### Genetic [edit]

Most of the known causes of congenital heart disease are sporadic genetic changes, either focal mutations or deletion or addition of segments of DNA.[14] Large chromosomal abnormalities such as trisomies 21, 13, and 18 cause about 5–8% of cases of CHD,[13] with trisomy 21 being the most common genetic cause.[14] Small chromosomal abnormalities also frequently lead to congenital heart disease, and examples include microdeletion of the long arm of chromosome 22 (22q11, DiGeorge syndrome), the long arm of chromosome 1 (1q21), the short arm of chromosome 8 (8p23) and many other, less recurrent regions of the genome, as shown by high resolution genome-wide screening (Array comparative genomic hybridization).[15]

The genes regulating the complex developmental sequence have only been partly elucidated. Some genes are associated with specific defects. A number of genes have been associated with cardiac manifestations. Mutations of a heart muscle protein, α-myosin heavy chain (MYH6) are associated with atrial septal defects. Several proteins that interact with MYH6 are also associated with cardiac defects. The transcription factor GATA4 forms a complex with the TBX5 which interacts with MYH6. Another factor, the homeobox (developmental) gene, NKX2-5 also interacts with MYH6. Mutations of all these proteins are associated with both atrial and ventricular septal defects; In addition, NKX2-5 is associated with defects in the electrical conduction of the heart and TBX5 is related to the Holt-Oram syndrome which includes electrical conduction defects and abnormalities of the upper limb. Another T-box gene, TBX1, is involved in velo-cardio-facial syndrome DiGeorge syndrome, the most common deletion which has extensive symptoms including defects of the cardiac outflow tract including tetralogy of Fallot.[16]

**Examples of gene products and associated features**

The notch signaling pathway, a regulatory mechanism for cell growth and differentiation, plays broad roles in several aspects of cardiac development. Notch elements are involved in determination of the right and left sides of the body plan, so the directional folding of the heart tube can be impacted. Notch signaling is involved early in the formation of the endocardial cushions and continues to be active as the develop into the septa and valves. It is also involved in the development of the ventricular wall and the connection of the outflow tract to the great vessels. Mutations in the gene for one of the notch ligands, *Jagged1*, are identified in the majority of examined cases of arteriohepatic dysplasia (Alagille syndrome), characterized by defects of the great vessels (pulmonary artery stenosis), heart (tetralogy of Fallot in 13% of cases), liver, eyes, face, and bones. Though less than 1% of all cases, where no defects are found in the *Jagged1* gene, defects are found in *Notch2* gene. In 10% of cases, no mutation is found in either gene. For another member of the gene family, mutations in the *Notch1* gene are associated with bicuspid aortic valve, a valve with two leaflets instead of three. *Notch1* is also associated with calcification of the aortic valve, the third most common cause of heart disease in adults.[18][19]

Mutations of a cell regulatory mechanism, the Ras/MAPK pathway are responsible for a variety of

syndromes, including Noonan syndrome, LEOPARD syndrome, Costello syndrome and cardiofaciocutaneous syndrome in which there is cardiac involvement.[20] While the conditions listed are known genetic causes, there are likely many other genes which are more subtle. It is known that the risk for congenital heart defects is higher when there is a close relative with one.[14]

### Environmental [edit]

Known environmental factors include certain infections during pregnancy such as Rubella, drugs (alcohol, hydantoin, lithium and thalidomide) and maternal illness (diabetes mellitus, phenylketonuria, and systemic lupus erythematosus).[21]

Being overweight or obese increases the risk of congenital heart disease.[6] Additionally, as maternal obesity increases, the risk of heart defects also increases.[22] A distinct physiological mechanism has not been identified to explain the link between maternal obesity and CHD, but both prepregnancy folate deficiency and diabetes have been implicated in some studies.[23]

## Mechanism [edit]

*Main article: Heart development*

There is a complex sequence of events that result in a well formed heart at birth and disruption of any portion may result in a defect.[14] The orderly timing of cell growth, cell migration, and programmed cell death ("apoptosis") has been studied extensively and the genes that control the process are being elucidated.[16] Around day 15 of development, the cells that will become the heart exist in two horseshoe shaped bands of the middle tissue layer (mesoderm),[16] and some cells migrate from a portion of the outer layer (ectoderm), the neural crest, which is the source of a variety of cells found throughout the body. On day 19 of development, a pair of vascular elements, the "endocardial tubes", form. The tubes fuse when cells between then undergo programmed death and cells from the first heart field migrate to the tube, and form a ring of heart cells (myocytes) around it by day 21. On day 22, the heart begins to beat and by day 24, blood is circulating.[24]

At day 22, the circulatory system is bilaterally symmetrical with paired vessels on each side and the heart consisting of a simple tube located in the midline of the body layout. The portions that will become the atria and will be located closest to the head are the most distant from the head. From days 23 through 28, the heart tube folds and twists, with the future ventricles moving left of center (the ultimate location of the heart) and the atria moving towards the head.[24]

On day 28, areas of tissue in the heart tube begin to expand inwards; after about two weeks, these expansions, the membranous "septum primum" and the muscular "endocardial cushions", fuse to form the four chambers of the heart. A failure to fuse properly will result in a defect that may allow blood to leak between chambers. After this happens, cells which have migrated from the neural crest begin to divide the bulbus cordis, the main outflow tract is divided in two by the growth a spiraling septum, becoming the great vessels—the ascending segment of the aorta and the pulmonary trunk. If the separation is incomplete, the result is a "persistent truncus arteriosis". The vessels may be reversed ("transposition of the great vessels"). The two halves of the split tract must migrate into the correct positions over the appropriate ventricles. A failure may result in some blood flowing into the wrong vessel (*e.g.*overriding aorta). The four-chambered heart and the great vessels have features required for fetal growth. The lungs are unexpanded and cannot accommodate the full circulatory volume. Two structures exist to shunt blood flow away from the lungs. Cells in part of the septum primum die creating a hole while muscle cells, the "septum secundum", grow along the right atrial side the septum primum, except for one region, leaving a gap through which blood can pass from the right artium to the left atrium, the foramen ovale. A small vessel, the *ductus arteriosus* allows blood from the pulmonary artery to pass to the aorta.[24]

### Changes at birth [edit]

The ductus arteriosus stays open because of circulating factors including prostaglandins. The foramen ovale

stays open because of the flow of blood from the right atrium to the left atrium. As the lungs expand, blood flows easily through the lungs and the membranous portion of the foramen ovale (the septum primum) flops over the muscular portion (the septum secundum). If the closure is incomplete, the result is a patent foramen ovale. The two flaps may fuse, but many adults have a foramen ovale that stays closed only because of the pressure difference between the atria.[24]

### Theories [edit]

Rokitansky (1875) explained congenital heart defects as breaks in heart development at various ontogenesis stages.[25] Spitzer (1923) treats them as returns to one of the phylogenesis stages.[26] Krimsky (1963), synthesizing two previous points of view, considered congenital heart diseases as a stop of development at the certain stage of ontogenesis, corresponding to this or that stage of the phylogenesis.[27] Hence these theories can explain feminine and neutral types of defects only.

## Diagnosis [edit]

Many congenital heart defects can be diagnosed prenatally by fetal echocardiography. This is a test which can be done during the second trimester of pregnancy, when the woman is about 18–24 weeks pregnant.[28][29] It can be an abdominal ultrasound or transvaginal ultrasound.

If a baby is born with cyanotic heart disease, the diagnosis is usually made shortly after birth due to the blue colour of their skin (called cyanosis).[29]

If a baby is born with a septal defect or an obstruction defect, often their symptoms are only noticeable after several months or sometimes even after many years.[29]

### Classification [edit]

A number of classification systems exist for congenital heart defects. In 2000 the International Congenital Heart Surgery Nomenclature was developed to provide a generic classification system.[30]

### Hypoplasia [edit]

*Main articles: Hypoplastic left heart syndrome and Hypoplastic right heart syndrome*

Hypoplasia can affect the heart, typically resulting in the underdevelopment of the right ventricle or the left ventricle. This causes only one side of the heart to be capable of pumping blood to the body and lungs effectively. Hypoplasia of the heart is rare but is the most serious form of CHD. It is called hypoplastic left heart syndrome when it affects the left side of the heart and hypoplastic right heart syndrome when it affects the right side of the heart. In both conditions, the presence of a patent ductus arteriosus (and, when hypoplasia affects the right side of the heart, a patent foramen ovale) is vital to the infant's ability to survive until emergency heart surgery can be performed, since without these pathways blood cannot circulate to the body (or lungs, depending on which side of the heart is defective). Hypoplasia of the heart is generally a cyanotic heart defect.[31]

### Obstruction defects [edit]

*Main article: Ventricular outflow tract obstruction*

Obstruction defects occur when heart valves, arteries, or veins are abnormally narrow or blocked. Common defects include pulmonic stenosis, aortic stenosis, and coarctation of the aorta, with other types such as bicuspid aortic valve stenosis and subaortic stenosis being comparatively rare. Any narrowing or blockage can cause heart enlargement or hypertension.[32]

### Septal defects [edit]

The septum is a wall of tissue which separates the left heart from the right heart. Defects in the interatrial

septum or the interventricular septum allow blood to flow from the right side of the heart to the left, reducing the heart's efficiency.[32] Ventricular septal defects are collectively the most common type of CHD,[33] although approximately 30% of adults have a type of atrial septal defect called probe patent foramen ovale.[34]

### Cyanotic defects [edit]

Cyanotic heart defects are called such because they result in cyanosis, a bluish-grey discoloration of the skin due to a lack of oxygen in the body. Such defects include persistent truncus arteriosus, total anomalous pulmonary venous connection, tetralogy of Fallot, transposition of the great vessels, and tricuspid atresia.[32]

### Defects [edit]

- Aortic stenosis
- Atrial septal defect (ASD)
- Atrioventricular septal defect (AVSD)
- Bicuspid aortic valve
- Dextrocardia
- Double inlet left ventricle (DILV)
- Double outlet right ventricle (DORV)
- Ebstein's anomaly
- Hypoplastic left heart syndrome (HLHS)
- Hypoplastic right heart syndrome (HRHS)
- Mitral stenosis
- Pulmonary atresia
- Pulmonary stenosis
- Transposition of the great vessels
  - dextro-Transposition of the great arteries (d-TGA)
  - levo-Transposition of the great arteries (l-TGA)
- Tricuspid atresia
- Persistent truncus arteriosus
- Ventricular septal defect (VSD)
- Wolff-Parkinson-White syndrome (WPW)

Some conditions affect the great vessels or other vessels in close proximity to the heart, but not the heart itself, but are often classified as congenital heart defects.

- Coarctation of the aorta (CoA)
- Double aortic arch, aberrant subclavian artery, and other malformations of the great arteries
- Interrupted aortic arch (IAA)
- Patent ductus arteriosus (PDA)
- Scimitar syndrome (SS)
  - Partial anomalous pulmonary venous connection (PAPVC)
  - Total anomalous pulmonary venous connection (TAPVC)

Some constellations of multiple defects are commonly found together.

- tetralogy of Fallot (ToF)
- pentalogy of Cantrell
- Shone's syndrome/ Shone's complex / Shone's anomaly

## Treatment [edit]

Sometimes CHD improves without treatment. Other defects are so small that they do not require any treatment. Most of the time CHD is serious and requires surgery and/or medications. Medications include

diuretics, which aid the body in eliminating water, salts, and digoxin for strengthening the contraction of the heart. This slows the heartbeat and removes some fluid from tissues. Some defects require surgical procedures to restore circulation back to normal and in some cases, multiple surgeries are needed.

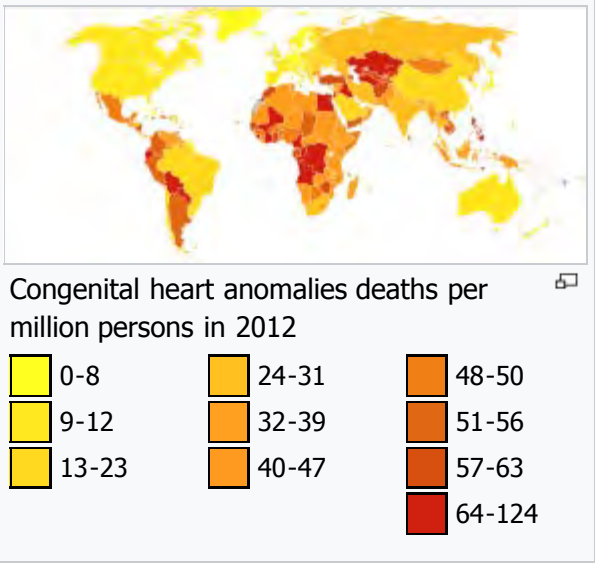
Interventional cardiology now offers patients minimally invasive alternatives to surgery for some patients. The Melody Transcatheter Pulmonary Valve (TPV), approved in Europe in 2006 and in the U.S. in 2010 under a Humanitarian Device Exemption (HDE), is designed to treat congenital heart disease patients with a dysfunctional conduit in their right ventricular outflow tract (RVOT). The RVOT is the connection between the heart and lungs; once blood reaches the lungs, it is enriched with oxygen before being pumped to the rest of the body. Transcatheter pulmonary valve technology provides a less-invasive means to extend the life of a failed RVOT conduit and is designed to allow physicians to deliver a replacement pulmonary valve via a catheter through the patient's blood vessels.

Most patients require lifelong specialized cardiac care, first with a pediatric cardiologist and later with an adult congenital cardiologist. There are more than 1.8 million adults living with congenital heart defects.[35]

## Epidemiology [edit]

Heart defects are among the most common birth defect.[9] In 2013 they were present in 34.3 million people.

Congenital heart defects resulted in about 223,000 deaths globally in 2010 down from 278,000 deaths in 1990.[36]



## Terminology [edit]

Congenital heart defects are known by a number of names including congenital heart anomaly, congenital heart disease, heart defects, and congenital cardiovascular malformations.[37]

# Down syndrome

From Wikipedia, the free encyclopedia

**Down syndrome** (**DS** or **DNS**), also known as **trisomy 21**, is a genetic disorder caused by the presence of all or part of a third copy of chromosome 21.[1] It is typically associated with physical growth delays, characteristic facial features and mild to moderate intellectual disability.[2] The average IQ of a young adult with Down syndrome is 50, equivalent to the mental ability of an 8- or 9-year-old child, but this can vary widely.[3]

The parents of the affected individual are typically genetically normal.[4] The extra chromosome occurs by chance.[5] The possibility increases from less than 0.1% in 20-year-old mothers to 3% in those age 45.[6] There is no known behavioral activity or environmental factor that changes the possibility.[5] Down syndrome can be identified during pregnancy by prenatal screening followed by diagnostic testing or after birth by direct observation and genetic testing.[7] Since the introduction of screening, pregnancies with the diagnosis are often terminated.[8][9] Regular screening for health problems common in Down syndrome is recommended throughout the person's life.[3]

There is no cure for Down syndrome.[10] Education and proper care have been shown to improve quality of life.[11] Some children with Down syndrome are educated in typical school classes, while others require more specialized education.[12] Some individuals with Down syndrome graduate from high school and a few attend post-secondary education.[13] In adulthood, about 20% in the United States do paid work in some capacity[14] with many requiring a sheltered work environment.[12] Support in financial and legal matters is often needed.[15] Life expectancy is around 50 to 60 years in the developed world with proper health care.[3][15]

Down syndrome is one of the most common chromosome abnormalities in humans.[3] It occurs in about one per 1000 babies born each year.[2] In 2013, Down syndrome was present in 8.5 million individuals and resulted in 36,000 deaths down from 43,000 deaths in 1990.[16][17] It is named after John Langdon Down, the British doctor who fully described the syndrome in 1866.[18] Some aspects of the condition were described earlier by Jean-Étienne Dominique Esquirol in 1838 and Édouard Séguin in 1844.[19] The genetic cause of Down syndrome—an extra copy of chromosome 21—was identified by French researcher Jérôme

# Signs and symptoms

Those with Down syndrome nearly always have physical and intellectual disabilities.[20] As adults, their mental abilities are typically similar to those of an 8- or 9-year-old.[3] They also typically have poor immune function[4] and generally reach developmental milestones at a later age.[15] They have an increased risk of a number of other health problems, including congenital heart defect, epilepsy, leukemia, thyroid diseases, and mental disorders, among others.[18]

| Characteristics | Percentage | Characteristics | Percentag |
|---|---|---|---|
| Mental | 99%[21] | Abnormal teeth | 60%[22] |

| | | | |
|---|---|---|---|
| impairment | | | |
| Stunted growth | 90%[23] | Slanted eyes | 60%[4] |
| Umbilical hernia | 90%[24] | Shortened hands | 60%[22] |
| Increased skin back of neck | 80%[18] | Short neck | 60%[22] |
| Low muscle tone | 80%[25] | Obstructive sleep apnea | 60%[18] |
| Narrow roof of mouth | 76%[22] | Bent fifth finger tip | 57%[4] |
| Flat head | 75%[4] | Brushfield spots in the iris | 56%[4] |
| Flexible ligaments | 75%[4] | Single transverse palmar crease | 53%[4] |
| Proportionally large tongue[26] | 75%[25] | Protruding tongue | 47%[22] |
| Abnormal outer ears | 70%[18] | Congenital heart disease | 40%[22] |
| Flattened nose | 68%[4] | Strabismus | ~35%[2] |
| Separation of first and second toes | 68%[22] | Undescended testicles | 20%[27] |

An eight-year-old boy with Down syndrome

## Physical

People with Down syndrome may have some or all of these physical characteristics: a small chin, slanted eyes, poor muscle tone, a flat nasal bridge, a single crease of the palm, and a protruding tongue due to a small mouth and relatively large tongue.[25][26] These airway changes lead to obstructive sleep apnea in around half of those with Down syndrome.[18] Other common features include: a flat and wide face,[25] a short neck, excessive joint flexibility, extra space between big toe and second toe, abnormal patterns on the fingertips and short fingers.[22][25] Instability of the atlantoaxial joint occurs in about 20% and may lead to spinal cord injury in 1–2%.[3][15] Hip

Feet of a boy with Down syndrome

dislocations may occur without trauma in up to a third of people with Down syndrome.[18]

Growth in height is slower, resulting in adults who tend to have short stature—the average height for men is 154 cm (5 ft 1 in) and for women is 142 cm (4 ft 8 in).[28] Individuals with Down syndrome are at increased risk for obesity as they age.[18] Growth charts have been developed specifically for children with Down syndrome.[18]

## Neurological

Most individuals with Down syndrome have mild (IQ: 50–69) or moderate (IQ: 35–50) intellectual disability with some cases having severe (IQ: 20–35) difficulties.[2][29] Those with mosaic Down syndrome typically have IQ scores 10–30 points higher.[30] As they age, people with Down syndrome typically perform less well than their same-age peers.[29][31] Some after 30 years of age may lose their ability to speak.[3] This syndrome causes about a third of cases of intellectual disability.[4] Many developmental milestones are delayed with the ability to crawl typically occurring around 8 months rather than 5 months and the ability to walk independently typically occurring around 21 months rather than 14 months.[32]

Commonly, individuals with Down syndrome have better language understanding than ability to speak.[18][29] Between 10 and 45% have either a stutter or rapid and irregular speech, making it difficult to understand them.[33] They typically do fairly well with social skills.[18] Behavior problems are not generally as great an issue as in other syndromes associated with intellectual disability.[29] In children with Down syndrome, mental illness occurs in nearly 30% with autism occurring in 5–10%.[15] People with Down syndrome experience a wide range of emotions.[34] While people with Down syndrome are generally happy,[35] symptoms of depression and anxiety may develop in early adulthood.[3]

Children and adults with Down syndrome are at increased risk of epileptic seizures, which occur in 5–10% of children and up to 50% of adults.[3] This includes an increased risk of a specific type of seizure called infantile spasms.[18] Many (15%) who live 40 years or longer develop Alzheimer disease.[36] In those who reach 60 years of age, 50–70% have the disease.[3]

## Senses

Brushfield spots, visible in the irises of a baby with Down syndrome

Hearing and vision disorders occur in more than half of people with Down syndrome.[18] Vision problems occur in 38 to 80%.[2] Between 20 and 50% have strabismus, in which the two eyes do not move together.[2] Cataracts (cloudiness of the lens of the eye) occur in 15%,[15] and may be present at birth.[2] Keratoconus (a thin, cone-shaped cornea)[3] and glaucoma (increased eye pressure) are also more common,[2] as are refractive errors requiring glasses or contacts.[3] Brushfield spots (small white or grayish/brown spots on the outer part of the iris) are present in 38 to 85% of individuals.[2]

Hearing problems are found in 50–90% of children with Down syndrome.[37] This is often the result of otitis media with effusion which occurs in 50–70%[15] and chronic ear infections which occur in 40 to 60%.[38] Ear infections often begin in the first year of life and are partly due to poor eustachian tube function.[39][40]

Excessive ear wax can also cause hearing loss due to obstruction of the outer ear canal.[3] Even a mild degree of hearing loss can have negative consequences for speech, language understanding, and academics.[2][40] Additionally, it is important to rule out hearing loss as a factor in social and cognitive deterioration.[41] Age-related hearing loss of the sensorineural type occurs at a much earlier age and affects 10–70% of people with Down syndrome.[3]

## Heart

The rate of congenital heart disease in newborns with Down syndrome is around 40%.[22] Of those with heart disease, about 80% have an atrioventricular septal defect or ventricular septal defect with the former being more common.[3] Mitral valve problems become common as people age, even in those without heart problems at birth.[3] Other problems that may occur include tetralogy of Fallot and patent ductus arteriosus.[39] People with Down syndrome have a lower risk of hardening of the arteries.[3]

## Cancer

Although the overall risk of cancer is not changed,[42] the risk of leukemia and testicular cancer is increased and risk of solid cancers is reduced.[3] Solid cancers are believed to be less common due to increased expression of tumor suppressor genes present on chromosome 21.[43]

Cancers of the blood are 10 to 15 times more common in children with Down syndrome.[18] In particular, acute lymphoblastic leukemia is 20 times more common and the megakaryoblastic form of acute myeloid leukemia is 500 times more common.[44] Transient myeloproliferative disease, a disorder of blood cell production that does not occur outside of Down syndrome, affects 3–10% of infants.[44][45] The disorder is typically not serious but occasionally can be.[45] It resolves most times without treatment; however, in those who have had it, a 20 to 30% risk of developing acute lymphoblastic leukemia at a later time exists.[45]

## Endocrine

Problems of the thyroid gland occur in 20–50% of individuals with Down syndrome.[3][18] Low thyroid is the most common form, occurring in almost half of all individuals.[3] Thyroid problems can be due to a poorly or nonfunctioning thyroid at birth (known as congenital hypothyroidism) which occurs in 1%[15] or can develop later due to an attack on the thyroid by the immune system resulting in Graves' disease or autoimmune hypothyroidism.[46] Type 1 diabetes mellitus is also more common.[3]

## Gastrointestinal

Constipation occurs in nearly half of people with Down syndrome and may result in changes in behavior.[18] One potential cause is Hirschsprung's disease, occurring in 2–15%, which is due to a lack of nerve cells controlling the colon.[47] Other frequent congenital problems include duodenal atresia, pyloric stenosis, Meckel diverticulum, and imperforate anus.[39] Celiac disease affects about 7–20%[3][18] and gastroesophageal reflux disease is also more common.[39]

## Teeth

Individuals with Down syndrome tend to be more susceptible to gingivitis as well as early, severe periodontal disease, necrotising ulcerative gingivitis, and early tooth loss, especially in the lower front teeth.[48][49] While plaque and poor oral hygiene are contributing factors, the severity of these periodontal disease cannot be explained solely by external factors.[49] Research suggests that the severity is likely a result of a weakened immune system.[49][50] The weakened immune system also contributes to increased incidence of yeast infections in the mouth (from Candida albicans).[50]

Individuals with Down syndrome also tend to have a more alkaline saliva resulting in a greater resistance to tooth decay, despite decreased quantities of saliva,[51] less effective oral hygiene habits and higher plaque indexes.[48][50][51][52]

Higher rates of tooth wear and bruxism are also common.[50] Other common oral manifestations of Down syndrome include enlarged hypotonic tongue, crusted and hypotonic lips, mouth breathing, narrow palate with crowded teeth, class III malocclusion with an underdeveloped maxilla and posterior crossbite, delayed exfoliation of baby teeth and delayed eruption of adult teeth, shorter roots on teeth, and often missing and malformed (usually smaller) teeth.[48][50][51][52] Less common manifestations include cleft lip and palate, enamel hypocalcification (20% prevalence).[52]

### Fertility

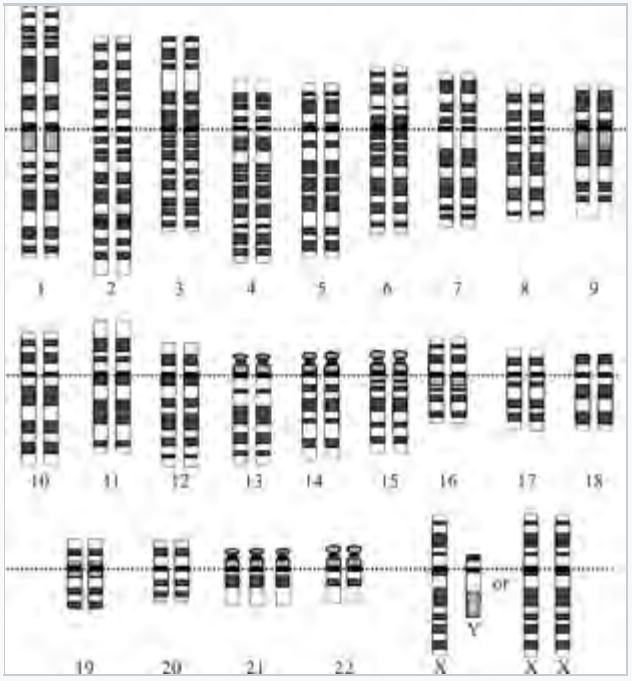
Males with Down syndrome usually do not father children, while females have lower rates of fertility relative to those who are unaffected.[53] Fertility is estimated to be present in 30–50% of females.[54] Menopause typically occurs at an earlier age.[3] The poor fertility in males is thought to be due to problems with sperm development; however, it may also be related to not being sexually active.[53] As of 2006, three instances of males with Down syndrome fathering children and 26 cases of females having children have been reported.[53] Without assisted reproductive technologies, around half of the children of someone with Down syndrome will also have the syndrome.[53][55]

## Genetics

*Main article: Genetics of Down syndrome*

Down syndrome is caused by having three copies of the genes on chromosome 21, rather than the usual two.[1][56] The parents of the affected individual are typically genetically normal.[4] Those who have one child with Down syndrome have about a 1% risk of having a second child with the syndrome, if both parents are found to have normal karyotypes.[54]

The extra chromosome content can arise through several different ways. The most common cause (about 92–95% of cases) is a complete extra copy of chromosome 21, resulting in trisomy 21.[55][57] In 1.0 to 2.5% of cases, some of the cells in the body are normal and others have trisomy 21, known as mosaic Down syndrome.[54][58] The other common mechanisms that can give rise to Down syndrome include: a Robertsonian translocation, isochromosome, or ring chromosome. These contain additional material from chromosome 21 and occur in about 2.5% of cases.[18][54] An isochromosome results when the two long arms of a chromosome separate together rather than the long and short arm separating together during egg or sperm development.[55]



Karyotype for trisomy Down syndrome: Notice the three copies of chromosome 21

### Trisomy 21

Trisomy 21 (also known by the karyotype 47,XX,+21 for females and 47,XY,+21 for males)[59] is caused by a failure of the 21st chromosome to separate during egg or sperm development.[55] As a result, a sperm or egg cell is produced with an extra copy of chromosome 21; this cell thus has 24 chromosomes. When combined with a normal cell from the other parent, the baby has 47 chromosomes, with three copies of

chromosome 21.[1][55] About 88% of cases of trisomy 21 result from nonseparation of the chromosomes in the mother, 8% from nonseparation in the father, and 3% after the egg and sperm have merged.[60]

### Translocation

The extra chromosome 21 material may also occur due to a Robertsonian translocation in 2–4% of cases.[54][61] In this situation, the long arm of chromosome 21 is attached to another chromosome, often chromosome 14.[62] In a male affected with Down syndrome, it results in a karyotype of 46XY,t(14q21q).[62][63] This may be a new mutation or previously present in one of the parents.[64] The parent with such a translocation is usually normal physically and mentally;[62] however, during production of egg or sperm cells, a higher chance of creating reproductive cells with extra chromosome 21 material exists.[61] This results in a 15% chance of having a child with Down syndrome when the mother is affected and a less than 5% probability if the father is affected.[64] The probability of this type of Down syndrome is not related to the mother's age.[62] Some children without Down syndrome may inherit the translocation and have a higher probability of having children of their own with Down syndrome.[62] In this case it is sometimes known as familial Down syndrome.[65]

## Mechanism

The extra genetic material present in DS results in overexpression of a portion of the 310 genes located on chromosome 21.[56] This overexpression has been estimated at around 50%.[54] Some research has suggested the Down syndrome critical region is located at bands 21q22.1–q22.3,[66] with this area including genes for amyloid, superoxide dismutase, and likely the ETS2 proto oncogene.[67] Other research, however, has not confirmed these findings.[56] microRNAs is also proposed to be involved.[68]

The dementia which occurs in Down syndrome is due to an excess of amyloid beta peptide produced in the brain and is similar to Alzheimer's disease.[69] This peptide is processed from amyloid precursor protein, the gene for which is located on chromosome 21.[69] Senile plaques and neurofibrillary tangles are present in nearly all by 35 years of age, though dementia may not be present.[4] Those with DS also lack a normal number of lymphocytes and produce less antibodies which contributes to their increased risk of infection.[18]

### Epigenetics

Down syndrome is associated with an increased risk of many chronic diseases that are typically associated with older age such as Alzheimer's disease. The accelerated aging suggest that trisomy 21 increases the biological age of tissues, but molecular evidence for this hypothesis is sparse. According to a biomarker of tissue age known as epigenetic clock, trisomy 21 increases the age of blood and brain tissue (on average by 6.6 years).[70]

## Screening

Guidelines recommend screening for Down syndrome to be offered to all pregnant women, regardless of age.[71][72] A number of tests are used, with varying levels of accuracy. They are typically used in combination to increase the detection rate.[18] None can be definitive, thus if screening is positive, either amniocentesis or chorionic villous sampling is required to confirm the diagnosis.[71] Screening in both the first and second trimesters is better than just screening in the first trimester.[71] The different screening techniques in use are able to pick up 90 to 95% of cases with a false-positive rate of 2 to 5%.[73]

**First- and second-trimester screening**[71]

| | Week of | | | |
|---|---|---|---|---|

| Screen | pregnancy when performed | Detection rate | False positive | Description |
|---|---|---|---|---|
| Combined test | 10–13.5 wks | 82–87% | 5% | Uses ultrasound to measure nuchal translucency in addition to blood tests for free or total beta-hCG and PAPP-A |
| Quad screen | 15–20 wks | 81% | 5% | Measures the maternal serum alpha-fetoprotein, unconjugated estriol, hCG, and inhibin-A |
| Integrated test | 15–20 wks | 94–96% | 5% | Is a combination of the quad screen, PAPP-A, and NT |
| Cell-free fetal DNA | From 10 wks[74] | 96–100%[75] | 0.3%[76] | A blood sample is taken from the mother by venipuncture and is sent for DNA analysis. |

### Ultrasound

Ultrasound imaging can be used to screen for Down syndrome. Findings that indicate increased risk when seen at 14 to 24 weeks of gestation include a small or no nasal bone, large ventricles, nuchal fold thickness, and an abnormal right subclavian artery, among others.[77] The presence or absence of many markers is more accurate.[77] Increased fetal nuchal translucency (NT) indicates an increased risk of Down syndrome picking up 75–80% of cases and being falsely positive in 6%.[78]

Ultrasound of fetus with Down syndrome showing a large bladder

### Blood tests

Several blood markers can be measured to predict the risk of Down syndrome during the first or second trimester.[73][79] Testing in both trimesters is sometimes recommended and test results are often combined with ultrasound results.[73] In the second trimester, often two or three tests are used in combination with two or three of: α-fetoprotein, unconjugated estriol, total hCG, and free βhCG detecting about 60–70% of cases.[79]

Testing of the mother's blood for fetal DNA is being studied and appears promising in the first trimester.[75][80] The International Society for Prenatal Diagnosis considers it a reasonable screening option for those women whose pregnancies are at a high risk for trisomy 21.[81] Accuracy has been reported at 98.6% in the first trimester of pregnancy.[18] Confirmatory testing by invasive techniques (amniocentesis, CVS) is still required to confirm the screening result.[81]

Enlarged NT and absent nasal bone in a fetus at 11 weeks with Down syndrome

## Diagnosis

### Before birth

When screening tests predict a high risk of Down syndrome, a more invasive diagnostic test (amniocentesis

or chorionic villus sampling) is needed to confirm the diagnosis.[71] If Down syndrome occurs in one in 500 pregnancies and the test used has a 5% false-positive rate, this means, of 26 women who test positive on screening, only one will have Down syndrome confirmed.[73] If the screening test has a 2% false-positive rate, this means one of eleven who test positive on screening have a fetus with DS.[73] Amniocentesis and chorionic villus sampling are more reliable tests, but they increase the risk of miscarriage between 0.5 and 1%.[82] The risk of limb problems is increased in the offspring due to the procedure.[82] The risk from the procedure is greater the earlier it is performed, thus amniocentesis is not recommended before 15 weeks gestational age and chorionic villus sampling before 10 weeks gestational age.[82]

### Abortion rates

About 92% of pregnancies in Europe with a diagnosis of Down syndrome are terminated.[9] In the United States, termination rates are around 67%, but this rate varied from 61% to 93% among different populations evaluated.[8] When nonpregnant people are asked if they would have a termination if their fetus tested positive, 23–33% said yes, when high-risk pregnant women were asked, 46–86% said yes, and when women who screened positive are asked, 89–97% say yes.[83]

### After birth

The diagnosis can often be suspected based on the child's physical appearance at birth.[15] An analysis of the child's chromosomes is needed to confirm the diagnosis, and to determine if a translocation is present, as this may help determine the risk of the child's parents having further children with Down syndrome.[15] Parents generally wish to know the possible diagnosis once it is suspected and do not wish pity.[18]

## Management

Efforts such as early childhood intervention, screening for common problems, medical treatment where indicated, a good family environment, and work-related training can improve the development of children with Down syndrome. Education and proper care can improve quality of life.[11] Raising a child with Down syndrome is more work for parents than raising an unaffected child.[84] Typical childhood vaccinations are recommended.[18]

### Health screening

A number of health organizations have issued recommendations for screening those with Down syndrome for particular diseases.[85] This is recommended to be done systematically.[18]

At birth, all children should get an electrocardiogram and ultrasound of the heart.[18] Surgical repair of heart problems may be required as early as three months of age.[18] Heart valve problems may occur in young adults, and further ultrasound evaluation may be needed in adolescents and in early adulthood.[18] Due to the elevated risk of testicular cancer, some recommend checking the person's testicles yearly.[3]

**Recommended screening**

| Testing | Children[85] | Adults[3] |
|---|---|---|
| Hearing | 6 months, 12 months, then yearly | 3–5 years |
| T4 and TSH | 6 months, then yearly | |
| Eyes | 6 months, then yearly | 3–5 years |
| Teeth | 2 years, then every 6 months | |
| Coeliac disease | Between 2 and 3 years of age, or earlier if symptoms occur | |
| Sleep study | 3 to 4 years, or earlier if symptoms of obstructive sleep apnea occur | |
| Neck X-rays | Between 3 and 5 years of age | |

## Cognitive development

Hearing aids or other amplification devices can be useful for language learning in those with hearing loss.[18] Speech therapy may be useful and is recommended to be started around 9 months of age.[18] As those with Down's typically have good hand-eye coordination, learning sign language may be possible.[29] Augmentative and alternative communication methods, such as pointing, body language, objects, or pictures, are often used to help with communication.[86] Behavioral issues and mental illness are typically managed with counseling or medications.[15]

Education programs before reaching school age may be useful.[2] School-age children with Down syndrome may benefit from inclusive education (whereby students of differing abilities are placed in classes with their peers of the same age), provided some adjustments are made to the curriculum.[87] Evidence to support this, however, is not very strong.[88] In the United States, the Individuals with Disabilities Education Act of 1975 requires public schools generally to allow attendance by students with Down's.[89]

Individuals with Down syndrome may learn better visually. Drawing may help with language, speech, and reading skills. Children with Down syndrome still often have difficulty with sentence structure and grammar, as well as developing the ability to speak clearly.[90] Several types of early intervention can help with cognitive development. Efforts to develop motor skills include physical therapy, speech and language therapy, and occupational therapy. Physical therapy focuses specifically on motor development and teaching children to interact with their environment. Speech and language therapy can help prepare for later language. Lastly, occupational therapy can help with skills needed for later independence.[91]

## Other

Tympanostomy tubes are often needed[18] and often more than one set during the person's childhood.[37] Tonsillectomy is also often done to help with sleep apnea and throat infections.[18] Surgery, however, does not always address the sleep apnea and a continuous positive airway pressure (CPAP) machine may be useful.[37] Physical therapy and participation in physical education may improve motor skills.[92] Evidence to support this in adults, however, is not very good.[93]

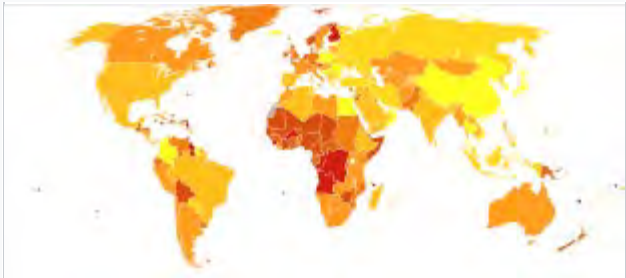
Efforts to prevent respiratory syncytial virus (RSV) infection with human monoclonal antibodies should be considered, especially in those with heart problems.[2] In those who develop dementia there is no evidence for memantine,[94] donepezil,[95] rivastigmine,[96] or galantamine.[97]

Plastic surgery has been suggested as a method of improving the appearance and thus the acceptance of people with Down's.[98] It has also been proposed as a way to improve speech.[98] Evidence, however, does not support a meaningful difference in either of these outcomes.[98] Plastic surgery on children with Down syndrome is uncommon,[99] and continues to be controversial.[98] The U.S. National Down Syndrome Society views the goal as one of mutual respect and acceptance, not appearance.[99]

Many alternative medical techniques are used in Down syndrome; however, they are poorly supported by evidence.[98] These include: dietary changes, massage, animal therapy, chiropractics and naturopathy, among others.[98] Some proposed treatments may also be harmful.[54]

# Prognosis

Between 5 and 15% of children with Down syndrome in Europe attend regular school.[100] Some graduate from high school; however, most do not.[13] Of those with intellectual disability in the United States who attended high school about 40% graduated.[101] Many learn to read and write and some are able to do paid work.[13] In adulthood about 20% in the United States do paid work in some



Deaths due to Downs syndrome per million persons in 2012

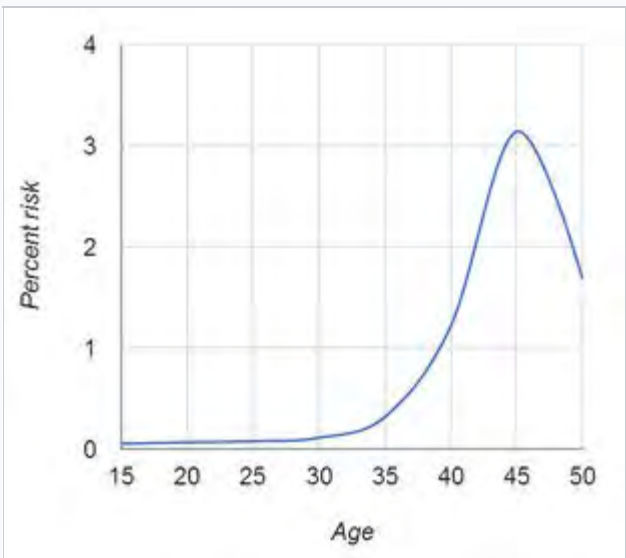
| | | |
|---|---|---|
| 0-0 | 3-3 | 6-6 |
| 1-1 | 4-4 | 7-8 |
| 2-2 | 5-5 | 9-16 |

capacity.[14][102] In Europe, however, less than 1% have regular jobs.[100] Many are able to live semi-independently,[4] but they often require help with financial, medical, and legal matters.[15] Those with mosaic Down syndrome usually have better outcomes.[54]

Individuals with Down syndrome have a higher risk of early death than the general population.[18] This is most often from heart problems or infections.[2][3] Following improved medical care, particularly for heart and gastrointestinal problems, the life expectancy has increased.[2] This increase has been from 12 years in 1912,[103] to 25 years in the 1980s,[2] to 50 to 60 years in the developed world in the 2000s.[3][15] Currently between 4 and 12% die in the first year of life.[45] The probability of long-term survival is partly determined by the presence of heart problems. In those with congenital heart problems 60% survive to 10 years and 50% survive to 30 years of age.[4] In those without heart problems 85% survive to 10 years and 80% survive to 30 years of age.[4] About 10% live to 70 years of age.[55] The National Down Syndrome Society have developed information regarding the positive aspects of life with Down syndrome.[104]

## Epidemiology

Globally, as of 2010, Down syndrome occurs in about 1 per 1000 births[2] and results in about 17,000 deaths.[105] More children are born with Down syndrome in countries where abortion is not allowed and in countries where pregnancy more commonly occurs at a later age.[2] About 1.4 per 1000 live births in the United States[106] and 1.1 per 1000 live births in Norway are affected.[3] In the 1950s, in the United States, it occurred in 2 per 1000 live births with the decrease since then due to prenatal screening and abortions.[64] The number of pregnancies with Down syndrome is more than two times greater with many spontaneously aborting.[15] It is the cause of 8% of all congenital disorders.[2]



The risk of having a Down syndrome pregnancy in relation to a mother's age[6]

Maternal age affects the chances of having a pregnancy with Down syndrome.[6] At age 20, the chance is one in 1441; at age 30, it is one in 959; at age 40, it is one in 84; and at age 50 it is one in 44.[6] Although the probability increases with maternal age, 70% of children with Down syndrome are born to women 35 years of age and younger, because younger people have more children.[6] The father's older age is also a risk factor in women older than 35, but not in women younger than 35, and may partly explain the increase in risk as women age.[107]

## History

It has been suggested that this Early Netherlandish painting depicts a person with Down syndrome as one of the angels.[108]

English physician John Langdon Down first described Down syndrome in 1862, recognizing it as a distinct type of mental disability, and again in a more widely published report in 1866.[18][109][110] Édouard Séguin described it as separate from cretinism in 1944.[19][111] By the 20th century, Down syndrome had become the most recognizable form of mental disability.

In antiquity, many infants with disabilities were either killed or abandoned.[19] A number of historical pieces of art are believed to portray Down syndrome, including pottery from AD 500 from South America and the 16th-century painting *The Adoration of the Christ Child*.[19]

In the 20th century, many individuals with Down syndrome were institutionalized, few of the associated medical problems were treated, and most died in infancy or early adult life. With the rise of the eugenics movement, 33 of the then 48 U.S. states and several countries began programs of forced sterilization of individuals with Down syndrome and comparable degrees of disability. Action T4 in Nazi Germany made public policy of a program of systematic involuntary euthanization.[112]

With the discovery of karyotype techniques in the 1950s, it became possible to identify abnormalities of chromosomal number or shape.[111] In 1959, Jérôme Lejeune reported the discovery that Down syndrome resulted from an extra chromosome.[18] However, Lejeune's claim to the discovery has been disputed,[113] and in 2014, the Scientific Council of the French Federation of Human Genetics unanimously awarded its Grand Prize to his colleague Marthe Gautier for this discovery.[114] As a result of this discovery, the condition became known as trisomy 21.[115] Even before the discovery of its cause, the presence of the syndrome in all races, its association with older maternal age, and its rarity of recurrence had been noticed. Medical texts had assumed it was caused by a combination of inheritable factors that had not been identified. Other theories had focused on injuries sustained during birth.[116]

# Society and culture

## Name

Due to his perception that children with Down syndrome shared facial similarities with those of Blumenbach's Mongolian race, John Langdon Down used the term 'mongoloid'.[55][117] He felt that the existence of Down syndrome confirmed that all peoples were genetically related.[118] In the 1950s with discovery of the underlying cause as being related to chromosomes, concerns about the race based nature of the name increased.[119]

In 1961, 19 scientists suggested that "mongolism" had "misleading connotations" and had become "an embarrassing term".[120][121] The World Health Organization (WHO) dropped the term in 1965 after a request by the delegation from the Mongolia People's Republic.[120] While the term mongoloid (also mongolism, Mongolian imbecility or idiocy) continued to be used until the early 1980s, it is now considered unacceptable and is no longer in common use.[120][122]

In 1975, the United States National Institutes of Health (NIH) convened a conference to standardize the naming and recommended replacing the possessive form, "Down's syndrome" with "Down syndrome".[123] However, both the possessive and nonpossessive forms remain in use by the general population.[124] The term "trisomy 21" is also used frequently.[121][125]

## Ethics

Some argue that not to offer screening for Down syndrome is unethical.[126] As it is a medically reasonable procedure, per informed consent, people should at least be given information about it.[126] It will then be the woman's choice, based on her personal beliefs, how much or how little screening she wishes.[127][128] When results from testing become available, it is also considered unethical not to give the results to the person in question.[126][129]

Some deem it reasonable for parents to select a child who would have the highest well-being.[130] One criticism of this reasoning is it often values those with disabilities less.[131] Others argue that Down syndrome shouldn't be prevented or cured and that eliminating Down syndrome amounts to genocide.[132][133] The disability rights movement does not have a position on screening,[134] although some members consider testing and abortion discriminatory.[134] Some in the United States who are pro-life support abortion if the fetus is disabled, while others do not.[135] Of a group of 40 mothers in the United States who have had one child with Down syndrome, half agreed to screening in the next pregnancy.[135]

Within the US, some Protestants denominations see abortion as acceptable when a fetus has Down syndrome,[136] while Orthodox Christians and Roman Catholics often do not.[136] Some of those against screening refer to it as a form of "eugenics".[136] Disagreement exists within Islam regarding the acceptability of abortion in those carrying a fetus with Down syndrome.[137] Some Islamic countries allow abortion, while others do not.[137] Women may face stigmatization whichever decision they make.[138]

## Advocacy groups

Advocacy groups for individuals with Down syndrome began to be form after the Second World War.[139] These were organizations advocating for the inclusion of people with Down syndrome into the general school system and for a greater understanding of the condition among the general population,[139] as well as groups providing support for families with children living with Down syndrome.[139] Before this individuals with Down syndrome were often placed in mental hospitals or asylums. Organizations included the Royal Society for Handicapped Children and Adults founded in the UK in 1946 by Judy Fryd,[139][140] Kobato Kai founded in Japan in 1964,[139] the National Down Syndrome Congress founded in the United States in 1973 by Kathryn McGee and others,[139][141] and the National Down Syndrome Society founded in 1979 in the United States.[139]

The first World Down Syndrome Day was held on 21 March 2006.[142] The day and month were chosen to correspond with 21 and trisomy, respectively.[143] It was recognized by the United Nations General Assembly in 2011.[142]

# Research

*See also: Down syndrome research and Mouse models of Down syndrome*

Efforts are underway to determine how the extra chromosome 21 material causes Down syndrome, as currently this is unknown,[144] and to develop treatments to improve intelligence in those with the syndrome.[145] One hope is to use stem cells.[144] Other methods being studied include the use of antioxidants, gamma secretase inhibition, adrenergic agonists, and memantine.[146] Research is often carried out on an animal model, the Ts65Dn mouse.[147]

# Epilepsy

From Wikipedia, the free encyclopedia

*"Epilepsia" and "Epileptic" redirect here. For the journal, see Epilepsia (journal). For the novel, see Epileptic (graphic novel).*

**Epilepsy** is a group of neurological diseases characterized by epileptic seizures.[1][2] Epileptic seizures are episodes that can vary from brief and nearly undetectable to long periods of vigorous shaking.[3] These episodes can result in physical injuries including occasionally broken bones.[3] In epilepsy, seizures tend to recur, and have no immediate underlying cause.[1] Isolated seizures that are provoked by a specific cause such as poisoning are not deemed to represent epilepsy.[4] People with epilepsy in some areas of the world experience stigma due to the condition.[3]

The cause of most cases of epilepsy is unknown, although some people develop epilepsy as the result of brain injury, stroke, brain tumors, infections of the brain, and birth defects.[3] Known genetic mutations are directly linked to a small proportion of cases.[5][6] Epileptic seizures are the result of excessive and abnormal nerve cell activity in the cortex of the brain.[4] The diagnosis involves ruling out other conditions that might cause similar symptoms such as fainting and determining if another cause of seizures is present such as alcohol withdrawal or electrolyte problems. This may be partly done by imaging the brain and performing blood tests. Epilepsy can often be confirmed with an electroencephalogram (EEG), but a normal test does not rule out the condition.[5]

Epilepsy that occurs as a result of other issues may be preventable.[3] Seizures are controllable with medication in about 70% of cases.[7] Inexpensive options are often available.[3] In those whose seizures do not respond to medication, then surgery, neurostimulation, or dietary changes may be considered.[8][9] Not all cases of epilepsy are lifelong, and many people improve to the point that treatment is no longer needed.[3]

As of 2013 about 22 million people have epilepsy.[10] Nearly 80% of cases occur in the developing world.[3] In 2013 it resulted in 116,000 deaths up from 112,000 deaths in 1990.[11] Epilepsy is more common in older people.[12][13] In the developed world, onset of new cases occurs most frequently in babies and the elderly.[14] In the developing world onset is more common in older children and young adults, due to differences in the frequency of the underlying causes.[15] About 5–10% of people will have an unprovoked seizure by the age of 80,[16] and the chance of experiencing a second seizure is between 40 and 50%.[17] In many areas of the world those with epilepsy either have restrictions placed on their ability to drive or are not permitted to drive until they are free of seizures for a specific length of time.[18] The word epilepsy is from Ancient Greek: ἐπιλαμβάνειν "to seize, possess, or afflict".[19]

Video explanation

# Signs and symptoms [edit]

Epilepsy is characterized by a long-term risk of recurrent seizures.[20] These seizures may present in several ways depending on the part of the brain involved and the person's age.[20][21]

Play media

An instructional video about epileptic seizures

## Seizures [edit]

*Main article: Epileptic seizure*

The most common type (60%) of seizures are convulsive.[21] Of these, one-third begin as generalized seizures from the start, affecting both hemispheres of the brain.[21] Two-thirds begin as partial seizures (which affect one hemisphere of the brain) which may then progress to generalized seizures.[21] The remaining 40% of seizures are non-convulsive. An example of this type is the absence seizure, which presents as a decreased level of consciousness and usually lasts about 10 seconds.[22][23]

Partial seizures are often preceded by certain experiences, known as auras.[24] They include sensory (visual, hearing, or smell), psychic,

autonomic, and motor phenomena.[22] Jerking activity may start in a specific muscle group and spread to surrounding muscle groups in which case it is known as a Jacksonian march.[25] Automatisms may occur, which are non-consciously-generated activities and mostly simple repetitive movements like smacking of the lips or more complex activities such as attempts to pick up something.[25]

There are six main types of generalized seizures: tonic-clonic, tonic, clonic, myoclonic, absence, and atonic seizures.[26] They all involve loss of consciousness and typically happen without warning.

Tonic-clonic seizures occur with a contraction of the limbs followed by their extension along with arching of the back which lasts 10–30 seconds (the tonic phase). A cry may be heard due to contraction of the chest muscles, followed by a shaking of the limbs in unison (clonic phase). Tonic seizures produce constant contractions of the muscles. A person often turns blue as breathing is stopped. In clonic seizures there is shaking of the limbs in unison. After the shaking has stopped it may take 10–30 minutes for the person to return to normal; this period is called the "postictal state" or "postictal phase." Loss of bowel or bladder control may occur during a seizure.[27] The tongue may be bitten at either the tip or on the sides during a seizure.[28] In tonic-clonic seizure, bites to the sides are more common.[28] Tongue bites are also relatively common in psychogenic non-epileptic seizures.[28]

A still image of a generalized seizure

Myoclonic seizures involve spasms of muscles in either a few areas or all over.[29] Absence seizures can be subtle with only a slight turn of the head or eye blinking.[22] The person does not fall over and returns to normal right after it ends.[22] Atonic seizures involve the loss of muscle activity for greater than one second.[25] This typically occurs on both sides of the body.[25]

About 6% of those with epilepsy have seizures that are often triggered by specific events and are known as reflex seizures.[30] Those with reflex epilepsy have seizures that are only triggered by specific stimuli.[31] Common triggers include flashing lights and sudden noises.[30] In certain types of epilepsy, seizures happen more often during sleep,[32] and in other types they occur almost only when sleeping.[33]

A bite to the tip of the tongue due to a seizure

## Postictal [edit]

After the active portion of a seizure (the ictal state) there is typically a period of recovery during which there is confusion, referred to as the postictal period before a normal level of consciousness returns.[24] It usually lasts 3 to 15 minutes[34] but may last for hours.[35] Other common symptoms include feeling tired, headache, difficulty speaking, and abnormal behavior.[35] Psychosis after a seizure is relatively common, occurring in 6–10% of people.[36] Often people do not remember what happened during this time.[35] Localized weakness, known as Todd's paralysis, may also occur after a partial seizure. When it occurs it typically lasts for seconds to minutes but may rarely last for a day or two.[37]

## Psychosocial [edit]

Epilepsy can have adverse effects on social and psychological well-being.[21] These effects may include social isolation, stigmatization, or disability.[21] They may result in lower educational achievement and worse employment outcomes.[21] Learning disabilities are common in those with the condition, and especially among children with epilepsy.[21] The stigma of epilepsy can also affect the families of those with the disorder.[27]

Certain disorders occur more often in people with epilepsy, depending partly on the epilepsy syndrome present.[38] [39]

These include depression, anxiety, obsessive–compulsive disorder (OCD), and migraine. Attention deficit hyperactivity disorder affects three to five times more children with epilepsy than children without the condition.[40] ADHD and epilepsy have significant consequences on a child's behavioral, learning, and social development.[41] Epilepsy is also more common in children with autism.[42]

## Causes [edit]

*See also: Causes of seizures*

Epilepsy can have both genetic and acquired causes, with interaction of these factors in many cases.[43] Established acquired causes include serious brain trauma, stroke, tumours and problems in the brain as a result of a previous infection.[43] In about 60% of cases the cause is unknown.[21][27] Epilepsies caused by genetic, congenital, or developmental conditions are more common among younger people, while brain tumors and strokes are more likely in older people.[21]

Seizures may also occur as a consequence of other health problems;[26] if they occur right around a specific cause, such as a stroke, head injury, toxic ingestion or metabolic problem, they are known as acute symptomatic seizures and are in the broader classification of seizure-related disorders rather than epilepsy itself.[44][45]

### Genetics [edit]

Genetics is believed to be involved in the majority of cases, either directly or indirectly.[6] Some epilepsies are due to a single gene defect (1–2%); most are due to the interaction of multiple genes and environmental factors.[6] Each of the single gene defects is rare, with more than 200 in all described.[46] Most genes involved affect ion channels, either directly or indirectly.[43] These include genes for ion channels themselves, enzymes, GABA, and G protein-coupled receptors.[29]

In identical twins, if one is affected there is a 50–60% chance that the other will also be affected.[6] In non-identical twins the risk is 15%.[6] These risks are greater in those with generalized rather than partial seizures.[6] If both twins are affected, most of the time they have the same epileptic syndrome (70–90%).[6] Other close relatives of a person with epilepsy have a risk five times that of the general population.[47] Between 1 and 10% of those with Down syndrome and 90% of those with Angelman syndrome have epilepsy.[47]

### Acquired [edit]

Epilepsy may occur as a result of a number of other conditions including tumors, strokes, head trauma, previous infections of the central nervous system, genetic abnormalities, and as a result of brain damage around the time of birth.[26][27] Of those with brain tumors, almost 30% have epilepsy, making them the cause of about 4% of cases.[47] The risk is greatest for tumors in the temporal lobe and those that grow slowly.[47] Other mass lesions such as cerebral cavernous malformations and arteriovenous malformations have risks as high as 40–60%.[47] Of those who have had a stroke, 2–4% develop epilepsy.[47] In the United Kingdom strokes account for 15% of cases and it is believed to be the cause in 30% of the elderly.[21][47] Between 6 and 20% of epilepsy is believed to be due to head trauma.[47] Mild brain injury increases the risk about two-fold while severe brain injury increases the risk seven-fold.[47] In those who have experienced a high-powered gunshot wound to the head, the risk is about 50%.[47]

Some evidence links epilepsy and coeliac disease and non-celiac gluten sensitivity, while other evidence does not. There appears to be a specific syndrome which includes coeliac disease, epilepsy and calcifications in the brain.[48][49] A 2012 review estimates that between 1% and 6% of people with epilepsy have CD while 1% of the general population has the condition.[49]

The risk of epilepsy following meningitis is less than 10%; that disease more commonly causes seizures during the infection itself.[47] In herpes simplex encephalitis the risk of a seizure is around 50%[47] with a high risk of epilepsy following (up to 25%).[50][51] Infection with the pork tapeworm, which can result in neurocysticercosis, is the cause of up to half of epilepsy cases in areas of the world where the parasite is common.[47] Epilepsy may also occur after other brain infections such as cerebral malaria, toxoplasmosis, and toxocariasis.[47] Chronic alcohol use increases the risk of epilepsy: those who drink six units of alcohol per day have a two and a half fold increase in risk.[47] Other risks include Alzheimer's disease, multiple sclerosis, tuberous sclerosis, and autoimmune encephalitis.[47] Getting

vaccinated does not increase the risk of epilepsy.[47] Malnutrition is a risk factor seen mostly in the developing world, although it is unclear however if it is a direct cause or an association.[15] People with cerebral palsy have an increased risk of epilepsy, with half of people with spastic quadriplegia and spastic hemiplegia having the disease.[52]

## Mechanism [edit]

Normally brain electrical activity is non-synchronous.[22] Its activity is regulated by various factors both within the neuron and the cellular environment. Factors within the neuron include the type, number and distribution of ion channels, changes to receptors and changes of gene expression.[53] Factors around the neuron include ion concentrations, synaptic plasticity and regulation of transmitter breakdown by glial cells.[53][54]

### Epilepsy [edit]

The exact mechanism of epilepsy is unknown,[55] but a little is known about its cellular and network mechanisms. However, it is unknown under which circumstances the brain shifts into the activity of a seizure with its excessive synchronization.[56][57]

In epilepsy, the resistance of excitatory neurons to fire during this period is decreased.[22] This may occur due to changes in ion channels or inhibitory neurons not functioning properly.[22] This then results in a specific area from which seizures may develop, known as a "seizure focus".[22] Another mechanism of epilepsy may be the up-regulation of excitatory circuits or down-regulation of inhibitory circuits following an injury to the brain.[22][58] These secondary epilepsies occur through processes known as epileptogenesis.[22][58] Failure of the blood–brain barrier may also be a causal mechanism as it would allow substances in the blood to enter the brain.[59]

### Seizures [edit]

There is evidence that epileptic seizures are usually not a random event. Seizures are often brought on by factors such as stress, alcohol abuse, flickering light, or a lack of sleep, among others. The term seizure threshold is used to indicate the amount of stimulus necessary to bring about a seizure. Seizure threshold is lowered in epilepsy.[56]

In epileptic seizures a group of neurons begin firing in an abnormal, excessive,[21] and synchronized manner.[22] This results in a wave of depolarization known as a paroxysmal depolarizing shift.[60] Normally, after an excitatory neuron fires it becomes more resistant to firing for a period of time.[22] This is due in part to the effect of inhibitory neurons, electrical changes within the excitatory neuron, and the negative effects of adenosine.[22]

Partial seizures begin in one hemisphere of the brain while generalized seizures begin in both hemispheres.[26] Some types of seizures may change brain structure, while others appear to have little effect.[61] Gliosis, neuronal loss, and atrophy of specific areas of the brain are linked to epilepsy but it is unclear if epilepsy causes these changes or if these changes result in epilepsy.[61]

## Diagnosis [edit]

The diagnosis of epilepsy is typically made based on observation of the seizure onset and the underlying cause.[21] An electroencephalogram (EEG) to look for abnormal patterns of brain waves and neuroimaging (CT scan or MRI) to look at the structure of the brain are also usually part of the workup.[21] While figuring out a specific epileptic syndrome is often attempted, it is not always possible.[21] Video and EEG monitoring may be useful in difficult cases.[62]

An EEG can aid in locating the focus of the epileptic seizure.

### Definition [edit]

Epilepsy is a disorder of the brain defined by any of the following conditions:[2]

1. At least two unprovoked (or reflex) seizures occurring

greater than 24 hours apart
2. One unprovoked (or reflex) seizure and a probability of further seizures similar to the general recurrence risk (at least 60%) after two unprovoked seizures, occurring over the next 10 years
3. Diagnosis of an epilepsy syndrome

Furthermore, epilepsy is considered to be resolved for individuals who had an age-dependent epilepsy syndrome but are now past that age or those who have remained seizure-free for the last 10 years, with no seizure medicines for the last 5 years.[2]

This 2014 definition of the International League Against Epilepsy[2] is a clarification of the ILAE 2005 conceptual definition, according to which epilepsy is "a disorder of the brain characterized by an enduring predisposition to generate epileptic seizures and by the neurobiologic, cognitive, psychological, and social consequences of this condition. The definition of epilepsy requires the occurrence of at least one epileptic seizure."[63][64]

It is, therefore, possible to outgrow epilepsy or to undergo treatment that causes epilepsy to be resolved, but with no guarantee that it will not return. In the definition, epilepsy is now called a disease, rather than a disorder. This was a decision of the executive committee of the ILAE, taken because the word "disorder," while perhaps having less stigma than does "disease," also does not express the degree of seriousness that epilepsy deserves.[2]

The definition is practical in nature and is designed for clinical use. In particular, it aims to clarify when an "enduring predisposition" according to the 2005 conceptual definition is present. Researchers, statistically-minded epidemiologists, and other specialized groups may choose to use the older definition or a definition of their own devising. The ILAE considers doing so is perfectly allowable, so long as it is clear what definition is being used.[2]

## Classification [edit]

In contrast to the classification of seizures which focuses on what happens during a seizure, the classification of epilepsies focuses on the underlying causes. When a person is admitted to hospital after an epileptic seizure the diagnostic workup results preferably in the seizure itself being classified (e.g. tonic-clonic) and in the underlying disease being identified (e.g. hippocampal sclerosis).[62] The name of the diagnosis finally made depends on the available diagnostic results and the applied definitions and classifications (of seizures and epilepsies) and its respective terminology.

The International League Against Epilepsy (ILAE) provided a classification of the epilepsies and epileptic syndromes in 1989 as follows:[65]

1. Localization-related epilepsies and syndromes
    1. Unknown cause (e.g. benign childhood epilepsy with centrotemporal spikes)
    2. Symptomatic/cryptogenic (e.g. temporal lobe epilepsy)
2. Generalized
    1. Unknown cause (e.g. childhood absence epilepsy)
    2. Cryptogenic or symptomatic (e.g. Lennox-Gastaut syndrome)
    3. Symptomatic (e.g. early infantile epileptic encephalopathy with burst suppression)
3. Epilepsies and syndromes undetermined whether partial or generalized
    1. With both generalized and partial seizures (e.g. epilepsy with continuous spike-waves during slow wave sleep)
4. Special syndromes (with situation-related seizures)[65]

This classification was widely accepted but has also been criticized mainly because the underlying causes of epilepsy (which are a major determinant of clinical course and prognosis) were not covered in detail.[66] In 2010 the ILAE Commission for Classification of the Epilepsies addressed this issue and divided epilepsies into three categories (genetic, structural/metabolic, unknown cause)[67] that were refined in their 2011 recommendation into four categories and a number of subcategories reflecting recent technologic and scientific advances.[68]

1. Unknown cause (mostly genetic or presumed genetic origin)
    1. Pure epilepsies due to single gene disorders
    2. Pure epilepsies with complex inheritance
2. Symptomatic (associated with gross anatomic or pathologic abnormalities)

1. Mostly genetic or developmental causation
    1. Childhood epilepsy syndromes
    2. Progressive myoclonic epilepsies
    3. Neurocutaneous syndromes
    4. Other neurologic single gene disorders
    5. Disorders of chromosome function
    6. Developmental anomalies of cerebral structure
2. Mostly acquired causes
    1. Hippocampal sclerosis
    2. Perinatal and infantile causes
    3. Cerebral trauma, tumor or infection
    4. Cerebrovascular disorders
    5. Cerebral immunologic disorders
    6. Degenerative and other neurologic conditions
3. Provoked (a specific systemic or environmental factor is the predominant cause of the seizures)
    1. Provoking factors
    2. Reflex epilepsies
4. Crytogenic (presumed symptomatic nature in which the cause has not been identified)[68]

## Syndromes [edit]

*Main article: Epilepsy syndromes*

Cases of epilepsy may be organized into epilepsy syndromes by the specific features that are present. These features include the age that seizure begin, the seizure types, EEG findings, among others. Identifying an epilepsy syndrome is useful as it helps determine the underlying causes as well as what anti-seizure medication should be tried.[26][69]

The ability to categorize a case of epilepsy into a specific syndrome occurs more often with children since the onset of seizures is commonly early.[45] Less serious examples are benign rolandic epilepsy (2.8 per 100,000), childhood absence epilepsy (0.8 per 100,000) and juvenile myoclonic epilepsy (0.7 per 100,000).[45] Severe syndromes with diffuse brain dysfunction caused, at least partly, by some aspect of epilepsy, are also referred to as epileptic encephalopathies. These are associated with frequent seizures that are resistant to treatment and severe cognitive dysfunction, for instance Lennox–Gastaut syndrome and West syndrome.[70] Genetics is believed to play an important role in epilepsies by a number of mechanisms. Simple and complex modes of inheritance have been identified for some of them. However, extensive screening have failed to identify many single gene variants of large effect.[71] More recent exome and genome sequencing studies have begun to reveal a number of de novo gene mutations that are responsible for some epileptic encephalopathies, including CHD2 and SYNGAP1[72][73][74] and DNM1, GABBR2, FASN and RYR3.[75]

Syndromes in which causes are not clearly identified are difficult to match with categories of the current classification of epilepsy. Categorization for these cases was made somewhat arbitrarily.[68] The *idiopathic* (unknown cause) category of the 2011 classification includes syndromes in which the general clinical features and/or age specificity strongly point to a presumed genetic cause.[68] Some childhood epilepsy syndromes are included in the unknown cause category in which the cause is presumed genetic, for instance benign rolandic epilepsy. Others are included in *symptomatic* despite a presumed genetic cause (in at least in some cases), for instance Lennox-Gastaut syndrome.[68] Clinical syndromes in which epilepsy is not the main feature (e.g. Angelman syndrome) were categorized *symptomatic* but it was argued to include these within the category *idiopathic*.[68] Classification of epilepsies and particularly of epilepsy syndromes will change with advances in research.

## Tests [edit]

An electroencephalogram (EEG) can assist in showing brain activity suggestive of an increased risk of seizures. It is only recommended for those who are likely to have had an epileptic seizure on the basis of symptoms. In the diagnosis of epilepsy, electroencephalography may help distinguish the type of seizure or syndrome present. In children it is typically only needed after a second seizure. It cannot be used to rule out the diagnosis and may be falsely positive in those without the disease. In certain situations it may be useful to perform the EEG while the affected individual is sleeping or sleep deprived.[62]

Diagnostic imaging by CT scan and MRI is recommended after a first non-febrile seizure to detect structural problems [62]

in and around the brain. MRI is generally a better imaging test except when bleeding is suspected, for which CT is more sensitive and more easily available.[16] If someone attends the emergency room with a seizure but returns to normal quickly, imaging tests may be done at a later point.[16] If a person has a previous diagnosis of epilepsy with previous imaging, repeating the imaging is usually not needed even if there are subsequent seizures.[62]

For adults, the testing of electrolyte, blood glucose and calcium levels is important to rule out problems with these as causes.[62] An electrocardiogram can rule out problems with the rhythm of the heart.[62] A lumbar puncture may be useful to diagnose a central nervous system infection but is not routinely needed.[16] In children additional tests may be required such as urine biochemistry and blood testing looking for metabolic disorders.[62][76]

A high blood prolactin level within the first 20 minutes following a seizure may be useful to help confirm an epileptic seizure as opposed to psychogenic non-epileptic seizure.[77][78] Serum prolactin level is less useful for detecting partial seizures.[79] If it is normal an epileptic seizure is still possible[78] and a serum prolactin does not separate epileptic seizures from syncope.[80] It is not recommended as a routine part of the diagnosis of epilepsy.[62]

### Differential diagnosis [edit]

Diagnosis of epilepsy can be difficult. A number of other conditions may present very similar signs and symptoms to seizures, including syncope, hyperventilation, migraines, narcolepsy, panic attacks and psychogenic non-epileptic seizures (PNES).[81][82] In particular a syncope can be accompanied by a short episode of convulsions.[83] Nocturnal frontal lobe epilepsy, often misdiagnosed as nightmares, was considered to be a parasomnia but later identified to be an epilepsy syndrome.[84] Attacks of the movement disorder paroxysmal dyskinesia may be taken for epileptic seizures.[85] The cause of a drop attack can be, among many others, an atonic seizure.[82]

Children may have behaviors that are easily mistaken for epileptic seizures but are not. These include breath-holding spells, bed wetting, night terrors, tics and shudder attacks.[82] Gastroesophageal reflux may cause arching of the back and twisting of the head to the side in infants, which may be mistaken for tonic-clonic seizures.[82]

Misdiagnosis is frequent (occurring in about 5 to 30% of cases).[21] Different studies showed that in many cases seizure-like attacks in apparent treatment-resistant epilepsy have a cardiovascular cause.[83][86] Approximately 20% of the people seen at epilepsy clinics have PNES[16] and of those who have PNES about 10% also have epilepsy;[87] separating the two based on the seizure episode alone without further testing is often difficult.[87]

## Prevention [edit]

While many cases are not preventable, efforts to reduce head injuries, provide good care around the time of birth, and reduce environmental parasites such as the pork tapeworm may be effective.[27] Efforts in one part of Central America to decrease rates of pork tapeworm resulted in a 50% decrease in new cases of epilepsy.[15]

## Management [edit]

Epilepsy is usually treated with daily medication once a second seizure has occurred,[21][62] but for those at high risk, medication may be started after the first seizure.[62] In drug-resistant cases different management options may be looked at including a special diet, the implantation of a neurostimulator, or neurosurgery.

### First aid [edit]

Rolling a person with an active tonic-clonic seizure onto their side and into the recovery position helps prevent fluids from getting into the lungs.[88] Putting fingers, a bite block or tongue depressor in the mouth is not recommended as it might make the person vomit or result in the rescuer being bitten.[24][88] Efforts should be taken to prevent further self-injury.[24] Spinal precautions are generally not needed.[88]

If a seizure lasts longer than 5 minutes or if there are more than two seizures in an hour without a return to a normal level of consciousness between them, it is considered a medical emergency known as status epilepticus.[62][89] This may require medical help to keep the airway open and protected;[62] a nasopharyngeal airway may be useful for this.[88] At home the recommended initial medication for seizure of a long duration is midazolam placed in the mouth.[90] Diazepam may also be used rectally.[90] In hospital, intravenous lorazepam is preferred.[62] If two doses of benzodiazepines are not effective, other medications such as phenytoin are

recommended.[62] Convulsive status epilepticus that does not respond to initial treatment typically requires admission to the intensive care unit and treatment with stronger agents such as thiopentone or propofol.[62]

## Medications [edit]

Anticonvulsants

The mainstay treatment of epilepsy is anticonvulsant medications, possibly for the person's entire life.[21] The choice of anticonvulsant is based on seizure type, epilepsy syndrome, other medications used, other health problems, and the person's age and lifestyle.[90] A single medication is recommended initially;[91] if this is not effective, switching to a single other medication is recommended.[62] Two medications at once is recommended only if a single medication does not work.[62] In about half, the first agent is effective; a second single agent helps in about 13% and a third or two agents at the same time may help an additional 4%.[92] About 30% of people continue to have seizures despite anticonvulsant treatment.[7]

There are a number of medications available. Phenytoin, carbamazepine and valproate appear to be equally effective in both partial and generalized seizures.[93][94] Controlled release carbamazepine appears to work as well as immediate release carbamazepine, and may have fewer side effects.[95][*needs update*] In the United Kingdom, carbamazepine or lamotrigine are recommended as first-line treatment for partial seizures, with levetiracetam and valproate as second-line due to issues of cost and side effects.[62] Valproate is recommended first-line for generalized seizures with lamotrigine being second-line.[62] In those with absence seizures, ethosuximide or valproate are recommended; valproate is particularly effective in myoclonic seizures and tonic or atonic seizures.[62] If seizures are well-controlled on a particular treatment, it is not usually necessary to routinely check the medication levels in the blood.[62]

The least expensive anticonvulsant is phenobarbital at around $5 USD a year.[15] The World Health Organization gives it a first-line recommendation in the developing world and it is commonly used there.[96][97] Access however may be difficult as some countries label it as a controlled drug.[15]

Adverse effects from medications are reported in 10 to 90% of people, depending on how and from whom the data is collected.[98] Most adverse effects are dose-related and mild.[98] Some examples include mood changes, sleepiness, or an unsteadiness in gait.[98] Certain medications have side effects that are not related to dose such as rashes, liver toxicity, or suppression of the bone marrow.[98] Up to a quarter of people stop treatment due to adverse effects.[98] Some medications are associated with birth defects when used in pregnancy.[62] Many of the common used medications, such as valproate, phenytoin, carbamazepine, phenobarbitol, and gabapentin have been reported to cause increased risk of birth defects,[99] especially when used during the first trimester.[100] Despite this, treatment is often continued once effective, because the risk of untreated epilepsy is believed to be greater than the risk of the medications.[100] Among the antiepileptic medications, levetiracetam and lamotrigine seem to carry the lowest risk of causing birth defects.[99]

Slowly stopping medications may be reasonable in some people who do not have a seizure for two to four years; however, around a third of people have a recurrence, most often during the first six months.[62][101] Stopping is possible in about 70% of children and 60% of adults.[27]

## Surgery [edit]

Epilepsy surgery may be an option for people with partial seizures that remain a problem despite other treatments.[102] These other treatments include at least a trial of two or three medications.[103] The goal of surgery is total control of seizures[104] and this may be achieved in 60–70% of cases.[103] Common procedures include cutting out the hippocampus via an anterior temporal lobe resection, removal of tumors, and removing parts of the neocortex.[103] Some procedures such as a corpus callosotomy are attempted in an effort to decrease the number of seizures rather than cure the condition.[103] Following surgery, medications may be slowly withdrawn in many [103]

cases.

Neurostimulation may be another option in those who are not candidates for surgery.[62] Three types have been shown to be effective in those who do not respond to medications: vagus nerve stimulation, anterior thalamic stimulation, and closed-loop responsive stimulation.[8]

### Diet [edit]

A ketogenic diet (high-fat, low-carbohydrate, adequate-protein) appears to decrease the number of seizures and eliminate seizures in some.[105] It is a reasonable option in those who have epilepsy that is not improved with medications and for whom surgery is not an option.[105] About 10% stay on the diet for a few years due to issues of effectiveness and tolerability.[9] Side effects include stomach and intestinal problems in 30%, and there are long term concerns of heart disease.[9] Less radical diets are easier to tolerate and may be effective.[9] It is unclear why this diet works.[106] Exercise has been proposed as possibly useful for preventing seizures[107] with some data to support this claim.[108]

In people with coeliac disease or non-celiac gluten sensitivity and occipital calcifications, a gluten-free diet may decrease the frequency of seizures.[49]

### Other [edit]

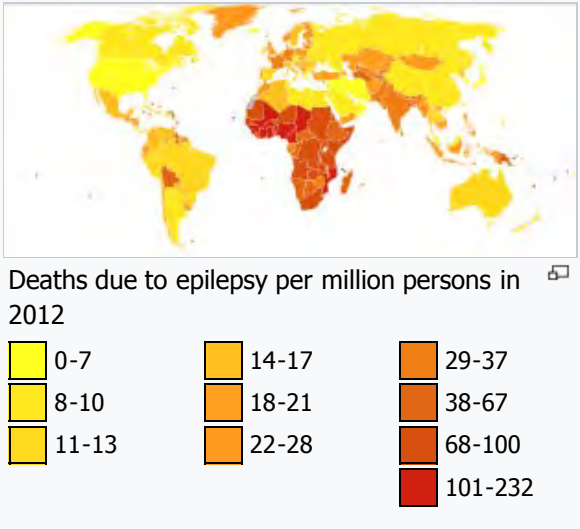
Avoidance therapy consists of minimizing or eliminating triggers. For example, in those who are sensitive to light, using a small television, avoiding video games, or wearing dark glasses may be useful.[109] Operant-based biofeedback based on the EEG waves has some support in those who do not respond to medications.[110] Psychological methods should not, however, be used to replace medications.[62] Some dogs, commonly referred to as seizure dogs, may help during or after a seizure.[111][112] It is not clear if dogs have the ability to predict seizures before they occur.[113]

### Alternative medicine [edit]

Alternative medicine, including acupuncture,[114] psychological interventions,[115] routine vitamins,[116] and yoga,[117] have no reliable evidence to support their use in epilepsy. There is not enough evidence to support the use of cannabis.[118][119] Melatonin, as of 2016, is insufficiently supported by evidence.[120] The trials were of poor methodological quality and it was not possible to draw any definitive conclusions.[120]

## Prognosis [edit]

Epilepsy cannot usually be cured, but medication can control seizures effectively in about 70% of cases.[7] Of those with generalized seizures, more than 80% can be well controlled with medications while this is true in only 50% of people with partial seizures.[8] One predictor of long-term outcome is the number of seizures that occur in the first six months.[21] Other factors increasing the risk of a poor outcome include little response to the initial treatment, generalized seizures, a family history of epilepsy, psychiatric problems, and waves on the EEG representing generalized epileptiform activity.[121] In the developing world, 75% of people are either untreated or not appropriately treated.[27] In Africa, 90% do not get treatment.[27] This is partly related to appropriate medications not being available or being too expensive.[27]



Deaths due to epilepsy per million persons in 2012

### Mortality [edit]

People with epilepsy are at an increased risk of death.[122] This increase is between 1.6 and 4.1 fold greater than that of the general population[123] and is often related to: the underlying cause of the seizures, status epilepticus, suicide, trauma, and sudden unexpected death in epilepsy (SUDEP).[122] Death from status epilepticus is primarily due to an underlying

problem rather than missing doses of medications.[122] The risk of suicide is increased between two and six times in those with epilepsy.[124][125] The cause of this is unclear.[124] SUDEP appears to be partly related to the frequency of generalized tonic-clonic seizures[126] and accounts for about 15% of epilepsy related deaths.[121] It is unclear how to decrease its risk.[126] The greatest increase in mortality from epilepsy is among the elderly.[123] Those with epilepsy due to an unknown cause have little increased risk.[123] In the United Kingdom, it is estimated that 40–60% of deaths are possibly preventable.[21] In the developing world, many deaths are due to untreated epilepsy leading to falls or status epilepticus.[15]

## Epidemiology [edit]

Epilepsy is one of the most common serious neurological disorders[127] affecting about 22 million people as of 2013.[10] It affects 1% of the population by age 20 and 3% of the population by age 75.[13] It is more common in males than females with the overall difference being small.[15][45] Most of those with the disorder (80%) are in the developing world.[27]

The estimated prevalence of active epilepsy (as of 2012) is in the range 3–10 per 1,000, with active epilepsy defined as someone with epilepsy who has had a least one unprovoked seizure in the last five years.[45][128] Epilepsy begins each year in 40–70 per 100,000 in developed countries and 80–140 per 100,000 in developing countries.[27] Poverty is a risk and includes both being from a poor country and being poor relative to others within one's country.[15] In the developed world epilepsy most commonly starts either in the young or in the old.[15] In the developing world its onset is more common in older children and young adults due to the higher rates of trauma and infectious diseases.[15] In developed countries the number of cases a year has decreased in children and increased among the elderly between the 1970s and 2003.[128] This has been attributed partly to better survival following strokes in the elderly.[45]

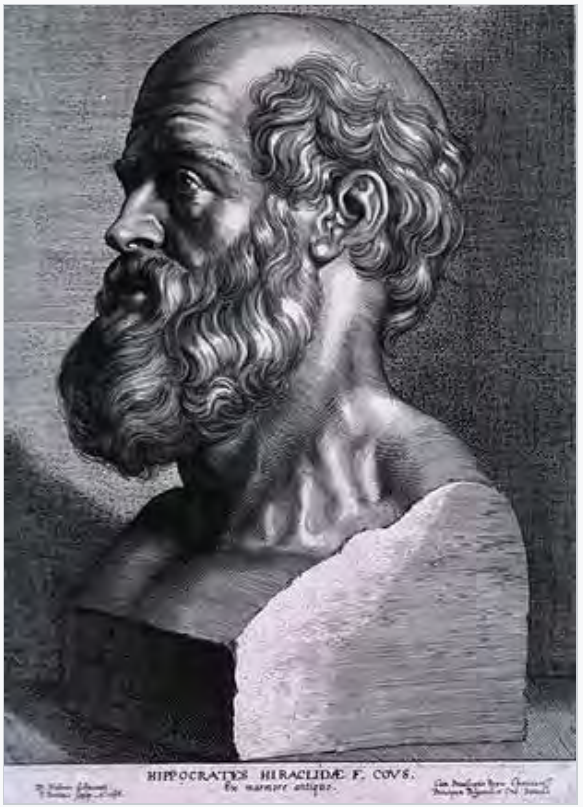
## History [edit]

*See also: On the Sacred Disease*

The oldest medical records show that epilepsy has been affecting people at least since the beginning of recorded history.[129] Throughout ancient history, the disease was thought to be a spiritual condition.[129] The world's oldest description of an epileptic seizure comes from a text in Akkadian (a language used in ancient Mesopotamia) and was written around 2000 BC.[19] The person described in the text was diagnosed as being under the influence of a Moon god, and underwent an exorcism.[19] Epileptic seizures are listed in the Code of Hammurabi (c. 1790 BC) as reason for which a purchased slave may be returned for a refund,[19] and the Edwin Smith Papyrus (c. 1700 BC) describes cases of individuals with epileptic convulsions.[19]

The oldest known detailed record of the disease itself is in the *Sakikku*, a Babylonian cuneiform medical text from 1067–1046 BC.[129] This text gives signs and symptoms, details treatment and likely outcomes,[19] and describes many features of the different seizure types.[129] As the Babylonians had no biomedical understanding of the nature of disease, they attributed the seizures to possession by evil spirits and called for treating the condition through spiritual means.[129] Around 900 BC, Punarvasu Atreya described epilepsy as loss of consciousness;[130] this definition was carried forward into the Ayurvedic text of Charaka Samhita (about 400 BC).[131]

The ancient Greeks had contradictory views of the disease. They thought of epilepsy as a form of spiritual possession, but also associated the condition with genius and the divine. One of the



Hippocrates, 17th century engraving by Peter Paul Rubens of an antique bust.

names they gave to it was the *sacred disease* (ἡ ἱερὰ νόσος).[19][132]
Epilepsy appears within Greek mythology: it is associated with the Moon goddesses Selene and Artemis, who afflicted those who upset them. The Greeks thought that important figures such as Julius Caesar and Hercules had the disease.[19] The notable exception to this divine and spiritual view was that of the school of Hippocrates. In the fifth century BC, Hippocrates rejected the idea that the disease was caused by spirits. In his landmark work *On the Sacred Disease*, he proposed that epilepsy was not divine in origin and instead was a medically treatable problem originating in the brain.[19][129] He accused those of attributing a sacred cause to the disease of spreading ignorance through a belief in superstitious magic.[19] Hippocrates proposed that heredity was important as a cause, described worse outcomes if the disease presents at an early age, and made note of the physical characteristics as well as the social shame associated with it.[19] Instead of referring to it as the *sacred disease*, he used the term *great disease*, giving rise to the modern term *grand mal*, used for tonic–clonic seizures.[19] Despite his work detailing the physical origins of the disease, his view was not accepted at the time.[129] Evil spirits continued to be blamed until at least the 17th century.[129]

In Ancient Rome people did not eat or drink with the same pottery as that used by someone who was affected.[133] People of the time would spit on their chest believing that this would keep the problem from affected them.[133] According to Apuleius and other ancient physicians, in order detect epilepsy it was common to light a piece of *gagates*, whose smoke would trigger the seizure.[134] Occasionally a spinning potter's wheel was used, perhaps a reference to photosensitive epilepsy.[135]

In most cultures, persons with epilepsy have been stigmatized, shunned, or even imprisoned; in the Salpêtrière, the birthplace of modern neurology, Jean-Martin Charcot found people with epilepsy side-by-side with the mentally ill, those with chronic syphilis, and the criminally insane.[136] In ancient Rome, epilepsy was known as the *morbus comitialis* ('disease of the assembly hall') and was seen as a curse from the gods. In northern Italy, epilepsy was once traditionally known as Saint Valentine's malady.[137]

In the mid-1800s, the first effective anti-seizure medication, bromide, was introduced.[98] The first modern treatment, phenobarbital, was developed in 1912, with phenytoin coming into use in 1938.[138]

## Society and culture [edit]

*See also: List of people with epilepsy*

### Stigma [edit]

Stigma is commonly experienced, around the world, by those with epilepsy.[139] It can affect people economically, socially and culturally.[139] In India and China, epilepsy may be used as justification to deny marriage.[27] People in some areas still believe those with epilepsy to be cursed.[15] In Tanzania, as in other parts of Africa, epilepsy is associated with possession by evil spirits, witchcraft, or poisoning and is believed by many to be contagious,[136] for which there is no evidence.[15] Before 1970 the United Kingdom had laws which prevented people with epilepsy from marrying.[27] The stigma may result in some people with epilepsy denying that they have ever had seizures.[45]

### Economics [edit]

Seizures result in direct economic costs of about one billion dollars in the United States.[16] Epilepsy resulted in economic costs in Europe of around 15.5 billion Euros in 2004.[21] In India epilepsy is estimated to result in costs of 1.7 billion USD or 0.5% of the GDP.[27] It is the cause of about 1% of emergency department visits (2% for emergency departments for children) in the United States.[140]

### Vehicles [edit]

*See also: Epilepsy and driving*

Those with epilepsy are at about twice the risk of being involved in a motor vehicular collision and thus in many areas of the world are not allowed to drive or only able to drive if certain conditions are met.[18] In some places physicians are required by law to report if a person has had a seizure to the licensing body while in others the requirement is only that they encourage the person in question to report it themselves.[18] Countries that require physician reporting include Sweden, Austria, Denmark and Spain.[18] Countries that require the individual to report

include the UK and New Zealand and the physician may report if they believe the individual has not already.[18] In Canada, the United States and Australia the requirements around reporting vary by province or state.[18] If seizures are well controlled most feel allowing driving is reasonable.[141] The amount of time a person must be free from seizures before they can drive varies by country.[141] Many countries require one to three years without seizures.[141] In the United States the time needed without a seizure is determined by each state and is between three months and one year.[141]

Those with epilepsy or seizures are typically denied a pilot license.[142] In Canada if an individual has had no more than one seizure, they may be considered after five years for a limited license if all other testing is normal.[143] Those with febrile seizures and drug related seizures may also be considered.[143] In the United States, the Federal Aviation Administration does not allow those with epilepsy to get a commercial pilot license.[144] Rarely, exceptions can be made for persons who have had an isolated seizure or febrile seizures and have remained free of seizures into adulthood without medication.[145] In the United Kingdom, a full national private pilot license requires the same standards as a professional driver's license.[146] This requires a period of ten years without seizures while off medications.[147] Those who do not meet this requirement may acquire a restricted license if free from seizures for five years.[146]

### Support organizations [edit]

There are organizations that provide support for people and families affected by epilepsy. The *Out of the Shadows* campaign, a joint effort by the World Health Organization, the International League Against Epilepsy and the International Bureau for Epilepsy, provides help internationally.[27] The Joint Epilepsy Council serves the UK and Ireland.[62] In the United States, the Epilepsy Foundation is a national organization that works to increase the acceptance of those with the disease, their ability to function in society and to promote research for a cure.[148] The Epilepsy Foundation, some hospitals, and some individuals also run support groups in the United States.[149]

## Research [edit]

Seizure prediction refers to attempts to forecast epileptic seizures based on the EEG before they occur.[150] As of 2011, no effective mechanism to predict seizures has been developed.[150] Kindling, where repeated exposures to events that could cause seizures eventually causes seizures more easily, has been used to create animal models of epilepsy.[151]

Gene therapy is being studied in some types of epilepsy.[152] Medications that alter immune function, such as intravenous immunoglobulins, are poorly supported by evidence.[153] Noninvasive stereotactic radiosurgery is, as of 2012, being compared to standard surgery for certain types of epilepsy.[154]

Common locations for the start of seizures and neural networks have been found to be affected in the majority of epilepsy.[155] Efforts to figure out how epilepsy occurs is working to take into account the different regions of the brain and the timing of their activity.[156]

## Other animals [edit]

*Main article: Epilepsy in animals*

Epilepsy occurs in a number of other animals including dogs and cats and is the most common brain disorder in dogs.[157] It is typically treated with anticonvulsants such as phenobarbital or bromide in dogs and phenobarbital in cats.[158] Imepitoin is also used in dogs.[159] While generalized seizures in horses are fairly easy to diagnose, it may be more difficult in non-generalized seizures and EEGs may be useful.[160]

# Female genital mutilation

From Wikipedia, the free encyclopedia

*"FGM" redirects here. For other uses, see FGM (disambiguation).*

**Female genital mutilation** (**FGM**), also known as **female genital cutting** and **female circumcision**, is the ritual removal of some or all of the external female genitalia. The practice is found in Africa, Asia and the Middle East, and within communities from countries in which FGM is common. UNICEF estimated in 2016 that 200 million women in 30 countries—27 African countries, Indonesia, Iraqi Kurdistan and Yemen—had undergone the procedures.[3]

Typically carried out by a traditional circumciser using a blade, FGM is conducted from days after birth to puberty and beyond. In half the countries for which national figures are available, most girls are cut before the age of five.[5] Procedures differ according to the country or ethnic group. They include removal of the clitoral hood and clitoral glans; removal of the inner labia; and removal of the inner and outer labia and closure of the vulva. In this last procedure (known as infibulation), a small hole is left for the passage of urine and menstrual fluid; the vagina is opened for intercourse and opened further for childbirth.[6]

The practice is rooted in gender inequality, attempts to control women's sexuality, and ideas about purity, modesty and beauty. It is usually initiated and carried out by women, who see it as a source of honour, and who fear that failing to have their daughters and granddaughters cut will expose the girls to social exclusion.[a] The health effects depend on the procedure; they can include recurrent infections, difficulty urinating and passing menstrual flow, chronic pain, the development of cysts, an inability to get pregnant, complications during childbirth, and fatal bleeding.[6] There are no known health benefits.[9]

There have been international efforts since the 1970s to persuade practitioners to abandon FGM. As a result it has been outlawed or restricted in most of the countries in which it occurs, although the laws are poorly enforced. The opposition to the practice is not without its critics, particularly among anthropologists, who have raised difficult questions about cultural relativism and the universality of human rights.[10]

# Terminology

## English

Until the 1980s FGM was widely known as female circumcision, implying an equivalence in severity with male circumcision.[11] From 1929 the Kenya Missionary Council referred to it as the sexual mutilation of women, following the lead of Marion Scott Stevenson, a Church of Scotland missionary.[12] References to the practice as mutilation increased throughout the 1970s.[13] In 1975 Rose Oldfield Hayes, an American anthropologist, used the term *female genital mutilation* in the title of a paper,[14] and four years later Fran Hosken, an Austrian-American feminist writer, called it mutilation in her influential *The Hosken Report: Genital and Sexual Mutilation of Females*.[15][16]

The Inter-African Committee on Traditional Practices Affecting the Health of Women and Children and the World Health Organization (WHO) began referring to it as female genital mutilation in 1990 and 1991 respectively.[17] Other terms used include *female genital cutting* (FGC) and *female genital mutilation/cutting* (FGM/C), preferred by those who work with practitioners.[13]

Samburu FGM ceremony, Laikipia plateau, Kenya, 2004

## Local terms

The many variants of FGM are reflected in dozens of terms in countries where it is common.[18] These often refer to

purification. In the Bambara language, spoken mostly in Mali, FGM is known as *bolokoli* ("washing your hands")[19] and in the Igbo language in eastern Nigeria as *isa aru* or *iwu aru* ("having your bath").[b] A common Arabic term for purification has the root *t-h-r*, used for male and female circumcision (*tahur* and *tahara*).[21] It is also known in Arabic as *khafḍ* or *khifaḍ*.[22][23]

Communities may refer to only two forms of FGM: "pharaonic" for infibulation and *sunna* circumcision for everything else.[24] *Sunna* means "path or way" in Arabic and refers to the tradition of Muhammad, although none of the procedures are required within Islam.[23] The term *infibulation* derives from *fibula*, Latin for clasp; the Ancient Romans reportedly fastened clasps through the foreskins or labia of slaves to prevent sexual intercourse. The surgical infibulation of women came to be known as pharaonic circumcision in Sudan, but as Sudanese circumcision in Egypt.[25] In Somalia it is known simply as *qodob* ("to sew up").[26]

# Methods

The procedures are generally performed by a traditional circumciser (cutter or *exciseuse*) in the girls' homes, with or without anaesthesia. The cutter is usually an older woman, but in communities where the male barber has assumed the role of health worker he will perform FGM too.[27][c]

When traditional cutters are involved, non-sterile devices are likely to be used, including knives, razors, scissors, glass, sharpened rocks and fingernails.[29]:491 According to a nurse in Uganda, quoted in 2007 in *The Lancet*, a cutter would use one knife on up to 30 girls at a time.[30]

Health professionals are often involved in Egypt, Kenya, Indonesia and Sudan. In Egypt 77 percent of FGM procedures, and in Indonesia over 50 percent, were performed by medical professionals as of 2008 and 2016.[31][3] Women in Egypt reported in 1995 that a local anaesthetic had been used on their daughters in 60 percent of cases, a general anaesthetic in 13 percent and neither in 25 percent (two percent were missing/don't know).[32]

# Classification

## Surveys, UN typology

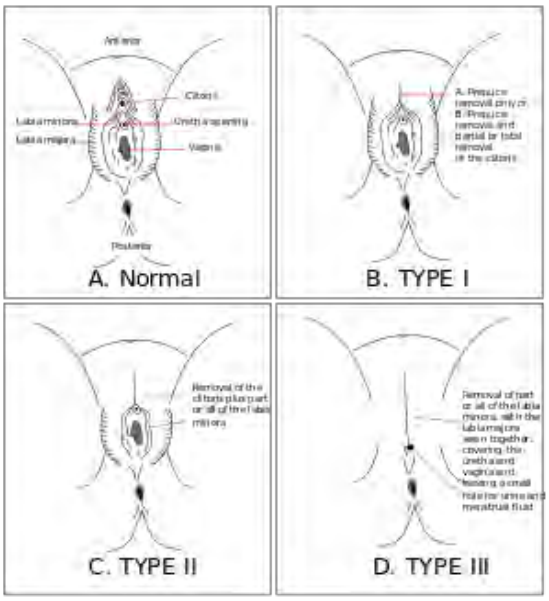
The WHO, UNICEF and UNFPA issued a joint statement in 1997 defining FGM as "all procedures involving partial or total removal of the external female genitalia or other injury to the female genital organs whether for cultural or other non-therapeutic reasons."[13] The procedures vary considerably according to ethnicity and individual practitioners. During a 1998 survey in Niger, women responded with over 50 different terms when asked what was done to them.[18] Translation problems are compounded by the women's confusion over which type of FGM they experienced, or even whether they experienced it.[33] Several studies have suggested that survey responses are unreliable.[d]

Standard questionnaires from United Nations bodies ask women whether they or their daughters have undergone the following: (1) cut, no flesh removed (pricking or symbolic circumcision); (2) cut, some flesh removed; (3) sewn closed; or (4) type not determined/unsure/doesn't know.[e] The most common procedures fall within the "cut, some flesh removed" category and involve complete or partial removal of the clitoral glans.[37]

## WHO Types I–II

The World Health Organization created a more detailed typology. Types I–III vary in how much tissue is removed (Type III is the UNICEF category "sewn closed"). Type IV describes miscellaneous procedures, including symbolic circumcision.[39][40]

Type Ia (circumcision)[41] involves removal of the clitoral hood only and is rarely performed alone.[f] The more common procedure is Type Ib (clitoridectomy), the complete or partial removal of the clitoral glans (the [1][43]



visible tip of the clitoris) and clitoral hood. The circumciser pulls the clitoral glans with her thumb and index finger and cuts it off.[g]

Type II (excision) is the complete or partial removal of the inner labia, with or without removal of the clitoral glans and outer labia. Type IIa is removal of the inner labia; IIb, removal of the clitoral glans and inner labia; and IIc, removal of the clitoral glans, inner and outer labia. *Excision* in French can refer to any form of FGM.[1]

## Type III

Type III (infibulation or pharaonic circumcision), the "sewn closed" category, involves the removal of the external genitalia and fusion of the wound. The inner and/or outer labia are cut away, with or without removal of the clitoral glans. Type IIIa is the removal and closure of the inner labia and IIIb the outer labia.[h] The practice is found largely in Djibouti, Eritrea, Ethiopia, Somalia and Sudan (though not South Sudan) in northeast Africa. Estimates of numbers vary: according to one in 2008, over eight million women in Africa have experienced it.[i] According to UNFPA in 2010, 20 percent of women with FGM have been infibulated.[46]

Types I–IV diagrams
Type IIIb: virgin, sexually active
— WHO[38] and *Swiss Medical Weekly*[6]

Comfort Momoh, a specialist midwife, describes Type III: "[E]lderly women, relatives and friends secure the girl in the lithotomy position. A deep incision is made rapidly on either side from the root of the clitoris to the fourchette, and a single cut of the razor excises the clitoris and both the labia majora and labia minora." Girls "may be pinned down so firmly that bones may fracture".[47] In Somalia the clitoral glans is removed and shown to the senior female relatives, who decide whether enough has been amputated. After this the labia are removed.[48] The amputated parts might be placed in a pouch for the girl to wear.[49]

A single hole of 2–3 mm is left for the passage of urine and menstrual fluid by inserting something, such as a twig, into the wound.[j][50] The vulva is then closed with surgical thread, agave or acacia thorns, or covered with a poultice such as raw egg, herbs and sugar.[29]:491[51] To help the tissue bond, the girl's legs are tied together, often from hip to ankle; the bindings are usually loosened after a week and removed after two to six weeks.[52][29]:491 The result is a "drum of skin extending across the [vaginal] orifice except for a small hole," Momoh writes.[47]

If the remaining hole is too large in the view of the girl's family, the procedure is repeated. The vagina is opened for sexual intercourse, for the first time either by a midwife with a knife or by the woman's husband with his penis. In some areas, including Somaliland, female relatives of the bride and groom might watch the opening of the vagina to check that the girl is a virgin.[53] Psychologist Hanny Lightfoot-Klein interviewed hundreds of women and men in Sudan in the 1980s about sexual intercourse with Type III:

> The penetration of the bride's infibulation takes anywhere from 3 or 4 days to several months. Some men are unable to penetrate their wives at all (in my study over 15%), and the task is often accomplished by a midwife under conditions of great secrecy, since this reflects negatively on the man's potency. Some who are unable to penetrate their wives manage to get them pregnant in spite of the infibulation, and the woman's vaginal passage is then cut open to allow birth to take place. ... Those men who do manage to penetrate their wives do so often, or perhaps always, with the help of the "little knife." This creates a tear which they gradually rip more and more until the opening is sufficient to admit the penis.[54]

The woman is opened further for childbirth and closed afterwards, a process known as defibulation (or deinfibulation) and reinfibulation. Reinfibulation can involve cutting the vagina again to restore the pinhole size of the

first infibulation. This might be performed before marriage, and after childbirth, divorce and widowhood.[k][55]

### Type IV

The WHO defines Type IV as "[a]ll other harmful procedures to the female genitalia for non-medical purposes", including pricking, piercing, incising, scraping and cauterization.[1] It includes nicking of the clitoris (symbolic circumcision), burning or scarring the genitals, and introducing substances into the vagina to tighten it.[56][57] Labia stretching is also categorized as Type IV.[58] Common in southern and eastern Africa, the practice is supposed to enhance sexual pleasure for the man and add to the sense of a woman as a closed space. From the age of eight, girls are encouraged to stretch their inner labia using sticks and massage. Girls in Uganda are told they may have difficulty giving birth without stretched labia.[l][60]

A definition of FGM from the WHO in 1995 included gishiri cutting and angurya cutting, found in Nigeria and Niger. These were removed from the WHO's 2008 definition because of insufficient information about prevalence and consequences.[61] Angurya cutting is excision of the hymen, usually performed seven days after birth. Gishiri cutting involves cutting the vagina's front or back wall with a blade or penknife, performed in response to infertility, obstructed labour and other conditions. In a study by Nigerian physician Mairo Usman Mandara, over 30 percent of women with gishiri cuts were found to have vesicovaginal fistulae (holes that allow urine to seep into the vagina).[62]

## Complications

### Short-term and late

FGM harms women's physical and emotional health throughout their lives.[64][65] It has no known health benefits.[9] The short-term and late complications depend on the type of FGM, whether the practitioner had medical training, and whether she used antibiotics and unsterilized or surgical single-use instruments. In the case of Type III, other factors include how small a hole was left for the passage of urine and menstrual blood, whether surgical thread was used instead of agave or acacia thorns, and whether the procedure was performed more than once (for example, to close an opening regarded as too wide or re-open one too small).[6]

**FGM ceremony in Indonesia**

Preparations
Girl before procedure
Nine-month-old afterwards

— Stephanie Sinclair
*The New York Times*, 2006[63]

Common short-term complications include swelling, excessive bleeding, pain, urine retention and healing problems/wound infection. A 2015 systematic review of 56 studies that recorded immediate complications suggested that each of these occurred in more than one in ten girls and women undergoing any form of FGM, including symbolic nicking of the clitoris (Type IV), although the risks increased with Type III. The review also suggested that there was under-reporting.[66] Other short-term complications include fatal bleeding, anaemia, urinary infection, septicaemia, tetanus, gangrene, necrotizing fasciitis (flesh-eating disease) and endometritis.[65][67][6] It is not known how many girls and women die as a result of the practice, because complications may not be recognized or reported.[68][69] The practitioners' use of shared instruments is thought to aid the transmission of hepatitis B, hepatitis C and HIV, although no epidemiological studies have shown this.[69]

FGM awareness session run by the African Union Mission to Somalia at the Walalah Biylooley refugee camp, Mogadishu

Late complications vary depending on the type of FGM.[6] They include the formation of scars and keloids that lead to strictures and obstruction, epidermoid cysts that may become infected, and neuroma formation (growth of nerve tissue) involving nerves that supplied the clitoris.[29]:491–492[70]

An infibulated girl may be left with an opening as small as 2–3 mm, which can cause prolonged, drop-by-drop urination, pain while urinating, and a feeling of needing to urinate all the time. Urine may collect underneath the scar, leaving the area under the skin constantly wet, which can lead to infection and the formation of small stones. The opening is larger in women who are sexually active or have given birth by vaginal delivery, but the urethra opening may still be obstructed by scar tissue. Vesicovaginal or rectovaginal fistulae can develop (holes that allow urine or faeces to seep into the vagina).[6][71] This and other damage to the urethra and bladder can lead to infections and incontinence, pain during sexual intercourse and infertility.[29]:491–492

Painful periods are common because of the obstruction to the menstrual flow, and blood can stagnate in the vagina and uterus. Complete obstruction of the vagina can result in hematocolpos and hematometra (where the vagina and uterus fill with menstrual blood).[6] The swelling of the abdomen that results from the collection of fluid, together with the lack of menstruation, can lead to suspicion of pregnancy. Asma El Dareer, a Sudanese physician, reported in 1979 that a girl in Sudan with this condition was killed by her family.[72]

## Pregnancy, childbirth

FGM may place women at higher risk of problems during pregnancy and childbirth, which are more common with the more extensive FGM procedures.[6] Infibulated women may try to make childbirth easier by eating less during pregnancy to reduce the baby's size. [73]:99 In women with vesicovaginal or rectovaginal fistulae, it is difficult to obtain clear urine samples as part of prenatal care, making the diagnosis of conditions such as pre-eclampsia harder.[29]:491–492 Cervical evaluation during labour may be impeded and labour prolonged or obstructed. Third-degree laceration (tears), anal-sphincter damage and emergency caesarean section are more common in infibulated women.[6][73]:97

Obstructed labour

— Nahid Toubia, RAINBO, 1999[73]

Neonatal mortality is increased. The WHO estimated in 2006 that an additional 10–20 babies die per 1,000 deliveries as a result of FGM. The estimate was based on a study conducted on 28,393 women attending delivery wards at 28 obstetric centres in Burkina Faso, Ghana, Kenya, Nigeria, Senegal and Sudan. In those settings all types of FGM were found to pose an increased risk of death to the baby: 15 percent higher for Type I, 32 percent for Type II and 55 percent for Type III. The reasons for this were unclear, but may be connected to genital and urinary tract infections and the presence of scar tissue. The researchers wrote that FGM was associated with an increased risk to the mother of damage to the perineum and excessive blood loss, as well as a need to resuscitate the baby, and stillbirth, perhaps because of a long second stage of labour.[74][75]

## Psychological effects, sexual function

According to a 2015 systematic review there is little high-quality information available on the psychological effects of FGM. Several small studies have concluded that women with FGM suffer from anxiety, depression and post-traumatic stress disorder.[69] Feelings of shame and betrayal can develop when women leave the culture that practises FGM and learn that their condition is not the norm, but within the practising culture they may view their FGM with pride, because for them it signifies beauty, respect for tradition, chastity and hygiene.[6]

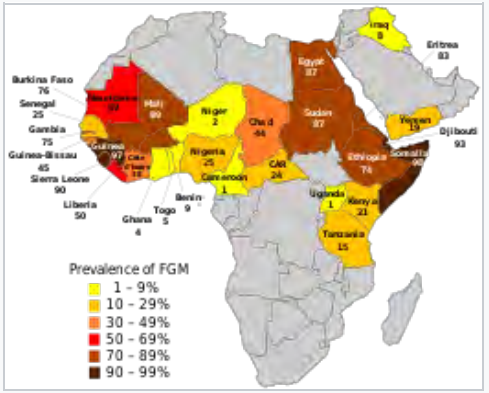
Studies on sexual function have also been small.[69] A 2013 meta-analysis of 15 studies involving 12,671 women from seven countries concluded that women with FGM were twice as likely to report no sexual desire and 52 percent more likely to report dyspareunia (painful sexual intercourse). One third reported reduced sexual feelings.[76][77]

# Distribution

## Household surveys

The prevalence of FGM is defined as the percentage of the 15–49 age group that has exerienced it.[81] These figures are based on nationally representative household surveys known as Demographic and Health Surveys (DHS), developed by Macro International and funded mainly by the United States Agency for International Development (USAID), and Multiple Indicator Cluster Surveys (MICS), conducted with financial and technical help from UNICEF.[33]

These surveys have been carried out in Africa, Asia, Latin America and elsewhere roughly every five years, since 1984 and 1995 respectively.[82] The first to ask about FGM was the 1989–1990 DHS in northern Sudan. The first publication to estimate FGM prevalence based on DHS data (in seven countries) was by Dara Carr of Macro International in 1997.[83]



FGM in Africa, Iraqi Kurdistan and Yemen, as of 2015.[78] (See map of

## Prevalence

*Further information: Prevalence of female genital mutilation by country*

FGM is found mostly in what Gerry Mackie called an "intriguingly contiguous" zone in Africa—east to west from Somalia to Senegal, and north to south from Egypt to Tanzania.[84] Nationally representative figures are available for 27 countries in Africa, as well as Indonesia, Iraqi Kurdistan and Yemen. Over 200 million women and girls are thought to be living with FGM in those 30 countries.[3][79]

The highest concentrations among the 15–49 age group are in Somalia (98 percent), Guinea (97 percent), Djibouti (93 percent), Egypt (91 percent) and Sierra Leone (90 percent).[85] As of 2013, 27.2 million women had undergone FGM in Egypt, 23.8 million in Ethiopia, and 19.9 million in Nigeria.[86] There is also a high concentration in Indonesia, where Type Ia (removal of the clitoral hood) and symbolic nicking (Type IV) are practised; the prevalence rate for the 0–11 group is 49 percent (13.4 million).[3][79]:2

Smaller studies or anecdotal reports suggest that FGM is also practised in Colombia, the Congo, Malaysia, Oman, Peru, Saudi Arabia, Sri Lanka, and the United Arab Emirates, as well as among the Bedouin in Israel; in Rahmah, Jordan; and among the Dawoodi Bohra in India.[3][87][88] It is also found within immigrant communities in Australasia, Europe, North America and Scandinavia.[89]

## Downward trend

Prevalence figures for the 15–19 age group and younger show a downward trend.[n] For example, Burkina Faso fell from 89 percent (1980) to 58 percent (2010); Egypt from 97 percent (1985) to 70 percent (2015); and Kenya from 41 percent (1984) to 11 percent (2014).[92]

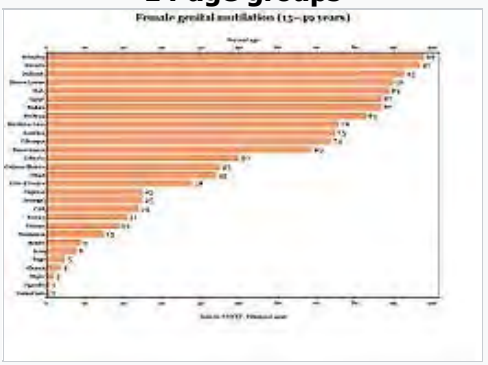
From 2010 household surveys asked women about the FGM status of all their living daughters.[93] The highest concentrations among girls aged 0–14 were in Gambia (56 percent), Mauritania (54 percent), Indonesia (49 percent for 0–11) and Guinea (46 percent).[3] The figures suggest that a girl was one third less likely in 2014 to undergo FGM than she was 30 years ago.[94] If the rate of decline continues, the number of girls cut will nevertheless rise from 3.6 million a year in 2013 to 4.1 million in 2050 because of population growth.[o]

## Rural areas, wealth, education

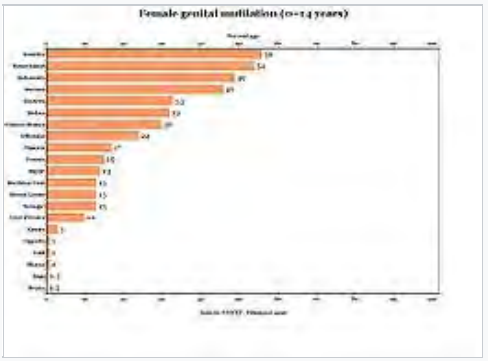
Surveys have found FGM to be more common in rural areas, less common in most countries among girls from the wealthiest homes, and (except in Sudan and Somalia) less common in girls whose mothers had access to primary or secondary/higher education. In Somalia and Sudan the situation was reversed: in Somalia the mothers' access to secondary/higher education was accompanied by a rise in prevalence of FGM in their daughters, and in Sudan access to any education was accompanied by a rise.[96]

Africa.)

**Prevalence within 15–49 and 0–14 age groups**



*(above)* Percentage aged 15–49 years who have undergone FGM in 29 key countries.



Percentage aged 0–14 who have undergone FGM in 21 key countries[m]

In Indonesia, 49 percent of girls aged 0–11 had undergone Type 1a or Type IV FGM (removal of the clitoral hood or symbolic nicking) as of 2013.[3][79][80]

## Age conducted

FGM is not invariably a rite of passage between childhood and adulthood, but is often performed on much younger children.[97] Girls are most commonly cut shortly after birth to age 15. In half the countries for which national figures were available in 2000–2010, most girls had been cut by age five.[98]

Over 80 percent (of those cut) are cut before the age of five in Nigeria, Mali, Eritrea, Ghana and Mauritania.[99] The 1997 Demographic and Health Survey in Yemen found that 76 percent of girls had been cut within two weeks of birth.[100] The percentage is reversed in Somalia, Egypt, Chad and the Central African Republic, where over 80 percent (of those cut) are cut between five and 14.[99] Just as the type of FGM is often linked to ethnicity, so is the mean age. In Kenya, for example, the Kisi cut around age 10 and the Kamba at 16.[101]

## Ethnicity

**Age and ethnicity**

Age of cutting
Highest and lowest prevalence by ethnicity

— UNICEF 2013[98]

A country's national prevalence often reflects a high sub-national prevalence among certain ethnicities, rather than a widespread practice.[102] In Iraq, for example, FGM is found mostly among the Kurds in Erbil (58 percent prevalence within age group 15–49, as of 2011), Sulaymaniyah (54 percent) and Kirkuk (20 percent), giving the country a national prevalence of eight percent.[103]

The practice is sometimes an ethnic marker, but may differ along national lines. In the northeastern regions of Ethiopia and Kenya, which share a border with Somalia, the Somali people practise FGM at around the same rate as they do in Somalia.[104] But in Guinea all Fulani women responding to a survey in 2012 said they had experienced FGM,[105] against 12 percent of the Fulani in Chad, while in Nigeria the Fulani are the only large ethnic group in the country not to practise it.[106]

## Type of FGM

Women are asked during surveys about the type of FGM they experienced:[107]

> - Was the genital area just nicked/cut without removing any flesh?
> - Was any flesh (or something) removed from the genital area?
> - Was your genital area sewn?

Most women report "cut, some flesh removed" (Types I and II).[108] According to Mackie in 2003, Type II is more common in Egypt,[109] while a 2011 study identified Type I as more common.[110] In Nigeria Type I is usually found in the south and the more severe forms in the north.[111]

Type III (infibulation) is concentrated in northeastern Africa, particularly Djibouti, Eritrea, Somalia and Sudan.[112] In surveys in 2002–2006, 30 percent of cut girls in Djibouti, 38 percent in Eritrea, and 63 percent in Somalia had experienced Type III.[113] There is also a high prevalence of infibulation among girls in Niger and Senegal,[114] and in 2013 it was estimated that in Nigeria three percent of the 0–14 age group had been infibulated.[115] The type of procedure is often linked to ethnicity. In Eritrea, for example, a survey in 2002 found that all Hedareb girls had been infibulated, compared with two percent of the Tigrinya, most of whom fell into the "cut, no flesh removed" category.[18]

# Reasons

## Support from women

**1996 Pulitzer Prize for Feature Photography**

Kenyan FGM ceremony: Photograph 7
Photograph 10
Photograph 13

— Stephanie Walsh, Newhouse News Service[116]

Dahabo Musa, a Somali woman, described infibulation in a 1988 poem as the "three feminine sorrows": the procedure itself, the wedding night when the woman is cut open, then childbirth when she is cut again.[117] Despite the evident suffering, it is women who organize all forms of FGM.[118][10] Anthropologist Rose Oldfield Hayes wrote in 1975 that educated Sudanese men who did not want their daughters to be infibulated (preferring clitoridectomy) would find the girls had been sewn up after the grandmothers arranged a visit to relatives.[14]:620, 624

Gerry Mackie has compared FGM to footbinding. Like FGM, footbinding was carried out on young girls, nearly universal where practised, tied to ideas about honour, chastity and appropriate marriage, and supported by women.[p] FGM practitioners see the procedures as marking not only ethnic boundaries but also gender difference. According to this view, FGM demasculinizes women, while male circumcision defeminizes men.[120]

Fuambai Ahmadu, an anthropologist and member of the Kono people of Sierra

Anthropologist Fuambai Ahmadu chose to undergo clitoridectomy as an adult.[121]

Leone, who in 1992 underwent clitoridectomy as an adult during a Sande society initiation, argued in 2000 that it is a male-centred assumption that the clitoris is important to female sexuality. African female symbolism revolves instead around the concept of the womb.[121] Infibulation draws on that idea of enclosure and fertility. "[G]enital cutting completes the social definition of a child's sex by eliminating external traces of androgyny," Janice Boddy wrote in 2007. "The female body is then covered, closed, and its productive blood bound within; the male body is unveiled, opened and exposed."[122]

In communities where infibulation is common, there is a preference for women's genitals to be smooth, dry and without odour, and both women and men may find the natural vulva repulsive.[123]:435–436 Men seem to enjoy the effort of penetrating an infibulation.[124] The local preference for dry sex causes women to introduce substances into the vagina to reduce lubrication, including leaves, tree bark, toothpaste and Vicks menthol rub.[125] The WHO includes this practice within Type IV FGM, because the added friction during intercourse can cause lacerations and increase the risk of infection.[126] Because of the smooth appearance of an infibulated vulva, there is also a belief that infibulation increases hygiene.[123]:437

Common reasons for FGM cited by women in surveys are social acceptance, religion, hygiene, preservation of virginity, marriageability and enhancement of male sexual pleasure.[127] In a study in northern Sudan, published in 1983, only 17.4 percent of women opposed FGM (558 out of 3,210), and most preferred excision and infibulation over clitoridectomy.[128] Attitudes are changing slowly. In Sudan in 2010, 42 percent of women who had heard of FGM said the practice should continue.[129] In several surveys since 2006, over 50 percent of women in Mali, Guinea, Sierra Leone, Somalia, Gambia and Egypt supported FGM's continuance, while elsewhere in Africa, Iraq and Yemen most said it should end, although in several countries only by a narrow margin.[130]

## Social obligation, poor access to information

Against the argument that women willingly choose FGM for their daughters, UNICEF calls the practice a "self-enforcing social convention" to which families feel they must conform to avoid uncut daughters facing social exclusion.[131]

Ellen Gruenbaum reports that, in Sudan in the 1970s, cut girls from an Arab ethnic group would mock uncut Zabarma girls with *Ya, Ghalfa!* ("Hey, unclean!"). The Zabarma girls would respond *Ya, mutmura!* (A *mutmara* was a storage pit for grain that was continually opened and closed, like an infibulated woman.) But despite throwing the insult back, the Zabarma girls would ask their mothers, "What's the matter? Don't we have razor blades like the Arabs?"[123]:432–433

Because of poor access to information, and because circumcisers downplay the causal connection, women may not associate the health consequences with the procedure. Lala Baldé, president of a women's association in Medina Cherif, a village in Senegal, told Mackie in 1998 that when girls fell ill or died, it was attributed to evil spirits. When informed of the causal relationship between FGM and ill health, Mackie wrote, the women broke down and wept. Mackie argued that surveys taken before and after this sharing of information would show very different levels of support for FGM.[132]

Molly Melching in 2007 on the 10th anniversary of the abandonment of FGM by Malicounda Bambara, Senegal

The American non-profit group Tostan, founded by Molly Melching in 1991, introduced community-empowerment programmes in several countries that focus on local democracy, literacy, and education about healthcare, giving women the tools to make their own decisions.[133] In 1997, using the Tostan programme, Malicounda Bambara in Senegal became the first village to abandon FGM.[134] By 2016, over 7,300 communities in six countries had pledged to abandon FGM and child marriage.[135]

## Religion

*Further information: Religious views on female genital mutilation*

Surveys have shown a widespread belief, particularly in Mali, Mauritania,

Keur Simbara, Senegal, abandoned FGM in 1998 after a three-year programme by Tostan.[136]

Guinea and Egypt, that FGM is a religious requirement.[137] Gruenbaum has argued that practitioners may not distinguish between religion, tradition and chastity, making it difficult to interpret the data.[138]

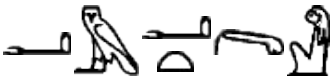
FGM's origins in northeastern Africa are pre-Islamic, but the practice became associated with Islam because of that religion's focus on female chastity and seclusion.[q] There is no mention of it in the Quran. It is praised in several *hadith* (sayings attributed to Muhammad) as noble but not required.[r][141] In 2007 the Al-Azhar Supreme Council of Islamic Research in Cairo ruled that FGM had "no basis in core Islamic law or any of its partial provisions."[142][s]

There is no mention of FGM in the Bible.[144] Christian missionaries in Africa were among the first to object to FGM,[145] but Christian communities in Africa do practise it. UNICEF reported in 2013 that, for example, 55 percent of Christian women and girls in Niger had experienced FGM, compared with two percent of their Muslim counterparts.[146] The only Jewish group known to have practised it are the Beta Israel of Ethiopia. Judaism requires male circumcision, but does not allow FGM.[147] FGM is also practised by animist groups, particularly in Guinea and Mali.[148]

# History

## Antiquity

The practice's origins are unknown, but its east-west, north-south distribution in Africa meets in Sudan. Gerry Mackie has suggested that infibulation began there with the Meroite civilization (c. 800 BCE — c. 350 CE), before the rise of Islam, to increase confidence in paternity.[151] According to historian Mary Knight, Spell 1117 (c. 1991–1786 BCE) of the Ancient Egyptian Coffin Texts may refer in hieroglyphs to an uncircumcised girl ('*m't*):



The spell was found on the sarcophagus of Sit-hedjhotep, now in the Egyptian Museum, and dates to Egypt's Middle Kingdom.[t] (Paul F. O'Rourke argues that '*m't* probably refers instead to a menstruating woman.)[152] The proposed circumcision of an Egyptian girl, Tathemis, is also mentioned on a Greek papyrus, from 163 BCE, in the British Museum:

> Sometime after this, Nephoris [Tathemis's mother] defrauded me, being anxious that it was time for Tathemis to be circumcised, as is the custom among the Egyptians. She asked that I give her 1,300 drachmae ... to clothe her ... and to provide her with a marriage dowry ... if she didn't do each of these or if she did not circumcise Tathemis in the month of Mecheir, year 18 [163 BCE], she would repay me 2,400 drachmae on the spot.[153]

**Spell 1117**

But if a man wants to know how to live, he should recite it [a magical spell] every day, after his flesh has been rubbed with the *b3d* [unknown substance] of an uncircumcised girl ['*m't*] and the flakes of skin [*šnft*] of an uncircumcised bald man.

— Inscription on Egyptian sarcophagus, c. 1991–1786 BCE[149][150]

The examination of mummies has shown no evidence of FGM. Citing the Australian pathologist Grafton Elliot Smith, who examined hundreds of mummies in the early 20th century, Knight writes that the genital area may resemble Type III because during mummification the skin of the outer labia was pulled toward the anus to cover the pudendal cleft, possibly to prevent sexual violation. It was similarly not possible to determine whether Types I

**Strabo**

This is one of the customs most zealously pursued by

or II had been performed, because soft tissues had deteriorated or been removed by the embalmers.[155]

> them [the Egyptians]: to raise every child that is born and to circumcise [*peritemnein*] the males and excise [*ektemnein*] the females ...
>
> — Strabo, *Geographica*, c. 25 BCE.[154]

The Greek geographer Strabo (c. 64 BCE – c. 23 CE) wrote about FGM after visiting Egypt around 25 BCE *(right)*.[u][v] The philosopher Philo of Alexandria (c. 20 BCE – 50 CE) also made reference to it: "the Egyptians by the custom of their country circumcise the marriageable youth and maid in the fourteenth (year) of their age, when the male begins to get seed, and the female to have a menstrual flow."[158] It is mentioned briefly in a work attributed to the Greek physician Galen (129 – c. 200 CE): "When [the clitoris] sticks out to a great extent in their young women, Egyptians consider it appropriate to cut it out."[w]

Another Greek physician, Aëtius of Amida (mid-5th to mid-6th century CE), offered more detail in book 16 of his *Sixteen Books on Medicine*, citing the physician Philomenes. The procedure was performed in case the clitoris, or *nymphê*, grew too large or triggered sexual desire when rubbing against clothing. "On this account, it seemed proper to the Egyptians to remove it before it became greatly enlarged", Aëtius wrote, "especially at that time when the girls were about to be married":

> The surgery is performed in this way: Have the girl sit on a chair while a muscled young man standing behind her places his arms below the girl's thighs. Have him separate and steady her legs and whole body. Standing in front and taking hold of the clitoris with a broad-mouthed forceps in his left hand, the surgeon stretches it outward, while with the right hand, he cuts it off at the point next to the pincers of the forceps.
>
> It is proper to let a length remain from that cut off, about the size of the membrane that's between the nostrils, so as to take away the excess material only; as I have said, the part to be removed is at that point just above the pincers of the forceps. Because the clitoris is a skinlike structure and stretches out excessively, do not cut off too much, as a urinary fistula may result from cutting such large growths too deeply.[x]

The genital area was then cleaned with a sponge, frankincense powder and wine or cold water, and wrapped in linen bandages dipped in vinegar, until the seventh day when calamine, rose petals, date pits or a "genital powder made from baked clay" might be applied.[161]

Whatever the practice's origins, infibulation became linked to slavery. Mackie cites the Portuguese missionary João dos Santos, who in 1609 wrote of a group inland from Mogadishu who had a "custome to sew up their Females, especially their slaves being young to make them unable for conception, which makes these slaves sell dearer, both for their chastitie, and for better confidence which their Masters put in them." The English explorer William Browne wrote in 1799 that the Egyptians practised excision, and that slaves in that country were infibulated to prevent pregnancy. Thus, Mackie argues, a "practice associated with shameful female slavery came to stand for honor."[162]

## Europe and the United States

Gynaecologists in 19th-century Europe and the United States removed the clitoris to treat insanity and masturbation.[164] British doctor Robert Thomas suggested clitoridectomy as a cure for nymphomania in 1813.[165][166] The first reported clitoridectomy in the West, described in *The Lancet* in 1825, was performed in 1822 in Berlin by Karl Ferdinand von Graefe on a 15-year-old girl who was masturbating excessively.[167][168]

Isaac Baker Brown "set to work

Isaac Baker Brown, an English gynaecologist, president of the Medical Society of London, and co-founder in 1845 of St. Mary's Hospital there, believed that masturbation, or "unnatural irritation" of the clitoris, caused hysteria, spinal irritation, fits, idiocy, mania and death.[168][169] He therefore "set to work to remove the clitoris whenever he had the opportunity of doing so", according to his obituary in the *Medical Times and Gazette* in 1873.[170] Brown performed several clitoridectomies between 1859 and 1866. When he published his views in *On the Curability of Certain Forms of Insanity, Epilepsy, Catalepsy, and Hysteria in*

*Females* (1866), doctors in London accused him of quackery and expelled him from the Obstetrical Society.[171][169][172]

> to remove the clitoris whenever he had the opportunity of doing so."[163]

In the United States J. Marion Sims followed Brown's work, and in 1862 slit the neck of a woman's uterus and amputated her clitoris, "for the relief of the nervous or hysterical condition as recommended by Baker Brown", after the patient complained of menstrual pain, convulsions and bladder problems.[173] Later that century A. J. Bloch, a surgeon in New Orleans, removed the clitoris of a two-year-old girl who was reportedly masturbating.[174] According to a 1985 paper in the *Obstetrical & Gynecological Survey*, clitoridectomy was performed in the US into the 1960s to treat hysteria, erotomania and lesbianism.[175]

# Opposition

## Colonial opposition in Kenya

*Further information: Female circumcision controversy (Kenya, 1929–1932)*

Protestant missionaries in British East Africa (present-day Kenya) began campaigning against FGM in the early 20th century, when Dr. John Arthur joined the Church of Scotland Mission (CSM) in Kikuyu. An important ethnic marker, the practice was known by the Kikuyu, the country's main ethnic group, as *irua* for both girls and boys. It involved excision (Type II) for girls and removal of the foreskin for boys. Unexcised Kikuyu women (*irugu*) were outcasts.[177]

Jomo Kenyatta, general secretary of the Kikuyu Central Association and Kenya's first prime minister from 1963, wrote in 1938 that, for the Kikuyu, the institution of FGM was the "*conditio sine qua non* of the whole teaching of tribal law, religion and morality." No proper Kikuyu man or woman would marry or have sexual relations with someone who was not circumcised. A woman's responsibilities toward the tribe began with her initiation. Her age and place within tribal history was traced to that day, and the group of girls with whom she was cut was named according to current events, an oral tradition that allowed the Kikuyu to track people and events going back hundreds of years.[178]

> *Muthirigu*
>
> Little knives in their sheaths
> That they may fight with the church,
> The time has come.
> Elders (of the church)
> When Kenyatta comes
> You will be given women's clothes
> And you will have to cook him his food.
>
> — from the *Muthirigu* (1929), Kikuyu dance-songs against church opposition to FGM[176]

Missionary Hulda Stumpf *(bottom left)* was murdered in Kikuyu in 1930 after opposing FGM.

Beginning with the CSM mission in 1925, several missionary churches declared that FGM was prohibited for African Christians. The CSM announced that Africans practising it would be excommunicated, which resulted in hundreds leaving or being expelled.[179] The stand-off turned FGM into a focal point of the Kenyan independence movement; the 1929–1931 period is known in the country's historiography as the female circumcision controversy.[180]

In 1929 the Kenya Missionary Council began referring to FGM as the "sexual mutilation of women", rather than circumcision, and a person's stance toward the practice became a test of loyalty, either to the Christian churches or to the Kikuyu Central Association.[181] Hulda Stumpf, an American missionary with the Africa Inland Mission who opposed FGM in the girls' school she helped to run, was murdered in 1930. Edward Grigg, the governor of Kenya, told the British Colonial Office that the killer, who was never identified, had tried to circumcise her.[182]

In 1956 the council of male elders (the *Njuri Nchecke*) in Meru announced a ban on FGM. Over the next three years, thousands of girls cut each other's genitals with razor blades as a symbol of defiance. The movement came to be known as *Ngaitana* ("I will circumcise myself"), because to avoid naming their friends the girls said they had cut themselves. Historian Lynn Thomas described the episode as significant in the history of FGM because it made clear that its victims were also its perpetrators.[183]

## Growth of opposition

The first known non-colonial campaign against FGM began in Egypt in the 1920s, when the Egyptian Doctors' Society called for a ban.[184] There was a parallel campaign in Sudan, run by religious leaders and British women. Infibulation was banned there in 1946, but the law was unpopular and barely enforced.[185][y] The Egyptian government banned infibulation in state-run hospitals in 1959, but allowed partial clitoridectomy if parents requested it.[187] (Egypt banned FGM entirely in 2007.)

In 1959 the UN asked the WHO to investigate FGM, but the latter responded that it was not a medical matter.[188] Feminists took up the issue throughout the 1970s.[189] The Egyptian physician and feminist Nawal El Saadawi criticized FGM in her book *Women and Sex* (1972); the book was banned in Egypt and El Saadawi lost her job as director general of public health.[190] She followed up with a chapter, "The Circumcision of Girls," in *The Hidden Face of Eve: Women in the Arab World* (1980), which described her own clitoridectomy when she was six years old:

Nawal El Saadawi criticized FGM in 1972, one of the first African feminists to do so publicly.

> I did not know what they had cut off from my body, and I did not try to find out. I just wept, and called out to my mother for help. But the worst shock of all was when I looked around and found her standing by my side. Yes, it was her, I could not be mistaken, in flesh and blood, right in the midst of these strangers, talking to them and smiling at them, as though they had not participated in slaughtering her daughter just a few moments ago.[191]

In 1975 Rose Oldfield Hayes, an American social scientist, became the first female academic to publish a detailed account of FGM, aided by her ability to discuss it directly with women in Sudan. Her article in *American Ethnologist* called it "female genital mutilation," rather than female circumcision, and brought it to wider academic attention.[14]:21

In 1977 Edna Adan Ismail, who worked at the time for the Somalia Ministry of Health, raised the health consequences of FGM with the Somali Women's Democratic Organization.[192] Two years later Fran Hosken, an Austria-American feminist, published *The Hosken Report: Genital and Sexual Mutilation of Females* (1979), the first to offer global figures. She estimated that 110,529,000 women in 20 African countries had experienced FGM.[193] The figures were speculative but consistent with later surveys.[194] Describing FGM as

## FGM opposition

### 1920s–1980s timeline

**1920s–1930s**

**1920s**: Egyptian Doctors' Society call for ban.[A 1]

**1929**: Marion Scott Stevenson, Church of Scotland missionary in Kenya, calls FGM "sexual mutilation of women." National Council of Churches of Kenya follow suit.[A 2]

Scottish missionaries require Kikuyu Christians to take an oath against FGM; most leave to form their own churches.

**1930, January**: American missionary Hulda Stumpf murdered in Kenya during protests about FGM.[A 3]

**1930s**: Religious leaders and British women lead campaign against FGM in Sudan.[A 4]

**1935**: Egyptian writer Salama Moussa writes about FGM in his *Ma Heia al Nahda* ("What is Renaissance?").[A 5]

**1940s–1960s**

**1946**: Sudan, under Anglo-Egyptian control, bans infibulation; the law is barely enforced.[A 6]

**1951, May**: Egyptian medical journal, *Al Doktor*, issues booklet on dangers of FGM.[A 7]

**1957–1958**: Egyptian journalist Amina al Sa'eed and *Hawwaa* magazine editor Rabee' Gheith publish articles on FGM.[A 7]

**Late 1950s**: Sudanese Women's Union campaigns against FGM in their

a "training ground for male violence," Hosken accused female practitioners of "participating in the destruction of their own kind."[15]:5 The language caused a rift between Western and African feminists; African women boycotted a session featuring Hosken during the UN's Mid-Decade Conference on Women in Copenhagen in July 1980.[195]

In 1979 the WHO held a seminar, "Traditional Practices Affecting the Health of Women and Children," in Khartoum, Sudan, and in 1981, also in Khartoum, 150 academics and activists signed a pledge to fight FGM after a workshop held by the Babiker Badri Scientific Association for Women's Studies (BBSAWS), "Female Circumcision Mutilates and Endangers Women – Combat it!" Another BBSAWS workshop in 1984 invited the international community to write a joint statement for the United Nations.[196] It recommended that the "goal of all African women" should be the eradication of FGM and that, to sever the link between FGM and religion, clitoridectomy should no longer be referred to as *sunna*.[197]

The Inter-African Committee on Traditional Practices Affecting the Health of Women and Children, founded in 1984 in Dakar, Senegal, called for an end to the practice, as did the UN's World Conference on Human Rights in Vienna in 1993. The conference listed FGM as a form of violence against women, marking it as a human-rights violation, rather than a medical issue.[198] Throughout the 1990s and 2000s governments in Africa and the Middle East passed legislation banning or restricting FGM. In 2003 the African Union ratified the Maputo Protocol on the rights of women, which supported the elimination of FGM.[199] By 2015 laws restricting FGM had been

magazine, *Sawt el Maraa*.[A 8]

**1959**: Egypt bans infibulation in state-run hospitals; allows partial clitoridectomy if parents request it.[A 9]

UN asks the WHO to investigate FGM; WHO responds that it is not a medical issue.[A 10]

**1960s**: Central African Republic, Ghana and Guinea, after gaining independence, pass laws restricting FGM.

**1969**: Guinean gynaecologist Aja Tounkara Diallo Fatimata begins 28-year practice of performing fake clitoridectomies to satisfy families.[A 11]

**1970s**

**1970**: Egyptian physician Nawal El Saadawi criticizes FGM in *Al-Mar'a wa Al-Jins* (*Women and Sex*).[A 12]

**1972**: Saadawi's *The Naked Face of Women* describes her own circumcision.[A 13]

**1975**: United Nations International Women's Year.

American social scientist Rose Oldfield Hayes calls it "female genital mutilation" in paper on FGM in Sudan.[A 14]

French writer Benoîte Groult calls FGM "the best kept secret in the world" in her *Ainsi soit-elle*.[A 15]

Austrian-American feminist Fran Hosken begins writing about FGM in *Women's International Network News* (*WIN News*).

Benoite Groult was influential in the European campaign against FGM.

**1976–1985**: UN's Decade for Women.

**1976**: British journalist Jill Tweedie calls FGM "ritual mutilation of the female genitalia."[A 16]

**1977, March**: Edna Adan Ismail of Somalia's Ministry of Health speaks against FGM to Somali Democratic Women's Organization.[A 17]

**1978**: American feminist Mary Daly criticizes FGM in *Gyn/Ecology*.[A 18]

Senegalese writer Awa Thiam writes about FGM in *La Parole aux Négresses* (*Speak out Black Sisters*, 1986).[A 19]

**1979**: Fran Hosken publishes *The Hosken Report: Genital and Sexual Mutilation of Females*, the first to estimate global figures.[A 20]

UN conference, Lusaka, Zambia, calls on women's groups to mobilize against FGM.[A 21]

February: WHO holds seminar, "Traditional Practices Affecting the Health of Women and Children," Khartoum, Sudan.[A 22]

October: Cairo Family Planning Association holds seminar, "Bodily Mutilation of Females."[A 23]

December: UN General Assembly adopts Convention on the Elimination of All Forms of Discrimination against Women.[A 24]

**1980s**

**1980**: British writer Scilla McLean writes report on FGM for Minority Rights Group in France.[A 25]

March: Robin Morgan and Gloria Steinem call it "female genital mutilation" in *Ms* magazine.[A 26]

passed in at least 23 of the 27 African countries in which it is concentrated, although several fell short of a ban.[z]

## United Nations

In December 1993 the United Nations General Assembly included FGM in resolution 48/104, the Declaration on the Elimination of Violence Against Women, and from 2003 sponsored International Day of Zero Tolerance to Female Genital Mutilation, held every 6 February.[204][205]

UNICEF began in 2003 to promote an evidence-based social norms approach to the evaluation of intervention, using ideas from game theory about how communities reach decisions about FGM, and building on the work of Gerry Mackie on the ending of footbinding in China.[206] In 2005 the UNICEF Innocenti Research Centre in Florence published its first report on FGM.[207]

UNFPA and UNICEF launched a joint programme in Africa in 2007 to reduce FGM by 40 percent within the 0–15 age group and eliminate it from at least one country by 2012, goals that were not met.[208][aa] In 2008 several UN bodies recognized FGM as a human-rights violation,[209] and in 2012 the General Assembly passed resolution 67/146, "Intensifying global efforts for the elimination of female genital mutilations."[210]

## Non-practising countries

*Further information: Prevalence of female genital mutilation by country*

Immigration spread the practice to Australia, New Zealand,

Gloria Steinem

July: African women boycott session featuring Fran Hosken at UN's Mid-Decade Conference on Women, Copenhagen.[A 27]

**1981**: French Association of Anthropologists publishes statement that "a certain feminism resuscitates (today) the moralistic arrogance of yesterday's colonialism."[A 28]

**1981**: Lillian Passmore Sanderson publishes *Against the Mutilation of Women*.

**1982**: Sudanese physician Asma El Dareer publishes study of FGM in Sudan, *Woman, Why Do You Weep? Circumcision and its Consequences*.[A 29]

Somali writer Raqiya Haji Dualeh Abdalla publishes *Sisters in Affliction: Circumcision and Infibulation of Women in Africa*.[A 30]

**1983**: Efua Dorkenoo founds FORWARD in London.[A 31]

**1984**: Inter-African Committee on Traditional Practices founded in Dakar, Senegal, calls for an end to the practice.[A 32]

Europe, North America and Scandinavia, all of which outlawed it entirely or restricted it to consenting adults.[211] Sweden outlawed it in 1982, the first Western country to do so.[212]:611 Several former colonial powers, including Belgium, Britain, France and the Netherlands, introduced new laws or made clear that it was covered by existing legislation.[213] As of 2013 legislation banning FGM had been passed in 33 countries outside Africa and the Middle East.[200]

## North America

*Further information: Female genital mutilation in the United States*

Canada recognized FGM as a form of persecution in July 1994, when it granted refugee status to Khadra Hassan Farah, who had fled Somalia to avoid her daughter being cut.[214] In 1997 section 268 of its Criminal Code was amended to ban FGM, except where "the person is at least eighteen years of age and there is no resulting bodily harm."[215][200] As of May 2016 there had been no prosecutions.[216]

In the United States an estimated 513,000 women and girls had experienced FGM or were at risk as of 2012.[217][218][ab] A Nigerian woman successfully contested deportation in March 1994 on the grounds that her daughters might be cut,[220] and in 1996 Fauziya Kasinga from Togo became the first to be granted asylum to escape FGM.[221] In 1996 the Federal Prohibition of Female Genital Mutilation Act made it illegal to perform FGM on minors for non-medical reasons, and in 2013 the Transport for Female Genital Mutilation Act prohibited transporting a minor out of the country for the purpose of FGM. In addition, 24 states have legislation banning FGM.[217]:2 The American Academy of Pediatrics opposes all forms of the practice.[ac] The first FGM conviction in the US was in 2006, when Khalid Adem, who had emigrated from Ethiopia, was sentenced to ten years after severing his two-year-old daughter's clitoris with a pair of scissors.[224][ad]

Mary Karooro Okurut, Uganda's Minister of Gender, Labour and Social Development, speaking in 2014 to the first Girl Summit in London, aimed at ending FGM and child marriage.[203]

## Europe

*Further information: Female genital mutilation in the United Kingdom*

According to the European Parliament, 500,000 women in Europe had undergone FGM as of March 2009.[227] France is known for its tough stance against FGM.[228] Up to 30,000 women there were thought to have experienced it as of 1995. According to Colette Gallard, a family-planning counsellor, when FGM was first encountered in France, the reaction was that Westerners ought not to intervene. It took the deaths of two girls in 1982, one of them three months old, for that attitude to change.[229] In 1991 a French court ruled that the Convention Relating to the Status of Refugees offered protection to FGM victims; the decision followed an asylum application from Aminata Diop, who fled an FGM procedure in Mali.[230]

The practice is outlawed by a provision of France's penal code dealing with violence [231]

Efua Dorkenoo (1949–2014) received an OBE in 1994 for her work against FGM in the UK.[226]

against children. All children under six who were born in France undergo medical examinations that include inspection of the genitals, and doctors are obliged to report FGM.[228] The first civil suit was in 1982 and the first criminal prosecution in 1993.[232] In 1999 a woman was given an eight-year sentence for having performed FGM on 48 girls.[233] By 2014 over 100 parents and two practitioners had been prosecuted in over 40 criminal cases.[231][228]

Around 137,000 women and girls living in England and Wales were born in countries where FGM is practised (as of 2011).[234][235] Performing FGM on children or adults was outlawed under the Prohibition of Female Circumcision Act 1985.[236] This was replaced by the Female Genital Mutilation Act 2003 and Prohibition of Female Genital Mutilation (Scotland) Act 2005, which added a prohibition on arranging FGM outside the country for British citizens or permanent residents.[237][ae] The United Nations Committee on the Elimination of Discrimination against Women asked the government in 2013 to "ensure the full implementation of its legislation on FGM."[239] The first charges were brought the following year against a physician and another man, after the physician stitched an infibulated woman after opening her for childbirth. Both men were acquitted in 2015.[240]

## Criticism of opposition

### Tolerance versus human rights

Anthropologist Eric Silverman wrote in 2004 that FGM had "emerged as one of the central moral topics of contemporary anthropology." Anthropologists have accused FGM eradicationists of cultural colonialism. In turn, anthropologists have been criticized for their moral relativism and failure to defend the idea of universal human rights.[241]

Obioma Nnaemeka: "Westerners are quick to appropriate the power to name ..."[242]

According to the opposition's critics, the biological reductionism of the opposition to FGM, and the failure to appreciate FGM's cultural context, serves to "other" practitioners and undermines their agency—in particular when parents are referred to as "mutilators".[243] Africans who object to the tone of the opposition to FGM risk appearing to defend the practice.[244] Feminist theorist Obioma Nnaemeka—herself strongly opposed to FGM ("If one is circumcised, it is one too many")—argues that renaming it *female genital mutilation* introduced "a subtext of barbaric African and Muslim cultures and the West's relevance (even indispensability) in purging [it]".

According to Ugandan law professor Sylvia Tamale, early Western opposition to FGM stemmed from a Judeo-Christian judgment that African sexual and family practices—including dry sex, polygyny, bride price and levirate marriage—were primitive and required correction.[245] African feminists "do not condone the negative aspects of the practice", writes Tamale, but "take strong exception to the imperialist, racist and dehumanising infantilization of African women".[245]

The debate has highlighted a tension between anthropology and feminism, with the former's focus on tolerance and the latter's on equal rights for all women. According to the anthropologist Christine Walley, a common trope within the anti-FGM literature has been to present African women as victims of false consciousness participating in their own oppression, a position promoted by feminists in the 1970s and 1980s, including Fran Hosken, Mary Daly and Hanny Lightfoot-Klein.[246] It prompted the French Association of Anthropologists to issue a statement in 1981, at the height of the early debates, that "a certain feminism resuscitates

(today) the moralistic arrogance of yesterday's colonialism."[247]

Commentators highlight the appropriation of women's bodies as exhibits. Historian Chima Korieh cites the publication in 1996 of the Pulitzer-prize-winning photographs (above) of a 16-year-old Kenyan girl undergoing FGM. The photographs were published by 12 American newspapers, although the girl had not given permission for the images to be taken, much less published.[248]

## Comparison with other procedures

*See also: Labiaplasty § Criticism*

Nnaemeka argues that the crucial question, broader than FGM, is why the female body is subjected to so much "abuse and indignity", including in the West.[249] Several authors have drawn a parallel between FGM and cosmetic procedures.[250]:32[251] Ronán Conroy of the Royal College of Surgeons in Ireland wrote in 2006 that cosmetic genital procedures were "driving the advance of female genital mutilation" by encouraging women to see natural variations as defects.[252] Anthropologist Fadwa El Guindi compares FGM to breast enhancement, in which the maternal function of the breast becomes secondary to men's sexual pleasure.[253] Benoîte Groult made a similar point in 1975, citing FGM and cosmetic surgery as sexist and patriarchal.[254]

Carla Obermeyer maintains that FGM may be conducive to a subject's social well-being in the same way that rhinoplasty and male circumcision are.[255] In Egypt, despite the 2007 ban, women wanting FGM for their daughters seek *amalyet tajmeel* (cosmetic surgery) to remove what is viewed as excess genital tissue for a more acceptable appearance.[256]

Martha Nussbaum argues that a key moral and legal issue with FGM is that it is mostly conducted on children using physical force.

The WHO does not cite procedures such as labiaplasty and clitoral hood reduction as examples of FGM, but its definition aims to avoid loopholes, so several elective practices fall within its categories.[257] Some of the laws banning FGM, including in Canada and the US, focus only on minors. Several countries, including Sweden and the UK, have banned it regardless of consent, and the legislation would seem to cover cosmetic procedures. Sweden, for example, has banned "[o]perations on the external female genital organs which are designed to mutilate them or produce other permanent changes in them ... regardless of whether consent to this operation has or has not been given." Gynaecologist Birgitta Essén and anthropologist Sara Johnsdotter note that it seems the law distinguishes between Western and African genitals, and deems only African women (such as those seeking reinfibulation after childbirth) unfit to make their own decisions.[250]:33[212]:613

Arguing against suggested similarities between FGM and dieting or body shaping, philosopher Martha Nussbaum writes that a key difference is that FGM is mostly conducted on children using physical force. She argues that the distinction between social pressure and physical force is morally and legally salient, comparable to the distinction between seduction and rape. She argues further that the literacy of women in practising countries is generally poorer than in developed nations, and that this reduces their ability to make informed choices.[258]

Several commentators maintain that children's rights are violated with the genital alteration of intersex children, who are born with anomalies that physicians choose to correct. Legal scholars Nancy Ehrenreich and Mark Barr write that thousands of these procedures take place every year in the United States, and say that they are medically unnecessary, more extensive than FGM, and have more serious physical and mental consequences. They attribute the silence of anti-FGM campaigners about intersex procedures to white privilege and a refusal to acknowledge that "similar unnecessary and harmful genital cutting occurs in their own backyards."[259]

# Notes

a. ^ UNICEF 2013: "There is a social obligation to conform to the practice and a widespread belief that if they [families] do not, they are likely to pay a price that could include social exclusion, criticism, ridicule, stigma or the inability to find their daughters suitable marriage partners."[7]

Nahid F. Toubia, Eiman Hussein Sharief, 2003: "One of the great achievements of the past decade in the field of FGM is the shift in emphasis from the concern over the harmful interpreted with a high degree of caution ..."[90]

An additional complication in judging prevalence among girls is that, in countries running campaigns against FGM, women might not report that their daughters have been cut.[91]

o. ^ UNICEF 2014: "If there is no reduction in the practice between now and 2050, the number of girls cut each year will grow from 3.6 million in 2013 to 6.6 million in 2050.

physical effects it causes to understanding this act as a social phenomenon resulting from a gender definition of women's roles, in particular their sexual and reproductive roles. This shift in emphasis has helped redefine the issues from a clinical disease model (hence the terminology of eradication prevalent in the literature) to a problem resulting from the use of culture to protect social dominance over women's bodies by the patriarchal hierarchy. Understanding the operative mechanisms of patriarchal dominance must also include understanding how women, particularly older married women, are important keepers of that social hegemony."[8]

b. ^ For example, "a young woman must 'have her bath' before she has a baby".[20]

c. ^ UNICEF 2005: "The large majority of girls and women are cut by a traditional practitioner, a category which includes local specialists (cutters or *exciseuses*), traditional birth attendants and, generally, older members of the community, usually women. This is true for over 80 percent of the girls who undergo the practice in Benin, Burkina Faso, Côte d'Ivoire, Eritrea, Ethiopia, Guinea, Mali, Niger, Tanzania and Yemen. In most countries, medical personnel, including doctors, nurses and certified midwives, are not widely involved in the practice."[28]

d. ^ A 2003 study in Ghana found that in 1995 four percent said they had not undergone FGM, but in 2000 said they had, while 11 percent switched in the other direction.[34] In Tanzania in 2005, 66 percent reported FGM, but a medical exam found that 73 percent had undergone it.[35] In Sudan in 2006, a significant percentage of infibulated women and girls reported a less severe type.[36]

e. ^ UNICEF 2013: "These categories do not fully match the WHO typology. *Cut, no flesh removed* describes a practice known as nicking or pricking, which currently is categorized as Type IV. *Cut, some flesh removed* corresponds to Type I (clitoridectomy) and Type II (excision) combined. And *sewn closed* corresponds to Type III, infibulation."[18]

f. ^ WHO, 1995: "[There is a] common tendency to describe Type I as removal of the prepuce, whereas this has not been documented as a traditional form of female genital mutilation. However, in some countries, medicalized female genital mutilation can include removal of the prepuce only (Type Ia) (Thabet and Thabet, 2003), but this form appears to be relatively rare (Satti et al, 2006). Almost all known forms of female genital mutilation that remove tissue from the clitoris also cut all or part of the clitoral glans itself."[42]

g. ^ Susan Izett and Nahid Toubia, 1998: "[T]he clitoris is held between the thumb and index finger, pulled out and amputated with one stroke of a sharp object."[44]

h. ^ WHO 2014: "Narrowing of the vaginal orifice with creation of a covering seal by cutting and appositioning the labia minora and/or the labia majora, with or without excision of the clitoris (infibulation).

"Type IIIa, removal and apposition of the labia minora; Type IIIb, removal and apposition of the labia majora."[1]

i. ^ USAID 2008: "Infibulation is practiced largely in countries located in northeastern Africa: Djibouti, Eritrea, Ethiopia, Somalia, and Sudan. ... Sudan alone accounts for about 3.5 million of the women. ... [T]he estimate of the total number of women infibulated in [Djibouti, Somalia, Eritrea, northern Sudan, Ethiopia, Guinea, Mali, Burkina Faso, Senegal, Chad, Nigeria, Cameroon and Tanzania, for

But if the rate of progress achieved over the last 30 years is maintained, the number of girls affected annually will go from 3.6 million today to 4.1 million in 2050.

"In either scenario, the total number of girls and women cut will continue to increase due to population growth. If nothing is done, the number of girls and women affected will grow from 133 million today to 325 million in 2050. However, if the progress made so far is sustained, the number will grow from 133 million to 196 million in 2050, and almost 130 million girls will be spared this grave assault to their human rights."[95]

p. ^ Gerry Mackie, 1996: "Footbinding and infibulation correspond as follows. Both customs are nearly universal where practiced; they are persistent and are practiced even by those who oppose them. Both control sexual access to females and ensure female chastity and fidelity. Both are necessary for proper marriage and family honor. Both are believed to be sanctioned by tradition. Both are said to be ethnic markers, and distinct ethnic minorities may lack the practices. Both seem to have a past of contagious diffusion. Both are exaggerated over time and both increase with status. Both are supported and transmitted by women, are performed on girls about six to eight years old, and are generally not initiation rites. Both are believed to promote health and fertility. Both are defined as aesthetically pleasing compared with the natural alternative. Both are said to properly exaggerate the complementarity of the sexes, and both are claimed to make intercourse more pleasurable for the male."[119]

q. ^ Gerry Mackie, 1996: "FGM is pre-Islamic but was exaggerated by its intersection with the Islamic modesty code of family honor, female purity, virginity, chastity, fidelity, and seclusion."[139]

r. ^ Gerry Mackie, 1996: "The Koran is silent on FGM, but several *hadith* (sayings attributed to Mohammed) recommend attenuating the practice for the woman's sake, praise it as noble but not commanded, or advise that female converts refrain from mutilation because even if pleasing to the husband it is painful to the wife."[140]

s. ^ Maggie Michael, Associated Press, 2007: "[Egypt's] supreme religious authorities stressed that Islam is against female circumcision. It's prohibited, prohibited, prohibited," Grand Mufti Ali Gomaa said on the privately owned al-Mahwar network."[143]

t. ^ Knight adds that Egyptologists are uncomfortable with the translation to *uncircumcised*, because there is no information about what constituted the circumcised state.[149]

u. ^ Strabo, *Geographica*, c. 25 BCE: "One of the customs most zealously observed among the Aegyptians is this, that they rear every child that is born, and circumcise [περιτέμνειν, *peritemnein*] the males, and excise [*ektemnein*] the females, as is also customary among the Jews, who are also Aegyptians in origin, as I have already stated in my account of them."[156]

Book XVI, chapter 4, 16.4.9: "And then to the Harbour of Antiphilus, and, above this, to the Creophagi [meat-eaters], of whom the males have their sexual glands mutilated [*kolobos*] and the women are excised [*ektemnein*] in the Jewish fashion."

v. ^ Knight 2001 writes that there is one extant reference from antiquity, from Xanthus of Lydia in the fifth century BCE, that may allude to FGM outside Egypt. Xanthus

women 15–49 years old] comes to 8,245,449, or just over eight million women."[45]

j. ^ Jasmine Abdulcadira, *Swiss Medical Weekly*, 2011:"In the case of infibulation, the urethral opening and part of the vaginal opening are covered by the scar. In a virgin infibulated woman the small opening left for the menstrual fluid and the urine is not wider than 2–3 mm; in sexually active women and after the delivery the vaginal opening is wider but the urethral orifice is often still covered by the scar."[6]

k. ^ Elizabeth Kelly, Paula J. Adams Hillard, *Current Opinion in Obstetrics & Gynecology*, 2005: "Women commonly undergo reinfibulation after a vaginal delivery. In addition to reinfibulation, many women in Sudan undergo a second type of re-suturing called El-Adel, which is performed to recreate the size of the vaginal orifice to be similar to the size created at the time of primary infibulation. Two small cuts are made around the vaginal orifice to expose new tissues to suture, and then sutures are placed to tighten the vaginal orifice and perineum. This procedure, also called re-circumcision, is primarily performed after vaginal delivery, but can also be performed before marriage, after cesarean section, after divorce, and sometimes even in elderly women as a preparation before death."[29]:491

l. ^ WHO 2005: "In some areas (e.g. parts of Congo and mainland Tanzania), FGM entails the pulling of the labia minora and/or clitoris over a period of about 2 to 3 weeks. The procedure is initiated by an old woman designated for this task, who puts sticks of a special type in place to hold the stretched genital parts so that they do not revert back to their original size. The girl is instructed to pull her genitalia every day, to stretch them further, and to put additional sticks in to hold the stretched parts from time to time. This pulling procedure is repeated daily for a period of about two weeks, and usually no more than four sticks are used to hold the stretched parts, as further pulling and stretching would make the genital parts unacceptably long."[59]:31

m. ^ In this table and above, these are the countries for which nationally representative figures are available (UNICEF 2016).

n. ^ UNICEF 2013: "The percentage of girls and women of reproductive age (15 to 49) who have experienced any form of FGM/C is the first indicator used to show how widespread the practice is in a particular country ... A second indicator of national prevalence measures the extent of cutting among daughters aged 0 to 14, as reported by their mothers. Prevalence data for girls reflect their current – not final – FGM/C status, since many of them may not have reached the customary age for cutting at the time of the survey. They are reported as being uncut but are still at risk of undergoing the procedure. Statistics for girls under age 15 therefore need to be

wrote, in a history of Lydia: "The Lydians arrived at such a state of delicacy that they were even the first to 'castrate' their women." Knight argues that the "castration", which is not described, may have kept women youthful, in the sense of allowing the Lydian king to have intercourse with them without pregnancy. Knight concludes that it may have been a reference to sterilization, not FGM.[157]

w. ^ Knight adds that the attribution to Galen is suspect.[159]

x. ^ A paragraph break has been added for ease of reading.[160]

y. ^ FGM is still practised in Sudan. Some states banned it in 2008–2009, but as of 2013, there was no national legislation.[186]

z. ^ For example, UNICEF 2013 lists Mauritania as having passed legislation against FGM, but (as of that year) it was banned only from being conducted in government facilities or by medical personnel.[200]

The following are countries in which FGM is common and in which restrictions are in place. An asterisk indicates a ban:

Benin (2003), Burkina Faso (1996*), Central African Republic (1966, amended 1996), Chad (2003), Côte d'Ivoire (1998), Djibouti (1995, amended 2009*), Egypt (2008*), Eritrea (2007*), Ethiopia (2004*), Ghana (1994, amended 2007), Guinea (1965, amended 2000*), Guinea-Bissau (2011*), Iraq (2011*), Kenya (2001, amended 2011*), Mauritania (2005), Niger (2003), Nigeria (2015*), Senegal (1999*), Somalia (2012*), Sudan, some states (2008–2009), Tanzania (1998), Togo (1998), Uganda (2010*), Yemen (2001*).[201][202]:12

aa. ^ Fifteen countries joined the programme: Djibouti, Egypt, Ethiopia, Guinea, Guinea-Bissau, Kenya, Senegal and Sudan in 2008; Burkina Faso, Gambia, Uganda and Somalia in 2009; and Eritrea, Mali and Mauritania in 2011.[208]

ab. ^ The Centers for Disease Control's previous estimate was 168,000 as of 1990.[219]

ac. ^ In 2010 the American Academy of Pediatrics suggested that "pricking or incising the clitoral skin" was a harmless procedure that might satisfy parents, but it withdrew the statement after complaints.[222][223]

ad. ^ In 2014 President Barack Obama spoke about FGM for the first time, calling it "a tradition that's barbaric and should be eliminated."[225]

ae. ^ Female Genital Mutilation Act 2003: "A person is guilty of an offence if he excises, infibulates or otherwise mutilates the whole or any part of a girl's labia majora, labia minora or clitoris," unless "necessary for her physical or mental health." Although the legislation refers to girls, it applies to women too.[238]

# Fetal alcohol spectrum disorder

From Wikipedia, the free encyclopedia

*"FASD" redirects here. For other uses, see FASD (disambiguation).*

**Fetal alcohol spectrum disorders** (**FASDs**) are a group of conditions that can occur in a person whose mother drank alcohol during pregnancy.[1] Problems may include an abnormal appearance, short height, low body weight, small head size, poor coordination, low intelligence, behavior problems, and problems with hearing or seeing.[1][2] Those affected are more likely to have trouble in school, legal problems, participate in high-risk behaviors, and have trouble with alcohol or other drugs.[3] The most severe form of the condition is known as **fetal alcohol syndrome** (**FAS**).[1] Other types include partial fetal alcohol syndrome (pFAS), alcohol-related neurodevelopmental disorder (ARND) and alcohol-related birth defects (ARBD).[1][4]

Fetal alcohol spectrum disorders are caused by drinking alcohol during pregnancy.[1] Surveys from the United States have found about 10% of pregnant women have drunk alcohol in the last month, and 20% to 30% drank at some point during the pregnancy.[5] About 4.7% of North American women who are pregnant have alcoholism.[6] The risk of problems depends on the amount consumed and the frequency of consumption as well as when during pregnancy the alcohol is consumed.[5] Other risk factors include an older mother, smoking, and poor diet.[5] There is no known safe amount or safe time to drink during pregnancy.[1][7] While drinking small amounts of alcohol does not cause abnormalities in the face, it may cause behavioral issues.[6] Alcohol crosses the blood brain barrier and both directly and indirectly affects a developing baby.[8] Diagnosis is based on signs and symptoms in the person.[1]

Fetal alcohol spectrum disorders are preventable by avoiding alcohol.[9] For this reason, medical authorities recommend no alcohol during pregnancy or while trying to become pregnant.[10][11][12] While the condition is permanent, treatment can improve outcomes.[1][13] Interventions may include parent-child interaction therapy, efforts to modify child behavior, and possibly medications.[14]

FASD is estimated to affect between 2% and 5% of people in the United States and Western Europe.[15] FAS is believed to occur in between 0.2 and 9 per 1000 live births in the United States.[15] In South Africa,[4]

some populations have rates as high as 9%. The negative effects of alcohol have been described since ancient times.[4] The lifetime cost per child with FAS was $2,000,000 in 2002.[15] The term *fetal alcohol syndrome* was first used in 1973.[4]

**Contents**

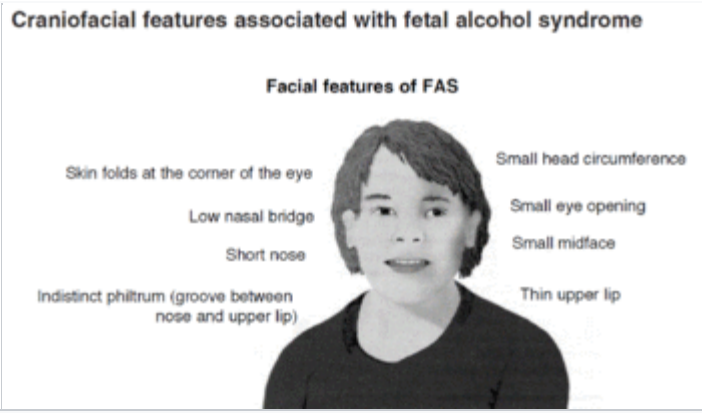
## Types [edit]

FASDs encompass a range of physical and neurodevelopmental problems that can result from prenatal alcohol exposure.[1] The most severe condition is called fetal alcohol syndrome (FAS),[1] which refers to individuals who have a specific set of birth defects and neurodevelopmental disorders characteristic of the diagnosis.[16] Partial fetal alcohol syndrome (pFAS) refers to individuals with a known, or highly suspected, history of prenatal alcohol exposure who have alcohol-related physical and neurodevelopmental deficits that don't meet the full criteria for FAS.[16] The subtypes of pFAS are alcohol-related neurodevelopmental disorder (ARND) and alcohol-related birth defects (ARBD).[16] In addition to FAS, pFAS, ARND, and ARBD, any other conditions believed to be related to prenatal alcohol exposure, such as spontaneous abortion and sudden infant death syndrome (SIDS), are also considered to be on the spectrum of related disorders.[16]

## Signs and symptoms [edit]

The key of FASD can vary between individuals

exposed to alcohol during pregnancy. While consensus exists for the definition and diagnosis of FAS, minor variations among the systems lead to differences in definitions and diagnostic cut-off criteria for other diagnoses across the FASD continuum. The central nervous system damage criteria particularly lack clear consensus. A working knowledge of the key features is helpful in understanding FASD diagnoses and conditions, and each is reviewed with attention to similarities and differences across the four diagnostic systems. More than 400 problems; however, can occur with FASD.[17]



Facial characteristics of a child with FAS

## Growth [edit]

In terms of FASD, growth deficiency is defined as significantly below average height, weight or both due to prenatal alcohol exposure, and can be assessed at any point in the lifespan. Growth measurements must be adjusted for parental height, gestational age (for a premature infant), and other postnatal insults (e.g., poor nutrition), although birth height and weight are the preferred measurements.[18] Deficiencies are documented when height or weight falls at or below the 10th percentile of standardized growth charts appropriate to the population.[19]

Criteria for FASD are least specific in the IOM diagnostic system ("low birth weight..., decelerating weight not due to nutrition..., [or] disproportional low weight to height" p. 4 of executive summary),[11] while the CDC and Canadian guidelines use the 10th percentile as a cut-off to determine growth deficiency.[2][20] The "4-Digit Diagnostic Code" allows for mid-range gradations in growth deficiency (between the 3rd and 10th percentiles) and severe growth deficiency at or below the 3rd percentile.[18] Growth deficiency (at severe, moderate, or mild levels) contributes to diagnoses of FAS and pFAS, but not ARND or static encephalopathy.

Growth deficiency is ranked as follows by the "4-Digit Diagnostic Code":[18]

- Severe: Height and weight at or below the 3rd percentile.
- Moderate: Either height or weight at or below the 3rd percentile, but not both.
- Mild: Either height or weight or both between the 3rd and 10th percentiles.
- None: Height and weight both above the 10th percentile.

In the initial studies that discovered FAS, growth deficiency was a requirement for inclusion in the studies; thus, all the original people with FAS had growth deficiency as an artifact of sampling characteristics used to establish criteria for the syndrome.[*citation needed*] That is, growth deficiency is a key feature of FASD because growth deficiency was a criterion for inclusion in the original study that determined the definition of FAS. This reinforces assertions that growth deficiency and FAS facial features are less critical for understanding the disability's of FASD than the neurobehavioral sequelae to the brain damage.[11]

## Facial features [edit]

Several characteristic craniofacial abnormalities are often visible in individuals with FAS.[21] The presence of FAS facial features indicates brain damage, though brain damage may also exist in their absence. FAS facial features (and most other visible, but non-diagnostic, deformities) are believed to be caused mainly during the 10th and 20th week of gestation.[22]

Refinements in diagnostic criteria since 1975 have yielded three distinctive and diagnostically significant facial features known to result from prenatal alcohol exposure and distinguishes FAS from other disorders with partially overlapping characteristics.[23][24] The three FAS facial features are:

- A smooth philtrum: The divot or groove between the nose and upper lip flattens with increased prenatal alcohol exposure.

Thin vermilion: The upper lip thins with increased prenatal alcohol exposure.
- Small palpebral fissures: Eye width decreases with increased prenatal alcohol exposure.

Measurement of FAS facial features uses criteria developed by the University of Washington. The lip and philtrum are measured by a trained physician with the Lip-Philtrum Guide,[25] a five-point Likert Scale with representative photographs of lip and philtrum combinations ranging from normal (ranked 1) to severe (ranked 5). Palpebral fissure length (PFL) is measured in millimeters with either calipers or a clear ruler and then compared to a PFL growth chart, also developed by the University of Washington.[26]

Ranking FAS facial features is complicated because the three separate facial features can be affected independently by prenatal alcohol. A summary of the criteria follows:[18][27]

- Severe: All three facial features ranked independently as severe (lip ranked at 4 or 5, philtrum ranked at 4 or 5, and PFL two or more standard deviations below average).
- Moderate: Two facial features ranked as severe and one feature ranked as moderate (lip *or* philtrum ranked at 3, *or* PFL between one and two standard deviations below average).
- Mild: A mild ranking of FAS facial features covers a broad range of facial feature combinations:
  - Two facial features ranked severe and one ranked within normal limits,
  - One facial feature ranked severe and two ranked moderate, or
  - One facial feature ranked severe, one ranked moderate and one ranked within normal limits.
- None: All three facial features ranked within normal limits.

## Central nervous system [edit]

Central nervous system (CNS) damage is the primary key feature of any FASD diagnosis. Prenatal alcohol exposure, which is classified as a teratogen, can damage the brain across a continuum of gross to subtle impairments, depending on the amount, timing, and frequency of the exposure as well as genetic predispositions of the fetus and mother.[11][28] While functional abnormalities are the behavioral and cognitive expressions of the FASD disability, CNS damage can be assessed in three areas: structural, neurological, and functional impairments.

All four diagnostic systems allow for assessment of CNS damage in these areas, but criteria vary. The IOM system requires structural or neurological impairment for a diagnosis of FAS, but also allows a "complex pattern" of functional anomalies for diagnosing PFAS and ARND.[11] The "4-Digit Diagnostic Code" and CDC guidelines allow for a positive CNS finding in any of the three areas for any FASD diagnosis, but functional anomalies must measure at two standard deviations or worse in three or more functional domains for a diagnoses of FAS, PFAS, and ARND.[18][20] The "4-Digit Diagnostic Code" also allows for an FASD diagnosis when only two functional domains are measured at two standard deviations or worse.[18] The "4-Digit Diagnostic Code" further elaborates the degree of CNS damage according to four ranks:

- Definite: Structural impairments or neurological impairments for FAS or static encephalopathy.
- Probable: Significant dysfunction of two standard deviations or worse in three or more functional domains.
- Possible: Mild to moderate dysfunction of two standard deviations or worse in one or two functional domains *or* by judgment of the clinical evaluation team that CNS damage cannot be dismissed.
- Unlikely: No evidence of CNS damage.

## Structural [edit]

Structural abnormalities of the brain are observable, physical damage to the brain or brain structures caused by prenatal alcohol exposure. Structural impairments may include microcephaly (small head size) of two or more standard deviations below the average, or other abnormalities in brain structure (e.g., agenesis of the corpus callosum, cerebellar hypoplasia).[11]

Microcephaly is determined by comparing head circumference (often called occipitofrontal circumference, or OFC) to appropriate OFC growth charts.[19] Other structural impairments must be observed through medical imaging techniques by a trained physician. Because imaging procedures are expensive and relatively inaccessible to most people, diagnosis of FAS is not frequently made via structural impairments, except for microcephaly.

Evidence of a CNS structural impairment due to prenatal alcohol exposure will result in a diagnosis of FAS, and neurological and functional impairments are highly likely.[2][11][18][20]

During the first trimester of pregnancy, alcohol interferes with the migration and organization of brain cells, which can create structural deformities or deficits within the brain.[29] During the third trimester, damage can be caused to the hippocampus, which plays a role in memory, learning, emotion, and encoding visual and auditory information, all of which can create neurological and functional CNS impairments as well.[30]

As of 2002, there were 25 reports of autopsies on infants known to have FAS. The first was in 1973, on an infant who died shortly after birth.[31] The examination revealed extensive brain damage, including microcephaly, migration anomalies, callosal dysgenesis, and a massive neuroglial, leptomeningeal heterotopia covering the left hemisphere.[32]

In 1977, Dr. Clarren described a second infant whose mother was a binge drinker. The infant died ten days after birth. The autopsy showed severe hydrocephalus, abnormal neuronal migration, and a small corpus callosum (which connects the two brain hemispheres) and cerebellum.[32] FAS has also been linked to brainstem and cerebellar changes, agenesis of the corpus callosum and anterior commissure, neuronal migration errors, absent olfactory bulbs, meningomyelocele, and porencephaly.[32]

## Neurological [edit]

When structural impairments are not observable or do not exist, neurological impairments are assessed. In the context of FASD, neurological impairments are caused by prenatal alcohol exposure which causes general neurological damage to the central nervous system (CNS), the peripheral nervous system, or the autonomic nervous system. A determination of a neurological problem must be made by a trained physician, and must not be due to a postnatal insult, such as a high fever, concussion, traumatic brain injury, etc.

All four diagnostic systems show virtual agreement on their criteria for CNS damage at the neurological level, and evidence of a CNS neurological impairment due to prenatal alcohol exposure will result in a diagnosis of FAS or pFAS, and functional impairments are highly likely.[2][11][18][20]

Neurological problems are expressed as either hard signs, or diagnosable disorders, such as epilepsy or other seizure disorders, or soft signs. Soft signs are broader, nonspecific neurological impairments, or symptoms, such as impaired fine motor skills, neurosensory hearing loss, poor gait, clumsiness, poor eye-hand coordination. Many soft signs have norm-referenced criteria, while others are determined through clinical judgment. "Clinical judgment" is only as good as the clinician, and soft signs should be assessed by either a pediatric neurologist, a pediatric neuropsychologist, or both.

## Functional [edit]

When structural or neurological impairments are not observed, all four diagnostic systems allow CNS damage due to prenatal alcohol exposure to be assessed in terms of functional impairments.[2][11][18][20] Functional impairments are deficits, problems, delays, or abnormalities due to prenatal alcohol exposure (rather than hereditary causes or postnatal insults) in observable and measurable domains related to daily functioning, often referred to as developmental disabilities. There is no consensus on a specific pattern of functional impairments due to prenatal alcohol exposure[11] and only CDC guidelines label developmental delays as such,[20] so criteria (and FASD diagnoses) vary somewhat across diagnostic systems.

The four diagnostic systems list various CNS domains that can qualify for functional impairment that can determine an FASD diagnosis:

- Evidence of a complex pattern of behavior or cognitive abnormalities inconsistent with developmental level in the following CNS domains – Sufficient for a pFAS or ARND diagnosis using IOM guidelines[11]
  - Learning disabilities, academic achievement, impulse control, social perception, communication, abstraction, math skills, memory, attention, judgment
- Performance at two or more standard deviations on standardized testing in three or more of the following CNS domains – Sufficient for an FAS, pFAS or static encephalopathy diagnosis using 4-Digit Diagnostic Code[18]

    - Executive functioning, memory, cognition, social/adaptive skills, academic achievement, language, motor skills, attention, activity level
- General cognitive deficits (e.g., IQ) at or below the 3rd percentile on standardized testing – Sufficient for an FAS diagnosis using CDC guidelines[20]
- Performance at or below the 16th percentile on standardized testing in three or more of the following CNS domains – Sufficient for an FAS diagnosis using CDC guidelines[20]
    - Cognition, executive functioning, motor functioning, attention and hyperactive problems, social skills, sensory processing disorder, social communication, memory, difficulties responding to common parenting practices
- Performance at two or more standard deviations on standardized testing in three or more of the following CNS domains – Sufficient for an FAS diagnosis using Canadian guidelines
    - Cognition, communication, academic achievement, memory, executive functioning, adaptive behavior, motor skills, social skills, social communication

### Related signs [edit]

Other conditions may commonly co-occur with FAS, stemming from prenatal alcohol exposure. However, these conditions are considered alcohol-related birth defects[11] and not diagnostic criteria for FAS.

- Heart: A heart murmur that frequently disappears by one year of age. Ventricular septal defect most commonly seen, followed by an atrial septal defect.
- Bones: Joint anomalies including abnormal position and function, altered palmar crease patterns, small distal phalanges, and small fifth fingernails.
- Kidneys: Horseshoe, aplastic, dysplastic, or hypoplastic kidneys.
- Eyes: Strabismus, optic nerve hypoplasia[33] (which may cause light sensitivity, decreased visual acuity, or involuntary eye movements).
- Occasional problems: ptosis of the eyelid, microophthalmia, cleft lip with or without a cleft palate, webbed neck, short neck, tetralogy of Fallot, coarctation of the aorta, spina bifida, and hydrocephalus.

## Cause [edit]

Fetal alcohol syndrome usually occurs when a pregnant woman has more than four standard drinks per day.[34] Milder symptoms have been found with two drinks per day during the early part of pregnancy.[34][35] Among those who are alcoholic about a third of children have FAS.[34]

Evidence of harm from less than two drinks per day or 10 drinks per week is not clear.[34][36] While small amounts of alcohol do not cause an abnormal appearance it may cause behavioral issues.[6] There is conflicting evidence regarding whether drinking by fathers before conception can cause FAS.[34]

## Mechanism [edit]

Despite intense research efforts, it has not been possible to identify a single clear-cut mechanism for development of FAS or FASD. On the contrary, clinical and animal studies have identified a broad spectrum of pathways through which maternal alcohol can negatively affect the outcome of a pregnancy. Clear conclusions with universal validity are difficult to draw, since different ethnic groups show considerable genetic polymorphism for the hepatic enzymes responsible for ethanol detoxification.[37]

Genetic examinations have revealed a continuum of long-lasting molecular effects that are not only timing specific but are also dosage specific; with even moderate amounts being able to cause alterations.[38]

A human fetus appears to be at triple risk from maternal alcohol consumption:[39][40]

1. The placenta allows free entry of ethanol and toxic metabolites like acetaldehyde into the fetal compartment. The so-called placental barrier is no barrier with respect to ethanol.
2. The developing fetal nervous system appears particularly sensitive to ethanol toxicity. The latter

impacts negatively on proliferation, differentiation, neuronal migration, axonic outgrowth, integration and fine tuning of the synaptic network. In short, all major processes in the developing central nervous system appear compromised.

3. Fetal tissues are quite different from adult tissues in function and purpose. For example, the main detoxicating organ in adults is the liver, whereas fetal liver is incapable of detoxicating ethanol as the ADH and ALDH enzymes have not yet been brought to expression at this early stage. Up to term, fetal tissues do not have significant capacity for the detoxification of ethanol, and the fetus remains exposed to ethanol in the amniotic fluid for periods far longer than the decay time of ethanol in the maternal circulation.

Generally, fetal tissues have far less antioxidant protection than adult tissues as they express no significant quantities ADH or ALDH, and far less antioxidant enzymes like SOD, glutathion transferases or glutathion peroxidases.[*citation needed*]

## Diagnosis [edit]

Because admission of alcohol use during pregnancy can stigmatize birth mothers, many are reluctant to admit drinking or to provide an accurate report of the quantity they drank. This complicates diagnosis and treatment [20] of the syndrome. As a result, diagnosis of the severity of FASD relies on protocols of observation of the child's physiology and behavior rather than maternal self-reporting. Presently, four FASD diagnostic systems that diagnose FAS and other FASD conditions have been developed in North America:

- The Institute of Medicine's guidelines for FAS, the first system to standardize diagnoses of individuals with prenatal alcohol exposure;[11]
- The University of Washington's "The 4-Digit Diagnostic Code," which ranks the four key features of FASD on a Likert scale of one to four and yields 256 descriptive codes that can be categorized into 22 distinct clinical categories, ranging from FAS to no findings;[18]
- The Centers for Disease Control's "Fetal Alcohol Syndrome: Guidelines for Referral and Diagnosis," which established consensus on the diagnosis FAS in the U.S. but deferred addressing other FASD conditions;[20] and
- Canadian guidelines for FASD diagnoses, which established criteria for diagnosing FASD in Canada and harmonized most differences between the IOM and University of Washington's systems.[2]

Each diagnostic system requires that a complete FASD evaluation includes an assessment of the four key features of FASD, described below. A positive finding on all four features is required for a diagnosis of FAS. However, prenatal alcohol exposure and central nervous system damage are the critical elements of the spectrum of FASD, and a positive finding in these two features is sufficient for an FASD diagnosis that is not "full-blown FAS".

While the four diagnostic systems essentially agree on criteria for fetal alcohol syndrome (FAS), there are still differences when full criteria for FAS are not met. This has resulted in differing and evolving nomenclature for other conditions across the spectrum of FASD, which may account for such a wide variety of terminology. Most individuals with deficits resulting from prenatal alcohol exposure do not express all features of FAS and fall into other FASD conditions.[11] The Canadian guidelines recommend the assessment and descriptive approach of the "4-Digit Diagnostic Code" for each key feature of FASD and the terminology of the IOM in diagnostic categories, excepting ARBD.[2]

Thus, other FASD conditions are partial expressions of FAS. However, these other FASD conditions may create disabilities similar to FAS if the key area of central nervous system damage shows clinical deficits in two or more of ten domains of brain functioning. Essentially, even though growth deficiency and/or FAS facial features may be mild or nonexistent in other FASD conditions, yet clinically significant brain damage of the central nervous system is present. In these other FASD conditions, an individual may be at greater risk for adverse outcomes because brain damage is present without associated visual cues of poor growth or the "FAS face" that might ordinarily trigger an FASD evaluation. Such individuals may be misdiagnosed with primary mental health disorders such as ADHD or oppositional defiance disorder without appreciation that brain damage is the underlying cause of these disorders, which requires a different treatment paradigm than typical mental health disorders. While other FASD conditions may not yet be included as an ICD or

DSM-IV-TR diagnosis, they nonetheless pose significant impairment in functional behavior because of underlying brain damage.

## Fetal alcohol syndrome [edit]

The following criteria must be fully met for an FAS diagnosis:[2][11][18][20]

1. Growth deficiency: Prenatal or postnatal height or weight (or both) at or below the 10th percentile[19]
2. FAS facial features: All three FAS facial features present[26]
3. Central nervous system damage: Clinically significant structural neurological, *or* functional impairment
4. Prenatal alcohol exposure: Confirmed or Unknown prenatal alcohol exposure

Fetal alcohol syndrome (FAS) is the first diagnosable condition of FASD that was discovered. FAS is the only expression of FASD that has garnered consensus among experts to become an official ICD-9 and ICD-10 diagnosis. To make this diagnosis or determine any FASD condition, a multi-disciplinary evaluation is necessary to assess each of the four key features for assessment. Generally, a trained physician will determine growth deficiency and FAS facial features. While a qualified physician may also assess central nervous system structural abnormalities and/or neurological problems, usually central nervous system damage is determined through psychological, speech-language, and occupational therapy assessments to ascertain clinically significant impairments in three or more of the Ten Brain Domains.[41] Prenatal alcohol exposure risk may be assessed by a qualified physician, psychologist, social worker, or chemical health counselor. These professionals work together as a team to assess and interpret data of each key feature for assessment and develop an integrative, multi-disciplinary report to diagnose FAS (or other FASD conditions) in an individual.

## Partial FAS [edit]

Partial FAS (pFAS), previously known as atypical FAS in the 1997 edition of the "4-Digit Diagnostic Code". People with pFAS have a confirmed history of prenatal alcohol exposure, but may lack growth deficiency or the complete facial stigmata. Central nervous system damage is present at the same level as FAS. These individuals have the same functional disabilities but "look" less like FAS.

The following criteria must be fully met for a diagnosis of Partial FAS:[2][11][18]

1. Growth deficiency: Growth or height may range from normal to deficient[19]
2. FAS facial features: Two or three FAS facial features present[26]
3. Central nervous system damage: Clinically significant structural, neurological, *or* functional impairment in three or more of the Ten Brain Domains[41]
4. Prenatal alcohol exposure: Confirmed prenatal alcohol exposure

## Fetal alcohol effects [edit]

Fetal alcohol effects (FAE) is a previous term for alcohol-related neurodevelopmental disorder and alcohol-related birth defects.[1] It was initially used in research studies to describe humans and animals in whom teratogenic effects were seen after confirmed prenatal alcohol exposure (or unknown exposure for humans), but without obvious physical anomalies.[42] Smith (1981) described FAE as an "extremely important concept" to highlight the debilitating effects of brain damage, regardless of the growth or facial features.[43] This term has fallen out of favor with clinicians because it was often regarded by the public as a less severe disability than FAS, when in fact its effects can be just as detrimental.[44]

## Alcohol-related neurodevelopmental disorder [edit]

Alcohol-related neurodevelopmental disorder (ARND) was initially suggested by the Institute of Medicine to replace the term FAE and focus on central nervous system damage, rather than growth deficiency or FAS facial features. The Canadian guidelines also use this diagnosis and the same criteria. While the "4-Digit

Diagnostic Code" includes these criteria for three of its diagnostic categories, it refers to this condition as static encephalopathy. The behavioral effects of ARND are not necessarily unique to alcohol however, so use of the term must be within the context of confirmed prenatal alcohol exposure.[45] ARND may be gaining acceptance over the terms FAE and ARBD to describe FASD conditions with central nervous system abnormalities or behavioral or cognitive abnormalities or both due to prenatal alcohol exposure without regard to growth deficiency or FAS facial features.[45][46]

The following criteria must be fully met for a diagnosis of ARND or static encephalopathy:[2][11][18]

1. Growth deficiency: Growth or height may range from normal to minimally deficient[19]
2. FAS facial features: Minimal or no FAS facial features present[26]
3. Central nervous system damage: Clinically significant structural, neurological, *or* functional impairment in three or more of the Ten Brain Domains[41]
4. Prenatal alcohol exposure: Confirmed prenatal alcohol exposure;0

## Alcohol-related birth defects [edit]

Alcohol-related birth defects (ARBD), formerly known as possible fetal alcohol effect (PFAE),[42] was a term proposed as an alternative to FAE and PFAE[47] The IOM presents ARBD as a list of congenital anomalies that are linked to maternal alcohol use but have no key features of FASD.[11] PFAE and ARBD have fallen out of favor because these anomalies are not necessarily specific to maternal alcohol consumption and are not criteria for diagnosis of FASD.[45] The Canadian guidelines recommend that ARBD should not be used as an umbrella term or diagnostic category for FASD.

## Exposure [edit]

Prenatal alcohol exposure is determined by interview of the biological mother or other family members knowledgeable of the mother's alcohol use during the pregnancy (if available), prenatal health records (if available), and review of available birth records, court records (if applicable), chemical dependency treatment records (if applicable), or other reliable sources.

Exposure level is assessed as *confirmed exposure*, *unknown exposure*, and *confirmed absence of exposure* by the IOM, CDC and Canadian diagnostic systems. The "4-Digit Diagnostic Code" further distinguishes confirmed exposure as *High Risk* and *Some Risk*:

- High Risk: Confirmed use of alcohol during pregnancy known to be at high blood alcohol levels (100 mg/dL or greater) delivered at least weekly in early pregnancy.
- Some Risk: Confirmed use of alcohol during pregnancy with use less than High Risk or unknown usage patterns.
- Unknown Risk: Unknown use of alcohol during pregnancy.
- No Risk: Confirmed absence of prenatal alcohol exposure.

## Confirmed exposure [edit]

Amount, frequency, and timing of prenatal alcohol use can dramatically impact the other three key features of FASD. While consensus exists that alcohol is a teratogen, there is no clear consensus as to what level of exposure is toxic.[11] The CDC guidelines are silent on these elements diagnostically. The IOM and Canadian guidelines explore this further, acknowledging the importance of significant alcohol exposure from regular or heavy episodic alcohol consumption in determining, but offer no standard for diagnosis. Canadian guidelines discuss this lack of clarity and parenthetically point out that "heavy alcohol use" is defined by the National Institute on Alcohol Abuse and Alcoholism as five or more drinks per episode on five or more days during a 30-day period.[48]

"The 4-Digit Diagnostic Code" ranking system distinguishes between levels of prenatal alcohol exposure as *high risk* and *some risk*. It operationalizes high risk exposure as a blood alcohol concentration (BAC) greater than 100 mg/dL delivered at least weekly in early pregnancy. This BAC level is typically reached by a 55 kg female drinking six to eight beers in one sitting.[18]

### Unknown exposure [edit]

For many adopted or adults and children in foster care, records or other reliable sources may not be available for review. Reporting alcohol use during pregnancy can also be stigmatizing to birth mothers, especially if alcohol use is ongoing.[20] In these cases, all diagnostic systems use an unknown prenatal alcohol exposure designation. A diagnosis of FAS is still possible with an unknown exposure level if other key features of FASD are present at clinical levels.

### Confirmed absence of exposure [edit]

Confirmed absence of exposure would apply to planned pregnancies in which no alcohol was used or pregnancies of women who do not use alcohol or report no use during the pregnancy. This designation is relatively rare, as most people presenting for an FASD evaluation are at least *suspected* to have had a prenatal alcohol exposure due to presence of other key features of FASD.[18][20]

### Ten brain domains [edit]

A recent effort to standardize assessment of functional CNS damage has been suggested by an experienced FASD diagnostic team in Minnesota. The proposed framework attempts to harmonize IOM, 4-Digit Diagnostic Code, CDC, and Canadian guidelines for measuring CNS damage vis-à-vis FASD evaluations and diagnosis. The standardized approach is referred to as the Ten Brain Domains and encompasses aspects of all four diagnostic systems' recommendations for assessing CNS damage due to prenatal alcohol exposure. The framework provides clear definitions of brain dysfunction, specifies empirical data needed for accurate diagnosis, and defines intervention considerations that address the complex nature of FASD with the intention to avoid common secondary disabilities.[41]

The proposed Ten Brain Domains include:[41]

- Achievement, adaptive behavior, attention, cognition, executive functioning, language, memory, motor skills, multisensory integration or soft neurological problems, social communication[41]

The Fetal Alcohol Diagnostic Program (FADP) uses unpublished Minnesota state criteria of performance at 1.5 or more standard deviations on standardized testing in three or more of the Ten Brain Domains to determine CNS damage. However, the Ten Brain Domains are easily incorporated into any of the four diagnostic systems' CNS damage criteria, as the framework only proposes the domains, rather than the cut-off criteria for FASD.[49]

### Differential diagnosis [edit]

The CDC reviewed nine syndromes that have overlapping features with FAS; however, none of these syndromes include all three FAS facial features, and none are the result of prenatal alcohol exposure:[20]

- Aarskog syndrome
- Williams syndrome
- Noonan syndrome
- Dubowitz syndrome
- Brachman-DeLange syndrome
- Toluene syndrome
- Fetal hydantoin syndrome
- Fetal valproate syndrome
- Maternal PKU fetal effects

## Prevention [edit]

The only certain way to prevent FAS is to avoid drinking alcohol during pregnancy.[45] In the United States, the Surgeon General recommended in 1981, and again in 2005, that women abstain from alcohol use while pregnant or while planning a pregnancy, the latter to avoid damage even in the earliest stages (even

weeks) of a pregnancy, as the woman may not be aware that she has conceived.[10] In the United States, federal legislation has required that warning labels be placed on all alcoholic beverage containers since 1988 under the Alcoholic Beverage Labeling Act.

There is some controversy surrounding the "zero-tolerance" approach taken by many countries when it comes to alcohol consumption during pregnancy. The assertion that moderate drinking causes FAS is said to lack strong evidence and, in fact, the practice of equating a responsible level of drinking with potential harm to the fetus may have negative social, legal, and health impacts.[50] In addition, special care should be taken when considering statistics on this disease, as prevalence and causation is often linked with FASD, which is more common and causes less harm, as opposed to FAS.[51]

## Treatment [edit]

There is no cure for FASD, but treatment is possible. Because CNS damage, symptoms, secondary disabilities, and needs vary widely by individual, there is no one treatment type that works for everyone.

### Medication [edit]

Psychoactive drugs are frequently tried on those with FASD as many FASD symptoms are mistaken for or overlap with other disorders, most notably ADHD.[52]

### Behavioral interventions [edit]

Behavioral interventions are based on the learning theory, which is the basis for many parenting and professional strategies and interventions.[46] Along with ordinary parenting styles, such strategies are frequently used by default for treating those with FAS, as the diagnoses oppositional defiance disorder (ODD), conduct disorder, reactive attachment disorder (RAD) often overlap with FAS (along with ADHD), and these are sometimes thought to benefit from behavioral interventions. Frequently, a person's poor academic achievement results in special education services, which also utilizes principles of learning theory, behavior modification, and outcome-based education.

### Developmental framework [edit]

Many books and handouts on FAS recommend a developmental approach, based on developmental psychology, even though most do not specify it as such and provide little theoretical background. Optimal human development generally occurs in identifiable stages (e.g., Jean Piaget's theory of cognitive development, Erik Erikson's stages of psychosocial development, John Bowlby's attachment framework, and other developmental stage theories). FAS interferes with normal development,[53] which may cause stages to be delayed, skipped, or immaturely developed. Over time, an unaffected child can negotiate the increasing demands of life by progressing through stages of development normally, but not so for a child with FAS.[53]

By knowing what developmental stages and tasks children follow, treatment and interventions for FAS can be tailored to helping a person meet developmental tasks and demands successfully.[53] If a person is delayed in the adaptive behavior domain, for instance, then interventions would be recommended to target specific delays through additional education and practice (e.g., practiced instruction on tying shoelaces), giving reminders, or making accommodations (e.g., using slip-on shoes) to support the desired functioning level. This approach is an advance over behavioral interventions, because it takes the person's developmental context into account while developing interventions.[*citation needed*]

### Advocacy model [edit]

The advocacy model takes the point of view that someone is needed to actively mediate between the environment and the person with FAS.[45] Advocacy activities are conducted by an advocate (for example, a family member, friend, or case manager) and fall into three basic categories. An advocate for FAS: (1)

interprets FAS and the disabilities that arise from it and explains it to the environment in which the person operates, (2) engenders change or accommodation on behalf of the person, and (3) assists the person in developing and reaching attainable goals.[45]

The advocacy model is often recommended, for example, when developing an Individualized Education Program (IEP) for the person's progress at school.[52]

An understanding of the developmental framework would presumably inform and enhance the advocacy model, but advocacy also implies interventions at a systems level as well, such as educating schools, social workers, and so forth on best practices for FAS. However, several organizations devoted to FAS also use the advocacy model at a community practice level as well.[54]

### Public health and policy [edit]

Treating FAS at the public health and public policy level promotes FAS prevention and diversion of public resources to assist those with FAS.[45] It is related to the advocacy model but promoted at a systems level (rather than with the individual or family), such as developing community education and supports, state or province level prevention efforts (e.g., screening for maternal alcohol use during OB/GYN or prenatal medical care visits), or national awareness programs. Several organizations and state agencies in the U.S. are dedicated to this type of intervention.[54]

The US Centers for Disease Control estimates 3 million women in the United States are at risk of having a baby with FASD, and recommended that women of child bearing age should be on birth control or abstain from drinking alcohol as the safest way to avoid this.[55]

## Prognosis [edit]

### Primary disabilities [edit]

The primary disabilities of FAS are the functional difficulties with which the child is born as a result of CNS damage due to prenatal alcohol exposure.[56] Often, primary disabilities are mistaken as *behavior problems*, but the underlying CNS damage is the originating source of a functional difficulty,[57] rather than a mental health condition, which is considered a secondary disability.

The exact mechanisms for functional problems of primary disabilities are not always fully understood, but animal studies have begun to shed light on some correlates between functional problems and brain structures damaged by prenatal alcohol exposure.[45] Representative examples include:

- Learning impairments are associated with impaired dendrites of the hippocampus[58]
- Impaired motor development and functioning are associated with reduced size of the cerebellum[59]
- Hyperactivity is associated with decreased size of the corpus callosum[60]

Functional difficulties may result from CNS damage in more than one domain, but common functional difficulties by domain include:[45][46][53][57] Note that this is not an exhaustive list of difficulties.

- Achievement: Learning disabilities
- Adaptive behavior: Poor impulse control, poor personal boundaries, poor anger management, stubbornness, intrusive behavior, too friendly with strangers, poor daily living skills, developmental delays
- Attention: Attention-Deficit/Hyperactivity Disorder (ADHD), poor attention or concentration, distractible
- Cognition: Intellectual disability, confusion under pressure, poor abstract skills, difficulty distinguishing between fantasy and reality, slower cognitive processing
- Executive functioning: Poor judgment, Information-processing disorder, poor at perceiving patterns, poor cause and effect reasoning, inconsistent at linking words to actions, poor generalization ability
- Language: Expressive or receptive language disorders, grasp parts but not whole concepts, lack understanding of metaphor, idioms, or sarcasm

Memory: Poor short-term memory, inconsistent memory and knowledge base
- Motor skills: Poor handwriting, poor fine motor skills, poor gross motor skills, delayed motor skill development (e.g., riding a bicycle at appropriate age)
- Sensory processing and soft neurological problems: sensory processing disorder, sensory defensiveness, undersensitivity to stimulation
- Social communication: Intrude into conversations, inability to read nonverbal or social cues, "chatty" but without substance

## Secondary disabilities [edit]

The secondary disabilities of FAS are those that arise later in life secondary to CNS damage. These disabilities often emerge over time due to a mismatch between the primary disabilities and environmental expectations; secondary disabilities can be ameliorated with early interventions and appropriate supportive services.[56]

Six main secondary disabilities were identified in a University of Washington research study of 473 subjects diagnosed with FAS, PFAS (partial fetal alcohol syndrome), and ARND (alcohol-related neurodevelopmental disorder):[45][56]

- Mental health problems: Diagnosed with ADHD, Clinical Depression, or other mental illness, experienced by over 90% of the subjects
- Disrupted school experience: Suspended or expelled from school or dropped out of school, experienced by 60% of the subjects (age 12 and older)
- Trouble with the law: Charged or convicted with a crime, experienced by 60% of the subjects (age 12 and older)
- Confinement: For inpatient psychiatric care, inpatient chemical dependency care, or incarcerated for a crime, experienced by about 50% of the subjects (age 12 and older)
- Inappropriate sexual behavior: Sexual advances, sexual touching, or promiscuity, experienced by about 50% of the subjects (age 12 and older)
- Alcohol and drug problems: Abuse or dependency, experienced by 35% of the subjects (age 12 and older)

Two additional secondary disabilities exist for adults:[45][56]

- Dependent living: Group home, living with family or friends, or some sort of assisted living, experienced by 80% of the subjects (age 21 and older)
- Problems with employment: Required ongoing job training or coaching, could not keep a job, unemployed, experienced by 80% of the subjects (age 21 and older)

## Protective factors and strengths [edit]

Eight factors were identified in the same study as universal protective factors that reduced the incidence rate of the secondary disabilities:[45][56]

- Living in a stable and nurturing home for over 73% of life
- Being diagnosed with FAS before age six
- Never having experienced violence
- Remaining in each living situation for at least 2.8 years
- Experiencing a "good quality home" (meeting 10 or more defined qualities) from age 8 to 12 years old
- Having been found eligible for developmental disability (DD) services
- Having basic needs met for at least 13% of life
- Having a diagnosis of FAS (rather than another FASD condition)

Malbin (2002) has identified the following areas of interests and talents as strengths that often stand out for those with FASD and should be utilized, like any strength, in treatment planning:[46]

- Music, playing instruments, composing, singing, art, spelling, reading, computers, mechanics, woodworking, skilled vocations (welding, electrician, etc.), writing, poetry
- Participation in non-impact sport or physical fitness activities

# Epidemiology [edit]

FASD is estimated to affect between 2% and 5% of people in the United States and Western Europe.[15] FAS is believed to occur in between 0.2 and 9 per 1000 live births in the United States.[15] The lifetime cost of an individual with FAS were estimated to be two million USD in 2002.[15]

## Australia [edit]

*See also: Drinking culture in Australia*

FASD among Australian youth is more common in indigenous Australians.[61] The only states that have registered birth defects in Australian youth are Western Australia, New South Wales, Victoria and South Australia.[62] In Australia only 12% of Australian health professionals are aware of the diagnostics and symptoms of FASD.[61] In Western Australia, the rate of births resulting in FASD is 0.02 per 1000 births for non-Indigenous Australians, however among indigenous births the rate is 2.76 per 1000 births.[62] In Victoria, there have been no registered FASD related births for indigenous Australians, but the rate for the general population in Victoria is 0.01-0.03 per 1000 births.[62] There have been no dedicated FASD clinics within Western Australia, but there are also no nationally supported diagnostic criteria anywhere in Australia.[63] Passive surveillance is a prevention technique used within Australia to assist in monitoring and establishing detectable defects during pregnancy and childhood.[62]

# History [edit]

From the 1960s to the 1980s, alcohol was commonly used as a tocolytic, a method to stop preterm labor. The method originated with Dr. Fritz Fuchs, the chairman of the department of obstetrics and gynecology at Cornell University Medical College.[64][65] Doctors recommended a small amount of alcohol to calm the uterus during contractions in early pregnancy or Braxton Hicks contractions. In later stages of pregnancy, the alcohol was administered intravenously and often in large amounts. "Women experienced similar effects as occur with oral ingestion, including intoxication, nausea and vomiting, and potential alcohol poisoning, followed by hangovers when the alcohol was discontinued."[66] Vomiting put the mother at a high risk for aspiration and was "a brutal procedure for all involved." [64] Because the alcohol was being given intravenously, the doctor could continue giving the treatment to the mother long after she had passed out, resulting in her being more intoxicated than would otherwise be possible. Such heavy intoxication is highly likely to contribute to FASD.[64]

## Historical references [edit]

Anecdotal accounts of prohibitions against maternal alcohol use from Biblical, ancient Greek, and ancient Roman sources imply a historical awareness of links between maternal alcohol use and negative child outcomes.[31] For example, in the King James' Version of the Bible, Judges 13:4 reads: "Now therefore beware, I pray thee, and drink not wine nor strong drink, and eat not any unclean *thing*" In 1725 British physicians petitioned the House of Commons on the effects of strong drink when consumed by pregnant women saying that such drinking is "…too often the cause of weak feeble and distempered children, who must be, instead, of an advantage and strength, a charge to their country."[67] There are many other such historical references. In Gaelic Scotland, the mother and nurse were not allowed to consume ale during pregnancy and breastfeeding (Martin Martin). Claims that alcohol consumption caused idiocy were part of the Teetotalism's message in the 19th century,[68] but such claims, despite some attempts to offer evidence, were ignored because no mechanism could be advanced.[69]

The earliest recorded observation of possible links between maternal alcohol use and fetal damage was made in 1899 by Dr. William Sullivan, a Liverpool prison physician who noted higher rates of stillbirth for 120 alcoholic female prisoners than their sober female relatives; he suggested the causal agent to be alcohol use.[70] This contradicted the predominating belief at the time that heredity caused intellectual

disability, poverty, and criminal behavior, which contemporary studies on the subjects usually concluded.[45] A case study by Henry H. Goddard of the Kallikak family—popular in the early 1900s—represents this earlier perspective,[71] though later researchers have suggested that the Kallikaks almost certainly had FAS.[72] General studies and discussions on alcoholism throughout the mid-1900s were typically based on a heredity argument.[73]

Prior to fetal alcohol syndrome being specifically identified and named in 1973, a few studies had noted differences between the children of mothers who used alcohol during pregnancy or breast-feeding and those who did not, but identified alcohol use as a possible contributing factor rather than heredity.[45]

## Recognition as a syndrome [edit]

Fetal Alcohol Syndrome was named in 1973 by two dysmorphologists, Drs. Kenneth Lyons Jones and David Weyhe Smith of the University of Washington Medical School in Seattle, United States. They identified a pattern of "craniofacial, limb, and cardiovascular defects associated with prenatal onset growth deficiency and developmental delay" in eight unrelated children of three ethnic groups, all born to mothers who were alcoholics.[74] The pattern of malformations indicated that the damage was prenatal. News of the discovery shocked some, while others were skeptical of the findings.[75]

Dr. Paul Lemoine of Nantes, France had already published a study in a French medical journal in 1968 about children with distinctive features whose mothers were alcoholics,[76] and in the U.S., Christy Ulleland and colleagues at the University of Washington Medical School had conducted an 18-month study in 1968–1969 documenting the risk of maternal alcohol consumption among the offspring of 11 alcoholic mothers.[77] The Washington and Nantes findings were confirmed by a research group in Gothenburg, Sweden in 1979.[78] Researchers in France, Sweden, and the United States were struck by how similar these children looked, though they were not related, and how they behaved in the same unfocused and hyperactive manner.[78]

Within nine years of the Washington discovery, animal studies, including non-human monkey studies carried out at the University of Washington Primate Center by Dr. Sterling Clarren, had confirmed that alcohol was a teratogen. By 1978, 245 cases of FAS had been reported by medical researchers, and the syndrome began to be described as the most frequent known cause of intellectual disability.

While many syndromes are eponymous, i.e. named after the physician first reporting the association of symptoms, Dr. Smith named FAS after the causal agent of the symptoms.[79] He reasoned that doing so would encourage prevention, believing that if people knew maternal alcohol consumption caused the syndrome, then abstinence during pregnancy would follow from patient education and public awareness.[79] At the time, nobody was aware of the full range of possible birth defects from FAS or its rate of prevalence.[79] Over time, as subsequent research and clinical experience suggested that a range of effects (including physical, behavioral, and cognitive) could arise from prenatal alcohol exposure, the term Fetal Alcohol Spectrum Disorder (FASD) was developed to include FAS as well as other conditions resulting from prenatal alcohol exposure.[79] Currently, FAS[11][42][74] is the only expression of prenatal alcohol exposure defined by the International Statistical Classification of Diseases and Related Health Problems and assigned ICD-9 and diagnoses.

# Klinefelter syndrome

From Wikipedia, the free encyclopedia

*Not to be confused with XYY syndrome.*

**Klinefelter syndrome** (**KS**) also known as **47,XXY** or **XXY**, is the set of symptoms that result from two or more X chromosomes in males.[1] The primary feature is sterility.[1] Often symptoms may be subtle and many people do not realize they are affected. Sometimes symptoms are more prominent and may include weaker muscles, greater height, poor coordination, less body hair, smaller genitals, breast growth, and less interest in sex.[2] Often it is only at puberty that these symptoms are noticed.[3] Intelligence is usually normal; however, reading difficulties and problems with speech are more common. Symptoms are typically more severe if three or more X chromosomes are present.[2]

Klinefelter syndrome usually occurs randomly. An older mother might increase the risk slightly. The condition is not inherited from one's parents.[4] The underlying mechanisms involves at least one extra X chromosome in addition to a Y chromosome such that there is a total of 47 or more chromosomes rather than the usual 46.[5] KS is diagnosed by the genetic test known as a karyotype.[3]

While there is no cure, a number of treatments may help.[6] Physical therapy, speech and language therapy, counselling, and adjustments of teaching methods may be useful. Testosterone replacement may be used in those who have significantly low levels. Enlarged breasts may be removed by surgery. About half of males affected with the help of assisted reproductive technology have a chance of having children; however, this is expensive and carries risks.[7] Males appear to have a higher risk of breast cancer than typical but still lower than that of females.[8] The condition has a nearly normal life expectancy.[6]

Klinefelter syndrome is one of the most common chromosomal disorders, occurring in 1:500 to 1:1000 live male births.[4][9] It is named after Harry Klinefelter who identified the condition in the 1940s.[10] In 1956 identification of the extra X chromosome was first noticed.[11] Mice can also have the XXY syndrome, making them a useful research model.[12]

## Signs and symptoms [edit]

While it is possible to characterise XXY males based on physical characteristics, substantial variation in physical and developmental traits mean the only reliable method of positive or negative identification is karyotype testing.

A person with typical untreated (surgery/hormones) Klinefelter 46,XY/47,XXY mosaic, diagnosed at age 19. Scar from biopsy may be visible on left nipple.

### Physical [edit]

As babies and children, XXY males may have weaker muscles and reduced strength. As they grow older, they tend to become taller than average. They may have less muscle control and coordination than other boys of their age.[13]

During puberty, the physical traits of the syndrome become more evident; because these boys do not produce as much testosterone as other boys, they have a less muscular body, less facial and body hair, and broader hips. As teens, XXY males may develop breast tissue[14] and also have weaker bones, and a lower energy level than other males.[13]

By adulthood, XXY males look similar to males without the condition, although they are often taller. In adults, possible characteristics vary widely and include little to no sign of affectedness, a lanky, youthful build and facial appearance, or a rounded body type with some degree of gynecomastia (increased breast tissue).[15] Gynecomastia is present to some extent in about a third of affected individuals, a slightly higher percentage than in the XY population. About 10% of XXY males have gynecomastia noticeable enough that they may choose to have cosmetic surgery.[16]

Affected males are often infertile, or may have reduced fertility. Advanced reproductive assistance is sometimes possible.[17]

The term *hypogonadism* in XXY symptoms is often misinterpreted to mean "small testicles" when it means decreased testicular hormone/endocrine function. Because of this (primary) hypogonadism, individuals will often have a low serum testosterone level but high serum follicle-stimulating hormone (FSH) and luteinizing hormone (LH) levels.[18] Despite this

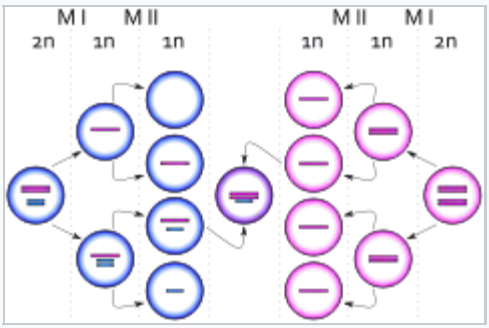
misunderstanding of the term, however, it is true that XXY men may also have microorchidism (i.e., small testicles).[18]

XXY males are also more likely than other men to have certain health problems that typically affect females, such as autoimmune disorders, breast cancer, venous thromboembolic disease, and osteoporosis.[13][19] In contrast to these potentially increased risks, it is currently thought that rare X-linked recessive conditions occur less frequently in XXY males than in normal XY males, since these conditions are transmitted by genes on the X chromosome, and people with two X chromosomes are typically only carriers rather than affected by these X-linked recessive conditions.[*citation needed*]

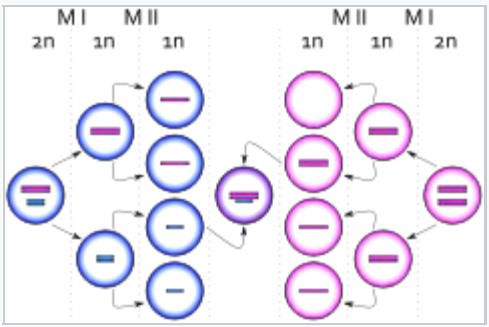
### Cognitive and developmental [edit]

Some degree of language learning or reading impairment may be present,[20] and neuropsychological testing often reveals deficits in executive functions, although these deficits can often be overcome through early intervention.[21] There may also be delays in motor development which can be addressed through occupational therapy and physical therapy.[22] XXY males may sit up, crawl, and walk later than other infants; they may also struggle in school, both academically and with sports.[13]

## Cause [edit]



Birth of a cell with karyotype XXY due to a non-disjunction event of one X chromosome from a Y chromosome during meiosis I in the male.



Birth of a cell with karyotype XXY due to a non-disjunction event of one X chromosome during meiosis II in the female.

The extra chromosome is retained because of a nondisjunction event during paternal or maternal meiosis I (gametogenesis). Nondisjunction occurs when homologous chromosomes, in this case the X and Y or two X sex chromosomes, fail to separate, producing a sperm with an X and a Y chromosome or an egg with two X chromosomes. Fertilizing a normal (X) egg with this sperm produces an XXY offspring (Klinefelter). Fertilizing a double X egg with a normal sperm also produces an XXY offspring (Klinefelter).

Another mechanism for retaining the extra chromosome is through a nondisjunction event during meiosis II in the egg. Nondisjunction will occur when sister chromatids on the sex chromosome, in this case an X and an X, fail to separate. (meiosis) An XX egg is produced which, when fertilized with a Y sperm, yields XXY offspring. This XXY chromosome arrangement is one of the most common genetic variations from the XY karyotype, occurring in about 1 in 500 live male births.[13] See also Triple X syndrome.

In mammals with more than one X chromosome, the genes on all but one X chromosome are not expressed; this is known as X inactivation. This happens in XXY males as well as normal XX females.[23] However, in XXY males, a few genes located in the pseudoautosomal regions of their X chromosomes, have corresponding genes on their Y chromosome and are capable of being expressed.[24]

The first published report of a man with a 47,XXY karyotype was by Patricia Jacobs and John Strong at Western General Hospital in Edinburgh, Scotland in 1959.[25] This karyotype was found in a 24-year-old man who had signs of Klinefelter syndrome. Jacobs described her discovery of this first reported human or mammalian chromosome aneuploidy in her 1981 William Allan Memorial Award address.[26]

### Variations [edit]

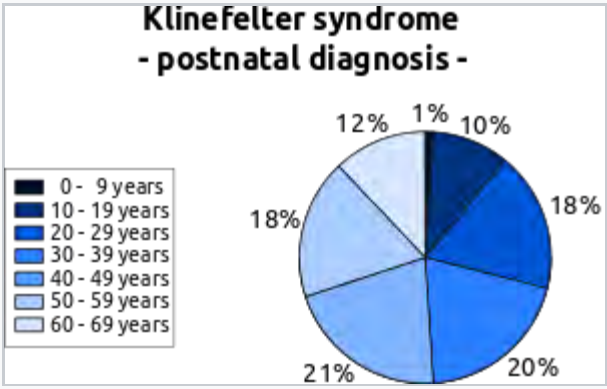
48,XXYY and 48,XXXY occur in 1 in 18,000–50,000 male births. The incidence of 49,XXXXY is 1 in 85,000 to 100,000 male births.[27] These variations are extremely rare. Additional chromosomal material can contribute to cardiac, neurological, orthopedic and other anomalies.

Males with Klinefelter syndrome may have a mosaic 47,XXY/46,XY constitutional karyotype and varying degrees of spermatogenic failure. Mosaicism 47,XXY/46,XX with clinical features suggestive of Klinefelter syndrome is very rare. Thus far, only about 10 cases have been described in literature.[28]

Analogous XXY syndromes are known to occur in cats—specifically, the presence of calico or tortoiseshell markings in male cats is an indicator of the relevant abnormal karyotype. As such, male cats with calico or tortoiseshell markings are a model organism for Klinefelter syndrome.[29]

## Diagnosis [edit]

About 10% of Klinefelter cases are found by prenatal diagnosis.[31] The first clinical features may appear in early childhood or, more frequently, during puberty, such as lack of secondary sexual characteristics and aspermatogenesis,[32] while tall stature as a symptom can be hard to diagnose during puberty. Despite the presence of small testes, only a quarter of the affected males are recognized as having Klinefelter syndrome at puberty.[33][34] Another quarter receive their diagnosis in late adulthood. About 64% of affected individuals are never recognized.[35] Often the diagnosis is made incidentally as a result of examinations and medical visits for reasons not linked to the condition.[36]



Percentages of Klinefelter's diagnosis divided by age groups, with most diagnoses occurring in adulthood.[30]

The standard diagnostic method is the analysis of the chromosomes' karyotype on lymphocytes. In the past, the observation of the Barr body was common practice as well.[34] To confirm mosaicism, it is also possible to analyze the karyotype using dermal fibroblasts or testicular tissue.[37]

Other methods may be: research of high serum levels of gonadotropins (follicle-stimulating hormone and luteinizing hormone), presence of azoospermia, determination of the sex chromatin,[38] and prenatally via chorionic villus sampling or amniocentesis. A 2002 literature review of elective abortion rates found that approximately 58% of pregnancies in the United States with a diagnosis of Klinefelter syndrome were terminated.[39]

### Differential diagnosis [edit]

The symptoms of Klinefelter syndrome are often variable; therefore, a karyotype analysis should be ordered when small testes, infertility, gynecomastia, long legs/arms, developmental delay, speech/language deficits, learning disabilities/academic issues and/or behavioral issues are present in an individual.[5] The differential diagnosis for the Klinefelter syndrome can include the following conditions: fragile X syndrome, Kallmann syndrome and Marfan syndrome. The cause of hypogonadism can be attributed to many other different medical conditions.

There have been some reports of individuals with Klinefelter syndrome who also have other chromosome abnormalities, such as Down syndrome.[40]

## Treatment [edit]

The genetic variation is irreversible, however, individuals who want to look more masculine can take testosterone.[41] Treating adolescents with implants of controlled release testosterone has shown good

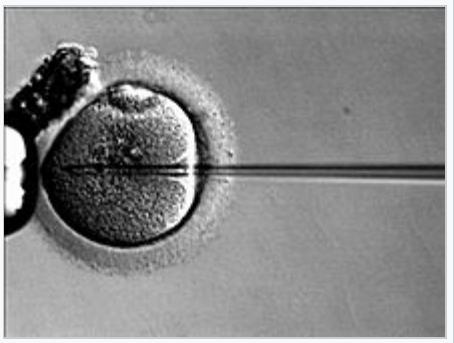
results when appropriately monitored.[42] Hormone therapy is also useful in preventing the onset of osteoporosis.

Often individuals that have noticeable breast tissue or hypogonadism experience depression and/or social anxiety because they are outside of social norms. An academic term for this is psychosocial morbidity.[43] At least one study indicates that planned and timed support should be provided for young men with Klinefelter syndrome to ameliorate current poor psychosocial outcomes.[43] The surgical removal of the breasts may be considered for both the psychological reasons and to reduce the risk of breast cancer.[44]

The use of behavioral therapy can mitigate any language disorders, difficulties at school and socialization. An approach by occupational therapy is useful in children with Down syndrome who have dyspraxia motor.[45]

### Infertility treatment [edit]

By 2010 over 100 successful pregnancies have been reported using IVF technology with surgically removed sperm material from males with Klinefelter syndrome.[46] Microdissection testicular sperm extraction in adult men with Klinefelter syndrome reported success rates of up to 45%.[47]



Intracytoplasmic sperm injection.

## Prognosis [edit]

Children with XXY differ little from other children. Although they can face problems during adolescence, often emotional and behavioral, and difficulties at school, most of them can achieve full independence from their families in adulthood. Most can lead a normal, healthy life.

The results of a study carried out on 87 Australian adults with the syndrome shows that those who have had a diagnosis and appropriate treatment from a very young age had a significant benefit with respect to those who had been diagnosed in adulthood.[48]

There is research suggesting Klinefelter syndrome substantially decreases life expectancy among affected individuals, though the evidence is not definitive.[49] A 1985 publication identified a greater mortality mainly due to diseases of the aortic valve, development of tumors and possible subarachnoid hemorrhages, reducing life expectancy by about 5 years.[50] Later studies have reduced this estimated reduction to an average of 2.1 years.[51] These results are still questioned data, are not absolute, and will need further testing.[49]

## Epidemiology [edit]

This syndrome, evenly spread in all ethnic groups, has a prevalence of 1-2 subjects every 1000 males in the general population.[33][52][53][54] 3.1% of infertile males have Klinefelter syndrome. The syndrome is also the main cause of male hypogonadism.[55]

According to 2008 meta-analysis, the prevalence of the syndrome has increased over the past decades; however, this does not appear to be related to increased age of the mother at conception, as no increase was observed in the rates of other trisomies of sex chromosomes (XXX and XYY).[56] The National Institutes of Health; however, state that older mothers might have a slightly increased risk.[4]

## History [edit]

The syndrome was named after Harry Klinefelter, who, in 1942, worked with Fuller Albright at Massachusetts General Hospital in Boston, Massachusetts, and first described it in the same year.[15][32]

The account given by Klinefelter came to be known as Klinefelter syndrome as his name appeared first on the published paper, and seminiferous tubule dysgenesis was no longer used.

# Sickle-cell disease

From Wikipedia, the free encyclopedia

**Sickle-cell disease** (**SCD**) is a group of blood disorders typically inherited from a person's parents.[1] The most common type is known as **sickle-cell anaemia** (**SCA**). It results in an abnormality in the oxygen-carrying protein haemoglobin found in red blood cells. This leads to a rigid, sickle-like shape under certain circumstances.[1] Problems in sickle cell disease typically begin around 5 to 6 months of age. A number of health problems may develop, such as attacks of pain ("sickle-cell crisis"), anemia, bacterial infections, and stroke.[2] Long term pain may develop as people get older. The average life expectancy in the developed world is 40 to 60 years.[1]

Sickle-cell disease occurs when a person inherits two abnormal copies of the haemoglobin gene, one from each parent.[3] Several subtypes exist, depending on the exact mutation in each haemoglobin gene.[1] An attack can be set off by temperature changes, stress, dehydration, and high altitude.[2] A person with a single abnormal copy does not usually have symptoms and is said to have sickle-cell trait.[3] Such people are also referred to as carriers.[4] Diagnosis is by a blood test, and some countries test all babies at birth for the disease. Diagnosis is also possible during pregnancy.[5]

The care of people with sickle-cell disease may include infection prevention with vaccination and antibiotics, high fluid intake, folic acid supplementation, and pain medication.[4][6] Other measures may include blood transfusion, and the medication hydroxycarbamide (hydroxyurea).[6] A small proportion of people can be cured by a transplant of bone marrow cells.[1]

As of 2013 about 3.2 million people have sickle-cell disease while an additional 43 million have sickle-cell trait.[7] About 80% of sickle-cell disease cases are believed to occur in sub-Saharan Africa.[8] It also occurs relatively frequently in parts of India, the Arabian peninsula, and among people of African origin living in other parts of the world.[9] In 2013, it resulted in 176,000 deaths, up from 113,000 deaths in 1990.[10] The condition was first described in the medical literature by the American physician James B. Herrick in 1910.[11][12] In 1949 the genetic transmission was determined by E. A. Beet and J. V. Neel. In 1954 the protective effect against malaria of [12]

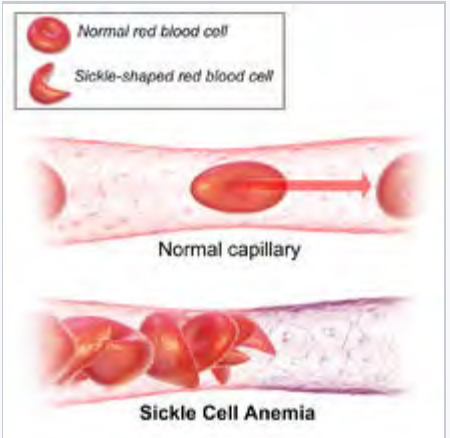
## Signs and symptoms [edit]

Sickle-cell disease may lead to various acute and chronic complications, several of which have a high mortality rate.[13]



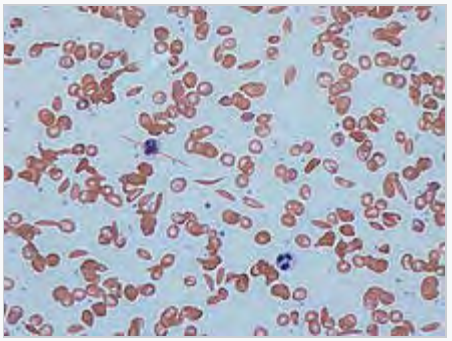
Sickle-cell anemia.

### Sickle-cell crisis [edit]

The terms "sickle-cell crisis" or "sickling crisis" may be used to describe several independent acute conditions occurring in patients with SCD. SCD results in anemia and crises that could be of many types including the vaso-occlusive crisis, aplastic crisis, sequestration crisis, haemolytic crisis, and others. Most episodes of sickle-cell crises last between five and seven days.[14] "Although infection, dehydration, and acidosis (all of which favor sickling) can act as triggers, in most instances, no predisposing cause is identified."[15]

## Vaso-occlusive crisis [edit]

The vaso-occlusive crisis is caused by sickle-shaped red blood cells that obstruct capillaries and restrict blood flow to an organ resulting in ischaemia, pain, necrosis, and often organ damage. The frequency, severity, and duration of these crises vary considerably. Painful crises are treated with hydration, analgesics, and blood transfusion; pain management requires opioid administration at regular intervals until the crisis has settled. For milder crises, a subgroup of patients manage on nonsteroidal anti-inflammatory drugs (NSAIDs) such as diclofenac or naproxen. For more severe crises, most patients require inpatient management for intravenous opioids; patient-controlled analgesia devices are commonly used in this setting. Vaso-occlusive crisis involving organs such as the penis[16] or lungs are considered an emergency and treated with red-blood cell transfusions. Incentive spirometry, a technique to encourage deep breathing to minimise the development of atelectasis, is recommended.[17]



Sickle-cells in human blood: both normal red blood cells and sickle-shaped cells are present.

## Splenic sequestration crisis [edit]

Because of its narrow vessels and function in clearing defective red blood cells, the spleen is frequently affected.[18] It is usually infarcted before the end of childhood in individuals suffering from sickle-cell anemia. This spleen damage increases the risk of infection from encapsulated organisms;[19][20] preventive antibiotics and vaccinations are recommended for those lacking proper spleen function.

Splenic sequestration crises are acute, painful enlargements of the spleen, caused by intrasplenic trapping of red cells and resulting in a precipitous fall in haemoglobin levels with the potential for hypovolemic shock. Sequestration crises are considered an emergency. If not treated, patients may die within 1–2 hours due to circulatory failure. Management is supportive, sometimes with blood transfusion. These crises are transient, they continue for 3–4 hours and may last for one day.[21]

## Acute chest syndrome [edit]

Acute chest syndrome (ACS) is defined by at least two of the following signs or symptoms: chest pain, fever, pulmonary infiltrate or focal abnormality, respiratory symptoms, or hypoxemia.[22] It is the second-most common complication and it accounts for about 25% of deaths in patients with SCD, majority of cases present with vaso-occlusive crises then they develop ACS.[23][24] Nevertheless, about 80% of patients have vaso-occlusive crises during ACS.

## Aplastic crisis [edit]

Aplastic crises are acute worsenings of the patient's baseline anaemia, producing pale appearance, fast heart rate, and fatigue. This crisis is normally triggered by parvovirus B19, which directly affects production of red blood cells by invading the red cell precursors and multiplying in and destroying them.[25] Parvovirus infection almost completely prevents red blood cell production for two to three days. In normal individuals, this is of little consequence, but the shortened red cell life of SCD patients results in an abrupt, life-threatening situation. Reticulocyte counts drop dramatically during the disease (causing reticulocytopenia), and the rapid turnover of red cells leads to the drop in haemoglobin. This crisis takes 4 days to one week to disappear. Most patients can be managed supportively; some need blood transfusion.[26]

## Haemolytic crisis [edit]

Haemolytic crises are acute accelerated drops in haemoglobin level. The red blood cells break down at a faster rate. This is particularly common in patients with coexistent G6PD deficiency.[27] Management is supportive, sometimes with blood transfusions.[17]

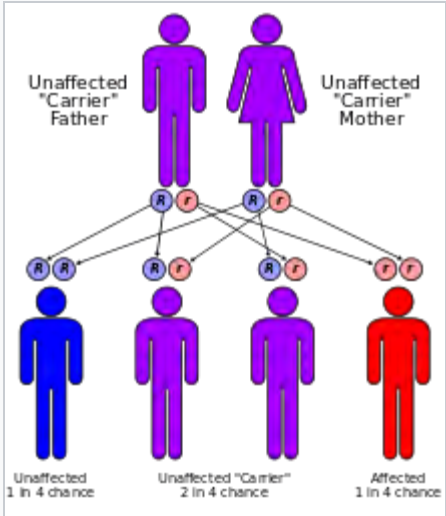
### Other [edit]

One of the earliest clinical manifestations is dactylitis, presenting as early as six months of age, and may occur in children with sickle-cell trait.[28] The crisis can last up to a month.[29] Another recognised type of sickle crisis, acute chest syndrome, is characterised by fever, chest pain, difficulty breathing, and pulmonary infiltrate on a chest X-ray. Given that pneumonia and sickling in the lung can both produce these symptoms, the patient is treated for both conditions.[30] It can be triggered by painful crisis, respiratory infection, bone-marrow embolisation, or possibly by atelectasis, opiate administration, or surgery.[*citation needed*] Hematopoietic ulcers may also occur.[31]

## Genetics [edit]

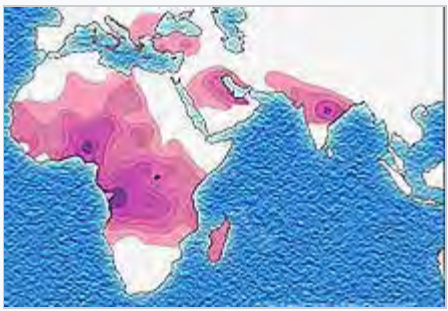
Normally, humans have haemoglobin A, which consists of two alpha and two beta chains, haemoglobin A2, which consists of two alpha and two delta chains, and haemoglobin F, consisting of two alpha and two gamma chains in their bodies. Of these, haemoglobin F dominates until about 6 weeks of age. Afterwards, haemoglobin A dominates throughout life.[*citation needed*]

Sickle-cell conditions have an autosomal recessive pattern of inheritance from parents. The types of haemoglobin a person makes in the red blood cells depend on what haemoglobin genes are inherited from her or his parents. If one parent has sickle-cell anaemia and the other has sickle-cell trait, then the child has a 50% chance of having sickle-cell disease and a 50% chance of having sickle-cell trait. When both parents have sickle-cell trait, a child has a 25% chance of sickle-cell disease, 25% do not carry any sickle-cell alleles, and 50% have the heterozygous condition.[32]



Sickle-cell disease is inherited in the autosomal recessive pattern.

Sickle-cell gene mutation probably arose spontaneously in different geographic areas, as suggested by restriction endonuclease analysis. These variants are known as Cameroon, Senegal, Benin, Bantu, and Saudi-Asian. Their clinical importance is because some are associated with higher HbF levels, e.g., Senegal and Saudi-Asian variants, and tend to have milder disease.[33]



Distribution of the sickle-cell trait shown in pink and purple

In people heterozygous for HgbS (carriers of sickling haemoglobin), the polymerisation problems are minor, because the normal allele is able to produce over 50% of the haemoglobin. In people homozygous for HgbS, the presence of long-chain polymers of HbS distort the shape of the red blood cell from a smooth doughnut-like shape to ragged and full of spikes, making it fragile and susceptible to breaking within capillaries. Carriers have symptoms only if they are deprived of oxygen (for example, while climbing a mountain) or while severely dehydrated. The sickle-cell disease occurs when the sixth amino acid, glutamic acid, is replaced by valine to change its structure and function; as such, sickle-cell anemia is also known as E6V. Valine is hydrophobic, causing the haemoglobin to collapse on itself occasionally. The structure is not changed otherwise. When enough haemoglobin collapses on itself the red blood cells become sickle-shaped.[*citation needed*]

The gene defect is a known mutation of a single nucleotide (see single-

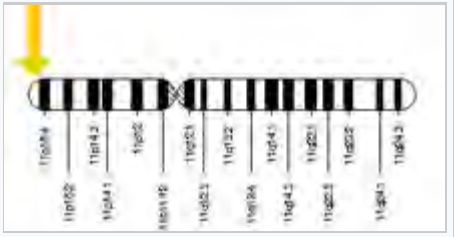
Modern distribution of malaria

nucleotide polymorphism - SNP) (A to T) of the β-globin gene, which results in glutamic acid (E/Glu) being substituted by valine (V/Val) at position 6. Note, historic numbering put this glutamic acid residue at position 6 due to skipping the methionine (M/Met) start codon in protein amino acid position numbering. Current nomenclature calls for counting the methionine as the first amino acid, resulting in the glutamic acid residue falling at position 7. Many references still refer to position 6 and both should likely be referenced for clarity. Haemoglobin S with this mutation is referred to as HbS, as opposed to the normal adult HbA. The genetic disorder is due to the mutation of a single nucleotide, from a GAG to GTG codon on the coding strand, which is transcribed from the template strand into a GUG codon. Based on genetic code, GAG codon translates to glutamic acid (E/Glu) while GUG codon translates to valine (V/Val) amino acid at position 6. This is normally a benign mutation, causing no apparent effects on the secondary, tertiary, or quaternary structures of haemoglobin in conditions of normal oxygen concentration. What it does allow for, under conditions of low oxygen concentration, is the polymerization of the HbS itself. The deoxy form of haemoglobin exposes a hydrophobic patch on the protein between the E and F helices. The hydrophobic side chain of the valine residue at position 6 of the beta chain in haemoglobin is able to associate with the hydrophobic patch, causing haemoglobin S molecules to aggregate and form fibrous precipitates.



HBB gene (responsible for sickle-cell anaemia) is located on the short (p) arm of chromosome 11 at position 15.5

The allele responsible for sickle-cell anaemia can be found on the short arm of chromosome 11, more specifically 11p15.5. A person who receives the defective gene from both father and mother develops the disease; a person who receives one defective and one healthy allele remains healthy, but can pass on the disease and is known as a carrier or heterozygote. Heterozygotes are still able to contract malaria, but their symptoms are generally less severe.[34]

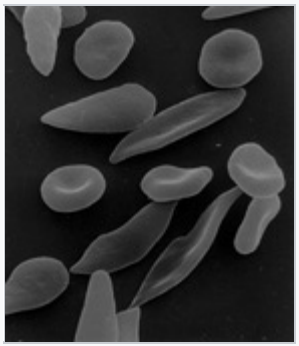
Due to the adaptive advantage of the heterozygote, the disease is still prevalent, especially among people with recent ancestry in malaria-stricken areas, such as Africa, the Mediterranean, India, and the Middle East.[35] Malaria was historically endemic to southern Europe, but it was declared eradicated in the mid-20th century, with the exception of rare sporadic cases.[36]

The malaria parasite has a complex lifecycle and spends part of it in red blood cells. In a carrier, the presence of the malaria parasite causes the red blood cells with defective haemoglobin to rupture prematurely, making the *Plasmodium* parasite unable to reproduce. Further, the polymerization of Hb affects the ability of the parasite to digest Hb in the first place. Therefore, in areas where malaria is a problem, people's chances of survival actually increase if they carry sickle-cell trait (selection for the heterozygote).

In the USA, with no endemic malaria, the prevalence of sickle-cell anaemia among African Americans is lower (about 0.25%) than in West Africa (about 4.0%) and is falling. Without endemic malaria, the sickle-cell mutation is purely disadvantageous and tends to decline in the affected population by natural selection, and now artificially through prenatal genetic screening. However, the African American community descends from a significant admixture of several African and non-African ethnic groups and also represents the descendants of survivors of slavery and the slave trade. Thus, a lower degree of endogamy and, particularly, abnormally high health-selective pressure through slavery may be the most plausible explanations for the lower prevalence of sickle-cell anaemia (and, possibly, other genetic diseases) among African Americans compared to West Africans. Another factor that limits the spread of sickle-cell genes in North America is the absence of cultural proclivities to polygamy, which allows affected males to continue

to seek unaffected children with multiple partners.[37]

## Pathophysiology [edit]



Scanning electron micrograph showing a mixture of red blood cells, some with round normal morphology, some with mild sickling showing elongation and bending

The loss of red blood cell elasticity is central to the pathophysiology of sickle-cell disease. Normal red blood cells are quite elastic, which allows the cells to deform to pass through capillaries. In sickle-cell disease, low oxygen tension promotes red blood cell sickling and repeated episodes of sickling damage the cell membrane and decrease the cell's elasticity. These cells fail to return to normal shape when normal oxygen tension is restored. As a consequence, these rigid blood cells are unable to deform as they pass through narrow capillaries, leading to vessel occlusion and ischaemia.

The actual anaemia of the illness is caused by haemolysis, the destruction of the red cells, because of their shape. Although the bone marrow attempts to compensate by creating new red cells, it does not match the rate of destruction.[38] Healthy red blood cells typically function for 90–120 days, but sickled cells only last 10–20 days.[39]

## Diagnosis [edit]

In HbSS, the complete blood count reveals haemoglobin levels in the range of 6–8 g/dl with a high reticulocyte count (as the bone marrow compensates for the destruction of sickled cells by producing more red blood cells). In other forms of sickle-cell disease, Hb levels tend to be higher. A blood film may show features of hyposplenism (target cells and Howell-Jolly bodies).

Sickling of the red blood cells, on a blood film, can be induced by the addition of sodium metabisulfite. The presence of sickle haemoglobin can also be demonstrated with the "sickle solubility test". A mixture of haemoglobin S (Hb S) in a reducing solution (such as sodium dithionite) gives a turbid appearance, whereas normal Hb gives a clear solution.

Abnormal haemoglobin forms can be detected on haemoglobin electrophoresis, a form of gel electrophoresis on which the various types of haemoglobin move at varying speeds. Sickle-cell haemoglobin (HgbS) and haemoglobin C with sickling (HgbSC)—the two most common forms—can be identified from there. The diagnosis can be confirmed with high-performance liquid chromatography. Genetic testing is rarely performed, as other investigations are highly specific for HbS and HbC.[40]

An acute sickle-cell crisis is often precipitated by infection. Therefore, a urinalysis to detect an occult urinary tract infection, and chest X-ray to look for occult pneumonia should be routinely performed.[41]

People who are known carriers of the disease often undergo genetic counseling before they have a child. A test to see if an unborn child has the disease takes either a blood sample from the fetus or a sample of amniotic fluid. Since taking a blood sample from a fetus has greater risks, the latter test is usually used. Neonatal screening provides not only a method of early detection for individuals with sickle-cell disease, but also allows for identification of the groups of people that carry the sickle cell trait.[42]

## Management [edit]

### Folic acid and penicillin [edit]

Folic acid daily for life is recommended. From birth to five years of age, penicillin daily due to the immature immune system that makes them more prone to early childhood illnesses is also recommended.

### Malaria prevention [edit]

The protective effect of sickle-cell trait does not apply to people with sickle cell disease; in fact, they are more vulnerable to malaria, since the most common cause of painful crises in malarial countries is infection with malaria. It has therefore been recommended that people with sickle-cell disease living in malarial countries should receive anti-malarial chemoprophylaxis for life.[43]

### Vaso-occlusive crisis [edit]

Most people with sickle-cell disease have intensely painful episodes called vaso-occlusive crises. However, the frequency, severity, and duration of these crises vary tremendously. Painful crises are treated symptomatically with pain medications; pain management requires opioid administration at regular intervals until the crisis has settled. For milder crises, a subgroup of patients manage on NSAIDs (such as diclofenac or naproxen). For more severe crises, most patients require inpatient management for intravenous opioids; patient-controlled analgesia (PCA) devices are commonly used in this setting. Diphenhydramine is also an effective agent that doctors frequently prescribe to help control itching associated with the use of opioids.[*citation needed*]

### Acute chest crisis [edit]

Management is similar to vaso-occlusive crisis, with the addition of antibiotics (usually a quinolone or macrolide, since cell wall-deficient ["atypical"] bacteria are thought to contribute to the syndrome),[44] oxygen supplementation for hypoxia, and close observation. Should the pulmonary infiltrate worsen or the oxygen requirements increase, simple blood transfusion or exchange transfusion is indicated. The latter involves the exchange of a significant portion of the person's red cell mass for normal red cells, which decreases the percent of haemoglobin S in the patient's blood. The patient with suspected acute chest syndrome should be admitted to the hospital with worsening A-a gradient an indication for ICU admission.[22]

### Hydroxyurea [edit]

The first approved drug for the causative treatment of sickle-cell anaemia, hydroxyurea, was shown to decrease the number and severity of attacks in a study in 1995 (Charache *et al.*)[45] and shown to possibly increase survival time in a study in 2003 (Steinberg *et al.*).[46] This is achieved, in part, by reactivating fetal haemoglobin production in place of the haemoglobin S that causes sickle-cell anaemia. Hydroxyurea had previously been used as a chemotherapy agent, and there is some concern that long-term use may be harmful, but this risk has been shown to be either absent or very small and it is likely that the benefits outweigh the risks.[13][47]

### Blood transfusion [edit]

Blood transfusions are often used in the management of sickle-cell disease in acute cases and to prevent complications by decreasing the number of red blood cells (RBC) that can sickle by adding normal red blood cells.[48] In children preventative red blood cell (RBC) transfusion therapy has been shown to reduce the risk of first stroke or silent stroke when transcranial Doppler (TCD) ultrasonography shows abnormal cerebral blood flow.[6] In those who have sustained a prior stroke event it also reduces the risk of recurrent stroke and additional silent strokes.[49][50]

### Bone marrow transplant [edit]

Bone marrow transplants have proven effective in children. Bone marrow transplants are the only known cure for SCD.[51] However, bone marrow transplants are difficult to obtain because of the specific HLA typing necessary. Ideally, a close relative (allogeneic) would donate the bone marrow necessary for transplantation.

## Prognosis [edit]

About 90% of people survive to age 20, and close to 50% survive beyond the fifth decade.[52] In 2001, according to one study performed in Jamaica, the estimated mean survival for people with sickle-cell was 53 years old for men and 58 years old for women with homozygous SCD.[53] The specific life expectancy in much of the developing world is unknown.[54]

## Complications [edit]

Sickle-cell anaemia can lead to various complications, including:

- Increased risk of severe bacterial infections due to loss of functioning spleen tissue (and comparable to the risk of infections after having the spleen removed surgically). These infections are typically caused by encapsulated organisms such as *Streptococcus pneumoniae* and *Haemophilus influenzae*. Daily penicillin prophylaxis is the most commonly used treatment during childhood, with some haematologists continuing treatment indefinitely. Patients benefit today from routine vaccination for *S. pneumoniae*.[55]
- Stroke, which can result from a progressive narrowing of blood vessels, prevents oxygen from reaching the brain. Cerebral infarction occurs in children and cerebral haemorrhage in adults.[*citation needed*]
- Silent stroke causes no immediate symptoms, but is associated with damage to the brain. Silent stroke is probably five times as common as symptomatic stroke. About 10–15% of children with SCD suffer strokes, with silent strokes predominating in the younger patients.[56][57]
- Cholelithiasis (gallstones) and cholecystitis may result from excessive bilirubin production and precipitation due to prolonged haemolysis.
- Avascular necrosis (aseptic bone necrosis) of the hip and other major joints may occur as a result of ischaemia.[58]
- Decreased immune reactions due to hyposplenism (malfunctioning of the spleen)[59]
- Priapism and infarction of the penis[60]
- Osteomyelitis (bacterial bone infection), the most common cause of osteomyelitis in SCD is *Salmonella* (especially the atypical serotypes *Salmonella typhimurium, Salmonella enteritidis, Salmonella choleraesuis* and *Salmonella paratyphi* B), followed by *Staphylococcus aureus* and Gram-negative enteric bacilli perhaps because intravascular sickling of the bowel leads to patchy ischaemic infarction.[61]
- Opioid tolerance can occur as a normal, physiologic response to the therapeutic use of opiates. Addiction to opiates occurs no more commonly among individuals with sickle-cell disease than among other individuals treated with opiates for other reasons.[*citation needed*]
- Acute papillary necrosis in the kidneys
- Leg ulcers[62]
- In eyes, background retinopathy, proliferative retinopathy, vitreous haemorrhages, and retinal detachments can result in blindness.[63] Regular annual eye checks are recommended.
- During pregnancy, intrauterine growth retardation, spontaneous abortion, and pre-eclampsia
- Chronic pain: Even in the absence of acute vaso-occlusive pain, many patients have unreported chronic pain.[64]
- Pulmonary hypertension (increased pressure on the pulmonary artery) can lead to strain on the right ventricle and a risk of heart failure; typical symptoms are shortness of breath, decreased exercise tolerance, and episodes of syncope.[*citation needed*] 21% of children and 30% of adults have evidence of pulmonary hypertension when tested; this is associated with reduced walking distance and increased mortality.[65]
- Chronic kidney failure due to sickle-cell nephropathy manifests itself with hypertension, protein loss in the urine, loss of red blood cells in urine and worsened anaemia. If it progresses to end-stage renal failure, it carries a poor prognosis.[66]

# Epidemiology [edit]

The highest frequency of sickle cell disease is found in tropical regions, particularly sub-Saharan Africa, tribal regions of India and the Middle-East.[67] Migration of substantial populations from these high prevalence areas to low prevalence countries in Europe has dramatically increased in recent decades and in some European countries sickle-cell disease has now overtaken more familiar genetic conditions such as

haemophilia and cystic fibrosis.[68] In 2013 it resulted in 176,000 deaths due to SCD up from 113,000 deaths in 1990.[10]

Sickle-cell disease occurs more commonly among people whose ancestors lived in tropical and sub-tropical sub-Saharan regions where malaria is or was common. Where malaria is common, carrying a single sickle-cell allele (trait) confers a selective advantage—in other words, being a heterozygote is advantageous. Specifically, humans with one of the two alleles of sickle-cell disease show less severe symptoms when infected with malaria.[69]

## Africa [edit]

Three-quarters of sickle-cell cases occur in Africa. A recent WHO report estimated that around 2% of newborns in Nigeria were affected by sickle cell anaemia, giving a total of 150,000 affected children born every year in Nigeria alone. The carrier frequency ranges between 10% and 40% across equatorial Africa, decreasing to 1–2% on the north African coast and <1% in South Africa.[70] There have been studies in Africa that show a significant decrease in infant mortality rate, ages 2–16 months, because of the sickle-cell trait. This happened in predominant areas of malarial cases.[71]

## United States [edit]

The number of people with the disease in the United States is approximately 1 in 5,000, mostly affecting Americans of Sub-Saharan African descent, according to the National Institutes of Health.[72] In the United States, about one out of 500 African-American children and one in every 36,000 Hispanic-American children have sickle-cell anaemia.[73] It is estimated that sickle-cell disease affects 90,000 Americans.[74] Most infants with SCD born in the United States are now identified by routine neonatal screening. As of 2016 all 50 states include screening for sickle cell disease as part of their newborn screen.[75]

## France [edit]

As a result of population growth in African-Caribbean regions of overseas France and immigration from North and sub-Saharan Africa to mainland France, sickle-cell disease has become a major health problem in France.[76] SCD has become the most common genetic disease in the country, with an overall birth prevalence of 1/2,415 in mainland France, ahead of phenylketonuria (1/10,862), congenital hypothyroidism (1/3,132), congenital adrenal hyperplasia (1/19,008) and cystic fibrosis (1/5,014) for the same reference period. In 2010, 31.5% of all newborns in mainland France (253,466 out of 805,958) were screened for SCD (this percentage was 19% in 2000). 341 newborns with SCD and 8,744 heterozygous carriers were found representing 1.1% of all newborns in mainland France. The Paris metropolitan district (Île-de-France) is the region that accounts for the largest number of newborns screened for SCD (60% in 2010). The second largest number of at-risk is in Provence-Alpes-Côte d'Azur at nearly 43.2% and the lowest number is in Brittany at 5.5%.[77][78]

## United Kingdom [edit]

In the United Kingdom (UK) it is thought that between 12,000 and 15,000 people have sickle cell disease [79] with an estimate of 250,000 carriers of the condition in England alone. As the number of carriers is only estimated, all newborn babies in the UK receive a routine blood test to screen for the condition.[80] Due to many adults in high-risk groups not knowing if they are carriers, pregnant women and both partners in a couple are offered screening so they can get counselling if they have the sickle cell trait.[81] In addition blood donors from those in high-risk groups are also screened to confirm whether they are carriers and whether their blood filters properly.[82] Donors who are found to be carriers are then informed and their blood, while often used for those of the same ethnic group, is not used for those with sickle cell disease who require a blood transfusion.[83]

## Middle East [edit]

In Saudi Arabia about 4.2% of the population carry the sickle-cell trait and 0.26% have sickle-cell disease. The highest prevalence is in the Eastern province where approximately 17% of the population carry the gene and 1.2% have sickle-cell disease.[84] In 2005 in Saudi Arabia a mandatory pre-marital test including HB electrophoresis was launched and aimed to decrease the incidence of SCD and thalassemia.[85]

In Bahrain a study published in 1998 that covered about 56,000 people in hospitals in Bahrain found that 2% of newborns have sickle cell disease, 18% of the surveyed people have the sickle cell trait, and 24% were carriers of the gene mutation causing the disease.[86] The country began screening of all pregnant women in 1992 and newborns started being tested if the mother was a carrier. In 2004, a law was passed requiring couples planning to get married to undergo free premarital counseling. These programs were accompanied by public education campaigns.[87]

### India and Nepal [edit]

Sickle-cell disease is common in ethnic groups of central India who share a genetic linkage with African communities,[*citation needed*] where the prevalence has ranged from 9.4 to 22.2% in endemic areas of Madhya Pradesh, Rajasthan and Chhattisgarh.[88] It is also endemic among Tharu people of Nepal and India; however, they have a sevenfold lower incidence of malaria despite living in a malaria infested zone.[89]

### Caribbean Islands [edit]

In Jamaica, 10% of the population carries the sickle-cell gene, making it the most prevalent genetic disorder in the country.[90]

## History [edit]

The first modern report of sickle-cell disease may have been in 1846, where the autopsy of an executed runaway slave was discussed; the key findings was the absence of the spleen.[91][92] There were also reports amongst African slaves in the United States exhibiting resistance to malaria but being prone to leg ulcers.[92] The abnormal characteristics of the red blood cells, which later lent their name to the condition, was first described by Ernest E. Irons (1877–1959), intern to the Chicago cardiologist and professor of medicine James B. Herrick (1861–1954), in 1910. Irons saw "peculiar elongated and sickle-shaped" cells in the blood of a man named Walter Clement Noel, a 20-year-old first-year dental student from Grenada. Noel had been admitted to the Chicago Presbyterian Hospital in December 1904 suffering from anaemia.[11][93] Noel was readmitted several times over the next three years for "muscular rheumatism" and "bilious attacks" but completed his studies and returned to the capital of Grenada (St. George's) to practice dentistry. He died of pneumonia in 1916 and is buried in the Catholic cemetery at Sauteurs in the north of Grenada.[11][12] Shortly after the report by Herrick, another case appeared in the *Virginia Medical Semi-Monthly* with the same title, "Peculiar Elongated and Sickle-Shaped Red Blood Corpuscles in a Case of Severe Anemia."[94] This article is based on a patient admitted to the University of Virginia Hospital on November 15, 1910.[95] In the later description by Verne Mason in 1922, the name "sickle cell anemia" is first used.[12][96] Childhood problems related to sickle cells disease were not reported until the 1930s, despite the fact that this cannot have been uncommon in African-American populations.[92]

The Memphis physician Lemuel Diggs, a prolific researcher into sickle cell disease, first introduced the distinction between sickle cell disease and trait in 1933, although it took until 1949 until the genetic characteristics were elucidated by James V. Neel and E.A. Beet.[12] 1949 was the year when Linus Pauling described the unusual chemical behaviour of haemoglobin S, and attributed this to an abnormality in the molecule itself.[12][97] The actual molecular change in HbS was described in the late 1950s BY Vernon Ingram.[12] The late 1940s and early 1950s saw further understanding in the link between malaria and sickle cell disease. In 1954, the introduction of haemoglobin electrophoresis allowed the discovery of particular subtypes, such as HbSC disease.[12]

Large scale natural history studies and further intervention studies were introduced in the 1970s and 1980s, leading to widespread use of prophylaxis against pneumococcal infections amongst other interventions. Bill Cosby's Emmy-winning 1972 TV movie, *To All My Friends on Shore*, depicted the story of the parents of a child suffering from sickle-cell disease.[98] The 1990s saw the development of hydroxycarbamide, and reports of cure through bone marrow transplantation appeared in 2007.[12]

Some old texts refer to it as drepanocytosis.[*citation needed*]

# Research [edit]

## Umbilical cord blood transplant [edit]

In December 1998, researchers from Emory University conducted an experimental bone marrow transplant procedure on a group of 22 children under 16 years old.[99] One of those patients, 12-year-old Keone Penn, was apparently the first person to be cured of sickle-cell disease through this method.[100] The stem cells were sourced from a donor unrelated to Penn. A 2007 Georgia Senate bill proposing the collection and donation of stem cell material, the "Saving the Cure Act", was nicknamed "Keone's Law" in his honor.[101]

By mid-2007 a similar set of clinical trials in Baltimore had also cured several adults.[102]

## Gene therapy [edit]

In 2001 it was reported that sickle-cell disease had been successfully treated in mice using gene therapy.[103][104] The researchers used a viral vector to make the mice—which have essentially the same defect that causes human sickle cell disease—express production of fetal haemoglobin (HbF), which an individual normally ceases to produce shortly after birth. In humans, using hydroxyurea to stimulate the production of HbF has been known to temporarily alleviate sickle cell disease symptoms. The researchers demonstrated that this gene therapy method is a more permanent way to increase therapeutic HbF production.[105]

Phase 1 clinical trials of gene therapy for sickle cell disease in humans were started in 2014. The clinical trials will assess the safety and initial evidence for efficacy of an autologous transplant of lentiviral vector-modified bone marrow for adults with severe sickle cell disease.[106][107] As of 2014, however, no randomized controlled trials have been reported.[108]

# Spina bifida

**Spina bifida** is a birth defect where there is incomplete closing of the backbone and membranes around the spinal cord. There are three main types: **spina bifida occulta**, **meningocele**, and **myelomeningocele**.[1] The most common location is the lower back, but in rare cases it may be the middle back or neck.[2] Occulta has no or only mild signs.[3] Signs of occulta may include a hairy patch, dimple, dark spot, or swelling on the back at the site of the gap in the spine. Meningocele typically causes mild problems with a sac of fluid present at the gap in the spine.[1] Myelomeningocele, also known as open spina bifida, is the most severe form. Associated problems include poor ability to walk, problems with bladder or bowel control, hydrocephalus, a tethered spinal cord, and latex allergy.[4] Learning problems are relatively uncommon.[4]

Spina bifida is believed to be due to a combination of genetic and environmental factors.[5] After having one child with the condition, or if one of the parents has the condition, there is a 4% chance that the next child will also be affected.[6] Not having enough folate in the diet before and during pregnancy also plays a significant role.[5] Other risk factors include certain antiseizure medications, obesity, and poorly controlled diabetes.[6] Diagnosis may occur either before or after a child is born. Before birth if a blood test or amniocentesis finds a high level of alpha-fetoprotein (AFP), there is a higher risk of spina bifida. Ultrasound examination may also detect the problem. Medical imaging can confirm the diagnosis after birth.[3] It is a type of neural tube defect with other types including anencephaly and encephalocele.[7]

Most cases of spina bifida can be prevented if the mother gets enough folate before and during pregnancy.[5] Adding folic acid to flour has been found to be effective for most women.[8] Open spina bifida can be surgically closed before or after birth. A shunt may be needed in those with hydrocephalus, and a tethered spinal cord may be surgically repaired. Devices to help with movement such as crutches or wheelchairs may be useful. Urinary catheterization may also be needed.[9]

About 5% of people have spina bifida occulta.[10] Rates of other types of spina bifida vary significantly by country, from 0.1 to 5 per 1000 births.[11] On average in developed countries it occurs in about 0.4 per 1000 births.[12] In the United States, it affected about 0.4 per 1000 births,[6][13] and in India, about 1.9 per 1000 births.[14] Part of this difference is believed to be due to race – with Caucasians at higher risk – and partly due to environmental factors.[15] The term is Latin for "split spine".

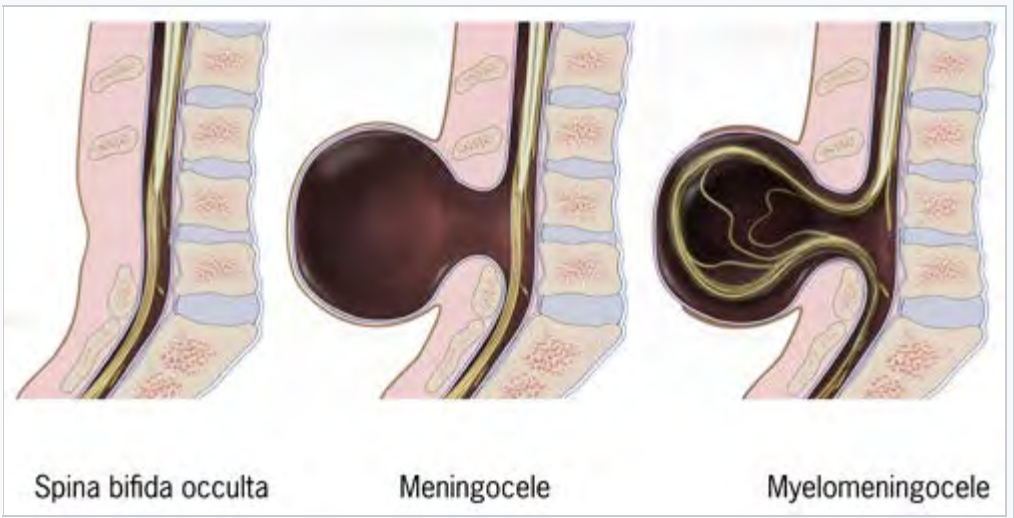
Video explanation

# Types [edit]

There are two types: spina bifida occulta and spina bifida cystica.[16] Spina bifida cystica can then be broken down into meningocele and myelomeningocele.[16]



Different types of spina bifida

## Spina bifida occulta

[edit]

*Occulta* is Latin for "hidden". This is the mildest form of spina bifida.[17] In occulta, the outer part of some of the vertebrae is not completely closed.[18] The splits in the vertebrae are so small that the spinal cord does not protrude. The skin at the site of the lesion may be normal, or it may have some hair growing from it; there may be a dimple in the skin, or a birthmark.[19] Unlike most other types of neural tube defects, spina bifida occulta is not associated with increased AFP, a common screening tool used to detect neural tube defects in utero. This is because, unlike most of the other neural tube defects, the dural lining is maintained.

Many people with this type of spina bifida do not even know they have it, as the condition is asymptomatic in most cases.[19] The incidence of spina bifida occulta is approximately 10-20% of the population,[20][21] and most people are diagnosed incidentally from spinal X-rays. A systematic review of radiographic research studies found no relationship between spina bifida occulta and back pain.[22] More recent studies not included in the review support the negative findings.[23][24][25]

However, other studies suggest spina bifida occulta is not always harmless. One study found that among patients with back pain, severity is worse if spina bifida occulta is present.[26][27] Among females, this could be mistaken for dysmenorrhea.

*Incomplete posterior fusion* is not a true spina bifida, and is very rarely of neurological significance.[28]

## Meningocele [edit]

A posterior meningocele (pronounced /məˈnɪŋgəˌsil/) or meningeal cyst (pronounced /mɪˈnɪndʒiəl/ /sɪst/) is the least common form of spina bifida. In this form, a single developmental defect allows the meninges to herniate between the vertebrae. As the nervous system remains undamaged, individuals with meningocele are unlikely to suffer long-term health problems, although cases of tethered cord have been reported. Causes of meningocele include teratoma and other tumors of the sacrococcyx and of the presacral space, and Currarino syndrome.

A meningocele may also form through dehiscences in the base of the skull. These may be classified by their localisation to occipital, frontoethmoidal, or nasal. Endonasal meningoceles lie at the roof of the nasal cavity and may be mistaken for a nasal polyp. They are treated surgically. Encephalomeningoceles are classified in the same way and also contain brain tissue.

## Myelomeningocele [edit]

Myelomeningocele, also known as meningomyelocele, is the type of spina bifida that often results in the most severe complications.[29] In individuals with myelomeningocele, the unfused portion of the spinal column allows the spinal cord to protrude through an opening. The meningeal membranes that cover the spinal cord also protrude through the opening, forming a sac enclosing the spinal elements, such as meninges, cerebrospinal fluid, and parts of the spinal cord and nerve roots.[30]

## Myeloschisis [edit]

Spina bifida with **myeloschisis** is the most severe form of myelomeningocele. In this type, the involved area is represented by a flattened, plate-like mass of nervous tissue with no overlying membrane. The exposure of these nerves and tissues make the baby more prone to life-threatening infections such as meningitis.[31]

The protruding portion of the spinal cord and the nerves that originate at that level of the cord are damaged or not properly developed. As a result, there is usually some degree of paralysis and loss of sensation below the level of the spinal cord defect. Thus, the more cranial the level of the defect, the more severe the associated nerve dysfunction and resultant paralysis may be. Symptoms may include ambulatory problems, loss of sensation, deformities of the hips, knees or feet, and loss of muscle tone.

# Signs and symptoms [edit]

## Physical problems [edit]

Physical signs of spina bifida may include:

- Leg weakness and paralysis[32]
- Orthopedic abnormalities (i.e., club foot, hip dislocation, scoliosis)[32]
- Bladder and bowel control problems, including incontinence, urinary tract infections, and poor kidney function[32]
- Pressure sores and skin irritations[32]
- Abnormal eye movement[33]

68% of children with spina bifida have an allergy to latex,[34] ranging from mild to life-threatening. The common use of latex in medical facilities makes this a particularly serious concern. The most common approach to avoid developing an allergy is to avoid contact with latex-containing products such as examination gloves and condoms and catheters that do not specify they are latex free, and many other products, such as some commonly used by dentists.[18]

The spinal cord lesion or the scarring due to surgery may result in a tethered spinal cord. In some individuals, this causes significant traction and stress on the spinal cord and can lead to a worsening of associated paralysis, scoliosis, back pain, and worsening bowel and/or bladder function.[35]

## Neurological problems [edit]

Many individuals with spina bifida have an associated abnormality of the cerebellum, called the Arnold Chiari II malformation. In affected individuals, the back portion of the brain is displaced from the back of the skull down into the upper neck. In about 90% of the people with myelomeningocele, hydrocephalus also occurs because the displaced cerebellum interferes with the normal flow of cerebrospinal fluid, causing an excess of the fluid to accumulate.[36] In fact, the cerebellum also tends to be smaller in individuals with spina bifida, especially for those with higher lesion levels.[33]

The corpus callosum is abnormally developed in 70-90% of individuals with spina bifida myelomeningocele; this affects the communication processes between the left and right brain hemispheres.[37] Further, white matter tracts connecting posterior brain regions with anterior regions appear less organized. White matter tracts between frontal regions have also been found to be impaired.[33]

Cortex abnormalities may also be present. For example, frontal regions of the brain tend to be thicker than expected, while posterior and parietal regions are thinner. Thinner sections of the brain are also associated with increased cortical folding.[33] Neurons within the cortex may also be displaced.[38]

## Executive function [edit]

Several studies have demonstrated difficulties with executive functions in youth with spina bifida,[39][40] with greater deficits observed in youth with shunted hydrocephalus.[41] Unlike typically developing children, youths with spina bifida do not tend to improve in their executive functioning as they grow older.[40] Specific areas of difficulty in some individuals include planning, organizing, initiating, and working memory. Problem-solving, abstraction, and visual planning may also be impaired.[42] Further, children with spina bifida may have poor cognitive flexibility. Although executive functions are often attributed to the frontal lobes of the brain, individuals with spina bifida have intact frontal lobes; therefore, other areas of the brain may be implicated.[41]

Individuals with spina bifida, especially those with shunted hydrocephalus, often have attention problems. Children with spina bifida and shunted hydrocephalus have higher rates of ADHD than children without those conditions (31% vs. 17%).[39] Deficits have been observed for selective attention and focused

attention, although poor motor speed may contribute to poor scores on tests of attention.[41][43] Attention deficits may be evident at a very early age, as infants with spina bifida lag behind their peers in orienting to faces.[44]

### Academic skills [edit]

Individuals with spina bifida may struggle academically, especially in the subjects of mathematics and reading. In one study, 60% of children with spina bifida were diagnosed with a learning disability.[45] In addition to brain abnormalities directly related to various academic skills, achievement is likely affected by impaired attentional control and executive functioning.[38] Children with spina bifida may perform well in elementary school, but begin to struggle as academic demands increase.

Children with spina bifida are more likely than their peers without spina bifida to be dyscalculic.[46] Individuals with spina bifida have demonstrated stable difficulties with arithmetic accuracy and speed, mathematical problem-solving, and general use and understanding of numbers in everyday life.[47] Mathematics difficulties may be directly related to the thinning of the parietal lobes (regions implicated in mathematical functioning) and indirectly associated with deformities of the cerebellum and midbrain that affect other functions involved in mathematical skills. Further, higher numbers of shunt revisions are associated with poorer mathematics abilities.[48] Working memory and inhibitory control deficiencies have been implicated for math difficulties,[49] although visual-spatial difficulties are not likely involved.[46] Early intervention to address mathematics difficulties and associated executive functions is crucial.[49]

Individuals with spina bifida tend to have better reading skills than mathematics skills.[48] Children and adults with spina bifida have stronger abilities in reading accuracy than in reading comprehension.[50] Comprehension may be especially impaired for text that requires an abstract synthesis of information rather than a more literal understanding.[51] Individuals with spina bifida may have difficulty with writing due to deficits in fine motor control and working memory.[50]

## Cause [edit]

Spina bifida is believed to be caused by a combination of genetic and environmental factors.[5] After having one child with the condition, or if a parent has the condition, there is a 4% chance the next child will also be affected.[6] A folic acid deficiency during pregnancy also plays a significant role.[5] Other risk factors include certain antiseizure medications, obesity, and poorly managed diabetes.[6] Drinking alcohol often, triggers macrocytosis which discard folate. After stopping the drinking of alcohol, a time period of months is needed to rejuvenate bone marrow, recover from macrocytosis.[52]

Those who are white or Hispanic have a higher risk. Girls are more prone to being born with spina bifida.[53]

## Pathophysiology [edit]

Spina bifida is sometimes caused by the failure of the neural tube to close during the first month of embryonic development (often before the mother knows she is pregnant). Some forms are known to occur with primary conditions that cause raised central nervous system pressure, which raises the possibility of a dual pathogenesis.[*citation needed*]

In normal circumstances, the closure of the neural tube occurs around the 23rd (rostral closure) and 27th (caudal closure) day after fertilization.[54] However, if something interferes and the tube fails to close properly, a neural tube defect will occur. Medications such as some anticonvulsants, diabetes, obesity, and having a relative with spina bifida can all affect the probability of neural tube malformation.

Extensive evidence from mouse strains with spina bifida indicates that there is sometimes a genetic basis for the condition. Human spina bifida, like other human diseases, such as cancer, hypertension and

atherosclerosis (coronary artery disease), likely results from the interaction of multiple genes and environmental factors.[*citation needed*]

Research has shown the lack of folic acid (folate) is a contributing factor in the pathogenesis of neural tube defects, including spina bifida. Supplementation of the mother's diet with folate can reduce the incidence of neural tube defects by about 70%, and can also decrease the severity of these defects when they occur.[55][56][57] It is unknown how or why folic acid has this effect.

Spina bifida does not follow direct patterns of heredity like muscular dystrophy or haemophilia. Studies show a woman having had one child with a neural tube defect such as spina bifida has about a 3% risk of having another affected child. This risk can be reduced with folic acid supplementation before pregnancy. For the general population, low-dose folic acid supplements are advised (0.4 mg/day).[*citation needed*]

## Prevention [edit]

There is neither a single cause of spina bifida nor any known way to prevent it entirely. However, dietary supplementation with folic acid has been shown to be helpful in reducing the incidence of spina bifida. Sources of folic acid include whole grains, fortified breakfast cereals, dried beans, leaf vegetables and fruits.[58]

Folate fortification of enriched grain products has been mandatory in the United States since 1998. The U.S. Food and Drug Administration, Public Health Agency of Canada[59] and UK recommended amount of folic acid for women of childbearing age and women planning to become pregnant is at least 0.4 mg/day of folic acid from at least three months before conception, and continued for the first 12 weeks of pregnancy.[60] Women who have already had a baby with spina bifida or other type of neural tube defect, or are taking anticonvulsant medication should take a higher dose of 4–5 mg/day.[60]

Certain mutations in the gene *VANGL1* are implicated as a risk factor for spina bifida: These mutations have been linked with spina bifida in some families with a history of spina bifida.[61]

## Screening [edit]

Open spina bifida can usually be detected during pregnancy by fetal ultrasound. Increased levels of maternal serum alpha-fetoprotein (MSAFP) should be followed up by two tests - an ultrasound of the fetal spine and amniocentesis of the mother's amniotic fluid (to test for alpha-fetoprotein and acetylcholinesterase). AFP tests are now mandated by some state laws (including California). and failure to provide them can have legal ramifications. In one case a man born with spina bifida was awarded a $2 million settlement after court found his mother's OBGYN negligent for not performing these tests.[62] Spina bifida may be associated with other malformations as in dysmorphic syndromes, often resulting in spontaneous miscarriage. In the majority of cases, though, spina bifida is an isolated malformation.

Genetic counseling and further genetic testing, such as amniocentesis, may be offered during the pregnancy, as some neural tube defects are associated with genetic disorders such as trisomy 18. Ultrasound screening for spina bifida is partly responsible for the decline in new cases, because many pregnancies are terminated out of fear that a newborn might have a poor future quality of life. With modern medical care, the quality of life of patients has greatly improved.[54]

Three-dimensional ultrasound image of the fetal spine at 21 weeks of pregnancy

Ultrasound view of the fetal spine at 21 weeks of pregnancy. In the longitudinal scan a lumbar myelomeningocele is seen.

# Treatment [edit]

There is no known cure for nerve damage caused by spina bifida. Standard treatment is surgery after delivery. This surgery aims to prevent further damage of the nervous tissue and to prevent infection, pediatric neurosurgeons operate to close the opening on the back. The spinal cord and its nerve roots are put back inside the spine and covered with meninges. In addition, a shunt may be surgically installed to provide a continuous drain for the excess cerebrospinal fluid produced in the brain, as happens with hydrocephalus. Shunts most commonly drain into the abdomen or chest wall.

## Pregnancy [edit]

Standard treatment is after delivery. There is tentative evidence about treatment before delivery while the baby is inside the womb for severe disease.[63] As of 2014 the evidence; however, remains insufficient to determine benefits and harms.[64]

Treatment of spina bifida during pregnancy is not without risk.[63] To the mother, this includes scarring of the uterus.[63] To the baby, there is the risk of preterm birth.[63]

Broadly, there are two forms of prenatal treatment. The first is open fetal surgery, where the uterus is opened and the spina bifida repair performed. The second is via fetoscopy. These techniques may be an option to standard therapy.[65]

## Childhood [edit]

Most individuals with myelomeningocele will need periodic evaluations by a variety of specialists:[66]

- Physiatrists coordinate the rehabilitation efforts of different therapists and prescribe specific therapies, adaptive equipment, or medications to encourage as high of a functional performance within the community as possible.
- Orthopedists monitor growth and development of bones, muscles, and joints.
- Neurosurgeons perform surgeries at birth and manage complications associated with tethered cord and hydrocephalus.
- Neurologists treat and evaluate nervous system issues, such as seizure disorders.
- Urologists to address kidney, bladder, and bowel dysfunction - many will need to manage their urinary systems with a program of catheterization. Bowel management programs aimed at improving elimination are also designed.
- Ophthalmologists evaluate and treat complications of the eyes.
- Orthotists design and customize various types of assistive technology, including braces, crutches, walkers, and wheelchairs to aid in mobility. As a general rule, the higher the level of the spina bifida defect, the more severe the paralysis, but paralysis does not always occur. Thus, those with low levels may need only short leg braces, whereas those with higher levels do best with a wheelchair, and some may be able to walk unaided.
- Physical therapists, occupational therapists, psychologists, and speech/language pathologists aid in rehabilitative therapies and increase independent living skills.

## Transition to adulthood [edit]

Although many children's hospitals feature integrated multidisciplinary teams to coordinate healthcare of

youth with spina bifida, the transition to adult healthcare can be difficult because the above healthcare professionals operate independently of each other, requiring separate appointments and communicate among each other much less frequently. Healthcare professionals working with adults may also be less knowledgeable about spina bifida because it is considered a childhood chronic health condition.[67] Due to the potential difficulties of the transition, adolescents with spina bifida and their families are encouraged to begin to prepare for the transition around ages 14–16, although this may vary depending on the adolescent's cognitive and physical abilities and available family support. The transition itself should be gradual and flexible. The adolescent's multidisciplinary treatment team may aid in the process by preparing comprehensive, up-to-date documents detailing the adolescent's medical care, including information about medications, surgery, therapies, and recommendations. A transition plan and aid in identifying adult healthcare professionals are also helpful to include in the transition process.[67]

Further complicating the transition process is the tendency for youths with spina bifida to be delayed in the development of autonomy,[68] with boys particularly at risk for slower development of independence.[69] An increased dependence on others (in particular family members) may interfere with the adolescent's self-management of health-related tasks, such as catheterization, bowel management, and taking medications.[70] As part of the transition process, it is beneficial to begin discussions at an early age about educational and vocational goals, independent living, and community involvement.[71]

## Epidemiology [edit]

About 5% of people have spina bifida occulta.[10] Rates of other types of spina bifida vary significantly by country from 0.1 to 5 per 1000 births.[11] On average in developed countries it occurs in about 0.4 per 1000 births.[12] In the United States it affected about 0.7 per 1000 births,[6] and in India about 1.9 per 1000 births.[14] Part of this difference is believed to be due to race with Caucasians at higher risk and part due to environmental factors.[15]

In the United States rates are higher on the East Coast than on the West Coast, and higher in white people (one case per 1000 live births) than in black people (0.1–0.4 case per 1000 live births). Immigrants from Ireland have a higher incidence of spina bifida than do natives.[72][73] Highest rates of the defect in the USA can be found in Hispanic youth.[74]

The highest incidence rates worldwide were found in Ireland and Wales, where three to four cases of myelomeningocele per 1000 population have been reported during the 1970s, along with more than six cases of anencephaly (both live births and stillbirths) per 1000 population. The reported overall incidence of myelomeningocele in the British Isles was 2.0–3.5 cases per 1000 births.[72][73] Since then, the rate has fallen dramatically with 0.15 per 1000 live births reported in 1998,[54] though this decline is partially accounted for because some fetuses are aborted when tests show signs of spina bifida (see Pregnancy screening above).

## Research [edit]

- 1980 - Fetal surgical techniques using animal models were first developed at the University of California, San Francisco by Michael R. Harrison, N. Scott Adzick and research colleagues.
- 1994 - A surgical model that simulates the human disease is the fetal lamb model of myelomeningocele (MMC) introduced by Meuli and Adzick in 1994. The MMC-like defect was surgically created at 75 days of gestation (term 145 to 150 days) by a lumbo-sacral laminectomy. Approximately 3 weeks after creation of the defect a reversed latissimus dorsi flap was used to cover the exposed neural placode and the animals were delivered by cesarean section just prior term. Human MMC-like lesions with similar neurological deficit were found in the control newborn lambs. In contrast, animals that underwent closure had near-normal neurological function and well-preserved cytoarchitecture of the covered spinal cord on histopathological examination. Despite mild paraparesis, they were able to stand, walk, perform demanding motor test and demonstrated no signs of incontinence. Furthermore, sensory function of the hind limbs was present clinically and confirmed electrophysiologically. Further studies showed that this

model, when combined with a lumbar spinal cord myelotomy leads to the hindbrain herniation characteristic of the Chiari II malformation and that in utero surgery restores normal hindbrain anatomy by stopping the leak of cerebrospinal fluid through the myelomeningocele lesion.[75][76][77][78]

Surgeons at Vanderbilt University, led by Joseph Bruner, attempted to close spina bifida in 4 human fetuses using a skin graft from the mother using a laparoscope. Four cases were performed before stopping the procedure - two of the four fetuses died.[79]

- 1998 - N. Scott Adzick and team at The Children's Hospital of Philadelphia performed open fetal surgery for spina bifida in an early gestation fetus (22 week gestation fetus) with a successful outcome.[80] Open fetal surgery for myelomeningocele involves surgically opening the pregnant mother's abdomen and uterus to operate on the fetus. The exposed fetal spinal cord is covered in layers with surrounding fetal tissue at mid-gestation (19–25 weeks) to protect it from further damage caused by prolonged exposure to amniotic fluid. Between 1998 and 2003, Dr. Adzick, and his colleagues in the Center for Fetal Diagnosis and Treatment at The Children's Hospital Of Philadelphia, performed prenatal spina bifida repair in 58 mothers and observed significant benefit in the babies.

Fetal surgery after 25 weeks has not shown benefit in subsequent studies.[81]

## MOMS trial [edit]

Management of myelomeningocele study (MOMS) was a phase III clinical trial designed to compare two approaches to the treatment of spina bifida: surgery before birth and surgery after birth.[82][83]

The trial concluded that the outcomes after prenatal spina bifida treatment are improved to the degree that the benefits of the surgery outweigh the maternal risks. This conclusion requires a value judgment on the relative value of fetal and maternal outcomes on which opinion is still divided.[84]

To be specific, the study found that prenatal repair resulted in:

- Reversal of the hindbrain herniation component of the Chiari II malformation
- Reduced need for ventricular shunting (a procedure in which a thin tube is introduced into the brain's ventricles to drain fluid and relieve hydrocephalus)
- Reduced incidence or severity of potentially devastating neurologic effects caused by the spine's exposure to amniotic fluid, such as impaired motor function

[85] At one year of age, 40 percent of the children in the prenatal surgery group had received a shunt, compared to 83 percent of the children in the postnatal group. During pregnancy, all the fetuses in the trial had hindbrain herniation. However, at age 12 months, one-third (36 percent) of the infants in the prenatal surgery group no longer had any evidence of hindbrain herniation, compared to only 4 percent in the postnatal surgery group.[85] Further surveillance is ongoing.[86]

## Fetoscopic surgery [edit]

In contrast to the open fetal operative approach performed in the MOMS trial, a minimally invasive fetoscopic approach (akin to 'keyhole' surgery) has been developed. This approach has been evaluated by independent authors of a controlled study which showed some benefit in survivors,[87] but others are more skeptical[88]

The observations in mothers and their fetuses that were operated over the past two and a half years by the matured minimally invasive approach showed the following results: Compared to the open fetal surgery technique, fetoscopic repair of myelomeningocele results in far less surgical trauma to the mother, as large incisions of her abdomen and uterus are not required. In contrast, the initial punctures have a diameter of 1.2 mm only. As a result, thinning of the uterine wall or dehisscence which have been among the most worriesome and criticized complications after the open operative approach do not occur following minimally invasive fetoscopic closure of spina bifida aperta. The risks of maternal chorioamniotis or fetal death as a result of the fetoscopic procedure run below 5%.[89][90][91] Women are discharged home from hospital one week after the procedure. There is no need for chronic administration of tocolytic agents since postoperative uterine contractions are barely ever observed. The current cost of the entire fetoscopic

procedure, including hospital stay, drugs, perioperative clinical, ECG, ultrasound and MRI-examinations, is approximately €16,000.

In 2012, these results of the fetoscopic approach were presented at various national and international meetings, among them at the 1st European Symposium "Fetal Surgery for Spina bifida" in April 2012 in Giessen, at the 15th Congress of the German Society for Prenatal Medicine and Obstetrics in May 2012 in Bonn,[92] at the World Congress of the Fetal Medicine Foundation in June 2012[93] and at the World Congress of the International Society of Obstetrics and Gynecology (ISUOG) in Copenhagen in September 2012,[94] and published in abstract form.[95][96][97][98][99][100][101][102]

Since then more data has emerged. In 2014, two papers were published on fifty one patients.[103][104] These papers suggested that the risk to the mother is small. The main risk appears to be preterm labour, on average at about 33 weeks.

# Sudden infant death syndrome

From Wikipedia, the free encyclopedia

**Sudden infant death syndrome** (**SIDS**), also known as **cot death** or **crib death**, is the sudden unexplained death of a child less than one year of age.[1] Diagnosis requires that the death remains unexplained even after a thorough autopsy and detailed death scene investigation.[2] SIDS usually occurs during sleep.[3] Typically death occurs between the hours of 00:00 and 09:00.[4] There is usually no evidence of struggle and no noise produced.[5]

The exact cause of SIDS is unknown.[6] The requirement of a combination of factors including a specific underlying susceptibility, a specific time in development, and an environmental stressor has been proposed.[3][6] These environmental stressors may include sleeping on the stomach or side, overheating, and exposure to tobacco smoke.[6] Accidental suffocation such as during bed sharing or from soft objects may also play a role.[3][7] Another risk factor is being born before 39 weeks of gestation.[8] SIDS makes up about 80% of sudden and unexpected infant deaths (SUIDs), with other causes including infections, genetic disorders, and heart problems. While child abuse in the form of intentional suffocation may be misdiagnosed as SIDS, this is believed to make up less than 5% of cases.[3]

The most effective method of reducing the risk of SIDS is putting a child less than one year old on its back to sleep.[8] Other measures include a firm mattress separate from but close to caregivers, no loose bedding, a relatively cool sleeping environment, using a pacifier, and avoiding exposure to tobacco smoke.[9] Breastfeeding and immunization may also be preventive.[9][10] Measures not shown to be useful include positioning devices and baby monitors.[9][10] Evidence is not sufficient for the use of fans.[9] Grief support for families impacted by SIDS is important, as the death of the infant is sudden, without witnesses, and often associated with an investigation.[3]

Rates of SIDS vary nearly tenfold in developed countries from one in a thousand to one in ten thousand.[3] Globally it resulted in about 15,000 deaths in 2013 down from 22,000 deaths in 1990.[11] SIDS was the third leading cause of death in children less than one year old in the United States in 2011.[12] It is the most common cause of death between one month and one year of age.[8] About 90% of cases happen before six months of age, with it being most frequent between two months and four months of age.[3][8] It is more common in boys than girls.[8]

## Contents

## Definition [edit]

SIDS is a diagnosis of exclusion and should be applied to only those cases in which an infant's death is sudden and unexpected, and remains unexplained after the performance of an adequate postmortem investigation, including:

1. an autopsy (by an experienced pediatric pathologist, if possible);
2. investigation of the death scene and circumstances of the death;
3. exploration of the medical history of the infant and family.

After investigation, some of these infant deaths are found to be caused by accidental suffocation, hyperthermia or hypothermia, neglect or some other defined cause.[13]

Australia and New Zealand are shifting to the term "sudden unexpected death in infancy" (SUDI) for professional, scientific, and coronial clarity.

> The term SUDI is now often used instead of sudden infant death syndrome (SIDS) because some coroners prefer to use the term 'undetermined' for a death previously considered to be SIDS. This change is causing diagnostic shift in the mortality data.[14]

In addition, the U.S. Centers for Disease Control and Prevention (CDC) has recently proposed that such deaths be called "sudden unexpected infant deaths" (SUID) and that SIDS is a subset of SUID.[15]

### Age [edit]

SIDS has a 4-parameter lognormal age distribution that spares infants shortly after birth — the time of maximal risk for almost all other causes of non-trauma infant death.

By definition, SIDS deaths occur under the age of one year, with the peak incidence occurring when the infant is at 2 to 4 months of age. This is considered a critical period because the infant's ability to rouse

from sleep is not yet mature.[3]

## Risk factors [edit]

The cause of SIDS is unknown. Although studies have identified risk factors for SIDS, such as putting infants to bed on their stomachs, there has been little understanding of the syndrome's biological process or its potential causes. The frequency of SIDS does appear to be influenced by social, economic, and cultural factors, such as maternal education, race or ethnicity, and poverty.[16] SIDS is believed to occur when an infant with an underlying biological vulnerability, who is at a critical development age, is exposed to an external trigger.[3] The following risk factors generally contribute either to the underlying biological vulnerability or represent an external trigger:

### Tobacco smoke [edit]

SIDS rates are higher for infants of mothers who smoke during pregnancy.[17][18] SID correlates with levels of nicotine and derivatives in the infant.[19] Nicotine and derivatives cause significant alterations in fetal neurodevelopment.[20]

### Sleeping [edit]

Placing an infant to sleep while lying on the stomach or the side increases the risk.[9] This increased risk is greatest at two to three months of age.[9] Elevated or reduced room temperature also increases the risk,[21] as does excessive bedding, clothing, soft sleep surfaces, and stuffed animals.[22] Bumper pads may increase the risk and, as there is little evidence of benefit from their use, they are not recommended.[9]

Sharing a bed with parents or siblings increases the risk for SIDS.[23] This risk is greatest in the first three months of life, when the mattress is soft, when one or more persons share the infant's bed, especially when the bed partners are using drugs or alcohol or are smoking.[9] The risk remains, however, even in parents who do not smoke or use drugs.[24] The American Academy of Pediatrics thus recommends "room-sharing without bed-sharing", stating that such an arrangement can decrease the risk of SIDS by up to 50%. Furthermore, the Academy recommended against devices marketed to make bed-sharing "safe", such as in-bed co-sleepers.[25]

### Breastfeeding [edit]

Breastfeeding is associated with a lower risk of SIDS.[26] It is not clear if co-sleeping among mothers who breastfeed without any other risk factors increased SIDS risk.[27]

### Pregnancy and infant factors [edit]

SIDS rates decrease with increasing maternal age, with teenage mothers at greatest risk.[17] Delayed or inadequate prenatal care also increases risk.[17] Low birth weight is a significant risk factor. In the United States from 1995 to 1998, the SIDS death rate for infants weighing 1000–1499 g was 2.89/1000, while for a birth weight of 3500–3999 g, it was only 0.51/1000.[28][29] Premature birth increases the risk of SIDS death roughly fourfold.[17][28] From 1995 to 1998, the U.S. SIDS rate for births at 37–39 weeks of gestation was 0.73/1000, while the SIDS rate for births at 28–31 weeks of gestation was 2.39/1000.[28]

Anemia has also been linked to SIDS[30] (note, however, that per item 6 in the list of epidemiologic characteristics below, extent of anemia cannot be evaluated at autopsy because an infant's total hemoglobin can only be measured during life.[31]). SIDS incidence rises from zero at birth, is highest from two to four months of age, and declines toward zero after the infant's first year.[32] Baby boys have a ~50% higher risk of SIDS than girls.[33]

### Genetics [edit]

Genetics plays a role, as SIDS is more prevalent in males.[34][35] There is a consistent 50% male excess in SIDS per 1000 live births of each sex. Given a 5% male excess birth rate, there appears to be 3.15 male SIDS cases per 2 female, for a male fraction of 0.61.[34][35] This value of 61% in the US is an average of 57% black male SIDS, 62.2% white male SIDS and 59.4% for all other races combined. Note that when multiracial parentage is involved, infant race is arbitrarily assigned to one category or the other; most often it is chosen by the mother. The X-linkage hypothesis for SIDS and the male excess in infant mortality have shown that the 50% male excess could be related to a dominant X-linked allele, occurring with a frequency of $^{1}/_{3}$ that is protective of transient cerebral anoxia. An unprotected male would occur with a frequency of $^{2}/_{3}$ and an unprotected female would occur with a frequency of $^{4}/_{9}$.

About 10 to 20% of SIDS cases are believed to be due to channelopathies, which are inherited defects in the ion channels which play an important role in the contraction of the heart.[36]

### Alcohol [edit]

Drinking of alcohol by parents is linked to SIDS.[37] A particular study found a positive correlation between the two during New Years celebrations and weekends.[38]

### Other [edit]

There is a tentative link with *Staphylococcus aureus* and *Escherichia coli*.[39]

Vaccinations do not increase the risk of SIDS; contrarily, they are linked to a 50% lower risk of SIDS.[40][41]

A 1998 report found that antimony- and phosphorus-containing compounds used as fire retardants in PVC and other cot mattress materials are not a cause of SIDS.[42] The report also states that toxic gas can not be generated from antimony in mattresses and that babies suffered SIDS on mattresses that did not contain the compound.

A set of risk factors SIDS has been identified with: seasonality: winter maximum, summer minimum; increasing SIDS rate with live birth order; low increased risk of SIDS in subsequent siblings of SIDS; apparent life-threatening events (ALTE) are not a risk factor for subsequent SIDS; SIDS risk is greatest during sleep.[43]

## Differential diagnosis [edit]

Some conditions that are often undiagnosed and could be confused with or comorbid with SIDS include:

- medium-chain acyl-coenzyme A dehydrogenase deficiency (MCAD deficiency);[44]
- infant botulism;[45]
- long QT syndrome (accounting for less than 2% of cases);[46]
- *Helicobacter pylori* bacterial infections;[47]
- shaken baby syndrome and other forms of child abuse;[48][49]
- overlaying, child smothering during carer's sleep[50]

For example, an infant with MCAD deficiency could have died by "classical SIDS" if found swaddled and prone with head covered in an overheated room where parents were smoking. Genes indicating susceptibility to MCAD and Long QT syndrome do not protect an infant from dying of classical SIDS. Therefore, presence of a susceptibility gene, such as for MCAD, means the infant may have died either from SIDS or from MCAD deficiency. It is currently impossible for the pathologist to distinguish between them.

A 2010 study looked at 554 autopsies of infants in North Carolina that listed SIDS as the cause of death, and suggested that many of these deaths may have been due to accidental suffocation. The study found

that 69% of autopsies listed other possible risk factors that could have led to death, such as unsafe bedding or sleeping with adults.[51]

Several instances of infanticide have been uncovered where the diagnosis was originally SIDS.[52][53] Estimate of the percentage of SIDS deaths that are actually infanticide vary from less than 1% to up to 5% of cases.[54]

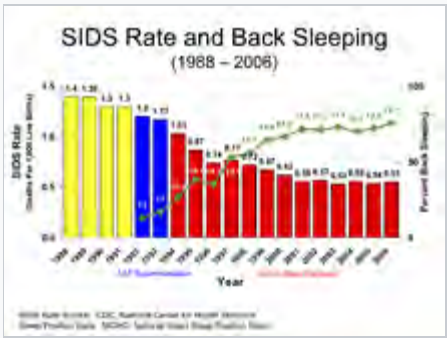
Some have underestimated the risk of two SIDS deaths occurring in the same family and the Royal Statistical Society issued a media release refuting this expert testimony in one UK case in which the conviction was subsequently overturned.[55]

## Prevention [edit]

A number of measures have been found to be effective in preventing SIDS including changing the sleeping position, breastfeeding, limiting soft bedding, immunizing the infant and using pacifiers.[9] The use of electronic monitors has not been found to be useful as a preventative strategy.[9] The effect that fans might have on the risk of SIDS has not been studied well enough to make any recommendation about them.[9] Evidence regarding swaddling is unclear regarding SIDS.[9] A 2016 review found tentative evidence that swaddling increases risk of SIDS, especially among babies placed on their stomachs or side while sleeping.[56]

### Sleep positioning [edit]

Sleeping on the back has been found to reduce the risk of SIDS.[57] It is thus recommended by the American Academy of Pediatrics and promoted as a best practice by the US National Institute of Child Health and Human Development (NICHD) "Safe to Sleep" campaign. The incidence of SIDS has fallen in a number of countries in which this recommendation has been widely adopted.[58] Sleeping on the back does not appear to increase the risk of choking even in those with gastroesophageal reflux disease.[9] While infants in this position may sleep more lightly this is not harmful.[9] Sharing the same room as one's parents but in a different bed may decrease the risk by half.[9]



A plot of SIDS rate from 1988 to 2006

### Pacifiers [edit]

The use of pacifiers appears to decrease the risk of SIDS although the reason is unclear.[9] The American Academy of Pediatrics considers pacifier use to prevent SIDS to be reasonable.[9] Pacifiers do not appear to affect breastfeeding in the first four months, even though this is a common misconception.[59]

### Bedding [edit]

Product safety experts advise against using pillows, overly soft mattresses, sleep positioners, bumper pads (crib bumpers), stuffed animals, or fluffy bedding in the crib and recommend instead dressing the child warmly and keeping the crib "naked."[60]

Blankets or other clothing should not be placed over a baby's head.[61]

### Sleep sacks [edit]

In colder environments where bedding is required to maintain a baby's body temperature, the use of a "baby sleep bag" or "sleep sack" is becoming more popular. This is a soft bag with holes for the baby's arms and head. A zipper allows the bag to be closed around the baby. A study published in the *European* [62]

*Journal of Pediatrics* in August 1998 has shown the protective effects of a sleep sack as reducing the incidence of turning from back to front during sleep, reinforcing putting a baby to sleep on its back for placement into the sleep sack and preventing bedding from coming up over the face which leads to increased temperature and carbon dioxide rebreathing. They conclude in their study, "The use of a sleeping-sack should be particularly promoted for infants with a low birth weight." The American Academy of Pediatrics also recommends them as a type of bedding that warms the baby without covering its head.[63]

### Vaccination [edit]

A large investigation into diphtheria-tetanus-pertussis vaccination and potential SIDS association by Berlin School of Public Health, Charité – Universitätsmedizin Berlin concluded: "Increased DTP immunisation coverage is associated with decreased SIDS mortality. Current recommendations on timely DTP immunisation should be emphasised to prevent not only specific infectious diseases but also potentially SIDS."[64]

Many other studies have also reached conclusions that vaccinations reduce the risk of SIDS. Studies generally show that SIDS risk is approximately halved by vaccinations.[65][66][67][68][69]

## Management [edit]

Families who are impacted by SIDS should be offered emotional support and grief counseling.[70] The experience and manifestation of grief at the loss of an infant are impacted by cultural and individual differences.[71]

## Epidemiology [edit]

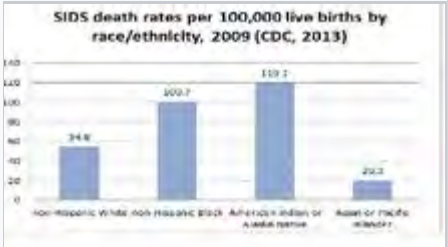
Globally SIDS resulted in about 22,000 deaths as of 2010, down from 30,000 deaths in 1990.[72] Rates vary significantly by population from 0.05 per 1000 in Hong Kong to 6.7 per 1000 in American Indians.[73]

SIDS was responsible for 0.54 deaths per 1,000 live births in the US in 2005.[28] It is responsible for far fewer deaths than congenital disorders and disorders related to short gestation, though it is the leading cause of death in healthy infants after one month of age.

SIDS deaths in the US decreased from 4,895 in 1992 to 2,247 in 2004.[74] But, during a similar time period, 1989 to 2004, SIDS being listed as the cause of death for sudden infant death (SID) decreased from 80% to 55%.[74] According to John Kattwinkel, chairman of the Centers for Disease Control and Prevention (CDC) Special Task Force on SIDS "A lot of us are concerned that the rate (of SIDS) isn't decreasing significantly, but that a lot of it is just code shifting".[74]

### Race [edit]

In 2013, there are persistent disparities in SIDS deaths among racial and ethnic groups in the U.S. In 2009, the rates of death range from 20.3 for Asian/Pacific Islander to 119.2 for American Indians/Alaska Native. African American infants have a 24% greater risk of having a SIDS related death [75] and experience a 2.5 greater incidence of SIDS than in Caucasian infants.[76] Rates are per 100,000 live births and enable more accurate comparison across groups of different total population size.



Rates of SIDS by race/ethnicity in the U.S., 2009, CDC, 2013

Research suggests that factors which contribute more directly to SIDS risk—maternal age, exposure to smoking, safe sleep practices, etc.—vary by racial and ethnic group and therefore risk exposure also varies by these groups.[3] Risk factors associated with prone sleeping patterns of African American families include mother's age, household poverty

index, rural/urban status of residence, and infant's age. More than 50% of African American infants were placed in non-recommended sleeping positions according to a study completed in South Carolina.[77] Cultural factors can be protective as well as problematic.[78]

The rate per 1000 births varies in different areas of the world:[21][79] Central Americans and South Americans - 0.20 Asian/Pacific Islanders - 0.28 Mexicans - 0.24 Puerto Ricans - 0.53 Whites - 0.51 African Americans - 1.08 American Indian - 1.24

## Society and culture [edit]

Much of the media portrayal of infants shows them in non-recommended sleeping positions.[9]

# Turner syndrome

From Wikipedia, the free encyclopedia

**Turner syndrome** (**TS**), also known as **45,X**, is a condition in which a female is partly or completely missing an X chromosome.[1] Signs and symptoms vary among those affected. Often, a short and webbed neck, low-set ears, low hairline at the back of the neck, short stature, and swollen hands and feet are seen at birth. Typically, they only develop menstrual periods and breasts with hormone treatment, and are unable to have children without reproductive technology. Heart defects, diabetes, and low thyroid hormone occur more frequently. Most people with TS have normal intelligence. Many, however, have troubles with spatial visualization that may be needed for mathematics.[2] Vision and hearing problems occur more often.[3]

Turner syndrome is not usually inherited from a person's parents.[4] No environmental risks are known, and the mother's age does not play a role.[4][5] Turner syndrome is due to a chromosomal abnormality in which all or part of one of the X chromosomes is missing or altered. While most people have 46 chromosomes, people with TS usually have 45.[6] The chromosomal abnormality may be present in just some cells in which case it is known as TS with mosaicism.[3] In these cases, the symptoms are usually fewer and possibly none occur at all.[7] Diagnosis is based on physical signs and genetic testing.[8]

No cure for Turner syndrome is known. Treatment, however, may help with symptoms. Human growth hormone injections during childhood may increase adult height. Estrogen replacement therapy can promote development of the breasts and hips. Medical care is often required to manage other health problems with which TS is associated.[9]

Turner syndrome occurs in between one in 2000[10] and one in 5000 females at birth.[11] All regions of the world and cultures are affected about equally.[4] Generally people with TS have a shorter life expectancy, mostly due to heart problems and diabetes.[3] Henry Turner first described the condition in 1938. In 1964, it was determined to be due to a chromosomal abnormality.[12]

## Signs and symptoms [edit]

Of the following common symptoms of Turner syndrome, an individual may have any combination of symptoms and is unlikely to have all symptoms.

Lymphedema, puffy legs of a newborn with Turner syndrome

- Short stature
- Lymphedema (swelling) of the hands and feet of a newborn
- Broad chest (shield chest) and widely spaced nipples
- Low posterior hairline
- Low-set ears
- Reproductive sterility
- Rudimentary ovaries gonadal streak (underdeveloped gonadal structures that later become fibrotic)
- Amenorrhoea, the absence of a menstrual period
- Increased weight, obesity
- Shortened metacarpal IV
- Small fingernails
- Characteristic facial features
- Webbed neck from cystic hygroma in infancy
- Aortic valve stenosis
- Coarctation of the aorta
- Bicuspid aortic valve
- Horseshoe kidney
- Visual impairments – sclera, cornea, glaucoma, etc.
- Ear infections and hearing loss
- High waist-to-hip ratio (the hips are not much bigger than the waist)
- Attention deficit hyperactivity disorder (problems with concentration, memory, attention with hyperactivity seen mostly in childhood and adolescence)
- Nonverbal learning disability (problems with math, social skills, and spatial relations)

Other features may include a small lower jaw (micrognathia), cubitus valgus,[13] soft upturned nails, palmar crease, and drooping eyelids. Less common are pigmented moles, hearing loss, and a high-arch palate (narrow maxilla). Turner syndrome manifests itself differently in each female affected by the condition;

therefore, no two individuals share the same features.

While most of the physical findings are harmless, significant medical problems can be associated with the syndrome. Most of these significant conditions are treatable with surgery and medication.[14]

## Prenatal [edit]

Despite the excellent postnatal prognosis, 99% of Turner-syndrome conceptions are thought to end in spontaneous abortion or stillbirth,[15] and as many as 15% of all spontaneous abortions have the 45,X karyotype.[16] Among cases that are detected by routine amniocentesis or chorionic villus sampling, one study found that the prevalence of Turner syndrome among tested pregnancies was 5.58 and 13.3 times higher, respectively, than among live neonates in a similar population.[17]

## Cardiovascular [edit]

The rate of cardiovascular malformations among patients with Turner syndrome ranges from 17% [18] to 45%.[19] The variations found in the different studies are mainly attributable to variations in noninvasive methods used for screening and the types of lesions that they can characterize.[20] However,[21] it could be simply attributable to the small number of subjects in most studies.

Different karyotypes may have differing rates of cardiovascular malformations. Two studies found a rate of cardiovascular malformations of 30%[22] and 38%[23] in a group of pure 45,X monosomy. Considering other karyotype groups, though, they reported a prevalence of 24.3%[22] and 11%[23] in people with mosaic X monosomy, and a rate of 11% in people with X chromosomal structural abnormalities.[22]

The higher rate in the group of pure 45,X monosomy is primarily due to a difference in the rate of aortic valve abnormalities and coarctation of the aorta, the two most common cardiovascular malformations.

## Congenital heart disease [edit]

The most commonly observed are congenital obstructive lesions of the left side of the heart, leading to reduced flow on this side of the heart. This includes bicuspid aortic valve and coarctation (narrowing) of the aorta. More than 50% of the cardiovascular malformations of individuals with Turner syndrome in one study were bicuspid aortic valves or coarctation of the aorta (usually preductal), alone or in combination.[21]

Other congenital cardiovascular malformations, such as partial anomalous venous drainage and aortic valve stenosis or aortic regurgitation, are also more common in Turner syndrome than in the general population. Hypoplastic left heart syndrome represents the most severe reduction in left-sided structures.

### Bicuspid aortic valve [edit]

Up to 15% of adults with Turner syndrome have bicuspid aortic valves, meaning only two, instead of three, parts to the valves in the main blood vessel leading from the heart are present. Since bicuspid valves are capable of regulating blood flow properly, this condition may go undetected without regular screening. However, bicuspid valves are more likely to deteriorate and later fail. Calcification also occurs in the valves,[24] which may lead to a progressive valvular dysfunction as evidenced by aortic stenosis or regurgitation.[25]

With a rate from 12.5%[22] to 17.5% (Dawson-Falk et al., 1992), bicuspid aortic valve is the most common congenital malformation affecting the heart in this syndrome. It is usually isolated, but it may be seen in combination with other anomalies, particularly coarctation of the aorta.

### Coarctation of the aorta [edit]

Between 5% and 10% of those born with Turner syndrome have coarctation of the aorta, a congenital narrowing of the descending aorta, usually just distal to the origin of the left subclavian artery (the artery that branches off the arch of the aorta to the left arm) and opposite to the duct (and so termed "juxtaductal"). Estimates of the prevalence of this malformation in patients with Turner syndrome range

from 6.9[22] to 12.5%. A coarctation of the aorta in a female is suggestive of Turner syndrome and suggests the need for further tests, such as a karyotype.

### Partial anomalous venous drainage [edit]

This abnormality is a relatively rare congenital heart disease in the general population. The prevalence of this abnormality also is low (around 2.9%) in Turner syndrome. However, its relative risk is 320 in comparison with the general population. Strangely, Turner syndrome seems to be associated with unusual forms of partial anomalous venous drainage.[22][26]

In a patient with Turner syndrome, these left-sided cardiovascular malformations can result in an increased susceptibility to bacterial endocarditis. Therefore, prophylactic antibiotics should be considered when procedures with a high risk of endocarditis are performed, such as dental cleaning.[25]

Turner syndrome is often associated with persistent hypertension, sometimes in childhood. In the majority of Turner syndrome patients with hypertension, no specific cause is known. In the remainder, it is usually associated with cardiovascular or kidney abnormalities, including coarctation of the aorta.

## Aortic dilation, dissection, and rupture [edit]

Two studies have suggested aortic dilatation in Turner syndrome, typically involving the root of the ascending aorta and occasionally extending through the aortic arch to the descending aorta, or at the site of previous coarctation of the aorta repair.[27]

- A study that evaluated 28 girls with Turner syndrome found a greater mean aortic root diameter in people with Turner syndrome than in the control group (matched for body surface area). Nonetheless, the aortic root diameters found in Turner syndrome patients were still well within the limits.[28]
- This has been confirmed by a study that evaluated 40 patients with Turner syndrome.[19] The study presented basically the same findings: a greater mean aortic root diameter, which nevertheless remains within the normal range for body surface area.

Whether aortic root diameters that are relatively large for body surface area but still well within normal limits imply a risk for progressive dilatation remains unproven.[21]

### Rate of aortic abnormalities [edit]

The prevalence of aortic root dilatation ranges from 8.8[27] to 42%[25] in patients with Turner syndrome. Even if not every aortic root dilatation necessarily goes on to an aortic dissection (circumferential or transverse tear of the intima), complications such as dissection, aortic rupture resulting in death may occur. The natural history of aortic root dilatation is still unknown, but it is linked to aortic dissection and rupture, which has a high mortality rate.[29]

Aortic dissection affects 1 to 2% of patients with Turner syndrome. As a result, any aortic root dilatation should be seriously taken into account, as it could become a fatal aortic dissection. Routine surveillance is highly recommended.[25]

### Risk factors for aortic rupture [edit]

Cardiovascular malformations (typically bicuspid aortic valve, coarctation of the aorta, and some other left-sided cardiac malformations) and hypertension predispose to aortic dilatation and dissection in the general population. Indeed, these same risk factors are found in more than 90% of patients with Turner syndrome who develop aortic dilatation. Only a small number of patients (around 10%) have no apparent predisposing risk factors. The risk of hypertension is increased three-fold in patients with Turner syndrome. Because of its relation to aortic dissection, blood pressure must be regularly monitored and hypertension should be treated aggressively with an aim to keep blood pressure below 140/80 mmHg. As with the other cardiovascular malformations, complications of aortic dilatation is commonly associated with 45,X karyotype.[25]

### Pathogenesis of aortic dissection and rupture [edit]

The exact role that these risk factors play in the process leading to rupture is unclear. Aortic root dilatation is thought to be due to a mesenchymal defect as pathological evidence of cystic medial necrosis has been found by several studies. The association between a similar defect and aortic dilatation is well established in such conditions such as Marfan syndrome. Also, abnormalities in other mesenchymal tissues (bone matrix and lymphatic vessels) suggests a similar primary mesenchymal defect in patients with Turner syndrome.[27] However, no evidence suggests that patients with Turner syndrome have a significantly higher risk of aortic dilatation and dissection in absence of predisposing factors. So, the risk of aortic dissection in Turner syndrome appears to be a consequence of structural cardiovascular malformations and hemodynamic risk factors rather than a reflection of an inherent abnormality in connective tissue. The natural history of aortic root dilatation is unknown, but because of its lethal potential, this aortic abnormality needs to be carefully followed.

## Skeletal [edit]

Normal skeletal development is inhibited due to a large variety of factors, mostly hormonal. The average height of a woman with Turner syndrome, in the absence of growth hormone treatment, is 4 ft 7 in (140 cm). Patients with Turner's mosaicism can reach normal average height.

The fourth metacarpal bone (fourth toe and ring finger) may be unusually short, as may the fifth.

Due to inadequate production of estrogen, many of those with Turner syndrome develop osteoporosis. This can decrease height further, as well as exacerbate the curvature of the spine, possibly leading to scoliosis. It is also associated with an increased risk of bone fractures.

## Kidney [edit]

About one-third of all women with Turner syndrome have one of three kidney abnormalities:

1. A single, horseshoe-shaped kidney on one side of the body
2. An abnormal urine-collecting system
3. Poor blood flow to the kidneys

Some of these conditions can be corrected surgically. Even with these abnormalities, the kidneys of most women with Turner syndrome function normally. However, as noted above, kidney problems may be associated with hypertension.

## Thyroid [edit]

Approximately one-third of all women with Turner syndrome have a thyroid disorder.[30] Usually it is hypothyroidism, specifically Hashimoto's thyroiditis. If detected, it can be easily treated with thyroid hormone supplements.

## Diabetes [edit]

Women with Turner syndrome are at a moderately increased risk of developing type 1 diabetes in childhood and a substantially increased risk of developing type 2 diabetes by adult years. The risk of developing type 2 diabetes can be substantially reduced by maintaining a healthy weight.

## Cognitive [edit]

Turner syndrome does not typically cause intellectual disability or impair cognition. However, learning difficulties are common among women with Turner syndrome, particularly a specific difficulty in perceiving spatial relationships, such as nonverbal learning disorder. This may also manifest itself as a difficulty with motor control or with mathematics.[*citation needed*] While it is not correctable, in most cases it does not cause difficulty in daily living. Most Turner syndrome patients are employed as adults and lead productive lives.

Also, a rare variety of Turner syndrome, known as "Ring-X Turner syndrome", has about a 60% association with intellectual disability[*clarification needed*]. This variety accounts for around 2–4% of all Turner syndrome [31]

cases.

### Reproductive [edit]

Women with Turner syndrome are almost universally infertile. While some women with Turner syndrome have successfully become pregnant and carried their pregnancies to term, this is very rare and is generally limited to those women whose karyotypes are not 45,X.[32][33] Even when such pregnancies do occur, there is a higher than average risk of miscarriage or birth defects, including Turner Syndrome or Down Syndrome.[34] Some women with Turner syndrome who are unable to conceive without medical intervention may be able to use IVF or other fertility treatments.[35]

Usually, estrogen replacement therapy is used to spur the growth of secondary sexual characteristics at the time when puberty should onset. While very few women with Turner Syndrome menstruate spontaneously, estrogen therapy requires a regular shedding of the uterine lining ("withdrawal bleeding") to prevent its overgrowth. Withdrawal bleeding can be induced monthly, like menstruation, or less often, usually every three months, if the patient desires. Estrogen therapy does not make a woman with nonfunctional ovaries fertile, but it plays an important role in assisted reproduction; the health of the uterus must be maintained with estrogen if an eligible woman with Turner Syndrome wishes to use IVF (using donated oocytes).

Turner syndrome is a cause of primary amenorrhea, premature ovarian failure (hypergonadotropic hypogonadism), streak gonads and infertility. Failure to develop secondary sex characteristics (sexual infantilism) is typical.

Especially in mosaic cases of Turner syndrome that contains Y-chromosome (e.g. 45,X/46,XY) due to the risk of development of ovarian malignancy (most common is gonadoblastoma) gonadectomy is recommended.[30] [36] Turner syndrome is characterized by primary amenorrhoea, premature ovarian failure, streak gonads and infertility. However, technology (especially oocyte donation) provides the opportunity of pregnancy in these patients.

As more women with Turner syndrome complete pregnancy thanks to modern techniques to treat infertility, it has to be noted that pregnancy may be a risk of cardiovascular complications for the mother. Indeed, several studies had suggested an increased risk for aortic dissection in pregnancy.[27] Three deaths have even been reported. The influence of estrogen has been examined but remains unclear. It seems that the high risk of aortic dissection during pregnancy in women with Turner syndrome may be due to the increased hemodynamic load rather than the high estrogen rate.[25] Of course, these findings are important and need to be remembered while following a pregnant patient with Turner syndrome.

## Cause [edit]

Turner syndrome is caused by the absence of one complete or partial copy of the X chromosome in some or all the cells. The abnormal cells may have only one X (monosomy) (45,X) or they may be affected by one of several types of partial monosomy like a deletion of the short p arm of one X chromosome (46,X,del(Xp)) or the presence of an isochromosome with two q arms (46,X,i(Xq))[37] Turner syndrome has distinct features due to the lack of pseudoautosomal regions, which are typically spared from X-inactivation.[38] In mosaic individuals, cells with X monosomy (45,X) may occur along with cells that are normal (46,XX), cells that have partial monosomies, or cells that have a Y chromosome (46,XY).[37] The presence of mosaicism is estimated to be relatively common in affected individuals (67–90%).[37]

### Inheritance [edit]

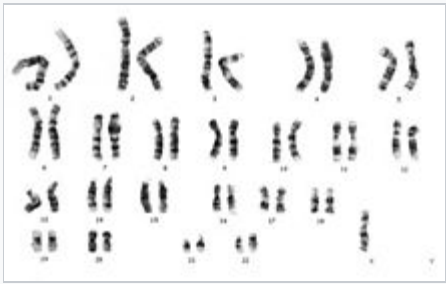
In the majority of cases where monosomy occurs, the X chromosome comes from the mother.[39] This may be due to a nondisjunction in the father. Meiotic errors that lead to the production of X with p arm deletions or abnormal Y chromosomes are also mostly found in the father.[40] Isochromosome X or ring chromosome X on the other hand are formed equally often by both parents.[40] Overall, the functional X chromosome usually comes from the mother.

In most cases, Turner syndrome is a sporadic event, and for the parents of an individual with Turner syndrome the risk of recurrence is not increased for subsequent pregnancies. Rare exceptions may include the presence of a balanced translocation of the X chromosome in a parent, or where the mother has 45,X mosaicism restricted to her germ cells.[41]

## Diagnosis [edit]

### Prenatal [edit]

Turner syndrome may be diagnosed by amniocentesis or chorionic villus sampling during pregnancy.



45,X karyotype, showing an unpaired X at the lower right

Usually, fetuses with Turner syndrome can be identified by abnormal ultrasound findings (*i.e.*, heart defect, kidney abnormality, cystic hygroma, ascites). In a study of 19 European registries, 67.2% of prenatally diagnosed cases of Turner Syndrome were detected by abnormalities on ultrasound. 69.1% of cases had one anomaly present, and 30.9% had two or more anomalies.[42]

An increased risk of Turner syndrome may also be indicated by abnormal triple or quadruple maternal serum screen. The fetuses diagnosed through positive maternal serum screening are more often found to have a mosaic karyotype than those diagnosed based on ultrasonographic abnormalities, and conversely, those with mosaic karyotypes are less likely to have associated ultrasound abnormalities.[42]

Although the recurrence risk is not increased, genetic counseling is often recommended for families who have had a pregnancy or child with Turner syndrome.

### Postnatal [edit]

Turner syndrome can be diagnosed postnatally at any age. Often, it is diagnosed at birth due to heart problems, an unusually wide neck or swelling of the hands and feet. However, it is also common for it to go undiagnosed for several years, typically until the girl reaches the age of puberty/adolescence and she fails to develop properly (the changes associated with puberty do not occur). In childhood, a short stature can be indicative of Turner syndrome.[43]

A test called a karyotype, also known as a chromosome analysis, analyzes the chromosomal composition of the individual. This is the test of choice to diagnose Turner syndrome.

## Treatment [edit]

As a chromosomal condition, there is no cure for Turner syndrome. However, much can be done to minimize the symptoms. For example:[44]

- Growth hormone, either alone or with a low dose of androgen, will increase growth and probably final adult height. Growth hormone is approved by the U.S. Food and Drug Administration for treatment of Turner syndrome and is covered by many insurance plans.[44][45] There is evidence that this is effective, even in toddlers.[46]
- Estrogen replacement therapy such as the birth control pill, has been used since the condition was described in 1938 to promote development of secondary sexual characteristics. Estrogens are crucial for maintaining good bone integrity, cardiovascular health and tissue health.[44] Women with Turner Syndrome who do not have spontaneous puberty and who are not treated with estrogen are at high risk for osteoporosis and heart conditions.
- Modern reproductive technologies have also been used to help women with Turner syndrome become

pregnant if they desire. For example, a donor egg can be used to create an embryo, which is carried by the Turner syndrome woman.[44]
- Uterine maturity is positively associated with years of estrogen use, history of spontaneous menarche, and negatively associated with the lack of current hormone replacement therapy.[47]

## Epidemiology [edit]

Approximately 99 percent of fetuses with Turner syndrome spontaneously terminate during the first trimester.[48] Turner syndrome accounts for about 10 percent of the total number of spontaneous abortions in the United States.[30] The rate of Turner syndrome in live female births is believed to be around 1 in 2000.

## History [edit]

The syndrome is named after Henry Turner, an endocrinologist from Illinois, who described it in 1938.[49] In Europe, it is often called Ullrich–Turner syndrome or even Bonnevie–Ullrich–Turner syndrome to acknowledge that earlier cases had also been described by European doctors.

The first published report of a female with a 45,X karyotype was in 1959 by Dr. Charles Ford and colleagues in Harwell, Oxfordshire, and Guy's Hospital in London.[50] It was found in a 14-year-old girl with signs of Turner syndrome.

## See also [edit]

- Other human sex chromosome aneuploids:
  - XYY syndrome,
  - Klinefelter syndrome (XXY),
  - Triple X syndrome,
- Dermatoglyphics,
- Noonan syndrome, a disorder which is often confused with Turner syndrome because of several physical features that they have in common.

# Abscess

From Wikipedia, the free encyclopedia

*This article is about the medical condition. For the death metal band, see Abscess (band).*

An **abscess** (Latin: *abscessus*) is a collection of pus that has built up within the tissue of the body. Signs and symptoms of abscesses include redness, pain, warmth, and swelling. The swelling may feel fluid filled when pressed.[1] The area of redness often extends beyond the swelling.[6] Carbuncles and boils are types of abscess that often involve hair follicles with carbuncles being larger.[7]

They are usually caused by a bacterial infection.[8] Often many different types of bacteria are involved in a single infection.[6] In the United States and many other areas of the world the most common bacteria present is *methicillin-resistant Staphylococcus aureus*.[1] Rarely, parasites can cause abscesses and this is more common in the developing world.[3] Diagnosis of a skin abscess is usually made based on what it looks like and is confirmed by cutting it open.[1] Ultrasound imaging may be useful in cases in which the diagnosis is not clear.[1] In abscesses around the anus, computer tomography (CT) may be important to look for deeper infection.[3]

Standard treatment for most skin or soft tissue abscesses is cutting it open and drainage.[4] There does not appear to be any benefit from also using antibiotics for this type of abscess in most people who are otherwise healthy.[1][9] A small amount of evidence supports not packing the cavity that remains with gauze after drainage.[1] Closing this cavity right after draining it rather than leaving it open may speed healing without increasing the risk of the abscess returning.[10] Sucking out the pus with a needle is often not sufficient.[1]

Skin abscesses are common and have become more common in recent years.[1] Risk factors include intravenous drug use with rates reported as high as 65% in this population.[2] In 2005 in the United States 3.2 million people went to the emergency department for an abscess.[5] In Australia around 13,000 people were hospitalized in 2008 with the condition.[11]

Five-day-old abscess. The black spot is a clogged hair follicle.

## Signs and symptoms [edit]

An abscess

Abscesses may occur in any kind of solid tissue but most frequently on skin surface (where they may be superficial pustules (boils) or deep skin abscesses), in the lungs, brain, teeth, kidneys and tonsils. Major complications are spreading of the abscess material to adjacent or remote tissues and extensive regional tissue death (gangrene).

The main symptoms and signs of a skin abscess are redness, heat, swelling, pain and loss of function. There may also be high temperature (fever) and chills.[12]

An internal abscess is more difficult to identify, but signs include pain in the affected area, a high temperature, and generally feeling unwell. Internal abscesses rarely heal themselves, so prompt medical attention is indicated if such an abscess is suspected. An abscess could potentially be fatal (although this is rare) if it compresses vital structures such as the trachea in the context of a deep neck abscess.[*citation needed*]

If superficial, abscesses may be fluctuant when palpated. This is a wave-like motion that is caused by movement of the pus inside the abscess.[13]

## Causes [edit]

Risk factors for abscess formation include intravenous drug use.[14] Another possible risk factor is a prior history of disc herniation or other spinal abnormality,[15] though this has not been proven.

Abscesses are caused by bacterial infection, parasites, or foreign substances. Bacterial infection is the most common cause.[8] Often many different types of bacteria are involved in a single infection.[6] In the United States and many other areas of the world the most common bacteria present is *methicillin-resistant Staphylococcus aureus*.[1] Among spinal subdural abscesses, methicillin-sensitive Staphylococcus aureus is the most common organism involved.[15]

Rarely parasites can cause abscesses and this is more common in the developing world.[3] Specific parasites known to do this include: dracunculiasis and myiasis.[3]

### Perianal abscess [edit]

See also: *Anorectal abscess*

Surgery of the anal fistula to drain an abscess treats the fistula and reduces likelihood of its recurrence and the need for repeated surgery.[16] There is no evidence that fecal incontinence is a consequence of this surgery for abscess drainage.[16]

Perianal abscesses can be seen in patients with for example inflammatory bowel disease (such as Crohn's disease) or diabetes. Often the abscess will start as an internal wound caused by ulceration, hard stool or penetrative objects with insufficient lubrication. This wound typically becomes infected as a result of the normal presence of feces in the rectal area, and then develops into an abscess. This often presents itself as a lump of tissue near the anus which grows larger and more painful with time. Like other abscesses, perianal abscesses may require prompt medical treatment, such as an incision and debridement or lancing.

### Incisional abscess [edit]

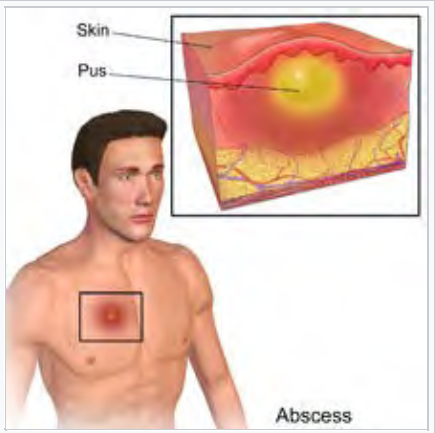
An *incisional abscess* is one that develops as a complication secondary to a surgical incision. It presents as redness and warmth at the margins of the incision with purulent drainage from it.[17] If the diagnosis is uncertain, the wound should be aspirated with a needle, with aspiration of pus confirming the diagnosis and availing for Gram stain and bacterial culture.[17]

## Pathophysiology [edit]

An abscess is a defensive reaction of the tissue to prevent the spread of infectious materials to other parts of the body.

The organisms or foreign materials kill the local cells, resulting in the release of cytokines. The cytokines trigger an inflammatory response, which draws large numbers of white blood cells to the area and increases the regional blood flow.

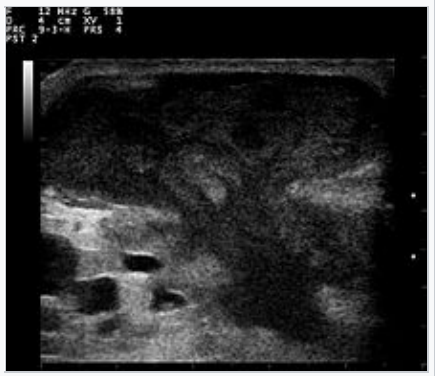
The final structure of the abscess is an abscess wall, or capsule, that is formed by the adjacent healthy cells in an attempt to keep the pus from infecting neighboring structures. However, such encapsulation tends to prevent immune cells from attacking bacteria in the pus, or from reaching the causative organism or foreign object.



A diagram of an abscess

## Diagnosis [edit]

An abscess is a localized collection of pus (purulent inflammatory tissue) caused by suppuration buried in a tissue, an organ, or a confined space, lined by pyogenic membrane.[18]



Ultrasound image of breast abscess, appearing as a mushroom-shaped dark (hypoechoic) area

### Classification [edit]

Abscesses may be classified as either *skin abscesses* or *internal abscesses*. Skin abscesses are common; internal abscesses tend to be harder to diagnose, and more serious.[12] Skin abscesses are also called cutaneous or subcutaneous abscesses.[19]

### IV drug use [edit]

For those with a history of intravenous drug use, an X-ray is recommended before treatment to verify that no needle fragments are present.[14] In this population if there is also a fever present infectious endocarditis should be considered.[14]

### Differential [edit]

Abscesses should be differentiated from empyemas, which are accumulations of pus in a preexisting rather than a newly formed anatomical cavity.

Other conditions that can cause similar symptoms include: cellulitis, a sebaceous cyst and necrotising fasciitis.[3]

Cellulitis typically also has an erythematous reaction, but does not confer any purulent drainage.[17]

# Treatment [edit]

The standard treatment for an uncomplicated skin or soft tissue abscess is opening and draining.[4] There does not appear to be any benefit from also using antibiotics in most cases.[1] A small amount of evidence did not find benefit from packing the abscess with gauze.[1]

## Incision and drainage [edit]

*See also: Incision and drainage*

The abscess should be inspected to identify if foreign objects are a cause, which may require their removal. If foreign objects are not the cause, incising and draining the abscess is standard treatment.[4][20]

In critical areas where surgery presents a high risk, it may be delayed or used as a last resort. The drainage of a lung abscess may be performed by positioning the patient in a way that enables the contents to be discharged via the respiratory tract. Warm compresses and elevation of the limb may be beneficial for a skin abscess.

Abscess five days after incision and drainage

Abscess following curettage

## Antibiotics [edit]

Most people who have an uncomplicated skin abscess should not use antibiotics.[4] Antibiotics in addition to standard incision and drainage is recommended in persons with severe abscesses, many sites of infection, rapid disease progression, the presence of cellulitis, symptoms indicating bacterial illness throughout the body, or a health condition causing immunosuppression.[1] People who are very young or very old may also need antibiotics.[1] If the abscess does not heal only with incision and drainage, or if the abscess is in a place that is difficult to drain such as the face, hands, or genitals, then antibiotics may be indicated.[1]

In those cases of abscess which do require antibiotic treatment, *Staphylococcus aureus* bacteria is a common cause and an anti-staphylococcus antibiotic such as flucloxacillin or dicloxacillin is used. The Infectious Diseases Society of America advises that the draining of an abscess is not enough to address community-acquired methicillin-resistant *Staphylococcus aureus* (MRSA), and in those cases, traditional antibiotics may be ineffective.[1] Alternative antibiotics effective against community-acquired MRSA often include clindamycin, doxycycline, minocycline, and trimethoprim-sulfamethoxazole.[1] The American College of Emergency Physicians advises that typical cases of abscess from MRSA get no benefit from having antibiotic treatment in addition to the standard treatment.[4] If the condition is thought to be cellulitis rather than abscess, consideration should be given to possibility of strep species as cause that are still sensitive to traditional anti-staphylococcus agents such as dicloxacillin or cephalexin in patients able to tolerate penicillin. Antibiotic therapy alone without surgical drainage of the abscess is seldom effective due to antibiotics often being unable to get into the abscess and their ineffectiveness at low pH levels.

Culturing the wound is not needed if standard follow-up care can be provided after the incision and drainage.[4] Performing a wound culture is unnecessary because it rarely gives information which can be used to guide treatment.[4]

## Packing [edit]

In North America, after drainage, an abscess cavity is often packed, perhaps with cloth, in an attempt to protect the healing wound. However, evidence from emergency medicine literature reports that packing wounds after draining causes pain to the person and does not decrease the rate of recurrence, bring more rapid healing, or

lead to fewer physician visits.[21]

### Loop Drainage [edit]

More recently, several North American hospitals have opted for less-invasive loop drainage over standard drainage and wound packing. In one study of 143 pediatric outcomes, a failure rate of 1.4% was reported in the loop group versus 10.5% in the packing group (P<.030),[22] while a separate study reported a 5.5% failure rate among loop patients.[23]

### Primary closure [edit]

Closing an abscess immediately after draining it appears to speed healing without increasing the risk of recurrence.[10] This may not apply to anorectal abscesses. While they heal faster, there may be a higher rate of recurrence than those left open.[24]

## Prognosis [edit]

Even without treatment they rarely result in death as they will naturally break through the skin.[3]

## Epidemiology [edit]

Skin abscesses are common and have become more common in recent years.[1] Risk factors include intravenous drug use with rates reported as high as 65% in this population.[2] In 2005 in the United States 3.2 million people went to the emergency department for an abscess.[5] In Australia around 13,000 people were hospitalized in 2008 for the disease.[11]

## Society and culture [edit]

The Latin medical aphorism "*ubi pus, ibi evacua*" expresses "where there is pus, there evacuate it" and is classical advice in the culture of Western medicine.

Needle exchange programmes often administer or provide referrals for abscess treatment to injection drug users as part of a harm reduction public health strategy.[25][26]

### Etymology [edit]

An abscess is so called because there is an *abscessus* (a going away or departure) of portions of the animal tissue from each other to make room for the suppurated matter lodged between them.[27]

The word carbuncle is believed to have originated from the Latin: *carbunculus*, originally a small coal; diminutive of *carbon-*, *carbo*: charcoal or ember, but also a carbuncle stone, "precious stones of a red or fiery colour", usually garnets.[28]

### Other types [edit]

The following types of abscess are listed in the medical dictionary:[29]

- acute abscess
- alveolar abscess
- amebic abscess
- apical abscess
- apical periodontal abscess
- appendiceal abscess
- Bartholin abscess
- Bezold abscess
- bicameral abscess
- hematogenous abscess
- hot abscess
- hypostatic abscess
- ischiorectal abscess
- lateral alveolar abscess
- lateral periodontal abscess
- mastoid abscess
- metastatic abscess
- migrating abscess
- phlegmonous abscess
- Pott abscess
- premammary abscess (including subareolar abscess)
- psoas abscess
- pulp abscess
- pyemic abscess
- radicular abscess
- residual abscess

- bone abscess
- Brain abscess
- Brodie abscess
- bursal abscess
- caseous abscess
- caseous lymphadenitis
- cheesy abscess
- cholangitic abscess
- chronic abscess
- collar stud abscess
- cold abscess
- crypt abscesses
- dental abscess
- diffuse abscess
- Douglas abscess
- dry abscess
- Dubois abscesses
- embolic abscess
- fecal abscess
- follicular abscess
- gas abscess
- gingival abscess
- gravitation abscess
- gummatous abscess
- Hidradenitis suppurativa
- miliary abscess
- Munro abscess
- orbital abscess
- otitic abscess
- palatal abscess
- pancreatic abscess
- parafrenal abscess
- parametric abscess
- paranephric abscess
- parapharyngeal abscess
- parotid
- Pautrier
- pelvic
- perforating
- periapical
- periappendiceal
- periarticular
- pericemental
- pericoronal abscess
- perinephric
- periodontal abscess
- perirectal
- peritonsillar abscess
- periureteral abscess
- periurethral abscess
- retrobulbar abscess
- retrocecal abscess
- retropharyngeal abscess
- ring abscess
- root abscess
- satellite abscess
- septicemic abscess
- stellate abscess
- stercoral abscess
- sterile abscess
- stitch abscess
- subdiaphragmatic abscess
- subepidermal abscess
- subhepatic abscess
- subperiosteal abscess
- subphrenic abscess
- subungual abscess
- sudoriferous abscess
- suture abscess
- thymic abscesses
- Tornwaldt abscess
- tropical abscess
- tubo-ovarian abscess
- verminous abscess
- wandering abscess
- worm abscess

# Acne vulgaris

From Wikipedia, the free encyclopedia

*This article is about a skin disease common during adolescence. For other acneiform skin diseases, see Acne (disambiguation).*

**Acne vulgaris**, also known as **acne**, is a long-term skin disease that occurs when hair follicles become clogged with dead skin cells and oil from the skin.[1] Acne is characterized by areas of blackheads, whiteheads, pimples, and greasy skin, and may result in scarring.[2][3][4] The resulting appearance can lead to anxiety, reduced self-esteem and, in extreme cases, depression or thoughts of suicide.[5][6]

Genetics is thought to be the cause in 80 % of cases.[3] The role of diet and cigarette smoking is unclear and neither cleanliness nor sunlight appear to be involved.[3][7][8] Acne affects primarily skin with a greater number of oil glands, including the face, upper part of the chest, and back.[9] During puberty, in both sexes, acne is often brought on by an increase in hormones such as testosterone.[10] Excessive growth of the bacterium *Propionibacterium acnes*, which is normally present on the skin, is often involved.[10]

Many treatment options are available including lifestyle changes, medications, and procedures. Eating fewer simple carbohydrates like sugar may help.[11] Treatments applied directly to the affected skin such as azelaic acid, benzoyl peroxide, and salicylic acid are commonly used.[12] Antibiotics and retinoids are available in both topical and by mouth formulations to treat acne.[12] However, resistance to antibiotics may develop.[13] Several types of birth control pills help against acne in women.[12] Isotretinoin pills are usually reserved for severe acne due to greater potential side effects.[12] Early and aggressive treatment is advocated by some to lessen the overall long-term impact to individuals.[6]

In 2013, acne was estimated to affect 660 million people globally, making it the 8th most common disease worldwide.[14][15] Acne commonly occurs in adolescence, affecting an estimated 80–90 % of teenagers in the Western world.[16][17][18] Lower rates are reported in some rural societies.[18][19] Children and adults may also be affected before and after puberty.[20] While less common in adulthood, nearly half of people in their twenties and thirties continue to have acne.[3] About 4% continue to have difficulties into their forties.[3]

Contents
1 Classification
2 Signs and symptoms

## Classification [edit]

Acne is commonly classified by severity as mild, moderate, or severe. This type of categorization can be an important factor in determining the appropriate treatment regimen.[17] Mild acne is classically defined as open (blackheads) and closed (whiteheads) clogged skin follicles (comedones) limited to the face with occasional inflammatory lesions.[17] Acne may be considered to be of moderate severity when a higher number of inflammatory papules and pustules occur on the face compared to mild cases of acne, and acne lesions also occur on the trunk of the body.[17] Lastly, severe acne is said to occur when nodules (the painful 'bumps' lying under the skin) are the characteristic facial lesions, and involvement of the trunk is extensive.[17][21]

Large nodules have been referred to as cysts in the past, and the term *nodulocystic* has been used in the medical literature to describe severe cases of inflammatory acne.[21] However, since true cysts are rare in those with acne, the term *severe nodular acne* is now the preferred terminology.[21]

## Signs and symptoms [edit]

Typical features of acne include seborrhea (increased sebum secretion), microcomedones, comedones, papules, pustules, nodules (large papules), and in many cases scarring.[22][23] The appearance of acne varies with skin color. It may result in psychological and social problems.[17]

### Scars [edit]

Acne scars are the result of inflammation within the dermal layer of skin, brought on by acne, and are estimated to affect 95% of people with acne vulgaris.[24] The scar is created by abnormal healing following this dermal inflammation.[24] Scarring is most likely to occur with severe nodular acne, but may occur with any form of acne vulgaris.[24] Acne scars are classified based on

A severe case of nodular acne

Nodular acne on the back

whether the abnormal healing response following dermal inflammation leads to excess collagen deposition or collagen loss at the site of the acne lesion.[24] Atrophic acne scars are the most common type of acne scar and have lost collagen from this healing response.[24] Atrophic scars may be further classified as ice-pick scars, boxcar scars, and rolling scars.[24] Ice-pick scars are typically described as narrow (less than 2 mm across), deep scars that extend into the dermis.[24] Boxcar scars are round or ovoid indented scars with sharp borders and vary in size from 1.5–4 mm across.[24] Rolling scars are wider than icepick and boxcar scars (4–5 mm across) and have a wave-like pattern of depth in the skin.[24]

Hypertrophic scars are less common, and are characterized by increased collagen content after the abnormal healing response.[24] They are described as firm and raised from the skin.[24][25] Hypertrophic scars remain within the original margins of the wound, whereas keloid scars can form scar tissue outside of these borders.[24] Keloid scars from acne occur more often in men and in people with darker colored skin, and usually occur on the trunk of the body rather than the face.[24]

### Pigmentation [edit]

Postinflammatory hyperpigmentation (PIH) is usually the result of nodular acne lesions. They often leave behind an inflamed darkened mark after the original acne lesion has resolved. PIH occurs more often in people with darker skin color.[26] Pigmented scar is a common but misleading term, as it suggests the color change is permanent. Often, PIH can be prevented by avoiding any aggravation of the nodule. These scars can fade with time. However, untreated scars can last for months, years, or even be permanent if deeper layers of skin are affected.[27] Daily use of SPF 15 or higher sunscreen can minimize pigmentation associated with acne.[27]

## Causes [edit]

### Genes [edit]

The predisposition to acne for specific individuals is likely explained in part by a genetic component, a theory which has been supported by twin studies as well as studies that have looked at rates of acne among first-degree relatives.[28] Acne susceptibility is likely due to the influence of multiple genes, as the disease does not follow a classic Mendelian inheritance pattern. There are multiple candidates for genes which are possibly related to acne, including polymorphisms in tumor necrosis factor-alpha (TNF-alpha), IL-1 alpha, and CYP1A1, among others.[16] The 308 G/A single nucleotide polymorphism in the gene for TNF is associated with acne risk.[29]

### Hormones [edit]

Hormonal activity, such as occurs during menstrual cycles and puberty, may contribute to the formation of acne. During puberty, an increase in sex hormones called androgens causes the follicular glands to grow larger and make more sebum.[9][30] Several hormones have been linked to acne, including the androgens testosterone,

dihydrotestosterone (DHT), and dehydroepiandrosterone sulfate (DHEA-S), as well as insulin-like growth factor 1 (IGF-1) and growth hormone (GH).[31] Both androgens and IGF-1 seem to be essential for acne to occur, as acne does not develop in individuals with complete androgen insensitivity syndrome (CAIS) or Laron syndrome (insensitivity to GH, resulting in extremely low IGF-1 levels).[32][33]

Medical conditions that commonly cause a high-androgen state, such as polycystic ovary syndrome, congenital adrenal hyperplasia, and androgen-secreting tumors, can cause acne in affected individuals.[34][35] Conversely, people who lack androgenic hormones or are insensitive to the effects of androgens rarely have acne.[34] An increase in androgen (and sebum) synthesis may also be seen during pregnancy.[35][36] Acne can be a side effect of testosterone replacement therapy or of anabolic steroid use.[2][37] Over-the-counter bodybuilding and dietary supplements are commonly found to contain illegally added anabolic steroids.[2][38]

### Infections [edit]

*Propionibacterium acnes* (*P. acnes*) is the anaerobic bacterium species that is widely suspected to contribute to the development of acne, but its exact role in this process is not entirely clear.[28] There are specific sub-strains of *P. acnes* associated with normal skin and others with moderate or severe inflammatory acne.[39] It is unclear whether these undesirable strains evolve on-site or are acquired, or possibly both depending on the person. These strains have the capability of either changing, perpetuating, or adapting to the abnormal cycle of inflammation, oil production, and inadequate sloughing of dead skin cells from acne pores. One particularly virulent strain has been circulating in Europe for at least 87 years.[40] Infection with the parasitic mite *Demodex* is associated with the development of acne.[23][41] However, it is unclear whether eradication of these mites improves acne.[41]

### Diet [edit]

The relationship between diet and acne is unclear, as there is no high-quality evidence which establishes any definitive link.[42] High-glycemic-load diets have been found to have different degrees of effect on acne severity by different studies.[11][43][44] Multiple randomized controlled trials and nonrandomized studies have found a lower-glycemic-load diet to be effective in reducing acne.[43] Additionally, there is weak observational evidence suggesting that dairy milk consumption is positively associated with a higher frequency and severity of acne.[41][43][45][46][47] Effects from other potentially contributing dietary factors, such as consumption of chocolate or salt, are not supported by the evidence.[45] Chocolate does contain varying amounts of sugar, which can lead to a high glycemic load, and it can be made with or without milk. There may be a relationship between acne and insulin metabolism, and one trial found a relationship between acne and obesity.[48] Vitamin $B_{12}$ may trigger skin outbreaks similar to acne (acneiform eruptions), or exacerbate existing acne, when taken in doses exceeding the recommended daily intake.[49]

### Smoking [edit]

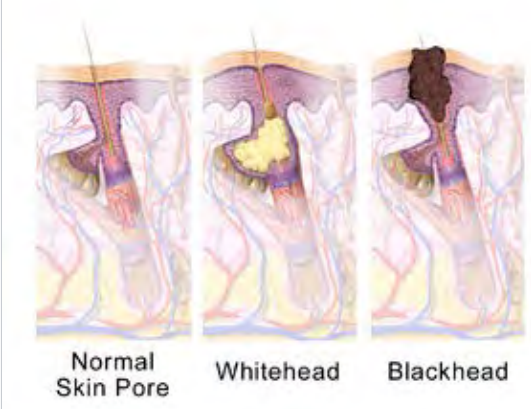
The relationship between cigarette smoking and acne severity is unclear and remains a point of debate.[3] Due to the observational nature of the evidence obtained from epidemiological studies, there are concerns that bias and confounding may have influenced the results.[3] Certain medical literature reviews have stated cigarette smoking clearly worsens acne[7] whereas others have stated it is unclear whether smoking is unrelated to, worsens, or improves acne severity.[3][8] Due to the various known negative health effects of cigarette smoking, it is not recommended as an approach to improving the appearance of acne.[3]

### Stress [edit]

Overall, few high-quality studies have been performed which demonstrate that stress causes or worsens acne.[50] While the connection between acne and stress has been debated, some research indicates that increased acne severity is associated with high stress levels in certain settings (e.g., in association with the hormonal changes seen in premenstrual syndrome).[51][52]

## Pathophysiology [edit]

Acne vulgaris is a chronic skin disease of the pilosebaceous unit and develops due to blockages in the skin's hair follicles. These blockages are thought to occur as a result of the following four abnormal processes: a higher than normal amount of sebum production (influenced by androgens), excessive deposition of the protein keratin leading to comedone formation, colonization of the follicle by *Propionibacterium acnes* (*P. acnes*) bacteria, and the local release of pro-inflammatory chemicals in the skin.[39]



Hair follicle anatomy demonstrating a healthy hair follicle (pictured left), a whitehead or closed comedone (middle picture), and a blackhead or open comedone (pictured right)

The earliest pathologic change is the formation of a plug (a microcomedone), which is driven primarily by excessive proliferation of keratinocytes in the hair follicle.[2] In normal skin, the skin cells that have died come up to the surface and exit the pore of the hair follicle.[1] However, increased production of oily sebum in those with acne causes the dead skin cells to stick together.[1] The accumulation of dead skin cell debris and oily sebum blocks the pore of the hair follicle, thus forming the microcomedone.[1] This is further exacerbated by the biofilm created by *P. acnes* within the hair follicle.[34] If the microcomedone is superficial within the hair follicle, the skin pigment melanin is exposed to air, resulting in its oxidation and dark appearance (known as a blackhead or open comedone).[1][2][17] In contrast, if the microcomedone occurs deep within the hair follicle, this causes the formation of a whitehead (known as a closed comedone).[1][2]

Dihydrotestosterone (DHT) is the main driver of androgen-induced sebum production in the skin.[2] Another androgenic hormone responsible for increased sebaceous gland activity is DHEA-S. Higher amounts of DHEA-S are secreted during adrenarche (a stage of puberty), and this leads to an increase in sebum synthesis. In a sebum-rich skin environment, the naturally occurring and largely commensal skin bacterium *P. acnes* readily grows and can cause inflammation within and around the follicle due to activation of the innate immune system.[1] *P. acnes* triggers skin inflammation in acne by increasing the production of several pro-inflammatory chemical signals (such as IL-1α, IL-8, TNF-α, and LTB4); IL-1α is known to be essential to comedone formation.[34]

A major mechanism of acne-related skin inflammation is mediated by *P. acnes*'s ability to bind and activate a class of immune system receptors known as toll-like receptors, especially toll-like receptor 2 (TLR2) and toll-like receptor 4 (TLR4).[34][53][54] Activation of TLR2 and TLR4 by *P. acnes* leads to increased secretion of IL-8, TNF-α, and IL-1α.[34] Release of these inflammatory signals attracts various immune cells to the hair follicle including neutrophils, macrophages, and Th1 cells.[34] IL-1α stimulates higher keratinocyte activity and reproduction, which in turn fuels comedone development.[34] Sebaceous gland cells also produce more antimicrobial peptides, such as HBD1 and HBD2, in response to binding of TLR2 and TLR4.[34]

*P. acnes* is also capable of provoking additional skin inflammation by altering sebum's fatty composition.[34] Squalene oxidation by *P. acnes* is of particular importance. Oxidation of squalene activates NF-κB and consequently increases IL-1α levels.[34] Additionally, squalene oxidation leads to increased activity of the 5-lipoxygenase enzyme responsible for conversion of arachidonic acid to leukotriene B4 (LTB4).[34] LTB4 promotes skin inflammation by acting on peroxisome proliferator-activated receptor alpha (PPARα).[34] PPARα increases activity of activator protein 1 (AP-1) and NF-κB, thereby leading to the recruitment of inflammatory T cells.[34] The inflammatory properties of *P. acnes* can be further explained by the bacterium's ability to convert sebum triglycerides to pro-inflammatory free fatty acids via secretion of the enzyme lipase.[34] These free fatty acids spur production of cathelicidin, HBD1, and HBD2, thus leading to further inflammation.[34]

This inflammatory cascade typically leads to the formation of inflammatory acne lesions, including papules, infected pustules, or nodules.[2] If the inflammatory reaction is severe, the follicle can break into the deeper layers of the dermis and subcutaneous tissue and cause the formation of deep nodules.[2][55][56] Involvement of AP-1 in the aforementioned inflammatory cascade also leads to activation of matrix metalloproteinases, which contribute to local tissue destruction and scar formation.[34]

## Diagnosis [edit]

There are several features that may indicate that a person's acne vulgaris is sensitive to hormonal influences. Historical and physical clues that may suggest hormone-sensitive acne include onset between ages 20 and 30; worsening the week before a woman's menstrual cycle; acne lesions predominantly over the jawline and chin; and inflammatory/nodular acne lesions.[2]

Several scales exist to grade the severity of acne vulgaris, but no single technique has been universally accepted as the diagnostic standard.[57][58] Cook's acne grading scale uses photographs to grade severity from 0 to 8 (0 being the least severe and 8 being the most severe). This scale was the first to use a standardized photographic protocol to assess acne severity; since its creation in 1979, Cook's grading scale has undergone several revisions.[58] Leeds acne grading technique counts acne lesions on the face, back, and chest and categorizes them as inflammatory or non-inflammatory. Leeds scores range from 0 (least severe) to 10 (most severe) though modified scales have a maximum score of 12.[58][59] The Pillsbury acne grading scale simply classifies the severity of the acne from 1 (least severe) to 4 (most severe).[57][60]

### Differential diagnosis [edit]

Skin conditions which may mimic acne vulgaris include angiofibromas, folliculitis, keratosis pilaris, perioral dermatitis, and rosacea, among others.[17] Age is one factor which may help distinguish between these disorders. Skin disorders such as perioral dermatitis and keratosis pilaris can appear similar to acne but tend to occur more frequently in childhood, whereas rosacea tends to occur more frequently in older adults.[17] Facial redness triggered by heat or the consumption of alcohol or spicy food is suggestive of rosacea.[61] The presence of comedones can also help health professionals differentiate acne from skin disorders that are similar in appearance.[12] Chloracne, due to exposure to certain chemicals, may look very similar to acne vulgaris.[62]

## Management [edit]

Many different treatments exist for acne, including alpha hydroxy acid, anti-androgen medications, antibiotics, antiseborrheic medications, azelaic acid, benzoyl peroxide, hormonal treatments, keratolytic soaps, nicotinamide, retinoids, and salicylic acid.[63] They are believed to work in at least four different ways, including the following: anti-inflammatory effects, hormonal manipulation, killing *P. acnes*, and normalizing skin cell shedding and sebum production in the pore to prevent blockage.[9] Commonly used medical treatments include topical therapies such as antibiotics, benzoyl peroxide, and retinoids, and systemic therapies including antibiotics, hormonal agents, and oral retinoids.[17][64]

Recommended therapies for first-line use in acne vulgaris treatment include topical retinoids, benzoyl peroxide, and topical or oral antibiotics.[65] Procedures such as light therapy and laser therapy are not considered to be first-line treatments and typically have an adjunctive role due to their high cost and the limited evidence of their efficacy.[64] Medications for acne work by targeting the early stages of comedone formation and are generally ineffective for visible skin lesions; improvement in the appearance of acne is typically expected between six and eight weeks after starting therapy.[2]

### Diet [edit]

A diet low in simple sugars is recommended as a method of improving acne.[43] As of 2014, evidence is insufficient to recommend milk restriction for this purpose.[43]

### Medications [edit]

### Benzoyl peroxide [edit]

Benzoyl peroxide (BPO) is a first-line treatment for mild and moderate acne due to its effectiveness and mild side-effects (mainly skin irritation). In the skin follicle, benzoyl peroxide kills *P.*

The common acne vulgaris treatment benzoyl peroxide cream

*acnes* by oxidizing its proteins through the formation of oxygen free radicals and benzoic acid, which is thought to interfere with the bacterium's metabolism and ability to make proteins.[66][67] Additionally, benzoyl peroxide is also mildly effective at breaking down comedones and inhibiting inflammation.[65][67] Benzoyl peroxide often causes dryness of the skin, slight redness, and occasional peeling when side effects occur.[68] This topical treatment does increase the skin's sensitivity to the sun, so sunscreen use is often advised during treatment, to prevent sunburn. Lower concentrations of benzoyl peroxide are just as effective as higher concentrations in treating acne but are associated with fewer side effects.[68] Unlike antibiotics, benzoyl peroxide does not appear to generate bacterial antibiotic resistance.[68] Benzoyl peroxide may be paired with a topical antibiotic or retinoid such as benzoyl peroxide/clindamycin and benzoyl peroxide/adapalene, respectively.[26]

## Retinoids [edit]

Retinoids are medications structurally related to vitamin A,[9] which possess anti-inflammatory properties, normalize the follicle cell life cycle, and reduce sebum production.[9][54] The retinoids appear to influence the cell life cycle in the follicle lining. This helps prevent the hyperkeratinization of these cells which can create a blockage. They are a first-line acne treatment,[2] especially for people with dark-colored skin, and are known to lead to faster improvement of postinflammatory hyperpigmentation.[26]

Frequently used topical retinoids include adapalene, isotretinoin, retinol, tazarotene, and tretinoin.[36] Topical retinoids often cause an initial flare-up of acne and facial flushing and can cause significant skin irritation. Generally speaking, retinoids increase the skin's sensitivity to sunlight and are therefore recommended for use at night.[2] Tretinoin is the least expensive of the topical retinoids and is the most irritating to the skin, whereas adapalene is the least irritating to the skin but costs significantly more than other retinoids.[2][69] Tazarotene is the most effective of the topical retinoids.[2] However, tazarotene is also the most expensive and is not as well-tolerated as other topical retinoids.[2][69] Retinol is a form of vitamin A that has similar but milder effects, and is used in many over-the-counter moisturizers and other topical products.

Isotretinoin is a retinoid which is taken orally and is very effective for severe nodular acne as well as moderate acne refractory to other treatments.[2][17] Improvement is typically seen after one to two months of use. Acne often resolves completely or is much milder after a 4- to 6-month course of oral isotretinoin.[2] After a single course, about 80% of people report an improvement, with more than 50% reporting complete remission.[17] About 20% of people require a second course.[17] A number of adverse effects may occur with isotretinoin use, including dry skin and lips, nose bleeds, muscle pains, increased liver enzymes, and increased lipid levels in the blood.[17] There is no clear evidence that use of oral retinoids increases the risk of psychiatric side effects such as depression and suicidality.[2][17] The use of oral isotretinoin in women of childbearing age is strictly regulated due to its known harmful effects in pregnancy.[17] For a woman of childbearing age to be considered a candidate for isotretinoin, she must have a confirmed negative pregnancy test and use an effective form of birth control.[17]

## Antibiotics [edit]

Antibiotics are frequently applied to the skin or taken orally to treat acne and are thought to work due to their antimicrobial activity against *P. acnes* and their anti-inflammatory properties.[17][68][70] With increasing resistance of *P. acnes* worldwide, antibiotics are becoming less effective,[68] especially macrolide antibiotics such as topical erythromycin.[70] Commonly used antibiotics, either applied to the skin or taken orally, include clindamycin, erythromycin, metronidazole, sulfacetamide, and tetracyclines such as doxycycline and minocycline.[36] When antibiotics are applied to the skin, they are typically used for mild to moderately severe [17]

acne and antibiotics taken orally are usually reserved for moderate and severe cases of inflammatory acne. Antibiotics taken orally are generally considered to be more effective than topical antibiotics, are highly effective against inflammatory acne, and produce faster resolution of inflammatory acne lesions than topical application of antibiotics.[2] It is recommended that oral antibiotics be stopped after three months and used in combination with benzoyl peroxide if their use is thought to be necessary for adequate treatment.[70]

The use of topical or oral antibiotics alone is discouraged due to concerns surrounding antibiotic resistance, but their use is recommended in combination with topical benzoyl peroxide or a retinoid.[2][70] Dapsone is not typically used as a first-line topical antibiotic due to its higher cost and lack of clear superiority over other antibiotics.[2] Dapsone is not recommended for use with benzoyl peroxide due to reports of yellow-orange skin discoloration with this combination of medications.[1]

## Hormonal agents [edit]

In women, acne can be improved with the use of any combined birth control pills.[71] Birth control pills decrease the ovaries' production of androgen hormones, resulting in lower skin production of sebum, and consequently reduce acne severity.[1] The combinations which contain third- or fourth-generation progestins such as desogestrel, drospirenone, or norgestimate may theoretically be more beneficial.[71] A 2014 systematic review found that antibiotics by mouth appear to be somewhat more effective than birth control pills at decreasing the number of inflammatory acne lesions at three months.[72] However, the two therapies are approximately equal in efficacy at six months for decreasing the number of inflammatory, non-inflammatory, and total acne lesions.[72] The authors of the analysis suggested that birth control pills may be a preferred first-line acne treatment over antibiotics by mouth in certain women due to similar efficacy at six months and a lack of associated antibiotic resistance.[72]

Antiandrogens such as cyproterone acetate and spironolactone have also been used successfully to treat acne, especially in women with signs of excessive androgen production such as increased hairiness, baldness, or increased skin production of oily sebum.[1][36] The aldosterone antagonist spironolactone is an effective treatment for acne in adult women, but unlike combination oral contraceptives, it is not approved by the United States Food and Drug Administration for this purpose.[2][26] Spironolactone is thought to be a useful acne treatment due to its ability to block the androgen receptor at higher doses.[26] It may be used with or without an oral contraceptive.[26] Hormonal therapies should not be used to treat acne during pregnancy or lactation as they have been associated with certain birth defects such as hypospadias and feminization of the male fetus or infant.[36] Finasteride is also likely to be an effective treatment for acne.[2]

## Azelaic acid [edit]

Azelaic acid has been shown to be effective for mild-to-moderate acne when applied topically at a 20% concentration.[55][73] Application twice daily for six months is necessary, and treatment is as effective as topical benzoyl peroxide 5%, isotretinoin 0.05%, and erythromycin 2%.[74] Treatment of acne with azelaic acid is less effective and more expensive than treatment with retinoids.[2] Azelaic acid is thought to be an effective acne treatment due to its antibacterial, anti-inflammatory, and antikeratinizing properties.[55] Additionally, azelaic acid has a slight skin-lightening effect due to its ability to inhibit melanin synthesis, and is therefore useful in treatment of individuals with acne who are also affected by postinflammatory hyperpigmentation.[2] Azelaic acid may cause skin irritation but is otherwise very safe.[75]

## Salicylic acid [edit]

Salicylic acid is a topically applied beta-hydroxy acid that stops bacteria from reproducing and has keratolytic properties.[76][77] Additionally, salicylic acid opens obstructed skin pores and promotes shedding of epithelial skin cells.[76] Salicylic acid is known to be less effective than retinoid therapy.[17] Dry skin is the most commonly seen side effect with topical application, though darkening of the skin has been observed in individuals with darker skin types who use salicylic acid.[2][9]

## Other medications [edit]

Topical and oral preparations of nicotinamide (the amide form of vitamin $B_3$) have been suggested as alternative medical treatments for acne.[78] Nicotinamide is thought to improve acne due to its anti-inflammatory properties, its ability to suppress sebum production, and its ability to promote wound healing.[78] Similarly, topical and oral preparations of zinc have also been proposed as effective treatments for acne; however, the evidence to support their use for this purpose is limited.[79] Zinc's benefits in acne are attributed to its beneficial effects against inflammation, sebum production, and *P. acnes*.[79] Tentative evidence has found that antihistamines may improve symptoms among those already taking isotretinoin. Antihistamines are thought to improve acne due to their anti-inflammatory properties and their ability to suppress sebum production.[80]

## Combination therapy [edit]

Combination therapy—using medications of different classes together, each with a different mechanism of action—has been demonstrated to be a more efficacious approach to acne treatment than monotherapy.[1][36] The use of topical benzoyl peroxide and antibiotics together has been shown to be more effective than antibiotics alone.[1] Similarly, using a topical retinoid with an antibiotic clears acne lesions faster than the use of antibiotics alone.[1] Frequently used combinations include the following: antibiotic + benzoyl peroxide, antibiotic + topical retinoid, or topical retinoid + benzoyl peroxide.[36] The pairing of benzoyl peroxide with a retinoid is preferred over the combination of a topical antibiotic with a retinoid since both regimens are effective but benzoyl peroxide does not lead to antibiotic resistance.[1]

## Procedures [edit]

Comedo extraction may temporarily help those with comedones that do not improve with standard treatment.[12] A procedure for immediate relief is the injection of corticosteroids into the inflamed acne comedone.[9]

Light therapy (also known as photodynamic therapy) is a method that involves delivering intense pulses of light to the area with acne following the application of a sensitizing substance such as aminolevulinic acid or methyl aminolevulinate.[1][73] This process is thought to kill bacteria and decrease the size and activity of the glands that produce sebum.[73] As of 2012, evidence for light therapy was insufficient to recommend it for routine use.[12] Disadvantages of light therapy include its cost, the need for multiple visits, and the time required to complete the procedure.[1] Light therapy appears to provide a short-term benefit, but data for long-term outcomes, and for outcomes in those with severe acne, are sparse.[9][81] However, light therapy may have a role for individuals whose acne has been resistant to topical medications.[1] Typical side effects of light therapy include skin peeling, temporary reddening of the skin, swelling, and postinflammatory hyperpigmentation.[1]

Dermabrasion is an effective therapeutic procedure for reducing the appearance of superficial atrophic scars of the boxcar and rolling varieties.[24] Ice-pick scars do not respond well to treatment with dermabrasion due to their depth.[24] However, the procedure is painful and has many potential side effects such as skin sensitivity to sunlight, redness, and decreased pigmentation of the skin.[24] Dermabrasion has fallen out of favor with the introduction of laser resurfacing.[24] Unlike dermabrasion, there is no evidence that microdermabrasion is an effective treatment for acne.[12]

Laser resurfacing can be used to reduce the scars left behind by acne.[82] Ablative fractional photothermolysis laser resurfacing was found to be more effective for reducing acne scar appearance than non-ablative fractional photothermolysis, but was associated with higher rates of postinflammatory hyperpigmentation (usually about one-month duration), facial redness (usually for 3–14 days), and pain during the procedure.[83] As of 2012, the evidence to support the routine use of laser resurfacing as a treatment modality for acne scars was insufficient.[12] Many studies that evaluated this form of treatment did not have a control group, did not compare laser resurfacing to effective medical treatments, or were of a short duration, thus limiting the quality of the evidence.[12]

Chemical peels can also be used to reduce the appearance of acne scars.[24] Mild chemical peels include those using glycolic acid, lactic acid, salicylic acid, Jessner's solution, or a lower concentration (20%) of trichloroacetic acid. These peels only affect the epidermal layer of the skin and can be useful in the treatment of superficial acne scars as well as skin pigmentation changes from inflammatory acne.[24] Higher concentrations of trichloroacetic acid (30–40%) are considered to be medium-strength peels and affect skin as deep as the

papillary dermis.[24] Formulations of trichloroacetic acid concentrated to 50% or more are considered to be deep chemical peels.[24] Medium- and deep-strength chemical peels are more effective for deeper atrophic scars, but are more likely to cause side effects such as skin pigmentation changes, infection, or milia.[24]

### Pregnancy [edit]

Although the late stages of pregnancy are associated with an increase in sebaceous gland activity in the skin, pregnancy has not been reliably associated with worsened acne severity.[84] In general, topically applied medications are considered the first-line approach to acne treatment during pregnancy, as topical therapies have little systemic absorption and are therefore unlikely to harm a developing fetus.[84] Highly recommended therapies include topically applied benzoyl peroxide (category C) and azelaic acid (category B).[84] Salicylic acid carries a category C safety rating due to higher systemic absorption (9–25%) and an association between the use of anti-inflammatory medications in the third trimester of pregnancy and adverse effects to the developing fetus including oligohydramnios and early closure of the ductus arteriosus.[36][84] Prolonged use of salicylic acid over significant areas of the skin or under occlusive dressings is not recommended as these methods increase systemic absorption and the potential for fetal harm.[84] Tretinoin (category C) and adapalene (category C) are very poorly absorbed, but certain studies have suggested teratogenic effects in the first trimester.[84] In studies examining the effects of topical retinoids during pregnancy, fetal harm has not been seen in the second and third trimesters.[84] Retinoids contraindicated for use during pregnancy include the topical retinoid tazarotene (category X) and oral retinoids isotretinoin (category X) and acitretin (category X).[84] Spironolactone is relatively contraindicated for use during pregnancy due to its antiandrogen effects.[2] Finasteride is also not recommended for use during pregnancy as it is highly teratogenic.[2]

Topical antibiotics deemed safe during pregnancy include clindamycin (category B), erythromycin (category B) and metronidazole (category B), due to negligible systemic absorption.[36][84] Nadifloxacin and dapsone (category C) are other topical antibiotics that may be used to treat acne in pregnant women, but have received less extensive study.[36][84] No adverse fetal events have been reported in association with topical use of dapsone during pregnancy.[84] If retinoids are used during pregnancy, there is a high risk of abnormalities occurring in the developing fetus; therefore, women of childbearing age are required to use effective birth control if retinoids are used to treat acne.[17] Oral antibiotics deemed safe for pregnancy (all category B) include azithromycin, cephalosporins, and penicillins.[84] Tetracyclines (category D) are contraindicated during pregnancy as they are known to deposit in developing fetal teeth, resulting in yellow discoloration and thinned tooth enamel.[2][84] Use of tetracyclines in pregnancy has also been associated with development of acute fatty liver of pregnancy and is avoided for this reason as well.[84]

### Alternative medicine [edit]

Complementary therapies have been investigated for treating people with acne.[85] Low-quality evidence suggests topical application of tea tree oil or bee venom may reduce the total number of skin lesions in those with acne.[85] Tea tree oil is thought to be approximately as effective as benzoyl peroxide or salicylic acid, but has been associated with cases of allergic contact dermatitis.[2] Proposed mechanisms for tea tree oil's anti-acne effects include antibacterial action against *P. acnes* and anti-inflammatory properties.[54] Numerous other plant-derived therapies have been observed to have positive effects against acne (e.g., basil oil and oligosaccharides from seaweed); however, few studies have been performed, and most have been of lower methodological quality.[86] There is a lack of high-quality evidence for the use of acupuncture, herbal medicine, or cupping therapy for acne.[85]

## Prognosis [edit]

Acne usually improves around the age of 20, but may persist into adulthood.[63] Permanent physical scarring may occur.[17] There is good evidence to support the idea that acne has a negative psychological impact, and that it worsens mood, lowers self-esteem, and is associated with a higher risk of anxiety disorders, depression, and suicidal thoughts.[41] Another psychological complication of acne vulgaris is acne excoriée, which occurs when a person persistently picks and scratches pimples, irrespective of the severity of their acne.[51][87] This can

lead to significant scarring, changes in the affected person's skin pigmentation, and a cyclic worsening of the affected person's anxiety about their appearance.[51]

## Epidemiology [edit]

Globally, acne affects approximately 650 million people, or about 9.4% of the population, as of 2010.[88] It affects nearly 90% of people in Western societies during their teenage years, and may persist into adulthood.[17] Acne that first develops between the ages of 21 and 25 is uncommon; however, acne affects 54% of women and 40% of men older than 25 years of age.[36][89] Acne vulgaris has a lifetime prevalence of 85%.[36] About 20% of those affected have moderate or severe cases.[28] It is slightly more common in females than males (9.8% versus 9.0%).[88] In those over 40 years old, 1% of males and 5% of females still have problems.[17]

Rates appear to be lower in rural societies.[19] While some research has found it affects people of all ethnic groups,[90] acne may not occur in the non-Westernized peoples of Papua New Guinea and Paraguay.[28]

Acne affects 40 to 50 million people in the United States (16%) and approximately 3 to 5 million in Australia (23%).[72][91] In the United States, acne tends to be more severe in Caucasians than in people of African descent.[9]

## History [edit]

Since at least as long ago as the reign of Cleopatra (69–30 BC), the application of sulfur to the skin has been recognized as a useful form of treatment for acne.[92] The sixth-century Greek physician Aëtius of Amida is credited with coining the term "ionthos" (ἰονθωξ,) or "acnae", which is believed to have been a reference to facial skin lesions that occur during "the 'acme' of life" (referring to puberty).[93]

In the 16th century, the French physician and botanist François Boissier de Sauvages de Lacroix provided one of the earlier descriptions of acne and used the term "psydracia achne" to describe small, red and hard tubercles that altered a person's facial appearance during adolescence and were neither itchy nor painful.[93] The recognition and characterization of acne progressed in 1776 when Josef Plenck (an Austrian physician) published a book that proposed the novel concept of classifying skin diseases by their elementary (initial) lesions.[93] Plenck's work was later refined when the English dermatologist Robert Willan authored his seminal 1808 treatise, which provided the first detailed descriptions of several skin disorders with morphologic terminology that continues to be used today.[93] Thomas Bateman continued and expanded on Robert Willan's work as his student and provided the medical literature's first descriptions and illustrations of acne accepted as accurate by modern dermatologists.[93]

Domolene ointment, a mid 1900s medication that was claimed to cure acne

Dermatologists originally hypothesized that acne represented a disease of the skin's hair follicle and occurred due to blockage of the pore by sebum. During the 1880s, bacteria were observed by microscopy in skin samples affected by acne and were regarded as the causal agents of comedones, sebum production, and ultimately acne.[93] During the mid-twentieth century, dermatologists realized that no single hypothesized factor (sebum, bacteria, or excess keratin) could completely explain the disease.[93] This led dermatologists to the current understanding that acne could be explained by a sequence of related events, beginning with blockage of the skin follicle by excessive dead skin cells, followed by bacterial invasion of the hair follicle pore, changes in sebum production, and inflammation.[93]

The approach to acne treatment also underwent significant changes during the twentieth century. Benzoyl peroxide was introduced as a medication to treat acne in the 1920s.[94] Acne treatment was again modified in the 1950s with the introduction of oral tetracycline antibiotics (such as minocycline), which reinforced the idea amongst dermatologists that bacterial growth on the skin plays an important role in causing acne.[93]

Subsequently, in the 1970s tretinoin (original trade name Retin A) was found to be an effective treatment for acne.[95] This preceded the development of oral isotretinoin (sold as Accutane and Roaccutane) in 1980.[96] Following the introduction of isotretinoin in the United States, it was recognized as a medication highly likely to cause birth defects if taken during pregnancy. In the United States, more than 2,000 women became pregnant while taking the drug between 1982 and 2003, with most pregnancies ending in abortion or miscarriage. About 160 babies with birth defects were born.[97][98]

## Society and culture [edit]

### Cost [edit]

The social and economic costs of treating acne vulgaris are substantial. In the United States, acne vulgaris is responsible for more than 5 million doctor visits and costs over $2.5 billion each year in direct costs.[7] Similarly, acne vulgaris is responsible for 3.5 million doctor visits each year in the United Kingdom.[17]

### Stigma [edit]

Misperceptions about acne's causative and aggravating factors are common and those affected by acne are often blamed for their condition.[99] Such blame can worsen the affected person's sense of self-esteem.[99] Acne vulgaris and its resultant scars have been associated with significant social difficulties that can last into adulthood.[100]

## Research [edit]

Efforts are underway to better understand the mechanisms involved in sebum production. The aim of this research is to develop medications targeting hormones known to increase sebum production (e.g., IGF-1 and alpha-melanocyte-stimulating hormone).[1] Additional sebum-lowering medications being researched include topical antiandrogens and PPAR modulators.[1] Another avenue of early-stage research has focused on how to best use laser and light therapy to selectively destroy sebaceous glands in the skin's hair follicles to reduce sebum production and improve acne appearance.[1]

The use of antimicrobial peptides against *P. acnes* is also under investigation as a novel method of treating acne and overcoming antibiotic resistance.[1] In 2007, the first genome sequencing of a *P. acnes* bacteriophage (PA6) was reported. The authors proposed applying this research toward development of bacteriophage therapy as an acne treatment in order to overcome the problems associated with long-term antibiotic therapy, such as bacterial resistance.[101] Oral and topical probiotics are also being evaluated as treatments for acne.[102] Probiotics have been hypothesized to have therapeutic effects for those affected by acne due to their ability to decrease skin inflammation and improve skin moisture by increasing the skin's ceramide content.[102] As of 2014, studies examining the effects of probiotics on acne in humans were limited.[102]

Decreased levels of retinoic acid in the skin may contribute to comedone formation. To address this deficiency, and potentially replace the use of irritating topical retinoids, methods to increase the skin's production of retinoid acid are being explored.[1] A vaccine against inflammatory acne has been tested successfully in mice, but has not yet been proven to be effective in humans.[103] Other workers have voiced concerns related to creating a vaccine designed to neutralize a stable community of normal skin bacteria that is known to protect the skin from colonization by more harmful microorganisms.[104]

# Allergy

From Wikipedia, the free encyclopedia

**Allergies**, also known as **allergic diseases**, are a number of conditions caused by hypersensitivity of the immune system to something in the environment that usually causes little or no problem in most people.[1] These diseases include hay fever, food allergies, atopic dermatitis, allergic asthma, and anaphylaxis.[2] Symptoms may include red eyes, an itchy rash, runny nose, shortness of breath, or swelling.[3] Food intolerances and food poisoning are separate conditions.[4][5]

Common allergens include pollen and certain food. Metals and other substances may also cause problems.[1] Food, insect stings, and medications are common causes of severe reactions. Their development is due to both genetic and environmental factors.[6] The underlying mechanism involves immunoglobulin E antibodies (IgE), part of the body's immune system, binding to an allergen and then to a receptor on mast cells or basophils where it triggers the release of inflammatory chemicals such as histamine.[7] Diagnosis is typically based on a person's medical history. Further testing of the skin or blood may be useful in certain cases.[5] Positive tests, however, may not mean there is a significant allergy to the substance in question.[8]

Early exposure to potential allergens may be protective.[9] Treatments for allergies include avoiding known allergens and the use of medications such as steroids and antihistamines.[10] In severe reactions injectable adrenaline (epinephrine) is recommended.[11] Allergen immunotherapy, which gradually exposes people to larger and larger amounts of allergen, is useful for some types of allergies such as hay fever and reactions to insect bites. Its use in food allergies is unclear.[10]

Allergies are common.[12] In the developed world, about 20% of people are affected by allergic rhinitis,[13] about 6% of people have at least one food allergy,[5][9] and about 20% have atopic dermatitis at some point in time.[14] Depending on the country about 1–18% of people have asthma.[15][16] Anaphylaxis occurs in between 0.05–2% of people.[17] Rates of many allergic diseases appear to be increasing.[11][18] The word "allergy" was first used by Clemens von Pirquet in 1906.[6]

Hives are a common allergic symptom.

## Signs and symptoms [edit]

Many allergens such as dust or pollen are airborne particles. In these cases, symptoms arise in areas in contact with air, such as eyes, nose, and lungs. For instance, allergic rhinitis, also known as hay fever, causes irritation of the nose, sneezing, itching, and redness of the eyes.[19] Inhaled allergens can also lead to increased production of mucus in the lungs, shortness of breath, coughing, and wheezing.[20]

Aside from these ambient allergens, allergic reactions can result from foods, insect stings, and reactions to medications like aspirin and antibiotics such as penicillin. Symptoms of food allergy include abdominal pain, bloating, vomiting, diarrhea, itchy skin, and swelling of the skin during hives. Food allergies rarely cause respiratory (asthmatic) reactions, or rhinitis.[21] Insect stings, antibiotics, and certain medicines produce a systemic allergic response that is also called anaphylaxis; multiple organ systems can be affected, including the digestive system, the respiratory system, and the circulatory system.[22][23][24] Depending on the rate of severity, it can cause a skin reactions, bronchoconstriction, swelling, low blood pressure, coma, and death. This type of reaction can be triggered suddenly, or the onset can be delayed. The nature of anaphylaxis is such that the reaction can seem to be subsiding, but may recur throughout a period of time.[24]

**Common symptoms**

| Affected organ | Symptom |
|---|---|
| Nose | Swelling of the nasal mucosa (allergic rhinitis) runny nose, sneezing |
| Sinuses | Allergic sinusitis |
| Eyes | Redness and itching of the conjunctiva (allergic conjunctivitis, watery) |
| Airways | Sneezing, coughing, bronchoconstriction, wheezing and dyspnea, sometimes outright attacks of asthma, in severe cases the airway constricts due to swelling known as laryngeal edema |
| Ears | Feeling of fullness, possibly pain, and impaired hearing due to the lack of eustachian tube drainage. |
| Skin | Rashes, such as eczema and hives (urticaria) |
| Gastrointestinal tract | Abdominal pain, bloating, vomiting, diarrhea |

### Skin [edit]

Substances that come into contact with the skin, such as latex, are also common causes of allergic reactions, known as contact dermatitis or eczema.[25] Skin allergies frequently cause rashes, or swelling and inflammation within the skin, in what is known as a "wheal and flare" reaction characteristic of hives and angioedema.[26]

With insect stings a large local reaction may occur (an area of skin redness greater than 10 cm in size).[27] It can last one to two days.[27] This reaction may also occur after immunotherapy.[28]

## Cause [edit]

Risk factors for allergy can be placed in two general categories, namely host and environmental factors.[29] Host factors include heredity, sex, race, and age, with heredity being by far the most significant. However, there have been recent increases in the incidence of allergic disorders that cannot be explained by genetic factors alone. Four major environmental candidates are alterations in exposure to infectious diseases during early childhood, environmental pollution, allergen levels, and dietary changes.[30]

### Foods [edit]

*Main article: Food allergy*

A wide variety of foods can cause allergic reactions, but 90% of allergic responses to foods are caused by cow's milk, soy, eggs, wheat, peanuts, tree nuts, fish, and shellfish.[31] Other food allergies, affecting less than 1 person per 10,000 population, may be considered "rare".[32] The use of hydrolysed milk baby formula versus standard milk baby formula does not appear to change the risk.[33]

The most common food allergy in the US population is a sensitivity to crustacea.[32] Although peanut allergies are notorious for their severity, peanut allergies are not the most common food allergy in adults or children. Severe or life-threatening reactions may be triggered by other allergens, and are more common when combined with asthma.[31]

Rates of allergies differ between adults and children. Peanut allergies can sometimes be outgrown by children. Egg allergies affect one to two percent of children but are outgrown by about two-thirds of children by the age of 5.[34] The sensitivity is usually to proteins in the white, rather than the yolk.[35]

Milk-protein allergies are most common in children.[36] Approximately 60% of milk-protein reactions are immunoglobulin E-mediated, with the remaining usually attributable to inflammation of the colon.[37] Some people are unable to tolerate milk from goats or sheep as well as from cows, and many are also unable to tolerate dairy products such as cheese. Roughly 10% of children with a milk allergy will have a reaction to beef. Beef contains a small amount of protein that is present in cow's milk.[38] Lactose intolerance, a common reaction to milk, is not a form of allergy at all, but rather due to the absence of an enzyme in the digestive tract.

Those with tree nut allergies may be allergic to one or to many tree nuts, including pecans, pistachios, pine nuts, and walnuts.[35] Also seeds, including sesame seeds and poppy seeds, contain oils in which protein is present, which may elicit an allergic reaction.[35]

Allergens can be transferred from one food to another through genetic engineering; however genetic modification can also remove allergens. Little research has been done on the natural variation of allergen concentrations in the unmodified crops.[39][40]

### Latex [edit]

Latex can trigger an IgE-mediated cutaneous, respiratory, and systemic reaction. The prevalence of latex allergy in the general population is believed to be less than one percent. In a hospital study, 1 in 800 surgical patients (0.125 percent) reported latex sensitivity, although the sensitivity among healthcare workers is higher, between seven and ten percent. Researchers attribute this higher level to the exposure of healthcare workers to areas with significant airborne latex allergens, such as operating rooms, intensive-care units, and dental suites. These latex-rich environments may sensitize healthcare workers who regularly inhale allergenic proteins.[41]

The most prevalent response to latex is an allergic contact dermatitis, a delayed hypersensitive reaction appearing as dry, crusted lesions. This reaction usually lasts 48–96 hours. Sweating or rubbing the area under the glove aggravates the lesions, possibly leading to ulcerations.[41] Anaphylactic reactions occur most often in sensitive patients who have been exposed to a surgeon's latex gloves during abdominal surgery, but other mucosal exposures, such as dental procedures, can also produce systemic reactions.[41]

Latex and banana sensitivity may cross-react. Furthermore, those with latex allergy may also have sensitivities to avocado, kiwifruit, and chestnut.[42] These people often have perioral itching and local urticaria. Only occasionally have these food-induced allergies induced systemic responses. Researchers suspect that the cross-reactivity of latex with banana, avocado, kiwifruit, and chestnut occurs because latex proteins are structurally homologous with some other plant proteins.[41]

### Medications [edit]

About 10% of people report that they are allergic to penicillin; however, 90% turn out not to be.[43] Serious allergies only occur in about 0.03%.[43]

## Toxins interacting with proteins [edit]

Another non-food protein reaction, urushiol-induced contact dermatitis, originates after contact with poison ivy, eastern poison oak, western poison oak, or poison sumac. Urushiol, which is not itself a protein, acts as a hapten and chemically reacts with, binds to, and changes the shape of integral membrane proteins on exposed skin cells. The immune system does not recognize the affected cells as normal parts of the body, causing a T-cell-mediated immune response.[44] Of these poisonous plants, sumac is the most virulent.[45] The resulting dermatological response to the reaction between urushiol and membrane proteins includes redness, swelling, papules, vesicles, blisters, and streaking.[46]

Estimates vary on the percentage of the population that will have an immune system response. Approximately 25 percent of the population will have a strong allergic response to urushiol. In general, approximately 80 percent to 90 percent of adults will develop a rash if they are exposed to .0050 milligrams ($7.7 \times 10^{-5}$ gr) of purified urushiol, but some people are so sensitive that it takes only a molecular trace on the skin to initiate an allergic reaction.[47]

## Genetics [edit]

Allergic diseases are strongly familial: identical twins are likely to have the same allergic diseases about 70% of the time; the same allergy occurs about 40% of the time in non-identical twins.[48] Allergic parents are more likely to have allergic children,[49] and those children's allergies are likely to be more severe than those in children of non-allergic parents. Some allergies, however, are not consistent along genealogies; parents who are allergic to peanuts may have children who are allergic to ragweed. It seems that the likelihood of developing allergies is inherited and related to an irregularity in the immune system, but the specific allergen is not.[49]

The risk of allergic sensitization and the development of allergies varies with age, with young children most at risk.[50] Several studies have shown that IgE levels are highest in childhood and fall rapidly between the ages of 10 and 30 years.[50] The peak prevalence of hay fever is highest in children and young adults and the incidence of asthma is highest in children under 10.[51]

Overall, boys have a higher risk of developing allergies than girls,[49] although for some diseases, namely asthma in young adults, females are more likely to be affected.[52] These differences between the sexes tend to decrease in adulthood.[49]

Ethnicity may play a role in some allergies; however, racial factors have been difficult to separate from environmental influences and changes due to migration.[49] It has been suggested that different genetic loci are responsible for asthma, to be specific, in people of European, Hispanic, Asian, and African origins.[53]

## Hygiene hypothesis [edit]

*Main article: Hygiene hypothesis*

Allergic diseases are caused by inappropriate immunological responses to harmless antigens driven by a TH2-mediated immune response. Many bacteria and viruses elicit a TH1-mediated immune response, which down-regulates TH2 responses. The first proposed mechanism of action of the hygiene hypothesis was that insufficient stimulation of the TH1 arm of the immune system leads to an overactive TH2 arm, which in turn leads to allergic disease.[54] In other words, individuals living in too sterile an environment are not exposed to enough pathogens to keep the immune system busy. Since our bodies evolved to deal with a certain level of such pathogens, when they are not exposed to this level, the immune system will attack harmless antigens and thus normally benign microbial objects—like pollen—will trigger an immune response.[55]

The hygiene hypothesis was developed to explain the observation that hay fever and eczema, both allergic diseases, were less common in children from larger families, which were, it is presumed, exposed to more infectious agents through their siblings, than in children from families with only one child. The hygiene hypothesis has been extensively investigated by immunologists and epidemiologists and has become an important theoretical framework for the study of allergic disorders. It is used to explain the increase in allergic diseases that have been seen since industrialization, and the higher incidence of allergic diseases in more developed countries. The hygiene hypothesis has now expanded to include exposure to symbiotic bacteria and parasites as important modulators of immune system development, along with infectious agents.

Epidemiological data support the hygiene hypothesis. Studies have shown that various immunological and autoimmune diseases are much less common in the developing world than the industrialized world and that

immigrants to the industrialized world from the developing world increasingly develop immunological disorders in relation to the length of time since arrival in the industrialized world.[56] Longitudinal studies in the third world demonstrate an increase in immunological disorders as a country grows more affluent and, it is presumed, cleaner.[57] The use of antibiotics in the first year of life has been linked to asthma and other allergic diseases.[58] The use of antibacterial cleaning products has also been associated with higher incidence of asthma, as has birth by Caesarean section rather than vaginal birth.[59][60]

### Stress [edit]

Chronic stress can aggravate allergic conditions. This has been attributed to a T helper 2 (TH2)-predominant response driven by suppression of interleukin 12 by both the autonomic nervous system and the hypothalamic–pituitary–adrenal axis. Stress management in highly susceptible individuals may improve symptoms.[61]

### Other environmental factors [edit]

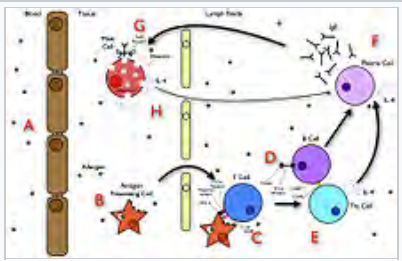
International differences have been associated with the number of individuals within a population have allergy. Allergic diseases are more common in industrialized countries than in countries that are more traditional or agricultural, and there is a higher rate of allergic disease in urban populations versus rural populations, although these differences are becoming less defined.[62]

Alterations in exposure to microorganisms is another plausible explanation, at present, for the increase in atopic allergy.[30] Endotoxin exposure reduces release of inflammatory cytokines such as TNF-α, IFNγ, interleukin-10, and interleukin-12 from white blood cells (leukocytes) that circulate in the blood.[63] Certain microbe-sensing proteins, known as Toll-like receptors, found on the surface of cells in the body are also thought to be involved in these processes.[64]

Gutworms and similar parasites are present in untreated drinking water in developing countries, and were present in the water of developed countries until the routine chlorination and purification of drinking water supplies.[65] Recent research has shown that some common parasites, such as intestinal worms (e.g., hookworms), secrete chemicals into the gut wall (and, hence, the bloodstream) that suppress the immune system and prevent the body from attacking the parasite.[66] This gives rise to a new slant on the hygiene hypothesis theory—that co-evolution of humans and parasites has led to an immune system that functions correctly only in the presence of the parasites. Without them, the immune system becomes unbalanced and oversensitive.[67] In particular, research suggests that allergies may coincide with the delayed establishment of gut flora in infants.[68] However, the research to support this theory is conflicting, with some studies performed in China and Ethiopia showing an increase in allergy in people infected with intestinal worms.[62] Clinical trials have been initiated to test the effectiveness of certain worms in treating some allergies.[69] It may be that the term 'parasite' could turn out to be inappropriate, and in fact a hitherto unsuspected symbiosis is at work.[69] For more information on this topic, see Helminthic therapy.

## Pathophysiology [edit]

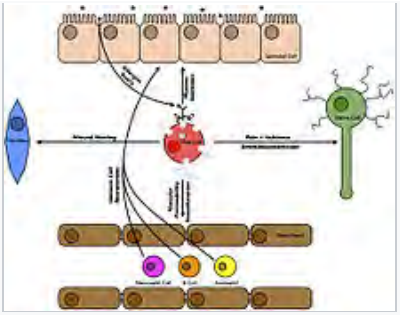
### Acute response [edit]



A summary diagram that explains how allergy develops.

In the early stages of allergy, a type I hypersensitivity reaction against an allergen encountered for the first time and presented by a professional antigen-presenting cell causes a response in a type of immune cell called a $T_H2$ lymphocyte, which belongs to a subset of T cells that produce a cytokine called interleukin-4 (IL-4). These $T_H2$ cells interact with other lymphocytes called B cells, whose role is production of antibodies. Coupled with signals provided by IL-4, this interaction stimulates the B cell to begin production of a large amount of a particular type of antibody known as IgE. Secreted IgE circulates in the blood and binds to an IgE-specific receptor (a kind of Fc receptor called FcεRI) on the surface of other kinds of immune cells called mast cells and basophils, which are both involved in the acute inflammatory response. The IgE-coated cells, at this stage, are sensitized to the allergen.[30]

If later exposure to the same allergen occurs, the allergen can bind to the IgE molecules held on the surface of the mast cells or basophils. Cross-linking of the IgE and Fc receptors occurs when more than one IgE-receptor complex interacts with the same allergenic molecule, and activates the sensitized cell.

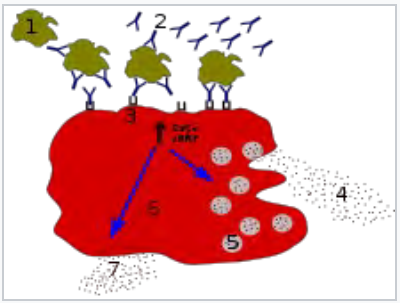


Tissues affected in allergic inflammation

Activated mast cells and basophils undergo a process called degranulation, during which they release histamine and other inflammatory chemical mediators (cytokines, interleukins, leukotrienes, and prostaglandins) from their granules into the surrounding tissue causing several systemic effects, such as vasodilation, mucous secretion, nerve stimulation, and smooth muscle contraction. This results in rhinorrhea, itchiness, dyspnea, and anaphylaxis. Depending on the individual, allergen, and mode of introduction, the symptoms can be system-wide (classical anaphylaxis), or localized to particular body systems; asthma is localized to the respiratory system and eczema is localized to the dermis.[30]

## Late-phase response [edit]

After the chemical mediators of the acute response subside, late-phase responses can often occur. This is due to the migration of other leukocytes such as neutrophils, lymphocytes, eosinophils and macrophages to the initial site. The reaction is usually seen 2–24 hours after the original reaction.[70] Cytokines from mast cells may play a role in the persistence of long-term effects. Late-phase responses seen in asthma are slightly different from those seen in other allergic responses, although they are still caused by release of mediators from eosinophils and are still dependent on activity of $T_H2$ cells.[71]

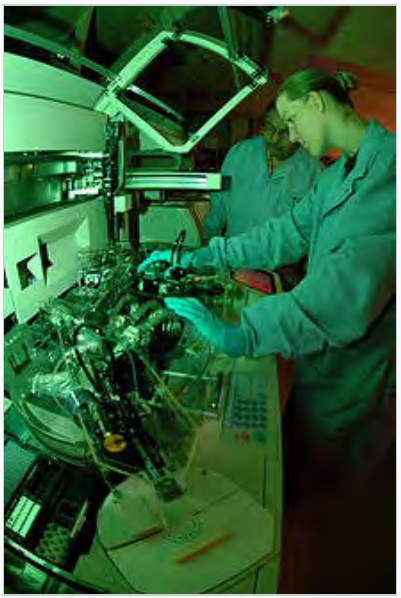


Degranulation process in allergy. Second exposure to allergen. **1** – antigen; **2** – IgE antibody; **3** – FcεRI receptor; **4** – preformed mediators (histamine, proteases, chemokines, heparin); **5** – granules; **6** – mast cell; **7** – newly formed mediators (prostaglandins, leukotrienes, thromboxanes, PAF)

## Allergic contact dermatitis [edit]

Although allergic contact dermatitis is termed an "allergic" reaction (which usually refers to type I hypersensitivity), its pathophysiology actually involves a reaction that more correctly corresponds to a type IV hypersensitivity reaction.[72] In type IV hypersensitivity, there is activation of certain types of T cells (CD8+) that destroy target cells on contact, as well as activated macrophages that produce hydrolytic enzymes.

# Diagnosis [edit]



An allergy testing machine being operated in the diagnostic immunology lab

Effective management of allergic diseases relies on the ability to make an accurate diagnosis.[73] Allergy testing can help confirm or rule out allergies.[74][75] Correct diagnosis, counseling, and avoidance advice based on valid allergy test results reduces the incidence of symptoms and need for medications, and improves quality of life.[74] To assess the presence of allergen-specific IgE antibodies, two different methods can be used: a skin prick test, or an allergy blood test. Both methods are recommended, and they have similar diagnostic value.[75][76]

Skin prick tests and blood tests are equally cost-effective, and health economic evidence shows that both tests were cost-effective compared with no test.[74] Also, early and more accurate diagnoses save cost due to reduced consultations, referrals to secondary care, misdiagnosis, and emergency admissions.[77]

Allergy undergoes dynamic changes over time. Regular allergy testing of relevant allergens provides information on if and how patient management can be changed, in order to improve health and quality of life. Annual testing is often the practice for determining whether allergy to milk, egg, soy, and wheat have been outgrown, and the testing interval is extended to 2–3 years for allergy to peanut, tree nuts, fish, and crustacean shellfish.[75] Results of follow-up testing can guide decision-making regarding whether and when it is safe to introduce or re-introduce allergenic food into the diet.[78]

## Skin prick testing [edit]

Skin testing is also known as "puncture testing" and "prick testing" due to the series of tiny punctures or pricks made into the patient's skin. Small amounts of suspected allergens and/or their extracts (*e.g.*, pollen, grass, mite proteins, peanut extract) are introduced to sites on the skin marked with pen or dye (the ink/dye should be carefully selected, lest it cause an allergic response itself). A small plastic or metal device is used to puncture or prick the skin. Sometimes, the allergens are injected "intradermally" into the patient's skin, with a needle and syringe. Common areas for testing include the inside forearm and the back.

Skin testing on arm

If the patient is allergic to the substance, then a visible inflammatory reaction will usually occur within 30 minutes. This response will range from slight reddening of the skin to a full-blown hive (called "wheal and flare") in more sensitive patients similar to a mosquito bite. Interpretation of the results of the skin prick test is normally done by allergists on a scale of severity, with +/− meaning borderline reactivity, and 4+ being a large reaction. Increasingly, allergists are measuring and recording the diameter of the wheal and flare reaction. Interpretation by well-trained allergists is often guided by relevant literature.[79] Some patients may believe they have determined their own allergic sensitivity from observation, but a skin test has been shown to be much better than patient observation to detect allergy.[80]

Skin testing on back

If a serious life-threatening anaphylactic reaction has brought a patient in for evaluation, some allergists will prefer an initial blood test prior to performing the skin prick test. Skin tests may not be an option if the patient has widespread skin disease, or has taken antihistamines in the last several days.

## Patch testing [edit]

Patch testing is a method used to determine if a specific substance causes allergic inflammation of the skin. It tests for delayed reactions. It is used to help ascertain the cause of skin contact allergy, or contact dermatitis. Adhesive patches, usually treated with a number of common allergic chemicals or skin sensitizers, are applied to the back. The skin is then examined for possible local reactions at least twice, usually at 48 hours after application of the patch, and again two or three days later.

Patch test

## Blood testing [edit]

An allergy blood test is quick and simple, and can be ordered by a licensed health care provider (*e.g.*, an allergy specialist), GP, or PED. Unlike skin-prick testing, a blood test can be performed irrespective of age, skin condition, medication, symptom, disease activity, and pregnancy. Adults and children of any age can take an allergy blood test. For babies and very young children, a single needle stick for allergy blood testing is often more gentle than several skin tests.

An allergy blood test is available through most laboratories. A sample of the patient's blood is sent to a laboratory for analysis, and the results are sent back a few days later. Multiple allergens can be detected with a single blood sample. Allergy blood tests are very safe, since the person is not exposed to any allergens during the testing procedure.

The test measures the concentration of specific IgE antibodies in the blood. Quantitative IgE test results increase the possibility of ranking how different substances may affect symptoms. A rule of thumb is that the higher the IgE antibody value, the greater the likelihood of symptoms. Allergens found at low levels that today do not result in symptoms can nevertheless help predict future symptom development. The quantitative allergy blood result can help determine what a patient is allergic to, help predict and follow the disease development, estimate the risk of a severe reaction, and explain cross-reactivity.[81][82]

A low total IgE level is not adequate to rule out sensitization to commonly inhaled allergens.[83] Statistical methods, such as ROC curves, predictive value calculations, and likelihood ratios have been used to examine the relationship of various testing methods to each other. These methods have shown that patients with a high total IgE have a high probability of allergic sensitization, but further investigation with allergy tests for specific IgE antibodies for a carefully chosen of allergens is often warranted.

Laboratory methods to measure specific IgE antibodies for allergy testing include enzyme-linked immunosorbent [84] [84] [85]

assay (ELISA, or EIA), radioallergosorbent test (RAST) and fluorescent enzyme immunoassay (FEIA).

### Other [edit]

**Challenge testing:** Challenge testing is when small amounts of a suspected allergen are introduced to the body orally, through inhalation, or via other routes. Except for testing food and medication allergies, challenges are rarely performed. When this type of testing is chosen, it must be closely supervised by an allergist.

**Elimination/Challenge tests:** This testing method is used most often with foods or medicines. A patient with a suspected allergen is instructed to modify his diet to totally avoid that allergen for a set time. If the patient experiences significant improvement, he may then be "challenged" by reintroducing the allergen, to see if symptoms are reproduced.

**Unreliable tests:** There are other types of allergy testing methods that are unreliable, including applied kinesiology (allergy testing through muscle relaxation), cytotoxicity testing, urine autoinjection, skin titration (Rinkel method), and provocative and neutralization (subcutaneous) testing or sublingual provocation.[86]

### Differential diagnosis [edit]

Before a diagnosis of allergic disease can be confirmed, other possible causes of the presenting symptoms should be considered.[87] Vasomotor rhinitis, for example, is one of many maladies that shares symptoms with allergic rhinitis, underscoring the need for professional differential diagnosis.[88] Once a diagnosis of asthma, rhinitis, anaphylaxis, or other allergic disease has been made, there are several methods for discovering the causative agent of that allergy.

## Prevention [edit]

The consumption of various foods during pregnancy has been linked to eczema; these include celery, citrus fruit, raw pepper, margarine, and vegetable oil.[89] A high intake of antioxidants, zinc, and selenium during pregnancy may help prevent allergies. This is linked to a reduced risk for childhood-onset asthma, wheezing, and eczema.[90] Further research needs to be conducted. Probiotic supplements taken during pregnancy or infancy may help to prevent atopic dermatitis.[91] After birth, an early introduction of solid food and high diversity before week 17 could increase a child's risk for allergies. Studies suggest that introduction of solid food and avoidance of highly allergenic food such as peanuts during the first year does not help in allergy prevention.[89]

## Management [edit]

Management of allergies typically involves avoiding what triggers the allergy and medications to improve the symptoms.[10] Allergen immunotherapy may be useful for some types of allergies.[10]

### Medication [edit]

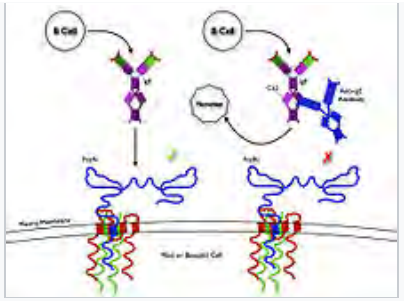
Several medications may be used to block the action of allergic mediators, or to prevent activation of cells and degranulation processes. These include antihistamines, glucocorticoids, epinephrine (adrenaline), mast cell stabilizers, and antileukotriene agents are common treatments of allergic diseases.[92] Anti-cholinergics, decongestants, and other compounds thought to impair eosinophil chemotaxis, are also commonly used. Though rare, the severity of anaphylaxis often requires epinephrine injection, and where medical care is unavailable, a device known as an epinephrine autoinjector may be used.[24]

### Immunotherapy [edit]

*Main article: Allergen immunotherapy*

Allergen immunotherapy is useful for environmental allergies, allergies to insect bites, and asthma.[10][93] Its benefit for food allergies is unclear and thus not recommended.[10] Immunotherapy involves exposing people to larger and larger amounts of allergen in an affect to change the immune system's response.[10]

Meta-analyses have found that injections of allergens under the skin is effective in the treatment in allergic rhinitis in children[94][95] and in asthma.[93] The benefits may last for years after treatment is stopped.[96] It is generally safe



Anti-allergy immunotherapy

and effective for allergic rhinitis and conjunctivitis, allergic forms of asthma, and stinging insects.[97]

The evidence also supports the use of sublingual immunotherapy for rhinitis and asthma but it is less strong.[96] For seasonal allergies the benefit is small.[98] In this form the allergen is given under the tongue and people often prefer it to injections.[96] Immunotherapy is not recommended as a stand-alone treatment for asthma.[96]

### Alternative medicine [edit]

An experimental treatment, enzyme potentiated desensitization (EPD), has been tried for decades but is not generally accepted as effective.[99] EPD uses dilutions of allergen and an enzyme, beta-glucuronidase, to which T-regulatory lymphocytes are supposed to respond by favoring desensitization, or down-regulation, rather than sensitization. EPD has also been tried for the treatment of autoimmune diseases but evidence does not show effectiveness.[99]

A review found no effectiveness of homeopathic treatments and no difference compared with placebo. The authors concluded that, based on rigorous clinical trials of all types of homeopathy for childhood and adolescence ailments, there is no convincing evidence that supports the use of homeopathic treatments.[100]

According to the NCCIH, the evidence is relatively strong that saline nasal irrigation and butterbur are effective, when compared to other alternative medicine treatments, for which the scientific evidence is weak, negative, or nonexistent, such as honey, acupuncture, omega 3's, probiotics, astragalus, capsaicin, grape seed extract, Pycnogenol, quercetin, spirulina, stinging nettle, tinospora or guduchi. [101][102]

## Epidemiology [edit]

The allergic diseases—hay fever and asthma—have increased in the Western world over the past 2–3 decades.[103] Increases in allergic asthma and other atopic disorders in industrialized nations, it is estimated, began in the 1960s and 1970s, with further increases occurring during the 1980s and 1990s,[104] although some suggest that a steady rise in sensitization has been occurring since the 1920s.[105] The number of new cases per year of atopy in developing countries has, in general, remained much lower.[104]

**Allergic conditions: Statistics and epidemiology**

| Allergy type | United States | United Kingdom[106] |
|---|---|---|
| Allergic rhinitis | 35.9 million[107] (about 11% of the population[108]) | 3.3 million (about 5.5% of the population[109]) |
| Asthma | 10 million have allergic asthma (about 3% of the population). The prevalence of asthma increased 75% from 1980 to 1994. Asthma prevalence is 39% higher in African Americans than in Europeans.[110] | 5.7 million (about 9.4%). In six- and seven-year-olds asthma increased from 18.4% to 20.9% over five years, during the same time the rate decreased from 31% to 24.7% in 13- to 14-year-olds. |
| Atopic eczema | About 9% of the population. Between 1960 and 1990 prevalence has increased from 3% to 10% in children.[111] | 5.8 million (about 1% severe). |
| Anaphylaxis | At least 40 deaths per year due to insect venom. About 400 deaths due to penicillin anaphylaxis. About 220 cases of anaphylaxis and 3 deaths per year | Between 1999 and 2006, 48 deaths occurred in people ranging from five months to |

| | | |
|---|---|---|
| | are due to latex allergy.[112] An estimated 150 people die annually from anaphylaxis due to food allergy.[113] | 85 years old. |
| Insect venom | Around 15% of adults have mild, localized allergic reactions. Systemic reactions occur in 3% of adults and less than 1% of children.[114] | Unknown |
| Drug allergies | Anaphylactic reactions to penicillin cause 400 deaths per year. | Unknown |
| Food allergies | About 6% of US children under age 3 and 3.5–4% of the overall US population.[*citation needed*] Peanut and/or tree nut (e.g. walnut) allergy affects about three million Americans, or 1.1% of the population.[113] | 5–7% of infants and 1–2% of adults. A 117.3% increase in peanut allergies was observed from 2001 to 2005, an estimated 25,700 people in England are affected. |
| Multiple allergies (Asthma, eczema and allergic rhinitis together) | Unknown | 2.3 million (about 3.7%), prevalence has increased by 48.9% between 2001 and 2005.[115] |

## Changing frequency [edit]

Although genetic factors govern susceptibility to atopic disease, increases in atopy have occurred within too short a time frame to be explained by a genetic change in the population, thus pointing to environmental or lifestyle changes.[104] Several hypotheses have been identified to explain this increased rate; increased exposure to perennial allergens due to housing changes and increasing time spent indoors, and changes in cleanliness or hygiene that have resulted in the decreased activation of a common immune control mechanism, coupled with dietary changes, obesity and decline in physical exercise.[103] The hygiene hypothesis maintains[116] that high living standards and hygienic conditions exposes children to fewer infections. It is thought that reduced bacterial and viral infections early in life direct the maturing immune system away from $T_H1$ type responses, leading to unrestrained $T_H2$ responses that allow for an increase in allergy.[67][117]

Changes in rates and types of infection alone however, have been unable to explain the observed increase in allergic disease, and recent evidence has focused attention on the importance of the gastrointestinal microbial environment. Evidence has shown that exposure to food and fecal-oral pathogens, such as hepatitis A, *Toxoplasma gondii*, and *Helicobacter pylori* (which also tend to be more prevalent in developing countries), can reduce the overall risk of atopy by more than 60%,[118] and an increased rate of parasitic infections has been associated with a decreased prevalence of asthma.[119] It is speculated that these infections exert their effect by critically altering $T_H1/T_H2$ regulation.[120] Important elements of newer hygiene hypotheses also include exposure to endotoxins, exposure to pets and growing up on a farm.[120]

# History [edit]

The concept of "allergy" was originally introduced in 1906 by the Viennese pediatrician Clemens von Pirquet, after he noted that some of his patients were hypersensitive to normally innocuous entities such as dust, pollen, or certain foods.[121] Pirquet called this phenomenon "allergy" from the Ancient Greek words ἄλλος *allos* meaning "other" and ἔργον *ergon* meaning "work".[122]

All forms of hypersensitivity used to be classified as allergies, and all were thought to be caused by an improper activation of the immune system. Later, it became clear that several different disease mechanisms were implicated, with the common link to a disordered activation of the immune system. In 1963, a new classification scheme was designed by Philip Gell and Robin Coombs that described four types of hypersensitivity reactions, known as Type I to Type IV hypersensitivity.[123] With this new classification, the word "allergy" was restricted to type I hypersensitivities (also called immediate hypersensitivity), which are characterized as rapidly developing reactions.

A major breakthrough in understanding the mechanisms of allergy was the discovery of the antibody class labeled immunoglobulin E (IgE). IgE was simultaneously discovered in 1966–67 by two independent groups:[124] Ishizaka's team at the Children's Asthma Research Institute and Hospital in Denver, Colorado,[125] and by Gunnar Johansson and Hans Bennich in Uppsala, Sweden.[126] Their joint paper was published in April 1969.[127]

### Diagnosis [edit]

Radiometric assays include the radioallergosorbent test (RAST test) method, which uses IgE-binding (anti-IgE) antibodies labeled with radioactive isotopes for quantifying the levels of IgE antibody in the blood.[128] Other newer methods use colorimetric or fluorescence-labeled technology in the place of radioactive isotopes.[*citation needed*]

The RAST methodology was invented and marketed in 1974 by Pharmacia Diagnostics AB, Uppsala, Sweden, and the acronym RAST is actually a brand name. In 1989, Pharmacia Diagnostics AB replaced it with a superior test named the ImmunoCAP Specific IgE blood test, which uses the newer fluorescence-labeled technology.[*citation needed*]

American College of Allergy Asthma and Immunology (ACAAI) and the American Academy of Allergy Asthma and Immunology (AAAAI) issued the Joint Task Force Report "Pearls and pitfalls of allergy diagnostic testing" in 2008, and is firm in its statement that the term RAST is now obsolete:

> The term RAST became a colloquialism for all varieties of (in vitro allergy) tests. This is unfortunate because it is well recognized that there are well-performing tests and some that do not perform so well, yet they are all called RASTs, making it difficult to distinguish which is which. For these reasons, it is now recommended that use of RAST as a generic descriptor of these tests be abandoned.[129]

The new version, the ImmunoCAP Specific IgE blood test, is the only specific IgE assay to receive FDA approval to quantitatively report to its detection limit of 0.1kU/l.[*citation needed*]

## Medical specialty [edit]

An allergist is a physician specially trained to manage and treat allergies, asthma and the other allergic diseases. In the United States physicians holding certification by the American Board of Allergy and Immunology (ABAI) have successfully completed an accredited educational program and evaluation process, including a proctored examination to demonstrate knowledge, skills, and experience in patient care in allergy and immunology.[130] Becoming an allergist/immunologist requires completion of at least nine years of training. After completing medical school and graduating with a medical degree, a physician will undergo three years of training in internal medicine (to become an internist) or pediatrics (to become a pediatrician). Once physicians have finished training in one of these specialties, they must pass the exam of either the American Board of Pediatrics (ABP), the American Osteopathic Board of Pediatrics (AOBP), the American Board of Internal Medicine (ABIM), or the American Osteopathic Board of Internal Medicine (AOBIM). Internists or pediatricians wishing to focus on the sub-specialty of allergy-immunology then complete at least an additional two years of study, called a fellowship, in an allergy/immunology training program. Allergist/immunologists listed as ABAI-certified have successfully passed the certifying examination of the ABAI following their fellowship.[131]

In the United Kingdom, allergy is a subspecialty of general medicine or pediatrics. After obtaining postgraduate exams (MRCP or MRCPCH), a doctor works for several years as a specialist registrar before qualifying for the General Medical Council specialist register. Allergy services may also be delivered by immunologists. A 2003 Royal College of Physicians report presented a case for improvement of what were felt to be inadequate allergy services in the UK.[132] In 2006, the House of Lords convened a subcommittee. It concluded likewise in 2007 that allergy services were insufficient to deal with what the Lords referred to as an "allergy epidemic" and its social cost; it made several recommendations.[133]

## Research [edit]

Low-allergen foods are being developed, as are improvements in skin prick test predictions; evaluation of the atopy patch test; in wasp sting outcomes predictions and a rapidly disintegrating epinephrine tablet, and anti-IL-5 for eosinophilic diseases.[134]

Aerobiology is the study of biological particles passively dispersed through the air. One aim is the prevention of allergies due to pollen.[135][136]

# Angular cheilitis

From Wikipedia, the free encyclopedia

**Angular cheilitis** (**AC**), is inflammation of one or both corners of the mouth.[2][4] Often the corners are red with skin breakdown and crusting. It can also be itchy or painful. The condition can last for days to years.[2] Angular cheilitis is a type of cheilitis (inflammation of the lips).[5]

Angular cheilitis can be caused by infection, irritation, or allergies. Infections include by the fungi such as *Candida albicans* and bacteria such as *Staph. aureus*. Irritants include poorly fitting dentures, licking the lips or drooling, mouth breathing resulting in a dry mouth, sun exposure, overclosure of the mouth, smoking, and minor trauma. Allergies may include to substances like toothpaste, makeup, and food. Often a number of factors are involved.[2] Other factors may include poor nutrition or poor immune function.[2][4] Diagnosis may be helped by testing for infections and patch testing for allergies.[2]

Treatment for angular cheilitis is typically based on the underlying causes along with the use of a barrier cream. Frequently an antifungal and antibacterial cream is also tried. Angular cheilitis is a fairly common problem,[2] with estimates that it affects 0.7% of the population.[6] It occurs most often in the 30s to 60s, although is also relatively common in children.[2] In the developing world, iron and vitamin deficiencies are a common cause.[4]

## Signs and symptoms [edit]

Angular cheilitis is a fairly non specific term which describes the presence of an inflammatory lesion in a particular anatomic site (i.e. the corner of the mouth). As there are different possible causes and contributing factors from one person to the next, the appearance of the lesion is somewhat variable. The lesions are more commonly symmetrically present on both sides of the mouth,[3] but sometimes only one side may be affected. In some cases, the lesion may be confined to the mucosa of the lips, and in other cases the lesion may extend past the vermilion border (the edge where the lining on the lips becomes the skin on the face) onto the facial skin. Initially, the corners of the mouth develop a gray-white thickening and adjacent erythema (redness).[2] Later, the usual appearance is a roughly triangular area of erythema, edema (swelling) and breakdown of skin at either corner of the mouth.[2][3] The mucosa of the lip may become fissured (cracked), crusted, ulcerated or atrophied.[2][3] There is not usually any bleeding.[7] Where the skin is involved, there may be radiating rhagades (linear fissures) from the corner of the mouth. Infrequently, the dermatitis (which may resemble eczema) can extend from the corner of the mouth to the skin of the cheek or chin.[3] If *Staphylococcus aureus* is involved, the lesion may show golden yellow crusts.[8] In chronic angular cheilitis, there may be suppuration (pus formation), exfoliation (scaling) and formation of granulation tissue.[2][3]

Angular cheilitis – a fissure running in the corner of the mouth with reddened, irritated facial skin adjacent.

A fairly mild case of angular cheilitis extending onto the facial skin in a young person (affected area is within the black oval).

Sometimes contributing factors can be readily seen, such as loss of lower face height from poorly made or worn dentures, which results in mandibular overclosure ("collapse of jaws").[9] If there is a nutritional deficiency underlying the condition, various other signs and symptoms such as glossitis (swollen tongue) may be present. In people with angular cheilitis who wear dentures, often there may be erythematous mucosa underneath the denture (normally the upper denture), an appearance consistent with denture-related stomatitis.[3] Typically the lesions give symptoms of soreness, pain, pruritus (itching) or burning or a raw feeling.[2][9]

## Causes [edit]

Angular cheilitis is thought to be multifactorial disorder of infectious origin,[10] with many local and systemic predisposing factors.[11] The sores in angular cheilitis are often infected with fungi (yeasts), bacteria, or a combination thereof;[8] this may represent a secondary, opportunistic infection by these pathogens. Some studies have linked the initial onset of angular cheilitis with nutritional deficiencies, especially of the B(B2-riboflavin) vitamins and iron (which causes iron deficiency anemia),[12] which in turn may be evidence of malnutrition or malabsorption. Angular cheilitis can be a manifestation of contact dermatitis,[13] which is considered in two groups; irritational and allergic.

### Infection [edit]

The involved organisms are:

- Candida species alone (usually *Candida albicans*), which accounts for about 20% of cases,[14]
- Bacterial species, either:

- *Staphylococcus aureus* alone, which accounts for about 20% of cases,[14]
- β-hemolytic streptococci alone. These types of bacteria have been detected in between 8–15% of cases of angular cheilitis,[2] but less commonly are they present in isolation,[10]

- Or a combination of the above organisms, (a polymicrobial infection)[8] with about 60% of cases involving both *C. albicans* and *S. aureus*.[14][15]

Candida can be detected in 93% of angular cheilitis lesions.[2] This organism is found in the mouths of about 40% of healthy individuals, and it is considered by some to be normal commensal component of the oral microbiota.[2] However, Candida shows dimorphism, namely a yeast form which is thought to be relatively harmless and a pathogenic hyphal form which is associated with invasion of host tissues. Potassium hydroxide preparation is recommended by some to help distinguish between the harmless and the pathogenic forms, and thereby highlight which cases of angular cheilitis are truly caused by Candida.[2] The mouth may act as a reservoir of Candida that reinfects the sores at the corners of the mouth and prevents the sores from healing.

A lesion caused by recurrence of a latent herpes simplex infection can occur in the corner of the mouth. Really this is herpes labialis (a cold sore), and is sometimes termed "angular herpes simplex".[2] A cold sore at the corner of the mouth behaves similarly to elsewhere on the lips, and follows a pattern of vesicle (blister) formation followed by rupture leaving a crusted sore which resolves in about 7–10 days, and recurs in the same spot periodically, especially during periods of stress. Rather than utilizing antifungal creams, angular herpes simplex is treated in the same way as a cold sore, with topical antiviral drugs such as aciclovir.

## Irritation contact dermatitis [edit]

*Main article: Irritant contact dermatitis*

22% of cases of angular cheilitis are due to irritants.[2] Saliva contains digestive enzymes, which may have a degree of digestive action on tissues if they are left in contact.[2] The corner of the mouth is normally exposed to saliva more than any other part of the lips. Reduced lower facial height (vertical dimension or facial support) is usually caused by edentulism (tooth loss), or wearing worn down, old dentures or ones which are not designed optimally. This results in overclosure of the mandible (collapse of the jaws),[9] which extenuates the angular skin folds at the corners of the mouth,[14] in effect creating an intertriginous skin crease. The tendency of saliva to pool in these areas is increased, constantly wetting the area,[10] which may cause tissue maceration and favors the development of a yeast infection.[14] As such, angular cheilitis is more commonly seen in edentulous people (people without any teeth).[9] It is by contrast uncommon in persons who retain their natural teeth.[16] Angular cheilitis is also commonly seen in denture wearers.[13] Angular cheilitis is present in about 30% of people with denture-related stomatitis.[10] It is thought that reduced vertical dimension of the lower face may be a contributing factor in up to 11% of elderly persons with angular cheilitis and in up to 18% of denture wearers who have angular cheilitis.[2] Reduced vertical dimension can also be caused by tooth migration, wearing orthodontic appliances, and elastic tissue damage caused by ultraviolet light exposure and smoking.[2]

A famous sketch by Leonardo da Vinci in preparation to depict the face of Judas Iscariot in The Last supper. The subject shows overclosure of the jaws and loss of facial support around the mouth.

Habits or conditions that keep the corners of the mouth moist might include chronic lip licking, thumb sucking (or sucking on other objects such as pens, pipes, lollipops), dental cleaning (e.g. flossing), chewing gum, hypersalivation, drooling and mouth breathing.[2][3][14] Some consider habitual lip licking or picking to be a form of nervous tic, and

Pronounced skin folds extending from the corner of the mouth.

do not consider this to be true angular cheilitis,[3] instead calling it *perlèche* (derived from the French word *pourlècher* meaning "to lick one's lips"),[2] or "factitious cheilitis" is applied to this habit.[2] The term "cheilocandidiasis" describes exfoliative (flaking) lesions of the lips and the skin around the lips, and is caused by a superficial candidal infection due to chronic lip licking.[14] Less severe cases occur during cold, dry weather, and is a form of chapped lips. Individuals may lick their lips in an attempt to provide a temporary moment of relief, only serving to worsen the condition.[17]

The sunscreen in some types of lip balm degrades over time into an irritant. Using expired lipbalm can initiate mild angular cheilitis, and when the person applies more lipbalm to alleviate the cracking, it only aggravates it. Because of the delayed onset of contact dermatitis and the recovery period lasting days to weeks, people typically do not make the connection between the causative agent and the symptoms.[*medical citation needed*]

## Nutritional deficiencies [edit]

Several different nutritional deficiency states of vitamins or minerals have been linked to AC.[4] It is thought that in about 25% of people with AC, iron deficiency or deficiency of B vitamins are involved.[4] Nutritional deficiencies may be a more common cause of AC in third world countries.[4] Chronic iron deficiency may also cause koilonychia (spoon shaped deformity of the fingernails) and glossitis (inflammation of the tongue). It is not completely understood how iron deficiency causes AC, but it is known that it causes a degree of immunocompromise (decreased efficiency of the immune system) which may in turn allow an opportunistic infection of candida.[4] Vitamin B2 deficiency (ariboflavinosis) may also cause AC, and other conditions such as redness of mucous membranes, magenta colored glossitis (pink inflammation of the tongue).[4] Vitamin B5 deficiency may also cause AC, along with glossitis, and skin changes similar to seborrhoeic dermatitis around the eyes, nose and mouth.[4] Vitamin B12 deficiency is sometimes responsible for AC, and commonly occurs together with folate deficiency (a lack of folic acid), which also causes glossitis and megaloblastic anemia.[4] Vitamin B3 deficiency (pellagra) is another possible cause, and in which other association conditions such as dermatitis, diarrhea, dementia and glossitis can occur.[4] Biotin (vitamin B7) deficiency has also been reported to cause AC, along with alopecia (hair loss) and dry eyes.[4] Zinc deficiency is known to cause AC.[18] Other symptoms may include diarrhea, alopecia and dermatitis.[4] Acrodermatitis enteropathica is an autosomal recessive genetic disorder causing impaired absorption of zinc, and is associated with AC.[4]

In general, these nutritional disorders may be caused by malnutrition, such as may occur in alcoholism or in strict vegan diets, or by malabsorption secondary to gastrointestinal disorders (e.g. Celiac disease or chronic pancreatitis) or gastrointestinal surgeries (e.g. pernicious anemia caused by ileal resection in Crohn's disease).[4]

## Systemic disorders [edit]

Some systemic disorders are involved in angular cheilitis by virtue of their association with malabsorption and the creation of nutritional deficiencies described above. Such examples include people with anorexia nervosa.[4] Other disorders may cause lip enlargement (e.g. orofacial granulomatosis),[4] which alters the local anatomy and extenuates the skin folds at the corners of the mouth. More still may be involved because they affect the immune system, allowing normally harmless organisms like Candida to become pathogenic and cause an infection. Xerostomia (dry mouth) is thought to account for about 5% of cases of [4]

AC. Xerostomia itself has many possible causes, but commonly the cause may be side effects of medications, or conditions such as Sjögren's syndrome. Conversely, conditions which cause drooling or sialorrhoea (excessive salivation) can cause angular cheilitis by creating a constant wet environment in the corners of the mouth. About 25% of people with Down syndrome appear to have AC.[4] This is due to relative macroglossia, an apparently large tongue in a small mouth, which may constantly stick out of the mouth causing maceration of the corners of the mouth with saliva. Inflammatory bowel diseases (such as Crohn's disease or ulcerative colitis) can be associated with angular cheilitis.[3] In Crohn's, it is likely the result of malabsorption and immunosuppressive therapy which gives rise to the sores at the corner of the mouth.[9] Glucagonomas are rare pancreatic endocrine tumors which secrete glucagon, and cause a syndrome of dermatitis, glucose intolerance, weight loss and anemia. AC is a common feature of glucagonoma syndrome.[19] Infrequently, angular cheilitis may be one of the manifestations of chronic mucocutaneous candidiasis,[14] and sometimes cases of oropharyngeal or esophageal candidiasis may accompany angular cheilitis.[2] Angular cheilitis may be present in human immunodeficiency virus infection,[11] neutropenia,[16] or diabetes.[3] Angular cheilitis is more common in people with eczema because their skin is more sensitive to irritants.[2] Other conditions possibly associated include plasma cell gingivitis,[7] Melkersson-Rosenthal syndrome,[4] or sideropenic dysphagia (also called Plummer-Vinson syndrome or Paterson-Brown-Kelly syndrome).[4]

### Drugs [edit]

Several drugs may cause AC as a side effect, by various mechanisms, such as creating drug-induced xerostomia. Various examples include isotretinoin, indinavir, and sorafenib.[4] Isotretinoin (Accutane), an analog of vitamin A, is a medication which dries the skin. Less commonly, angular cheilitis is associated with primary hypervitaminosis A,[20] which can occur when large amounts of liver (including cod liver oil and other fish oils) are regularly consumed or as a result from an excess intake of vitamin A in the form of vitamin supplements. Recreational drug users may develop AC. Examples include cocaine, methamphetamines, heroin, and hallucinogens.[4]

### Allergic contact dermatitis [edit]

*See also: Allergic contact cheilitis, Allergic contact dermatitis, and Allergic contact stomatitis*

Allergic reactions may account for about 25–34% of cases of generalized cheilitis (i.e., inflammation not confined to the angles of the mouth). It is unknown how frequently allergic reactions are responsible for cases of angular cheilitis, but any substance capable of causing generalized allergic cheilitis may present involving the corners of the mouth alone.

Patch test

Examples of potential allergens include substances that may be present in some types of lipstick, toothpaste, acne products, cosmetics, chewing gum, mouthwash, foods, dental appliances, and materials from dentures or mercury containing amalgam fillings.[2] It is usually impossible to tell the difference between irritant contact dermatitis and allergic contact dermatitis without a patch test.

## Diagnosis [edit]

Angular chielitis is normally a diagnosis made clinically. If the sore is unilateral, rather than bilateral, this suggests a local factor (*e.g.*, trauma) or a split syphilitic papule.[3][21] Angular cheilitis caused by mandibular overclosure, drooling, and other irritants is usually bilateral.[2]

The lesions are normally swabbed to detect if Candida or pathogenic bacterial species may be present. Persons with angular cheilitis who

wear dentures often also will have their denture swabbed in addition. A complete blood count (full blood count) may be indicated, including assessment of the levels of iron, ferritin, vitamin B12 (and possibly other B vitamins), and folate.[3]

Photographic Comparison of: 1) a Canker Sore - inside the mouth, 2) Herpes, 3) Angular Cheilitis and 4) Chapped Lips.

## Classification [edit]

Angular cheilitis could be considered to be a type of cheilitis or stomatitis. Where Candida species are involved, angular cheilitis is classed as a type of oral candidiasis, specifically a primary (group I) Candida-associated lesion.[11] This form angular cheilitis which is caused by Candida is sometimes termed "Candida-associated angular cheilitis",[11] or less commonly, "monilial perlèche".[2] Angular cheilitis can also be classified as acute (sudden, short-lived appearance of the condition) or chronic (lasts a long time or keeps returning), or refractory (the condition persists despite attempts to treat it).[2]

# Management [edit]

Angular cheilitis being treated with crystal violet tincture

There are 4 aspects to the treatment of angular cheilitis.[22] Firstly, potential reservoirs of infection inside the mouth are identified and treated.[22] Oral candidiasis, especially denture-related stomatitis is often found to be present where there is angular cheilitis, and if it is not treated, the sores at the corners of the mouth may often recur.[8][13] This involves having dentures properly fitted and disinfected. Commercial preparations are marketed for this purpose, although dentures may be left in dilute (1:10 concentration) household bleach overnight, but only if they are entirely plastic and do not contain any metal parts, and with rinsing under clean water before use.[9] Improved denture hygiene is often required thereafter, including not wearing the denture during sleep and cleaning it daily.[3] For more information, see Denture-related stomatitis.

Secondly, there may be a need to increase the vertical dimension of the lower face to prevent overclosure of the mouth and formation of deep skin folds.[22] This may require the construction of a new denture with an adjusted bite.[3] Rarely, in cases resistant to normal treatments, surgical procedures such as collagen injections (or other facial fillers such as autologous fat or crosslinked hyaluronic acid) are used in an attempt to restore the normal facial contour.[2][3] Other measures which seek to reverse the local factors that may be contributing to the condition include improving oral hygiene, stopping smoking or other tobacco habits and use of a barrier cream (e.g. zinc oxide paste) at night.[2]

Thirdly, treatment of the infection and inflammation of the lesions themselves is addressed. This is usually with topical antifungal medication,[8] such as clotrimazole,[14] amphotericin B,[22] ketoconazole,[16] or nystatin cream.[9] Some antifungal creams are combined with corticosteroids such as hydrocortisone[8] or triamcinolone[9] to reduce inflammation, and certain antifungals such as miconazole also have some antibacterial action.[8] Diiodohydroxyquinoline is another topical therapy for angular cheilitis.[14] If *Staphylococcus aureus* infection is demonstrated by microbiological culture to be responsible (or suspected), the treatment may be changed to fusidic acid cream,[8] an antibiotic which is effective against this type of bacteria. Aside from fusidic acid, neomycin,[22] mupirocin,[2] metronidazole,[7] and chlorhexidine[22] are alternative options in this scenario.

Finally, if the condition appears resistant to treatment, investigations for underlying causes such as anemia or nutrient deficiencies or HIV infection.[22] Identification of the underlying cause is essential for treating chronic cases. The lesions may resolve when the underlying disease is treated, e.g. with a course of oral iron or B vitamin supplements.[3] Patch testing is recommended by some in cases which are resistant to treatment and where allergic contact dermatitis is suspected.[2]

## Prognosis [edit]

Most cases of angular cheilitis respond quickly when antifungal treatment is used.[16] In more long standing cases, the severity of the condition often follows a relapsing and remitting course over time.[14] The condition can be difficult to treat and can be prolonged.[3]

## Epidemiology [edit]

AC is a relatively common condition,[11] accounting for between 0.7 – 3.8% of oral mucosal lesions in adults and between 0.2 – 15.1% in children, though overall it occurs most commonly in adults in the third to sixth decades of life.[2][3] It occurs worldwide, and both males and females are affected.[3] Angular cheilitis is the most common presentation of fungal and bacterial infections of the lips.[14]

# Atopic dermatitis

From Wikipedia, the free encyclopedia

**Atopic dermatitis** (**AD**), also known as **atopic eczema**, is a type of inflammation of the skin (dermatitis). It results in itchy, red, swollen, and cracked skin. Clear fluid may come from the affected areas, which often thicken over time.[1] The condition typically starts in childhood with changing severity over the years.[1][2] In children under one year of age much of the body may be affected. As people get older, the back of the knees and front of the elbows are the most common areas affected. In adults the hands and feet are the most commonly affected areas.[2] Scratching worsens symptoms and affected people have an increased risk of skin infections. Many people with atopic dermatitis develop hay fever or asthma.[1]

The cause is unknown but believed to involve genetics, immune system dysfunction, environmental exposures, and difficulties with the permeability of the skin.[1][2] If one identical twin is affected, there is an 85% chance the other also has the condition.[3] Those who live in cities and dry climates are more commonly affected. Exposure to certain chemicals or frequent hand washing makes symptoms worse. While emotional stress may make the symptoms worse it is not a cause. The disorder is not contagious.[1] The diagnosis is typically based on the signs and symptoms. Other diseases that must be excluded before making a diagnosis include contact dermatitis, psoriasis, and seborrheic dermatitis.[2]

Treatment involves avoiding things that make the condition worse, daily bathing with application of a moisturising cream afterwards, applying steroid creams when flares occur, and medications to help with itchiness.[2] Things that commonly make it worse include wool clothing, soaps, perfumes, chlorine, dust, and cigarette smoke. Phototherapy may be useful in some people. Steroid pills or creams based on calcineurin inhibitors may occasionally be used if other measures are not effective.[1][4] Antibiotics (either by mouth or topically) may be needed if a bacterial infection develops.[2] Dietary changes are only needed if food allergies are suspected.[1]

Atopic dermatitis affects about 20% of people at some point in their lives.[1][5] It is more common in younger children.[2] Males and females are equally affected.[1] Many people outgrow the condition.[2] Atopic dermatitis is sometimes called eczema, a term that also refers to a larger group of skin conditions.[1] Other names include "infantile eczema", "flexural eczema", "prurigo Besnier", "allergic eczema", and "neurodermatitis".[6]

## Variants

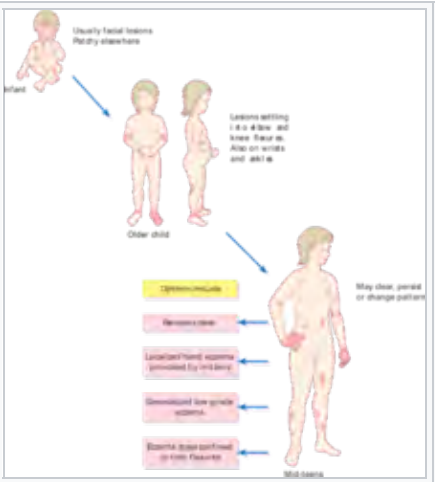
## Signs and symptoms [edit]

People with AD often have dry and scaly skin that spans the entire body, except perhaps the diaper area, and intensely itchy red, splotchy, raised lesions to form in the bends of the arms or legs, face, and neck.[7][8][9][10][11]

AD commonly occurs on the eyelids where signs such as Dennie-Morgan infraorbital fold, infra-auricular fissure, periorbital pigmentation can be seen.[12] Post-inflammatory hyperpigmentation on the neck gives the classic 'dirty neck' appearance. Lichenification, excoriation and erosion or crusting on the trunk may indicate secondary infection. Flexural distribution with ill-defined edges with or without hyperlinearily on the wrist, finger knuckles, ankle, feet and hand are also commonly seen.[13]



Pattern of atopic eczema varies with age

## Cause [edit]

The cause of AD is not known, although there is some evidence of genetic factors, and some evidence that growing up in a *sanitary* environment encourages AD.[8]

It seems to have a genetic component. Many people with AD have a family history of atopy. Atopy is an immediate-onset allergic reaction (type 1 hypersensitivity reaction) as asthma, food allergies, AD or hay fever.[7][8] In 2006 it was discovered that mutations in the gene for the production of filaggrin strongly increased the risk for developing atopic dermatitis. Most importantly two mutations were found that affect approximately 5% of people in Western Europe that may disrupt the production of filaggrin. Filaggrin is a protein that plays an important role in the retention of water in the stratum corneum. People who have these mutations often have dry skin.[14] Filaggrin also plays an important role in keeping the skin surface slightly acidic, hence giving it anti-microbial effects. It breaks down into trans-urocanic acid, which keeps the pH low.[15]

According to the hygiene hypothesis, when children are brought up exposed to allergens in the environment at a young age, their immune system is more likely to tolerate them, while children brought up in a modern "sanitary" environment are less likely to be exposed to those allergens at a young age, and, when they are finally exposed, develop allergies. There is some support for this hypothesis with respect to AD.

Those exposed to dogs while growing up have a lower risk of atopic dermatitis.[16] There is also support from epidemiological studies for a protective role for helminths against AD.[17] Likewise children with poor hygiene are at a lower risk for developing AD, as are children who drink unpasteurised milk.[17] Exposure to dust mites is believed to contribute to one's risk of developing AD.[18]

A diet high in fruits seems to have a protective effect against AD, whereas the opposite seems true for fast foods.[17]

Atopic dermatitis sometimes appears associated with celiac disease and non-celiac gluten sensitivity.[19][20]

## Diagnosis [edit]

*See also: SCORAD*

An atopy patch test can be used to determine whether or not a specific allergen is the cause of the rash. The test involves applying a series of allergens to the skin surface and evaluating the results in one to three days.[21][22]

People with atopic dermatitis are more likely to have Staphylococcus aureus living on them.[23]

Patch test

## Treatments [edit]

There is no known cure for AD, although treatments may reduce the severity and frequency of flares.[7]

### Lifestyle [edit]

Applying moisturisers may prevent the skin from drying out and decrease the need for other medications.[24] Affected persons often report that improvement of skin hydration parallels with improvement in AD symptoms.[7]

Health professionals often recommend that persons with AD bathe regularly in lukewarm baths, especially in salt water, to moisten their skin.[8][25] Avoiding woollen clothing is usually good for those with AD. Likewise silk, silver-coated clothing may help.[25] Dilute bleach baths have also been reported effective at managing AD.[25]

### Diet [edit]

Vitamin D is an effective treatment for AD.[26]

Studies have investigated the role of long chain polyunsaturated fatty acids (LCPUFA) supplementation and LCPUFA status in the prevention and treatment of atopic diseases, but the results are controversial. It remains unclear if the nutritional intake of n-3 fatty acids has a clear preventive or therapeutic role, or if n-6 fatty acids consumption promotes atopic diseases.[27]

Several probiotics seem to have a positive effect with a roughly 20% reduction in the rate of atopic dermatitis.[28] The best evidence is for multiple strains of bacteria.[29]

In people with celiac disease or non-celiac gluten sensitivity, a gluten free diet improves their symptoms and prevents the occurrence of new outbreaks.[19][20]

### Medication [edit]

Topical corticosteroids, such as hydrocortisone have proven themselves effective in managing AD.[7][8] If topical corticosteroids and moisturisers fail, short-term treatment with topical calcineurin inhibitors like tacrolimus or pimecrolimus may be tried, although they are usually avoided as they can cause skin cancer or lymphoma.[7][30] Alternatively systemic immunosuppressants may be tried such as ciclosporin, methotrexate, interferon gamma-1b, mycophenolate mofetil and azathioprine.[7][31] Antidepressants and naltrexone may be used to control pruritus (itchiness).[32]

### Light [edit]

A more novel form of treatment involves exposure to broad or narrow-band ultraviolet (UV) light. UV radiation exposure has been found to have a localized immunomodulatory effect on affected tissues and may be used to decrease the severity and frequency of flares.[33][34] In particular, the usage of UVA1 is more effective in treating acute flares, whereas narrow-band UVB is more effective in long-term management scenarios.[35] However, UV radiation has also been implicated in various types of skin cancer, and thus UV treatment is not without risk.[36]

## Epidemiology [edit]

Since the beginning of the twentieth century, many mucosal inflammatory disorders have become more common; atopic eczema (AE) is a classic example of such a disease. It now affects 15–30% of children and 2–10% of adults in developed countries and in the United States has nearly tripled in the past thirty to forty years.[8][37] Over 15 million American adults and children have atopic dermatitis.[38]

## Research [edit]

Evidence suggests that IL-4 is central in the pathogenesis of AD.[39] Therefore, there is a rationale for targeting IL-4 with anti-IL-4 inhibitors.[40]

# Candidiasis

From Wikipedia, the free encyclopedia

*Thrush (infection) redirects here. For other uses see thrush (disambiguation).*

**Candidiasis** is a fungal infection due to any type of *Candida* (a type of yeast).[2] When it affects the mouth, it is commonly called **thrush**.[2] Signs and symptoms include white patches on the tongue or other areas of the mouth and throat.[3] Other symptoms may include soreness and problems swallowing.[3] When it affects the vagina, it is commonly called a **yeast infection**.[2] Signs and symptoms include genital itching, burning, and sometimes a white "cottage cheese-like" discharge from the vagina.[4] Less commonly the penis may be affected, resulting in itchiness.[3] Very rarely, the infection may become invasive spreading throughout the body, resulting in fevers along with other symptoms depending on the parts of the body affected.[5]

More than 20 types of *Candida* can cause infection with *Candida albicans* being the most common.[2] Infections of the mouth are most common among children less than one month old, the elderly, and those with weak immune systems. Conditions that result in a weak immune system include HIV/AIDS, the medications used after organ transplantation, diabetes, and the use of corticosteroids. Other risks include dentures and following antibiotic therapy.[6] Vaginal infections occur more commonly during pregnancy, in those with weak immune systems, and following antibiotic use.[7] Risk for widespread infection includes being in an intensive care unit, following surgery, low birth weight infants, and those with weak immune systems.[8]

Efforts to prevent infections of the mouth include the use of chlorhexidine mouth wash in those with poor immune function and washing out the mouth following the use of inhaled steroids.[9] Little evidence supports probiotics for either prevention or treatment even among those with frequent vaginal infections.[10][11] For infections of the mouth, treatment with topical clotrimazole or nystatin is usually effective. Oral or intravenous fluconazole, itraconazole, or amphotericin B may be used if these do not work.[9] A number of topical antifungal medications may be used for vaginal infections including clotrimazole.[12] In those with widespread disease, an echinocandin such as caspofungin or micafungin is used.[13] A number of weeks of intravenous amphotericin B may be used as an alternative.[13] In certain groups at very high risk, antifungal medications may be used preventatively.[8][13]

Infections of the mouth occur in about 6% of babies less than a month old. About 20% of those receiving chemotherapy for cancer and 20% of those with AIDS also develop the disease.[14] About three-quarters of women have at least one yeast infection at some time during their lives.[15] Widespread disease is rare except in those who have risk factors.[16]

## Signs and symptoms [edit]

Signs and symptoms of candidiasis vary depending on the area affected.[17] Most candidal infections result in minimal complications such as redness, itching, and discomfort, though complications may be severe or even fatal if left untreated in certain populations. In healthy (immunocompetent) persons, candidiasis is usually a localized infection of the skin, fingernails or toenails (onychomycosis), or mucosal membranes, including the oral cavity and pharynx (thrush), esophagus, and the genitalia (vagina, penis, etc.);[18][19][20] less commonly in healthy individuals, the gastrointestinal tract,[21][22][23] urinary tract,[21] and respiratory tract[21] are sites of candida infection.

Skin candidiasis

In immunocompromised individuals, *Candida* infections in the esophagus occur more frequently than in healthy individuals and have a higher potential of becoming systemic, causing a much more serious condition, a fungemia called candidemia.[18][24][25] Symptoms of esophageal candidiasis include difficulty swallowing, painful swallowing, abdominal pain, nausea, and vomiting.[18][26]

Nail candidiasis (onychomycosis)

Thrush is commonly seen in infants. It is not considered abnormal in infants unless it lasts longer than a few weeks.[27]

Infection of the vagina or vulva may cause severe itching, burning, soreness, irritation, and a whitish or whitish-gray cottage cheese-like discharge. Symptoms of infection of the male genitalia (balanitis thrush) include red skin around the head of the penis, swelling, irritation, itchiness and soreness of the head of the penis, thick, lumpy discharge under the foreskin, unpleasant odour, difficulty retracting the foreskin (phimosis), and pain when passing urine or during sex.[28]

Common symptoms of gastrointestinal candidiasis in healthy individuals are anal itching, belching, bloating, indigestion, nausea, diarrhea, gas, intestinal cramps, vomiting, and gastric ulcers.[21][22][23] Perianal candidiasis can cause anal itching; the lesion can be erythematous, papular, or ulcerative in appearance, and it is not considered to be a sexually transmissible disease.[29] Abnormal proliferation of the candida in the gut may lead to dysbiosis.[30] While it is not yet clear, this alteration may be the source of symptoms generally described as the irritable bowel syndrome,[31][32] and other gastrointestinal diseases.[22][33]

## Causes [edit]

*Main article: Candida (fungus)*

*Candida* yeasts are generally present in healthy humans, frequently part of the human body's normal oral and intestinal flora, and particularly on the skin; however, their growth is normally limited by the human immune system and by competition of other microorganisms, such as bacteria occupying the same locations in the human body.[34] *Candida* requires moisture for growth, notably on the skin.[35] For example, wearing wet swimwear for long periods of time is believed to

Vagina yeast infection

be a risk factor.[36] In extreme cases, superficial infections of the skin or mucous membranes may enter into the bloodstream and cause systemic *Candida* infections.

Factors that increase the risk of candidiasis include HIV/AIDS, mononucleosis, cancer treatments, steroids, stress, antibiotic usage, diabetes, and nutrient deficiency. Hormone replacement therapy and infertility treatments may also be predisposing factors.[37] Treatment with antibiotics can lead to eliminating the yeast's natural competitors for resources in the oral and intestinal flora; thereby increasing the severity of the condition.[38] A weakened or undeveloped immune system or metabolic illnesses are significant predisposing factors of candidiasis.[39] Almost 15% of people with weakened immune systems develop a systemic illness caused by *Candida* species.[40] Diets high in simple carbohydrates have been found to affect rates of oral candidiases.[41]

*C. albicans* was isolated from the vaginas of 19% of apparently healthy women, i.e., those who experienced few or no symptoms of infection. External use of detergents or douches or internal disturbances (hormonal or physiological) can perturb the normal vaginal flora, consisting of lactic acid bacteria, such as lactobacilli, and result in an overgrowth of *Candida* cells, causing symptoms of infection, such as local inflammation.[42] Pregnancy and the use of oral contraceptives have been reported as risk factors.[43] Diabetes mellitus and the use of antibiotics are also linked to increased rates of yeast infections.[43]

In penile candidiasis, the causes include sexual intercourse with an infected individual, low immunity, antibiotics, and diabetes. Male genital yeast infections are less common, and incidences of infection are only a fraction of those in women; however, yeast infection on the penis from direct contact via sexual intercourse with an infected partner is not uncommon.[44]

## Diagnosis [edit]

Symptoms of vaginal candidiasis are also present in the more common bacterial vaginosis;[45] aerobic vaginitis is distinct and should be excluded in the differential diagnosis.[46] In a 2002 study, only 33% of women who were self-treating for a yeast infection actually had such an infection, while most had either bacterial vaginosis or a mixed-type infection.[47]

Agar plate culture of *C. albicans*

Diagnosis of a yeast infection is done either via microscopic examination or culturing. For identification by light microscopy, a scraping or swab of the affected area is placed on a microscope slide. A single drop of 10% potassium hydroxide (KOH) solution is then added to the specimen. The KOH dissolves the skin cells, but leaves the *Candida* cells intact, permitting visualization of pseudohyphae and budding yeast cells typical of many *Candida* species.

For the culturing method, a sterile swab is rubbed on the infected skin surface. The swab is then streaked on a culture medium. The culture is incubated at 37 °C (98.6 °F) for several days, to allow development of yeast or bacterial colonies. The characteristics (such as morphology and colour) of the colonies may allow initial diagnosis of the organism causing disease symptoms.[48]

KOH test on a vaginal wet mount, showing slings of pseudohyphae of *Candida albicans* surrounded by round vaginal epithelial cells, conferring a diagnosis of candidal vulvovaginitis

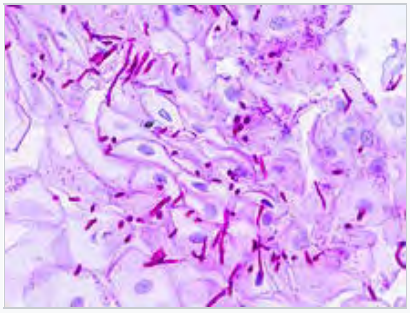
Respiratory, gastrointestinal, and esophageal candidiasis require an endoscopy to diagnose.[23][49] For gastrointestinal candidiasis, it is necessary to obtain a 3–5 milliliter sample of fluid from the duodenum for fungal culture.[23] The diagnosis of gastrointestinal candidiasis is based upon the culture containing in excess of 1,000 colony-forming units per milliliter.[23]

### Classification [edit]

Candidiasis may be divided into these types:

- Mucosal candidiasis
  - Oral candidiasis (thrush, oropharyngeal candidiasis)[18][20]
    - Pseudomembranous candidiasis[20]
    - Erythematous candidiasis[18][20]
    - Hyperplastic candidiasis[20]
    - Denture-related stomatitis[18][20] — *Candida* organisms are involved in

about 90% of cases
    - Angular cheilitis[18][20] — *Candida* species are responsible for about 20% of cases, mixed infection of *C. albicans* and *Staphylococcus aureus* for about 60% of cases.
    - Median rhomboid glossitis[20]
  - Candidal vulvovaginitis (vaginal yeast infection)[18][50]
  - Candidal balanitis — infection of the glans penis,[18] almost exclusively occurring in uncircumcised males[51]
  - Esophageal candidiasis (candidal esophagitis)[18][26]
  - Gastrointestinal candidiasis[21][22][23]
  - Respiratory candidiasis[18][21]
- Cutaneous candidiasis
  - Candidial folliculitis[18]
  - Candidal intertrigo[18]
  - Candidal paronychia[18]
  - Perianal candidiasis, may present as pruritus ani[1]:309
  - Candidid
  - Chronic mucocutaneous candidiasis[18]
  - Congenital cutaneous candidiasis
  - Diaper candidiasis: an infection of a child's diaper area[1]:309
  - Erosio interdigitalis blastomycetica
  - Candidial onychomycosis (nail infection) caused by *Candida*[18][52]
- Systemic candidiasis[18]
  - Candidemia, a form of fungemia which may lead to sepsis[18]
  - Invasive candidiasis (disseminated candidiasis) — organ infection by *Candida*[18]
  - Chronic systemic candidiasis (hepatosplenic candidiasis) — sometimes arises during recovery from neutropenia[18][53]
- Antibiotic candidiasis (iatrogenic candidiasis)



Micrograph of esophageal candidiasis showing hyphae, biopsy specimen, PAS stain

## Prevention [edit]

A diet that supports the immune system and is not high in simple carbohydrates contributes to a healthy balance of the oral and intestinal flora.[34][41] While yeast infections are associated with diabetes, the level of blood sugar control may not affect the risk.[54] Wearing cotton underwear may help to reduce the risk of developing skin and vaginal yeast infections, along with not wearing wet clothes for long periods of time.[7][36]

Oral hygiene can help prevent oral candidiasis when people have a weakened immune system.[6] For people undergoing cancer treatment, chlorhexidine mouthwash can prevent or reduce thrush.[6] People who use inhaled corticosteroids can reduce the risk of developing oral candidiasis by rinsing the mouth with water or mouthwash after using the inhaler.[6]

For women who experience recurrent yeast infections, there is limited evidence that oral or intravaginal probiotics help to prevent future infections.[10][55] This includes either as pills or as yogurt.[10]

## Treatment [edit]

Candidiasis is treated with antifungal medications; these include clotrimazole, nystatin, fluconazole, voriconazole, amphotericin B, and echinocandins.[13] Intravenous fluconazole or an intravenous echinocandin such as caspofungin are commonly used to treat immunocompromised or critically ill individuals.[13]

The 2016 revision of the clinical practice guideline for the management of candidiasis lists a large number of specific treatment regimens for *Candida* infections that involve different *Candida* species, forms of antifungal drug resistance, immune statuses, and infection localization and severity.[13] Gastrointestinal candidiasis in immunocompetent individuals is treated with 100–200 mg fluconazole per day for 2–3 weeks.[23]

### Localized infection [edit]

Mouth and throat candidiasis are treated with antifungal medication. Oral candidiasis usually responds to topical treatments; otherwise, systemic antifungal medication may be needed for oral infections. Candida esophagitis may be treated orally or intravenously; for severe or azole-resistant esophageal candidiasis, treatment with amphotericin B may be necessary.[9]

A one-time dose of fluconazole is 90% effective in treating a vaginal yeast infection.[56] Local treatment may include vaginal suppositories or medicated douches. Other types of yeast infections require different dosing. Gentian violet can be used for thrush in breastfeeding babies. *C. albicans* can develop resistance to fluconazole, this being more of an issue in those with HIV/AIDS who are often treated with multiple courses of fluconazole for recurrent oral infections.[57]

For vaginal yeast infection in pregnancy, topical imidazole or triazole antifungals are considered the therapy of choice owing to available safety data.[58] Systemic absorption of these topical formulations is minimal, posing little risk of transplacental transfer.[58] In vaginal yeast infection in pregnancy, treatment with topical azole antifungals is recommended for 7 days instead of a shorter duration.[58]

No benefit from probiotics has been found for active infections.[11]

### Blood infection [edit]

Systemic candidiasis occurs when Candida yeast enters the bloodstream and may spread (becoming disseminated candidiasis) to other organs, including the central nervous system, kidneys, liver, bones, muscles, joints, spleen, or eyes. Treatment typically consists of oral or intravenous antifungal medications.[59] In candidal infections of the blood, intravenous fluconazole or an echinocandin such as caspofungin may be used.[13] Amphotericin B is another option.[13]

## Prognosis [edit]

Among individuals being treated in intensive care units, the mortality rate is about 30-50% when systemic candidiasis develops.[60]

## Epidemiology [edit]

Oral candidiasis is the most common fungal infection of the mouth,[61] and it also represents the most common opportunistic oral infection in humans.[62] In the Western Hemisphere, about 75% of females are affected at some time in their lives with a vaginal yeast infection.

Esophageal candidiasis is the most common esophageal infection in persons with AIDS and accounts for about 50% of all esophageal infections, often coexisting with other esophageal diseases. About two-thirds of people with AIDS and esophageal candidiasis also have oral candidiasis.[26]

Candidal sepsis is rare.[63] Candida is the fourth most common cause of bloodstream infections among hospital patients in the United States.[64]

## History [edit]

Descriptions of what sounds like oral thrush go back to the time of Hippocrates *circa* 460–370 BCE.[17]

Vulvovaginal candidiasis was first described in 1849 by Wilkinson.[65] In 1875, Haussmann demonstrated the causative organism in both vulvovaginal and oral candidiasis is the same.[65]

With the advent of antibiotics following World War II, the rates of candidiasis increased. The rates then decreased in the 1950s following the development of nystatin.[66]

The colloquial term "thrush" refers to the resemblance of the white flecks present in some forms of candidiasis (*e.g.* pseudomembranous candidiasis) with the breast of the bird of the same name.[67] The term candidosis is largely used in British English, and candidiasis in American English.[65] *Candida* is also pronounced differently; in American English, the stress is on the "i", whereas in British English the stress is on the first syllable.

The genus *Candida* and species *C. albicans* were described by botanist Christine Marie Berkhout in her doctoral thesis

at the University of Utrecht in 1923. Over the years, the classification of the genera and species has evolved. Obsolete names for this genus include *Mycotorula* and *Torulopsis*. The species has also been known in the past as *Monilia albicans* and *Oidium albicans*. The current classification is *nomen conservandum*, which means the name is authorized for use by the International Botanical Congress (IBC).[68]

The genus *Candida* includes about 150 different species; however, only a few are known to cause human infections. *C. albicans* is the most significant pathogenic species. Other species pathogenic in humans include *C. tropicalis*, *C. glabrata*, *C. krusei*, *C. parapsilosis*, *C. dubliniensis*, and *C. lusitaniae*.

The name *Candida* was proposed by Berkhout. It is from the Latin word *toga candida*, referring to the white toga (robe) worn by candidates for the Senate of the ancient Roman republic.[65] The specific epithet *albicans* also comes from Latin, *albicare* meaning "to whiten".[65] These names refer to the generally white appearance of *Candida* species when cultured.

## Alternative medicine [edit]

A 2005 publication noted that "a large pseudoscientific cult"[69] has developed around the topic of *Candida*, with claims up to one in three people are affected by yeast-related illness, particularly a condition called "Candidiasis hypersensitivity".[70] Some practitioners of alternative medicine have promoted these purported conditions and sold dietary supplements as supposed cures; a number of them have been prosecuted.[71][72] In 1990, alternative health vendor Nature's Way signed an FTC consent agreement not to misrepresent in advertising any self-diagnostic test concerning yeast conditions or to make any unsubstantiated representation concerning any food or supplement's ability to control yeast conditions, with a fine of $30,000 payable to the National Institutes of Health for research in genuine candidiasis.[72]

"Candida species and other microorganisms are involved in this complicated fungal infection, but Candida albicans continues to be the most prevalent. In the past two decades, it has been observed an abnormal overgrowth in the gastrointestinal, urinary and respiratory tracts, not only in immunocompromised patients but also related to nosocomial infections and even in healthy individuals. There is a wide variety of causal factors that contribute to yeast infection which means that candidiasis is a good example of a multifactorial syndrome."

23. ^ a b c d e f g Erdogan A, Rao SS (April 2015). "Small intestinal fungal overgrowth". *Curr Gastroenterol Rep*. **17** (4): 16. doi:10.1007/s11894-015-0436-2. PMID 25786900. "Small intestinal fungal overgrowth (SIFO) is characterized by the presence of excessive number of fungal organisms in the small intestine associated with gastrointestinal (GI) symptoms. Candidiasis is known to cause GI symptoms particularly in immunocompromised patients or those receiving steroids or antibiotics. However, only recently, there is emerging literature that an overgrowth of fungus in the small intestine of non-immunocompromised subjects may cause unexplained GI symptoms. Two recent studies showed that 26 % (24/94) and 25.3 % (38/150) of a series of patients with unexplained GI symptoms had SIFO. The most common symptoms observed in these patients were belching, bloating, indigestion, nausea, diarrhea, and gas. The underlying mechanism(s) that predisposes to SIFO is unclear but small intestinal dysmotility and use of proton pump inhibitors has been implicated. However, further studies are needed; both to confirm these observations and to examine the clinical relevance of fungal overgrowth, both in healthy subjects and in patients with otherwise unexplained GI symptoms. ... For routine SIFO in an immunocompetent host, a 2–3 week oral course of fluconazole 100–200 mg will suffice."

# Cellulitis

From Wikipedia, the free encyclopedia

*This article is about infection of skin and its underlying connective tissue. For the dimpled appearance of skin, see cellulite.*

**Cellulitis** is a bacterial infection involving the inner layers of the skin. It specifically affects the dermis and subcutaneous fat. Signs and symptoms include an area of redness which increases in size over a couple of days. The borders of the area of redness are generally not sharp and the skin may be swollen. While the redness often turns white when pressure is applied this is not always the case. The area of infection is usually painful.[1] Lymphatic vessels may occasionally be involved,[1][2] and the person may have a fever and feel tired.[3]

The legs and face are the most common site involved, though cellulitis can occur on any part of the body. The leg is typically affected following a break in the skin. Other risk factors include obesity, leg swelling, and old age. For face infections a break in the skin beforehand is not usually the case. The bacteria most commonly involved are streptococci and *Staphylococcus aureus*. In contrast to cellulitis, erysipelas is a bacterial infection involving the more superficial layers of the skin, present with an area of redness with well-defined edges, and more often is associated with a fever. Diagnosis is usually based on the presenting signs and symptoms while cell culture is rarely possible.[1] Before making a diagnosis, more serious infections such as an underlying bone infection or necrotizing fasciitis should be ruled out.[2]

Treatment with antibiotics taken by mouth, such as cephalexin, amoxicillin, or cloxacillin, is often used.[1][4] In those who are seriously allergic to penicillin, erythromycin or clindamycin may be used.[4] When methicillin-resistant *S. aureus* (MRSA) is a concern, doxycycline or trimethoprim/sulfamethoxazole may, in addition, be recommended.[1] Concern is related to the presence of pus or previous MRSA infections.[1][3] Elevating the infected area may be useful[2] as may pain killers.[4]

Around 95% of people are better after seven to ten days of treatment.[3] Potential complications include abscess formation.[1] Bacterial skin infections affected about 155 million people and cellulitis occurred in about 37 million people in 2013.[5] This is about two of every 1000 people per year.[1] Cellulitis in 2013 resulted in about 30,000 deaths worldwide.[6] In the United Kingdom, cellulitis was the reason for 1.6% of admissions to hospital.[4]

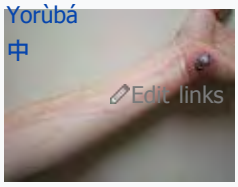
## Signs and symptoms [edit]

The typical signs and symptoms of cellulitis is an area which is red, hot, and painful. The photos shown here of are of mild to moderate cases, and are not representative of earlier stages of the condition.



Cellulitis following an abrasion: Note the red streaking up the arm from involvement of the lymphatic system.

Infected left shin in comparison to shin with no sign of symptoms

Cellulitis of the leg with foot involvement

## Causes [edit]

Cellulitis is caused by a type of bacteria entering the skin, usually by way of a cut, abrasion, or break in the skin. This break does not need to be visible. Group A *Streptococcus* and *Staphylococcus* are the most common of these bacteria, which are part of the normal flora of the skin, but normally cause no actual infection while on the skin's outer surface.

About 80% of cases of Ludwig's angina, or cellulitis of the submandibular space, are caused by dental infections. Mixed infections, due to both aerobes and anaerobes, are commonly associated with this type of cellulitis. Typically, this includes alpha-hemolytic streptococci, staphylococci, and bacteroides groups.[7]

Predisposing conditions for cellulitis include insect or spider bite, blistering, animal bite, tattoos, pruritic (itchy) skin rash, recent surgery, athlete's foot, dry skin, eczema, injecting drugs (especially subcutaneous or intramuscular injection or where an attempted intravenous injection "misses" or blows the vein), pregnancy, diabetes, and obesity, which can affect circulation, as well as burns and boils, though debate exists as to whether minor foot lesions contribute. Occurrences of cellulitis may also be associated with the rare condition hidradenitis suppurativa or dissecting cellulitis.

The appearance of the skin assists a doctor in determining a diagnosis. A doctor may also suggest blood tests, a wound culture, or other tests to help rule out a blood clot deep in the veins of the legs. Cellulitis in the lower leg is characterized by signs and symptoms similar to those of a deep vein thrombosis, such as warmth, pain, and swelling (inflammation).

This reddened skin or rash may signal a deeper, more serious infection of the inner layers of skin. Once below

the skin, the bacteria can spread rapidly, entering the lymph nodes and the bloodstream and spreading throughout the body. This can result in influenza-like symptoms with a high temperature and sweating or feeling very cold with shaking, as the sufferer cannot get warm.

In rare cases, the infection can spread to the deep layer of tissue called the fascial lining. Necrotizing fasciitis, also called by the media "flesh-eating bacteria", is an example of a deep-layer infection. It is a medical emergency.

### Risk factors [edit]

The elderly and those with immunodeficiency (a weakened immune system) are especially vulnerable to contracting cellulitis. Diabetics are more susceptible to cellulitis than the general population because of impairment of the immune system; they are especially prone to cellulitis in the feet, because the disease causes impairment of blood circulation in the legs, leading to diabetic foot/foot ulcers. Poor control of blood glucose levels allows bacteria to grow more rapidly in the affected tissue, and facilitates rapid progression if the infection enters the bloodstream. Neural degeneration in diabetes means these ulcers may not be painful, and thus often become infected. Those who have suffered poliomyelitis are also prone because of circulatory problems, especially in the legs.

Immunosuppressive drugs, and other illnesses or infections that weaken the immune system, are also factors that make infection more likely. Chickenpox and shingles often result in blisters that break open, providing a gap in the skin through which bacteria can enter. Lymphedema, which causes swelling on the arms and/or legs, can also put an individual at risk.

Diseases that affect blood circulation in the legs and feet, such as chronic venous insufficiency and varicose veins, are also risk factors for cellulitis.

Cellulitis is also common among dense populations sharing hygiene facilities and common living quarters, such as military installations, college dormitories, nursing homes, oil platforms, and homeless shelters.

## Diagnosis [edit]

Cellulitis is most often a clinical diagnosis, readily identified in many people by history and physical examination alone, with rapidly spreading areas of cutaneous swelling, redness and heat, occasionally associated with inflammation of regional lymph nodes. While classically distinguished as a separate entity from erysipelas by spreading more deeply to involve the subcutaneous tissues, many clinicians may classify erysipelas as cellulitis. Both are often treated similarly, but cellulitis associated with furuncles, carbuncles, or abscesses is usually caused S. aureus, which may affect treatment decisions, especially antibiotic selection.[8] Skin aspiration of non-purulent cellulitis, usually caused by streptococcal organisms, is rarely helpful for diagnosis and blood cultures are positive in fewer than 5% of all cases.[8]

It is important to evaluate for co-existent abscess as this finding usually requires surgical drainage as opposed to antibiotic therapy alone. Physicians' clinical assessment for abscess may be limited, especially in cases with extensive overlying induration, but use of bedside ultrasonography performed by an experienced practitioner readily discriminates between abscess and cellulitis and may change management in up to 56% of cases.[9] Use of ultrasound for abscess identification may also be indicated in cases of antibiotic failure. Cellulitis has a characteristic "cobblestoned" appearance indicative of subcutaneous edema without a defined hypoechoic, heterogeneous fluid collection that would indicate abscess.[10]

### Differential diagnosis [edit]

Other conditions that may mimic cellulitis include deep vein thrombosis, which can be diagnosed with a compression leg ultrasound, and stasis dermatitis, which is inflammation of the skin from poor blood flow. Signs of a more severe infection such as necrotizing fasciitis or gas gangrene that would require prompt surgical intervention include purple bullae, skin sloughing, subcutaneous edema and systemic toxicity.[8] Misdiagnosis can occur in up to 30% of people with suspected lower extremity cellulitis, leading to 50,000 to 130,000 unnecessary hospitalization and $195 to $515 million in avoidable healthcare spending annually in the United States.[11]

Associated musculoskeletal findings are sometimes reported. When it occurs with acne conglobata, hidradenitis suppurativa, and pilonidal cysts, the syndrome is referred to as the follicular occlusion triad or tetrad.[12]

Lyme disease can be misdiagnosed as staphylococcal- or streptococcal-induced cellulitis. Because the characteristic bullseye rash does not always appear in people infected with Lyme disease, the similar set of symptoms may be misdiagnosed as cellulitis. Standard treatments for cellulitis are not sufficient for curing Lyme disease. The only way to rule out Lyme disease is with a blood test, which is recommended during warm months in areas where the disease is endemic.[13]

## Prevention [edit]

In those who have previously had cellulitis, the use of antibiotics may help prevent future episodes.[14] This is recommended by CREST for those who have had more than two episodes.[4]

## Treatment [edit]

Antibiotics are usually prescribed, with the agent selected based on suspected organism and presence or absence of purulence,[8] although the best treatment choice is unclear.[15] If an abscess is also present surgical drainage is usually indicated, with antibiotics often prescribed for co-existent cellulitis, especially if extensive.[9] Pain relief is also often prescribed, but excessive pain should always be investigated as it is a symptom of necrotizing fasciitis. Elevation of the affected area is often recommended.

Steroids may speed recovery in those on antibiotics.[1]

### Antibiotics [edit]

Antibiotics choices depend on regional availability, but a penicillinase-resistant semisynthetic penicillin or a first-generation cephalosporin are currently recommended for cellulitis without abscess.[8] A course of antibiotics is not effective in between 6 and 37% of cases.[16]

## Epidemiology [edit]

Cellulitis in 2013 resulted in about 30,000 deaths worldwide, up from 27,000 in 1990.[6]

## Other animals [edit]

Horses may acquire cellulitis, usually secondarily to a wound (which can be extremely small and superficial) or to a deep-tissue infection, such as an abscess or infected bone, tendon sheath, or joint.[17][18] Cellulitis from a superficial wound usually creates less lameness (grade 1–2 of 5) than that caused by septic arthritis (grade 4–5). The horse exhibits inflammatory edema, which is hot, painful swelling. This swelling differs from stocking up in that the horse does not display symmetrical swelling in two or four legs, but in only one leg. This swelling begins near the source of infection, but eventually continues down the leg. In some cases, the swelling also travels distally. Treatment includes cleaning the wound and caring for it properly, the administration of NSAIDs, such as phenylbutazone, cold hosing, applying a sweat wrap or a poultice, and mild exercise. Veterinarians may also prescribe antibiotics. Cellulitis is also seen in staphylococcal and corynebacterial mixed infections in bulls.[19]

# Chickenpox

From Wikipedia, the free encyclopedia

*For other uses, see Chickenpox (disambiguation).*
*"Varicella" redirects here. For other uses, see Varicella (disambiguation).*
*Not to be confused with Fowlpox or Smallpox.*

**Chickenpox**, also known as **varicella**, is a highly contagious disease caused by the initial infection with varicella zoster virus (VZV).[1] The disease results in a characteristic skin rash that forms small, itchy blisters, which eventually scab over.[2] It usually starts on the chest, back, and face then spreads to the rest of the body.[2] Other symptoms may include fever, feeling tired, and headaches.[2] Symptoms usually last five to ten days.[2] Complications may occasionally include pneumonia, inflammation of the brain, or bacterial infections of the skin among others.[3] The disease is often more severe in adults than children.[4] Symptoms begin ten to twenty-one days after exposure to the virus.[5]

Chickenpox is an airborne disease which spreads easily through the coughs and sneezes of an infected person.[5] It may be spread from one to two days before the rash appears until all lesions have crusted over.[5] It may also spread through contact with the blisters.[5] Those with shingles may spread chickenpox to those who are not immune through contact with the blisters.[5] The disease can usually be diagnosed based on the presenting symptom; however, in unusual cases may be confirmed by polymerase chain reaction (PCR) testing of the blister fluid or scabs.[4] Testing for antibodies may be done to determine if a person is or is not immune.[4] People usually only get the disease once.[5] Although reinfections by the virus occur, these reinfections usually do not cause any symptoms.[7]

The varicella vaccine has resulted in a decrease in the number of cases and complications from the disease.[8] It protects about 70 to 90 percent of people from disease with a greater benefit for severe disease.[4] Routine immunization of children is recommended in many countries.[9] Immunization within three days of exposure may improve outcomes in children.[10] Treatment of those infected may include calamine lotion to help with itching, keeping the fingernails short to decrease injury from scratching, and the use of paracetamol (acetaminophen) to help with fevers.[5] For those at increased risk of complications antiviral medication such as aciclovir are recommended.[5]

Chickenpox occurs in all parts of the world.[4] As of 2013 140 million cases of chickenpox and herpes zoster occurred.[11] Before routine immunization the number of cases occurring each year was similar to the number of people born.[4] Since immunization the number of infections in [4]

[edit on Wikidata]

the United States has decreased nearly 90%. In 2013 chickenpox resulted in 7,000 deaths globally – down from 8,900 in 1990.[12] Death occurs in about 1 per 60,000 cases.[4] Chickenpox was not separated from smallpox until the late 19th century.[4] In 1888 its connection to shingles was determined.[4] The first documented use of the term *chicken pox* was in 1658.[13] Various explanations have been suggested for the use of "chicken" in the name, one being the relative mildness of the disease.[13]

## Signs and symptoms [edit]

The early (prodromal) symptoms in adolescents and adults are nausea, loss of appetite, aching muscles, and headache. This is followed by the characteristic rash or oral sores, malaise, and a low-grade fever that signal the presence of the disease. Oral manifestations of the disease (enanthem) not uncommonly may precede the external rash (exanthem). In children the illness is not usually preceded by prodromal symptoms, and the first sign is the rash or the spots in the oral cavity. The rash begins as small red dots on the face, scalp, torso, upper arms and legs; progressing over 10–12 hours to small bumps, blisters and pustules; followed by umbilication and the formation of scabs.[14][15]

A single blister, typical during the early stages of the rash

At the blister stage, intense itching is usually present. Blisters may also occur on the palms, soles, and genital area. Commonly, visible evidence of the disease develops in the oral cavity and tonsil areas in the form of small ulcers which can be painful or itchy or both; this enanthem (internal rash) can precede the exanthem (external rash) by 1 to 3 days or can be concurrent. These symptoms of chickenpox appear 10 to 21 days after exposure to a contagious person. Adults may have a more widespread rash and longer fever, and they are more likely to experience complications, such as varicella pneumonia.[14]

Because watery nasal discharge containing live virus usually precedes both exanthem (external rash) and enanthem (oral ulcers) by 1 to 2 days, the infected person actually becomes contagious one to two days before recognition of the disease. Contagiousness persists until all vesicular lesions have become dry crusts (scabs), which usually entails four or five days, by which time nasal shedding of live virus ceases.

The condition usually resolves by itself within a couple of weeks.[16] The rash may, however, last for up to one month, although the infectious stage does not last longer than a week or two.[*citation needed*]

Chickenpox is rarely fatal, although it is generally more severe in adult men than in women or children. Non-

immune pregnant women and those with a suppressed immune system are at highest risk of serious complications. Arterial ischemic stroke (AIS) associated with chickenpox in the previous year accounts for nearly one third of childhood AIS.[17] The most common late complication of chickenpox is shingles (herpes zoster), caused by reactivation of the *varicella zoster* virus decades after the initial, often childhood, chickenpox infection.

Lower leg of a child with chickenpox

## Pregnancy and neonates [edit]

During pregnancy the dangers to the fetus associated with a primary VZV infection are greater in the first six months. In the third trimester, the mother is more likely to have severe symptoms.[18] For pregnant women, antibodies produced as a result of immunization or previous infection are transferred via the placenta to the fetus.[19] Women who are immune to chickenpox cannot become infected and do not need to be concerned about it for themselves or their infant during pregnancy.[20]

Varicella infection in pregnant women could lead to spread via the placenta and infection of the fetus. If infection occurs during the first 28 weeks of gestation, this can lead to fetal varicella syndrome (also known as *congenital varicella syndrome*).[21] Effects on the fetus can range in severity from underdeveloped toes and fingers to severe anal and bladder malformation. Possible problems include:

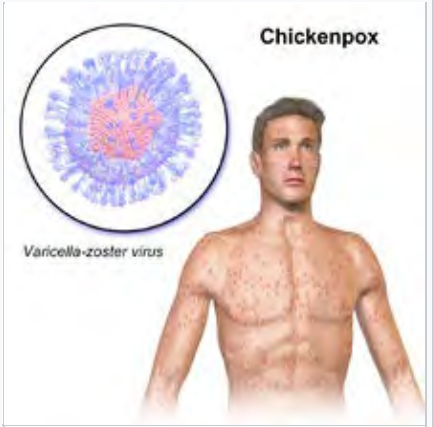
- Damage to brain: encephalitis,[22] microcephaly, hydrocephaly,[23] aplasia of brain
- Damage to the eye: optic stalk, optic cup, and lens vesicles, microphthalmia, cataracts, chorioretinitis, optic atrophy
- Other neurological disorder: damage to cervical and lumbosacral spinal cord, motor/sensory deficits, absent deep tendon reflexes, anisocoria/Horner's syndrome
- Damage to body: hypoplasia of upper/lower extremities, anal and bladder sphincter dysfunction
- Skin disorders: (cicatricial) skin lesions, hypopigmentation

Infection late in gestation or immediately following birth is referred to as "*neonatal varicella*".[24] Maternal infection is associated with premature delivery. The risk of the baby developing the disease is greatest following exposure to infection in the period 7 days before delivery and up to 8 days following the birth. The baby may also be exposed to the virus via infectious siblings or other contacts, but this is of less concern if the mother is immune. Newborns who develop symptoms are at a high risk of pneumonia and other serious complications of the disease.[25]

# Diagnosis [edit]

The diagnosis of chickenpox is primarily based on the signs and symptom, with typical early symptoms followed by a characteristic rash. Confirmation of the diagnosis is by examination of the fluid within the vesicles of the rash, or by testing blood for evidence of an acute immunologic response.

Vesicular fluid can be examined with a Tzanck smear, or better by testing for direct fluorescent antibody. The fluid can also be "cultured", whereby attempts are made to grow the virus from a fluid sample. Blood tests can be used to identify a response to acute infection (IgM) or previous infection and subsequent immunity (IgG).[26]



Chickenpox.

Prenatal diagnosis of fetal varicella infection can be performed using ultrasound, though a delay of 5 weeks following primary maternal infection is advised. A PCR (DNA) test of the mother's amniotic fluid can also be performed, though the risk of spontaneous abortion due to the amniocentesis procedure is higher than the risk of the baby's developing fetal varicella syndrome.[25]

## Pathophysiology [edit]

*Main article: Varicella zoster virus*

Exposure to VZV in a healthy child initiates the production of host immunoglobulin G (IgG), immunoglobulin M (IgM), and immunoglobulin A (IgA) antibodies; IgG antibodies persist for life and confer immunity. Cell-mediated immune responses are also important in limiting the scope and the duration of primary varicella infection. After primary infection, VZV is hypothesized to spread from mucosal and epidermal lesions to local sensory nerves. VZV then remains latent in the dorsal ganglion cells of the sensory nerves. Reactivation of VZV results in the clinically distinct syndrome of herpes zoster (i.e., *shingles*), postherpetic neuralgia,[27] and sometimes Ramsay Hunt syndrome type II.[28] Varicella zoster can affect the arteries in the neck and head, producing stroke, either during childhood, or after a latency period of many years.[29]

### Shingles [edit]

*Main article: Herpes zoster*

After a chickenpox infection, the virus remains dormant in the body's nerve tissues. The immune system keeps the virus at bay, but later in life, usually in an adult, it can be reactivated and cause a different form of the viral infection called shingles (also known as herpes zoster).[30] The United States Advisory Committee on Immunization Practices (ACIP) suggests that every adult over the age of 60 years get the *herpes zoster* vaccine.[31]

Shingles affects one in five adults infected with chickenpox as children, especially those who are immune-suppressed, particularly from cancer, HIV, or other conditions. Stress can bring on shingles as well, although scientists are still researching the connection.[32] Shingles are most commonly found in adults over the age of 60 who were diagnosed with chickenpox when they were under the age of 1.[33]

## Prevention [edit]

### Hygiene measures [edit]

The spread of chickenpox can be prevented by isolating affected individuals. Contagion is by exposure to respiratory droplets, or direct contact with lesions, within a period lasting from three days before the onset of the rash, to four days after the onset of the rash.[34] The chickenpox virus is susceptible to disinfectants, notably chlorine bleach (i.e., sodium hypochlorite). Like all enveloped viruses, it is sensitive to desiccation, heat and detergents.

### Vaccine [edit]

*Main article: Varicella vaccine*

The varicella vaccine is recommended in many countries.[9] Some countries require the varicella vaccination or an exemption before entering elementary school. A second dose is recommended five years after the initial immunization.[35] A vaccinated person is likely to have a milder case of chickenpox if they become infected.[36] Immunization within three days following household contact reduces infection rates and severity in children.[10]

It is part of the routine immunization schedule in the US.[37] Some European countries include it as part of universal vaccinations in children,[38] but not all countries provide the vaccine due to its cost.[9] In the UK as of 2014, the vaccine is only recommended in people who are particularly vulnerable to chickenpox.[39] In populations that have not been immunized or if immunity is questionable, a clinician may order an Enzyme immunoassay. An immunoessay measures the levels of antibodies against the virus that give immunity to a person. If the levels of antibodies are low (low titer) or questionable, reimmuization may be done.[40]

## Treatment [edit]

Treatment mainly consists of easing the symptoms. As a protective measure, people are usually required to stay at home while they are infectious to avoid spreading the disease to others. Cutting the nails short or wearing gloves may prevent scratching and minimize the risk of secondary infections.

Although there have been no formal clinical studies evaluating the effectiveness of topical application of calamine lotion (a topical barrier preparation containing zinc oxide, and one of the most commonly used interventions), it has an excellent safety profile.[41] It is important to maintain good hygiene and daily cleaning of skin with warm water to avoid secondary bacterial infection.[42] Scratching may also increase the risk of secondary infection.[43]

Paracetamol (acetaminophen) but not aspirin may be used to reduce fever. Aspirin use by someone with chickenpox may cause the serious, sometimes fatal disease of the liver and brain, Reye syndrome. People at risk of developing severe complications who have had significant exposure to the virus may be given intra-muscular varicella zoster immune globulin (VZIG), a preparation containing high titres of antibodies to varicella zoster virus, to ward off the disease.[44][45]

Antivirals are sometimes used.[46][47]

### Children [edit]

If aciclovir by mouth is started within 24 hours of rash onset, it decreases symptoms by one day but has no effect on complication rates.[48][49] Use of acyclovir therefore is not currently recommended for individuals with normal immune function. Children younger than 12 years old and older than one month are not meant to receive antiviral drugs unless they have another medical condition which puts them at risk of developing complications.[50]

Treatment of chickenpox in children is aimed at symptoms while the immune system deals with the virus. With children younger than 12 years, cutting nails and keeping them clean is an important part of treatment as they are more likely to scratch their blisters more deeply than adults.[51]

Aspirin is highly contraindicated in children younger than 16 years, as it has been related to Reye syndrome.[52]

### Adults [edit]

Infection in otherwise healthy adults tends to be more severe.[53] Treatment with antiviral drugs (e.g. acyclovir or valacyclovir) is generally advised, as long as it is started within 24–48 hours from rash onset.[50] Remedies to ease the symptoms of chickenpox in adults are basically the same as those used for children. Adults are more often prescribed antiviral medication, as it is effective in reducing the severity of the condition and the likelihood of developing complications. Antiviral medicines do not kill the virus but stop it from multiplying. Adults are advised to increase water intake to reduce dehydration and to relieve headaches. Painkillers such as paracetamol (acetaminophen) are recommended, as they are effective in relieving itching and other symptoms such as fever or pains. Antihistamines relieve itching and may be used in cases where the itching prevents sleep, because they also act as a sedative. As with children, antiviral medication is considered more useful for those adults who are more prone to develop complications. These include pregnant women or people who have a weakened immune system.[54]

Sorivudine, a nucleoside analogue, has been reported to be effective in the treatment of primary varicella in healthy adults (case reports only), but large-scale clinical trials are still needed to demonstrate its efficacy.[55]

After recovering from chickenpox, it is recommended by doctors that adults take one injection of VZV immune globulin and one injection of varicella vaccine or herpes zoster vaccine.[*citation needed*]

## Prognosis [edit]

The duration of the visible blistering caused by varicella zoster virus varies in children usually from 4 to 7 days, and the appearance of new blisters begins to subside after the fifth day. Chickenpox infection is milder in young children, and symptomatic treatment, with sodium bicarbonate baths or antihistamine medication may ease itching. It is recommended to keep new infants from birth up to age 6 months away from an infected person for 10 to 21 days because their immune systems are not developed enough to handle the stress it can bring on.[56] Paracetamol (acetaminophen) is widely used to reduce fever. Aspirin, or products containing aspirin, should not be given to children with chickenpox, as it can cause Reye's Syndrome.[57]

In adults, the disease is more severe,[58] though the incidence is much less common. Infection in adults is associated with greater morbidity and mortality due to pneumonia (either direct viral pneumonia or secondary bacterial pneumonia),[59] bronchitis (either viral bronchitis or secondary bacterial bronchitis),[59] hepatitis,[60] and encephalitis.[61] In particular, up to 10% of pregnant women with chickenpox develop pneumonia, the severity of which increases with onset later in gestation. In England and Wales, 75% of deaths due to chickenpox are in adults.[25] Inflammation of the brain, or encephalitis, can occur in immunocompromised individuals, although the risk is higher with herpes zoster.[62] Necrotizing fasciitis is also a rare complication.[63]

Varicella can be lethal to adults with impaired immunity. The number of people in this high-risk group has increased, due to the HIV epidemic and the increased use of immunosuppressive therapies.[64] Varicella is a particular problem in hospitals, when there are patients with immune systems weakened by drugs (e.g., high-dose steroids) or HIV.[65]

Secondary bacterial infection of skin lesions, manifesting as impetigo, cellulitis, and erysipelas, is the most common complication in healthy children. Disseminated primary varicella infection usually seen in the immunocompromised may have high morbidity. Ninety percent of cases of varicella pneumonia occur in the adult population. Rarer complications of disseminated chickenpox include myocarditis, hepatitis, and glomerulonephritis.[66]

Hemorrhagic complications are more common in the immunocompromised or immunosuppressed populations, although healthy children and adults have been affected. Five major clinical syndromes have been described: febrile purpura, malignant chickenpox with purpura, postinfectious purpura, purpura fulminans, and anaphylactoid purpura. These syndromes have variable courses, with febrile purpura being the most benign of the syndromes and having an uncomplicated outcome. In contrast, malignant chickenpox with purpura is a grave clinical condition that has a mortality rate of greater than 70%. The cause of these hemorrhagic chickenpox syndromes is not known.[66]

## Epidemiology [edit]

Primary varicella occurs in all countries worldwide. In 2013 the disease resulted in 7,000 deaths – down from 8,900 in 1990.[12]

In temperate countries, chickenpox is primarily a disease of children, with most cases occurring during the winter and spring, most likely due to school contact. It is one of the classic diseases of childhood, with the highest prevalence in the 4–10-year-old age group. Like rubella, it is uncommon in preschool children. Varicella is highly communicable, with an infection rate of 90% in close contacts. In temperate countries, most people become infected before adulthood, and 10% of young adults remain susceptible.

In the tropics, chickenpox often occurs in older people and may cause more serious disease.[67] In adults, the pock marks are darker and the scars more prominent than in children.[68]

In the United States, the Centers for Disease Control and Prevention (CDC) does not require state health departments to report infections of chickenpox, and only 31 states currently volunteer this information.[69]

However, in a 2013 study conducted by the social media disease surveillance tool called Sickweather, anecdotal reports of chickenpox infections on Facebook and Twitter were used to measure and rank states with the most infections per capita, with Maryland, Tennessee and Illinois in the top three.[70]

## Etymology [edit]

Why the term was used is not clear but it may be due to it being a relatively mild disease.[13] It has been said to be derived from *chickpeas*, based on resemblance of the vesicles to chickpeas,[13][71][72] or to come from the rash resembling chicken pecks.[72] Other suggestions include the designation *chicken* for a child (i.e., literally 'child pox'), a corruption of *itching-pox*,[71][73] or the idea that the disease may have originated in chickens.[74] Samuel Johnson explained the designation as "from its being of no very great danger."[75]

## Society and culture [edit]

Because chickenpox is usually more severe in adults than it is in children, some parents deliberately expose their children to the virus, sometimes by taking them to "chickenpox parties." Doctors counter that children are safer getting the vaccine, which is a weakened form of the virus, rather than getting the disease, which can be fatal.[76]

## Other animals [edit]

Humans are the only known animal that the disease affects naturally.[4] However, chickenpox has been caused in other primates, including chimpanzees[77] and gorillas.[78]
